Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

PRAMC_PRCR1 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PRAMC_PRCR1 field descriptions (continued)

Field	Description
22–23 PRI	AHB port arbitration mode. Use this register to select the AHB port arbitration mode. 00 Round Robin arbitration is selected. 01 Port p0 has priority over port p1. 10 Port p1 has priority over port p0. 11 Reserved.
24 P1_BO_DIS	Port p1 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
25 P0_BO_DIS	Port p0 read burst optimization disable. **NOTE:** The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency. 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response when PRCR1[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response when PRCR1[FT_DIS]=1
26 P1_RB_DIS	Port p1 read buffer disable. 0 Read buffer enabled and is used for servicing sequential, less-than-4-bit read requests. 1 Read buffer disabled and invalidated and all read requests generate array accesses.
27 P0_RB_DIS	Port p0 read buffer disable. 0 Read buffer enabled and is used for servicing sequential, less than 64-bit read requests. 1 Read buffer disabled and invalidated and all read requests generate array accesses.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FT_DIS	Flow through disabled. This field defines the AHB response on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset.

PRAMC_PRCR1 field descriptions (continued)

Field	Description
	NOTE: Do not change the FT_DIS bit value while accessing system RAM. Relocate code programming the FT_DIS bit to another memory area, e.g., local core memory. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

32.3 Functional description

This section describes the functions of the RAM controller.

32.3.1 Read / Write introduction

The RAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The RAM controller captures read data from the RAM array and drives it onto the AHB along with the associated dataphase termination signals. To facilitate operating at higher frequencies, the RAM controller can optionally incur a single wait state on the AHB response.

32.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

32.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to the PRAMC controller clock frequency.

32.3.2 Writes

This section discusses various write operations of the RAM controller.

32.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

32.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. Figure 32-2 provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to Reliability considerations.

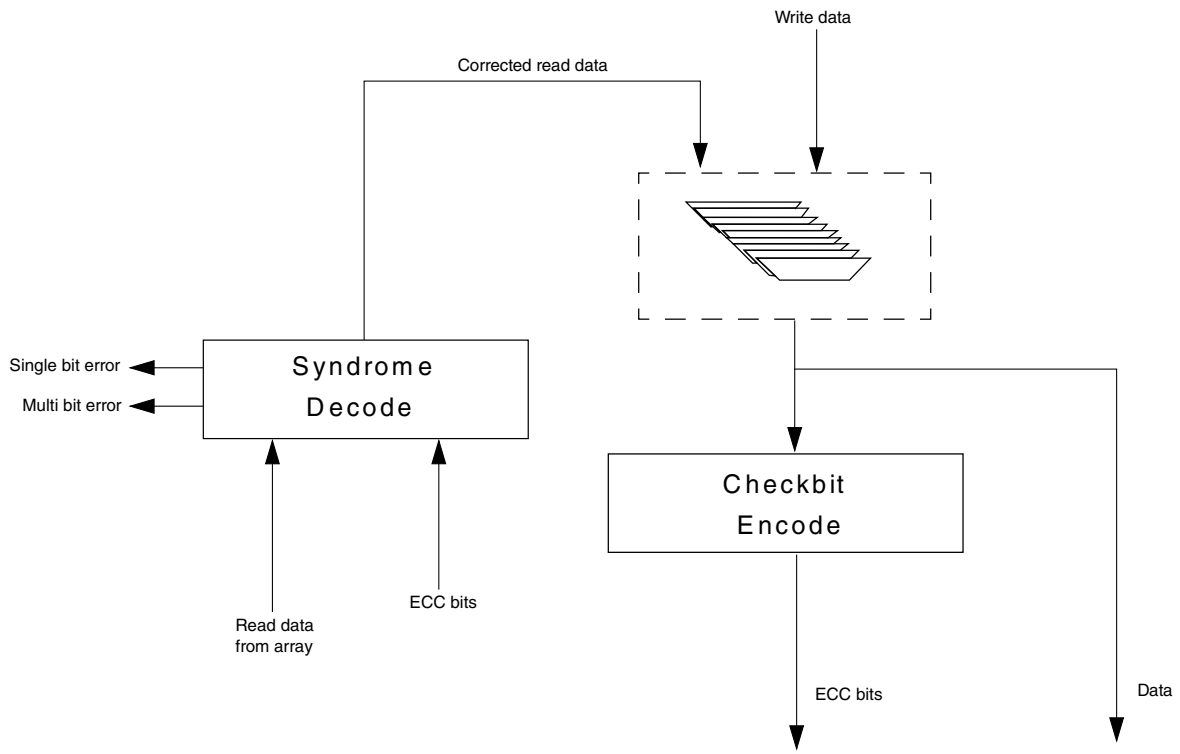

Figure 32-2. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

32.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

32.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

32.5 Reliability considerations

This section discusses reliability considerations of the RAM controller.

32.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 32-1. RAM controller basic H-matrix definition

		XOR sum	Data Bit[1]

	0		*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*				

1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

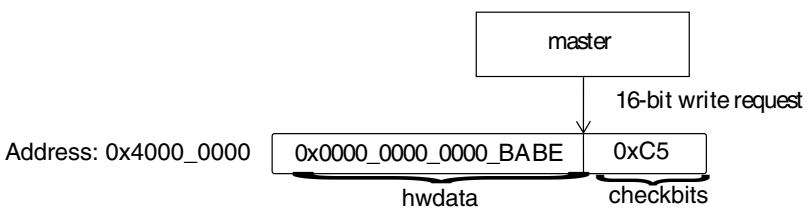
2. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

32.5.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

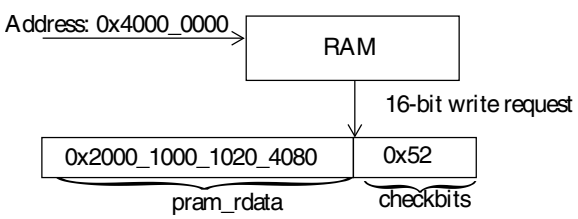
- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

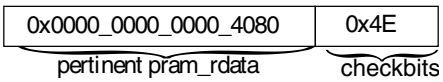


- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

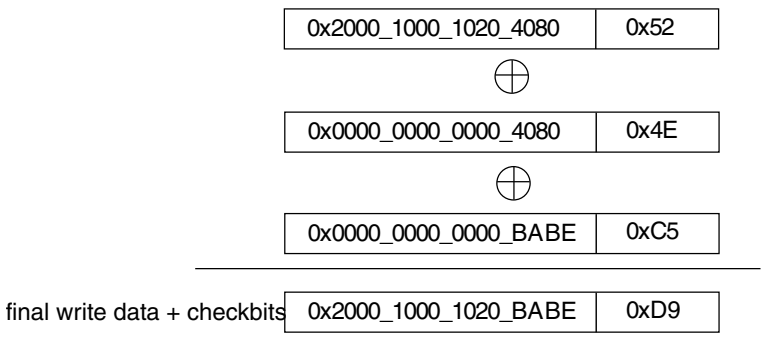
  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.



- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.



- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.



This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

32.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

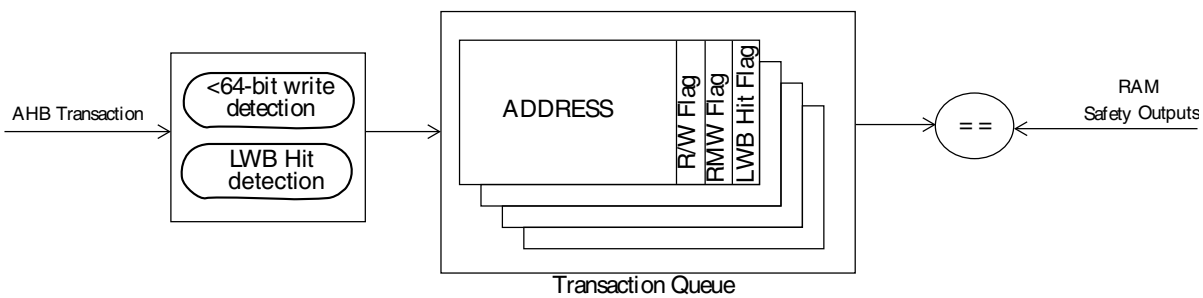


Figure 32-3. RAM controller transaction monitor block diagram

Chapter 33
Flash memory controller

33.1 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to the on-chip overlay RAM.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.
- It serves as the interface to the off-chip buddy device.[1]
- It serves as the interface to the External Bus Interface (EBI) memory space.

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

33.2 Features

The following list summarizes the key features of the flash memory controller:

1. The term "buddy device" refers to an optional companion chip with additional memory and debug features that is paired with a production chip during system development. It is not used in production devices.

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.
- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip calibration RAM, extended off-chip calibration RAM, on-chip system RAM, EBI memory
- Nexus trace stream interface supports message dumping to the on-chip overlay RAM

33.3 Block diagrams

Figure 33-1 provides a block diagram showing the flash memory controller and the attached flash array.

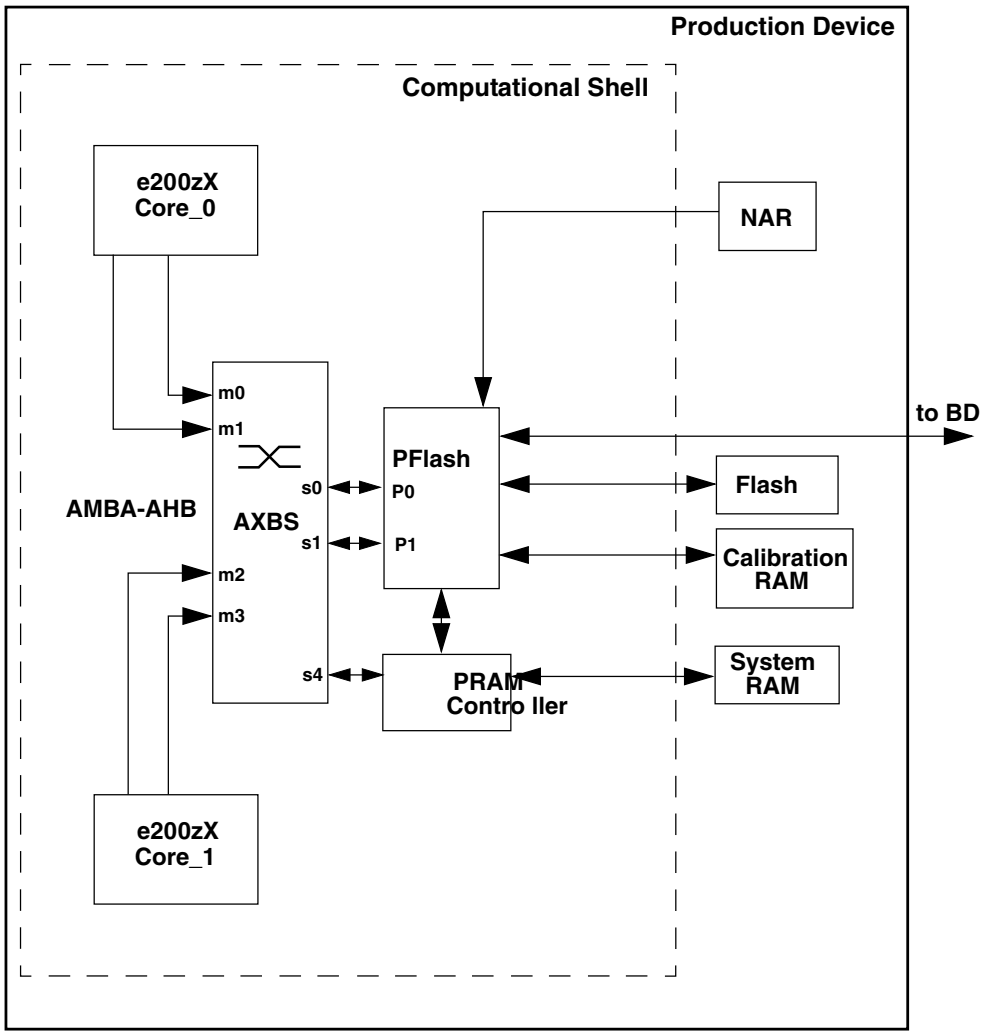

Figure 33-1. Platform-centric simple block diagram with flash memory ontroller

33.4 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configurationand overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario. There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.

33.4.1 Platform Flash Configuration Register 1 (PFLASH_PFCR1)

The PFlash Configuration Register 1 (PFCR1) controls the operation of Port p0 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for information on the masters.

PFLASH_PFCR1 field descriptions

Field	Description
0 P0_M15PFE	Port0 Master 15 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 15. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
1 P0_M14PFE	Port0 Master 14 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 14. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
2 P0_M13PFE	Port0 Master 13 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 13. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
3 P0_M12PFE	Port0 Master 12 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 12. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P0_M11PFE	Port0 Master 11 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 11. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P0_M10PFE	Port0 Master 10 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 10. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P0_M9PFE	Port0 Master 9 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 9. This bit is cleared by hardware reset.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P0_M8PFE	Port0 Master 8 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 8. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
8 P0_M7PFE	Port0 Master 7 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 7. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	NOTE: A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. The required settings are documented in the device data sheet. Higher operating frequencies require non-zero settings for this field for proper flash operation. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss.

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS]=1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

33.4.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)

The PFlash Configuration Register 2 (PFCR2) controls the operation of Port1 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for details about the masters.

11 P1_M4PFE	Port1 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P1_M3PFE	Port1 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P1_M2PFE	Port1 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P1_M1PFE	Port1 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P1_M0PFE	Port1 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P1_DPFEN	Port1 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P1_IPFEN	Port1 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P1_PFLIM	Port1 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss.

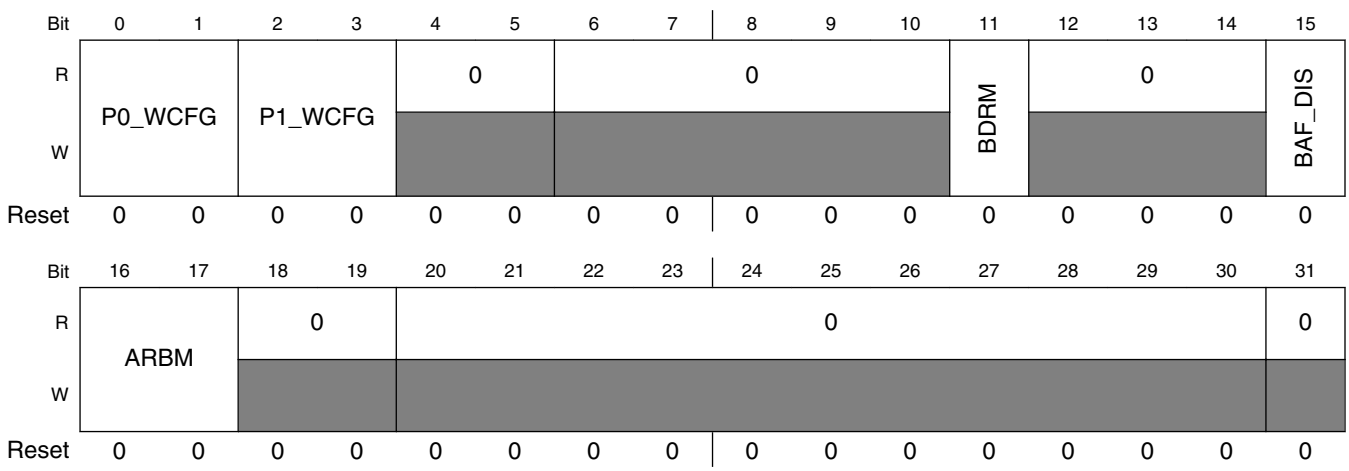
Table continues on the next page...

PFLASH_PFCR2 field descriptions (continued)

Field	Description
	10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit
31 P1_BFEN	Port1 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS]=0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

33.4.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)

Address: 0h base + 8h offset = 8h



PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
2–3 P1_WCFG	Port1 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 BDRM	Buddy Device Read Mode - This field controls the PFLASH_C55FM bus response when the master presents a read request targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address. This field is ignored on production ECUs where the Buddy Device is not present. On production ECUs, this memory map region is provided for the "OLDA" (on-line data acquisition) function. Read requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are terminated with error on the system bus. This field is ignored on write requests targeting the extended overlay RAM using the direct, non-remapped address. Write requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are ignored and terminate cleanly on the system bus. Write requests on engineering ECUs targeting the extended overlay RAM using the direct, non-remapped address are executed. This field is initialized by hardware reset. 0 Read requests targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address are aborted, and the request is terminated with error on the system bus. 1 Read requests targeting the extended overlay RAM on the Buddy Device(BD) using the direct, non-remapped address are allowed. The PFLASH_C55FM returns the requested data from the extended overlay RAM, which resides on the BD. Any system bus errors returned by the BD are passed onto the master.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.
16–17 ARBM	Arbitration Mode. This 2-bit field controls the arbitration of concurrent flash access requests from the two AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 10 Round-robin arbitration 11 Round-robin arbitration
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

33.4.4 Platform Flash Access Protection Register (PFLASH_PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

NOTE

See the chip-specific platform flash controller information for details about the actual masters available on the device.

Field	Description
28–29 M14AP	Master 14 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
30–31 M15AP	Master 15 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

33.4.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)

The PFCRCR is used to globally enable/disable the calibration remap function.

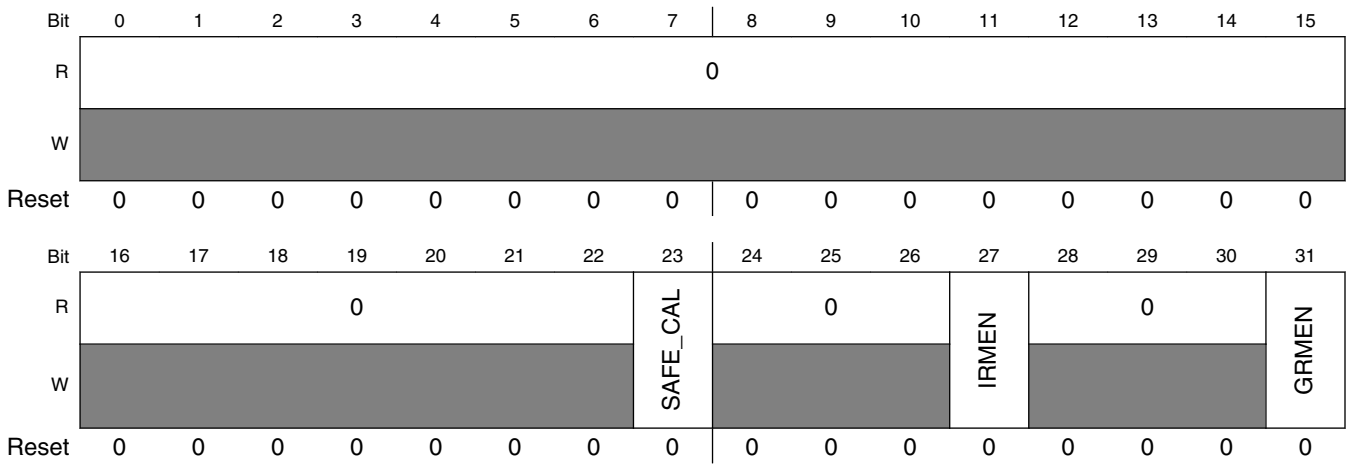
CAUTION

Overlay remap functions, when used with line read buffers enabled (PFLASH_PFCRx[BFy_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC_MCR[PGM]

Address: 0h base + 10h offset = 10h



PFLASH_PFCRCR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 32 to 16. This field is initialized by hardware reset. 1 Established calibration overlay regions are considered safety-critical. 0 Established calibration overlay regions are not considered safety-critical.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

33.4.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 32 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Address: 0h base + 14h offset = 14h

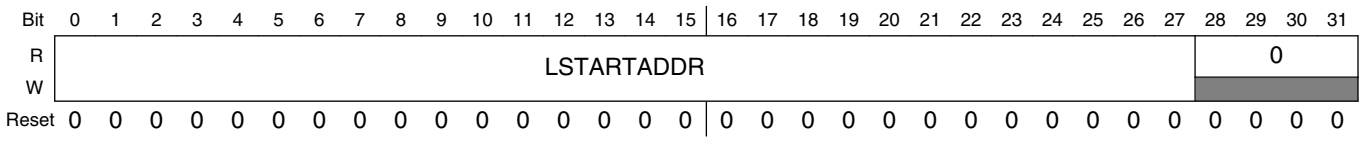
33.4.7 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 31d



PFLASH_PFCRD*n*_Word0 field descriptions

Field	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

33.4.8 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 31d

	the physical address which maps to the destination calibration overlay memory. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

33.4.9 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Address: 0h base + 108h offset + (16d × i), where i=0d to 31d

33.5 Functional description

The flash memory controller interfaces between:

- The AHB system bus ports
- Nexus trace
- Flash memory array
- Overlay RAM
- Off-chip Buddy Device
- System RAM
- EBI memory

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it

onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

33.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

33.5.2 Access protections

33.5.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in Platform Flash Access Protection Register (PFLASH_PFAPR). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

33.5.2.2 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on Port0 or Port1 are evaluated. If

the flash memory controller detects an attempted instruction fetch access to the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

33.5.3 Read cycles - buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. In the event of a buffer miss, a flash access is initiated. If globally enabled, the calibration remap evaluation is also performed. If the access is to be remapped, the appropriate access is routed to the destination memory.

If the flash access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as most-recently-used. If the flash access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

33.5.4 Read cycles - buffer hit

Single cycle read responses to the AHB are possible with the flash memory controller when the requested read access was previously loaded into one of the page buffers. In these "buffer hit" cases, read data is returned on the system bus with a zero wait-state response.

33.5.5 Error termination

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read Access Control or Write Access Control settings do not allow the access, thus causing a protection violation. See Platform Flash Access Protection Register (PFLASH_PFAPR) for more detail. In this case the flash memory controller does not initiate a flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See Platform Flash Configuration Register 3

(PFLASH_PFCR3) for more detail. In this case, the flash memory controller does not initiate a flash array access.
- Attempted access by an AHB master to a flash region, where the corresponding censorship control is asserted.
- The flash or overlay RAM returns an error response on an attempted access to a partition that is unavailable. (see Flash error response operation or Embedded Flash Memory).
- Attempted access by an AHB master to a reserved region in the flash memory map.

33.5.6 Flash error response operation

The flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

33.5.7 Censorship

The flash space is defined by regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- Secure code flash (instruction for security module)
- Secure data flash (data for security module)
- UTEST flash
- Security flash blocks

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

33.5.8 Security module exclusive control

During "Production at OEM" lifecycle state and beyond, the HSM can establish the secure flash blocks to be exclusive to the HSM and route program or erasing of secure flash blocks to the alternate programming interface.

The secure flash space is independently controlled for each of the following regions:

- 16 KB secure code flash block at address range 0x0060_C0000 - 0x0060_FFFF
- 64 KB secure code flash blockA at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code flash blockB at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data flash blocks at address range 0x0068_0000 - 0x0068_7FFF

The HSM provides flags to individually control the HSM-exclusivity for each of the secure flash regions. When a given secure flash block is marked as exclusive to the HSM, the HSM is the only system bus master granted access to that block and access attempts by non-HSM masters are terminated with error. Once HSM-exclusivity is established for a given secure flash block, the HSM is guaranteed access to that block, regardless of the state of the censorship controls. Secure flash exclusivity applies to read and write accesses.

33.5.9 Security Module Alternate Programming Interface

The secure flash space is independently controlled for each of the following regions:

- 16 KB secure code flash block at address range 0x0060_C0000 - 0x0060_FFFF
- 64 KB secure code flash blockA at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code flash blockB at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data flash blocks at address range 0x0068_0000 - 0x0068_7FFF

The HSM provides flags to individually control the routing interlock write for each of the four secure flash regions to either the main program/erase interface or the alternate program/erase interface. When a given secure flash block is assigned to the alternate program interface, the flash controller appropriately routes incoming interlock write requests within the given secure flash block address range to the flash's alternate program interface. Alternate program control can be controlled independent of HSM exclusivity for a given secure flash block

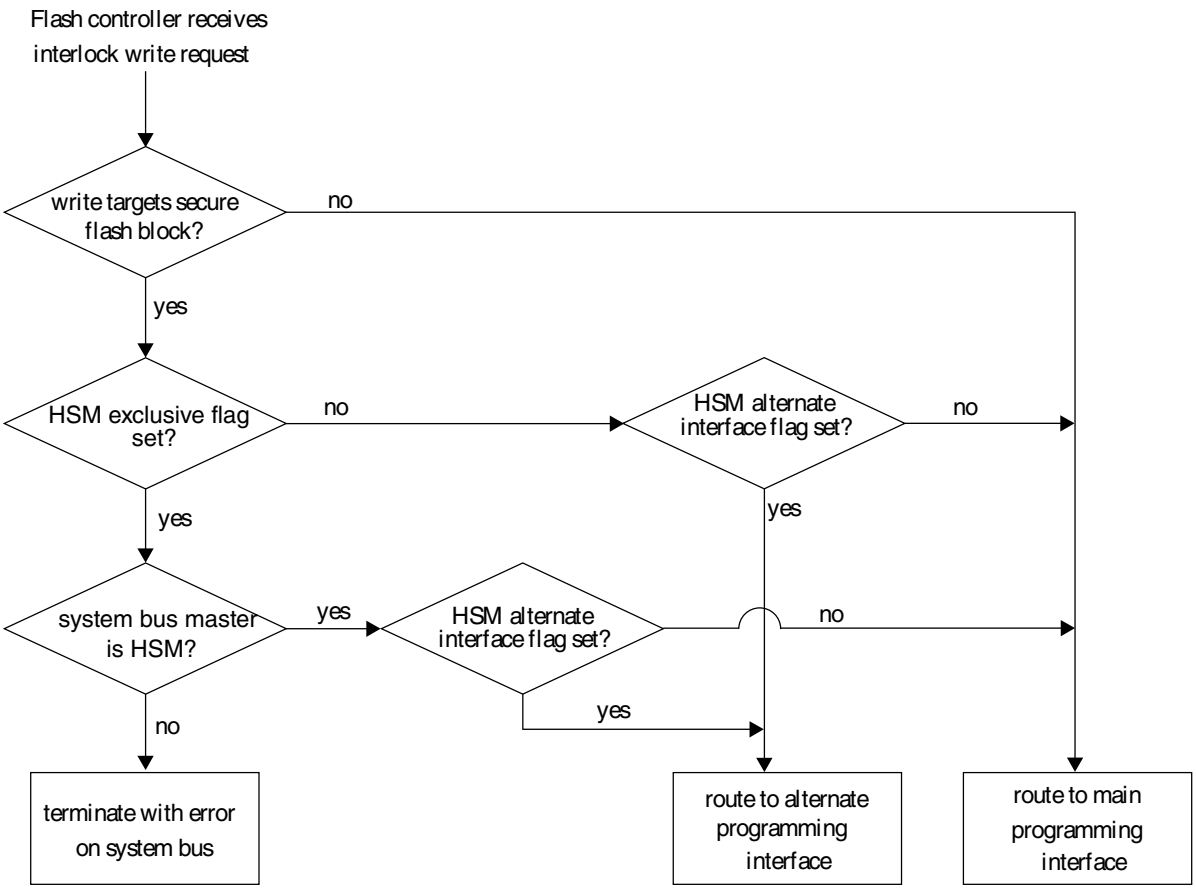

Figure 33-2. Interlock Write Alternate Programming Interface Routing Flowchart

33.5.10 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

33.5.11 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Platform Flash Configuration Register 1 (PFLASH_PFCR1)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

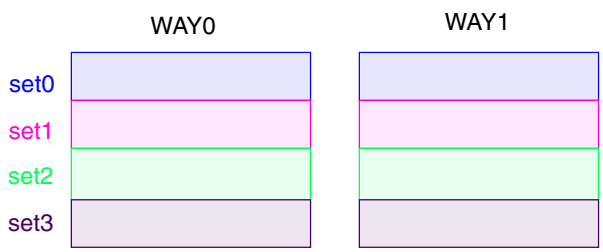

Figure 33-3. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Platform Flash Configuration Register 1 (PFLASH_PFCR1). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to ‘1’,
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. Either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted.

Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

33.5.12 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to Platform Flash Configuration Register 2 (PFLASH_PFCR2) for a description of these controls. Prefetches are never triggered by write cycles.

33.5.13 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

33.5.14 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to Platform Flash Configuration Register 3 (PFLASH_PFCR3). The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

33.5.15 EBI memory support

The PFLASH_C55FM supports memory accesses via the External Bus Interface (EBI). The EBI memory can serves as an extension of flash memory space with potential to be overlaid, or the EBI memory can serve as an overlay target for remapping flash accesses. Contents fetched from the EBI memory space can be stored locally in the PFLASH_C55FM mini-cache to facilitate zero-wait state subsequent accesses.

33.5.16 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM on-chip System RAM that can be used as overlay RAM.

Recall this family of devices includes a comprehensive set of features including dedicated overlay RAM arrays to aid calibration and debug. The overlay function supports the following features:

- Can be mapped over internal flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Can be used to hold device debug trace stream
  - Allows limited trace based debug without requirement for complex debug tool hardware and access to high speed trace port
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
  - Timing for calibration accesses to a particular overlay RAM is only guaranteed if it is not being used as a destination for trace streaming at the same time
  - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
  - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
  - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is only available on special ED devices.
- A portion of the system RAM can be used for overlay.

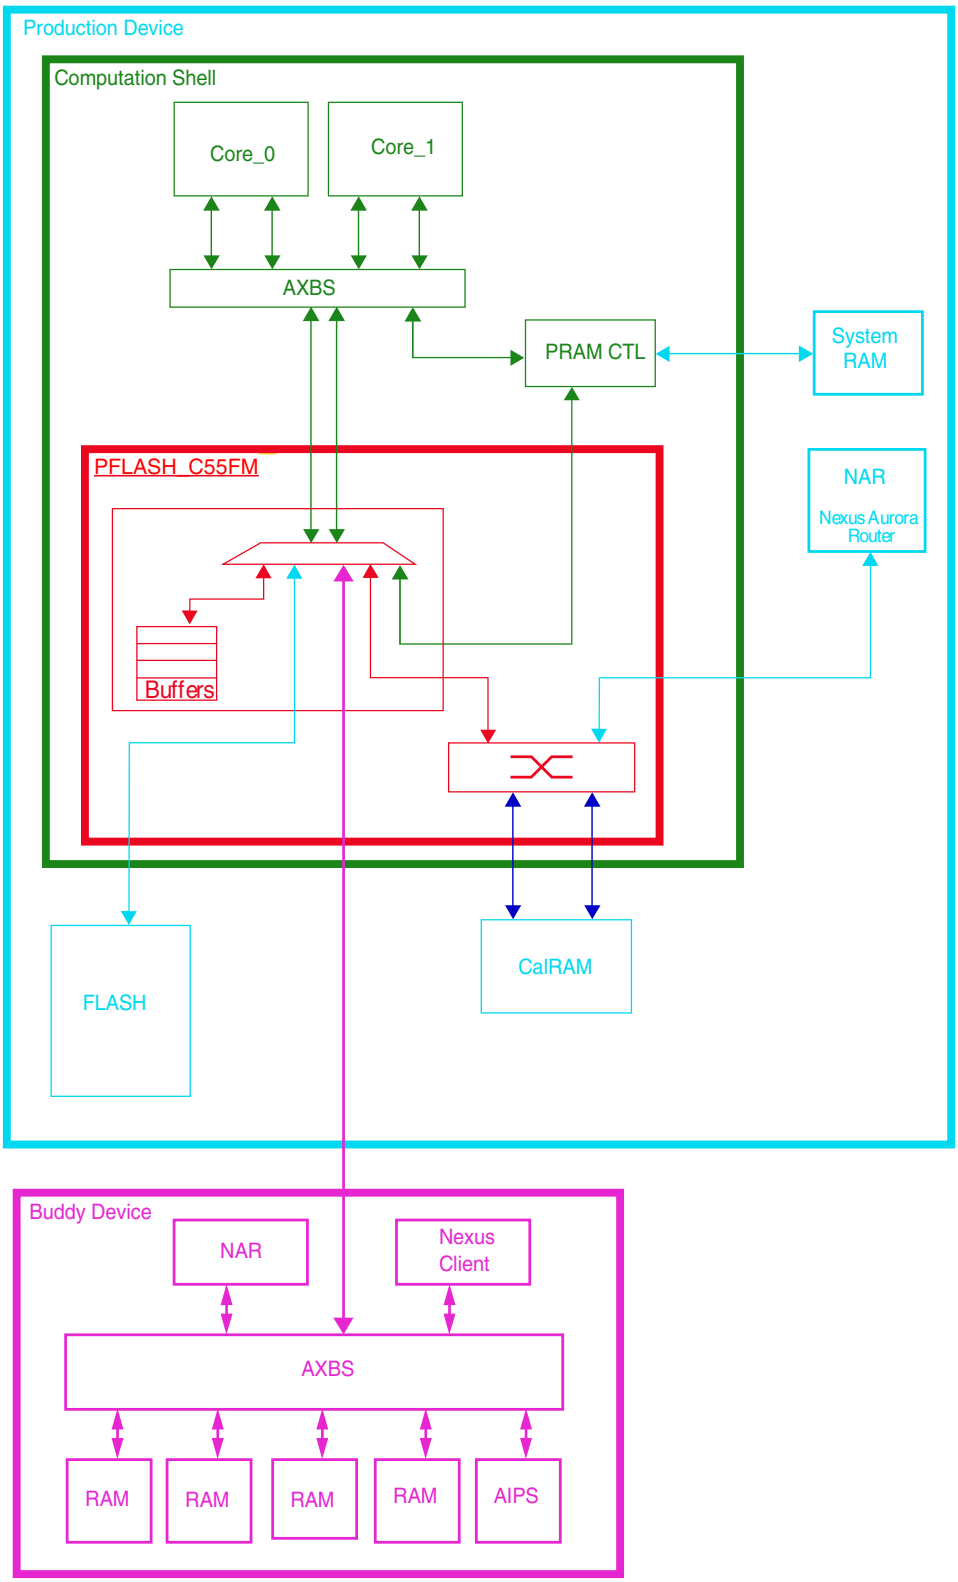

Figure 33-4. Flash memory controller and associated calibration remap targets

33.5.16.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

To better understand the functionality of the calibration remap, consider more detailed block diagrams, one showing the overall structure of the calibration remap function and another showing more detail on the actual remap logic. Recall the flash memory controller implements a hardware interconnection matrix connecting the three input ports and four destination memories. See Figure 33-5.

The following figure illustrates the calibration remap connection matrix.

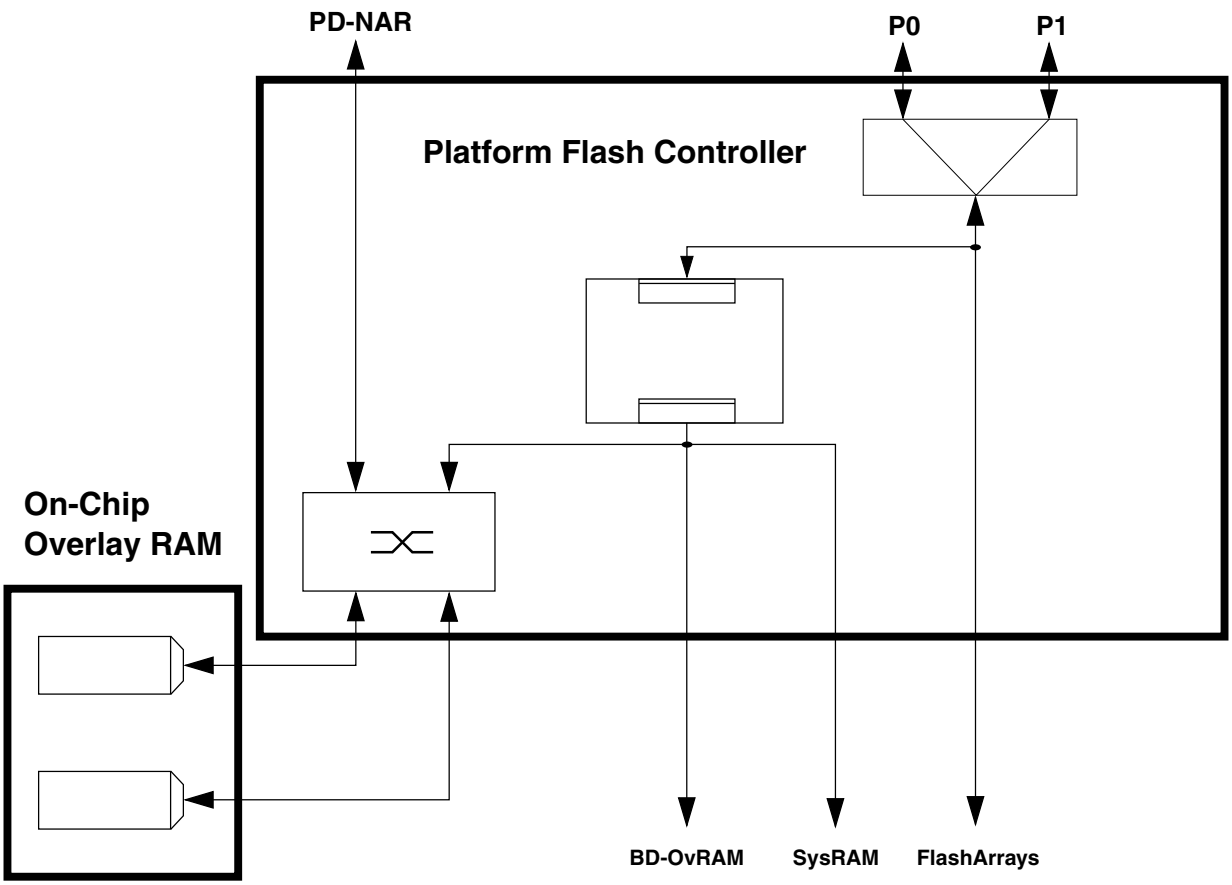

Figure 33-5. PFlash calibration remap connection matrix

Note the 64-bit on-chip overlay RAM is split into 2 equal-sized memories to allow concurrent accesses for calibration data from the P0, P1 (where these are the crossbar slave input ports) plus trace data writes from the Production Device Nexus Aurora Router (PD-NAR).

The translated physical address defines the destination memory. Table 33-1 shows the base addresses for the calibration data memories as defined by the system memory map.

Table 33-1. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1
On-chip Overlay RAM	0x0D00_----	P0, P1, PD-NAR
Buddy Device (Extended) Overlay RAM	0x0C{0,1}-_----	P0, P1

Note the trace data from the Nexus Aurora Router (PD-NAR) can only be routed to the on-chip overlay RAM; there is a different connection path in the Buddy Device from the BD-NAR into the extended overlay RAM.

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM, on-chip or buddy device (extended) overlay RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address. Byte-, halfword-, word-, and doubleword-sized data store references to the on-chip overlay RAM are supported. Byte-, halfword-, word-, and doubleword-sized store references to the buddy device (extended) overlay RAM are supported.

The read data interface of system RAM, on-chip overlay RAM, and buddy (extended) device is 64 bits wide for each, whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device. The access time when fetching data from the buddy device presents the longest latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(\mathrm{RWSC}+2) \geq \left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right) \geq (\mathrm{OverlayRAMTransferBurstLatency})$$

Equation 20. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping. Generally, not all areas of the flash memory map are available for calibration remapping. Secure flash blocks, EEPROM, BAF and UTEST are usually not available for calibration remapping. Flash access requests which present an address targeting the secure flash blocks, EEPROM, BAF or UTEST will bypass calibration remap evaluation and return flash data.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries. See Figure 33-6.

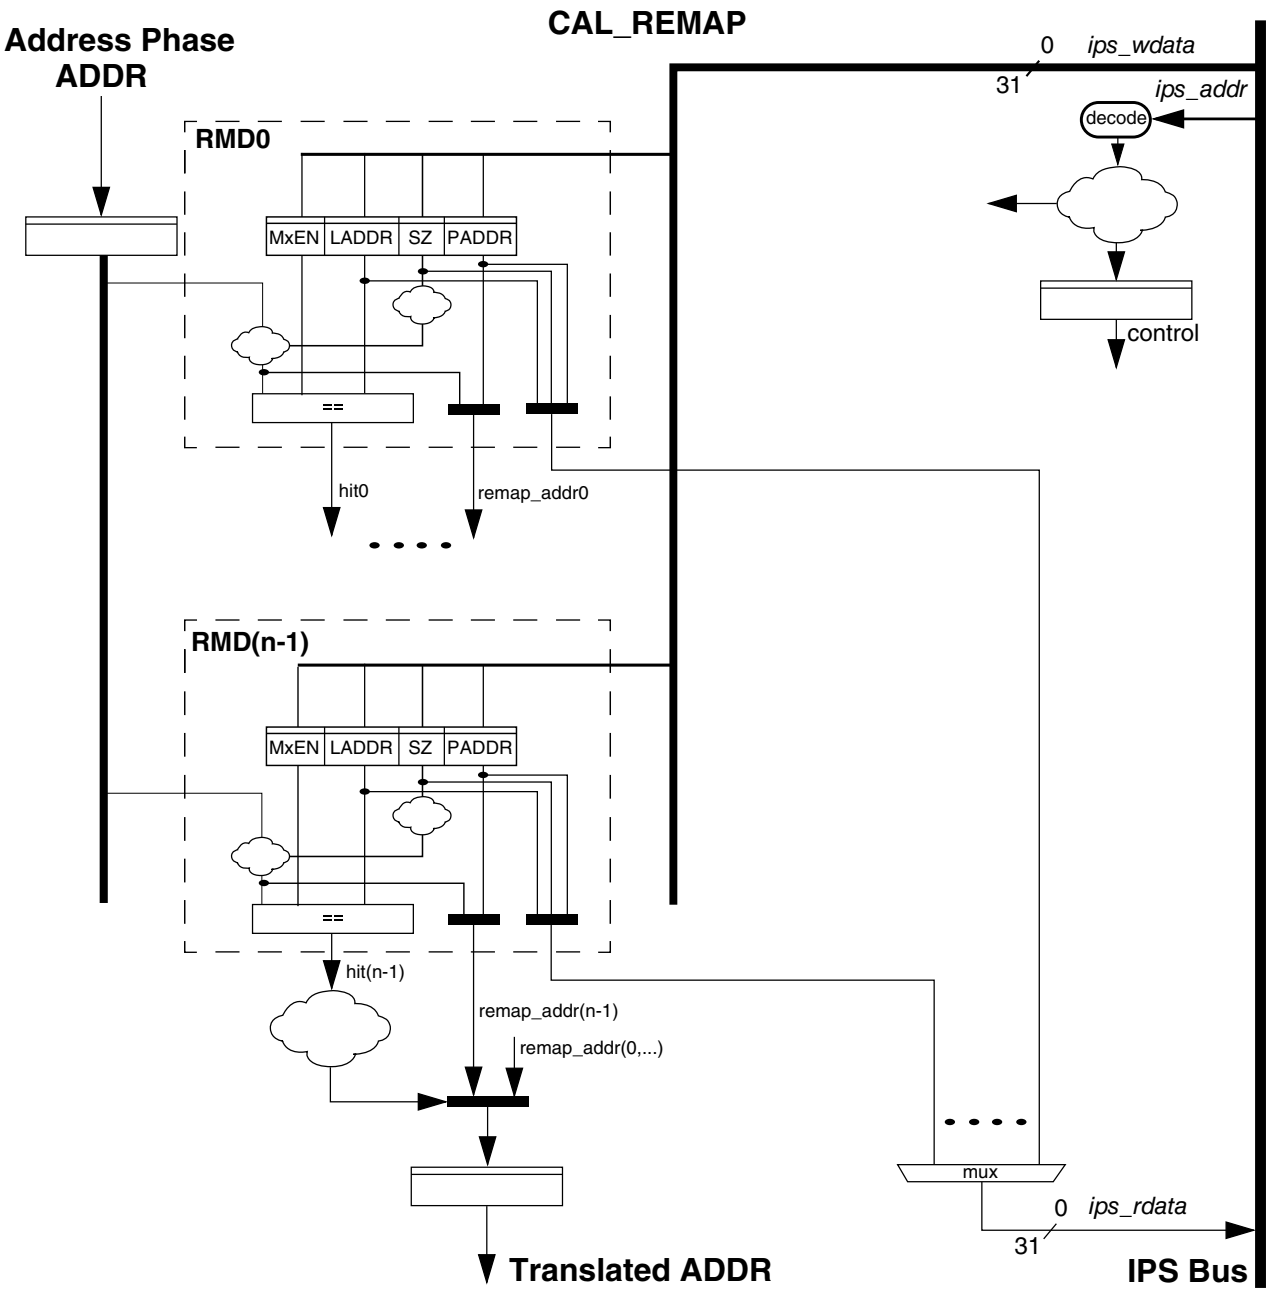

Figure 33-6. PFlash calibration remap logic detail

Each instantiation of the basic calibration remap function {RMD0,…, RMD(*n*-1)} in Figure 33-6 includes the three descriptor registers containing the logical start address (LADDR in the figure), the physical start address (PADDR), region size (SZ), and per-master enable bits (MxEN). The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration

remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

33.5.17 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

33.5.17.1 e2eECC End-to-End ECC

33.5.17.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

   addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

   addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

   Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

   fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

   addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

33.5.17.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

33.5.17.2.1 On-Chip Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

33.5.17.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, CRD0 – CRD31, and PFCRCR[SAFE_CAL]=1, the flash memory controller treats CRD0 – CRD15 and CRD16 – 32 as replicated sets of 16 calibration region descriptors, where:

- CRD0 and CRD16 are configured identically
- CRD1 and CRD17 are configured identically
- CRD2 and CRD18 are configured identically
- ...
- and CRD15 and CRD31 are configured identically

Expressed more generally, the contents of CRD[n] must be identical to the contents of CRD[(N/2) + n], where N is the total number of region descriptors and $0 \le n \le (N/2) - 1$.

Note

It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2) – 1] and the calibration regions defined in CRD[N/2] to CRD[N – 1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

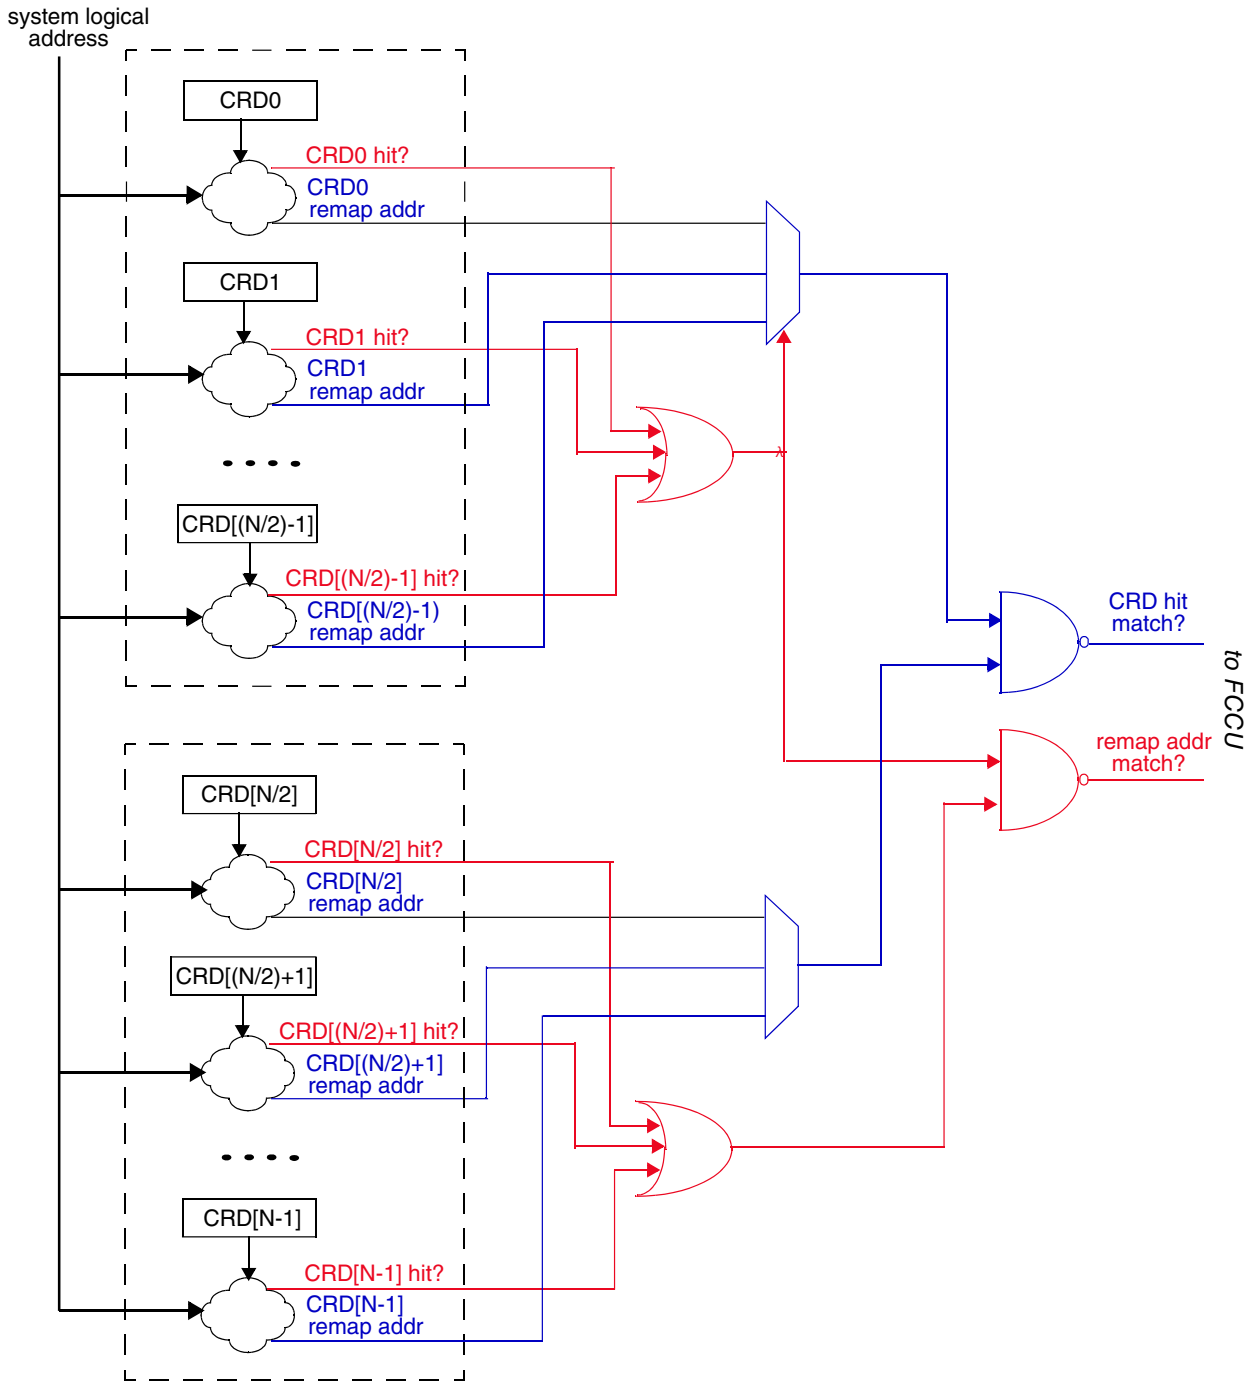

Figure 33-7. Safety-critical calibration remap datapath with redundancy

33.5.18 ECC on data flash accesses

ECC events detected on accesses to data flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU.

NOTE

EEPROM should be avoided for storage of executable code.

33.5.19 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 34
Embedded Flash Memory (c55fmc)

34.1 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

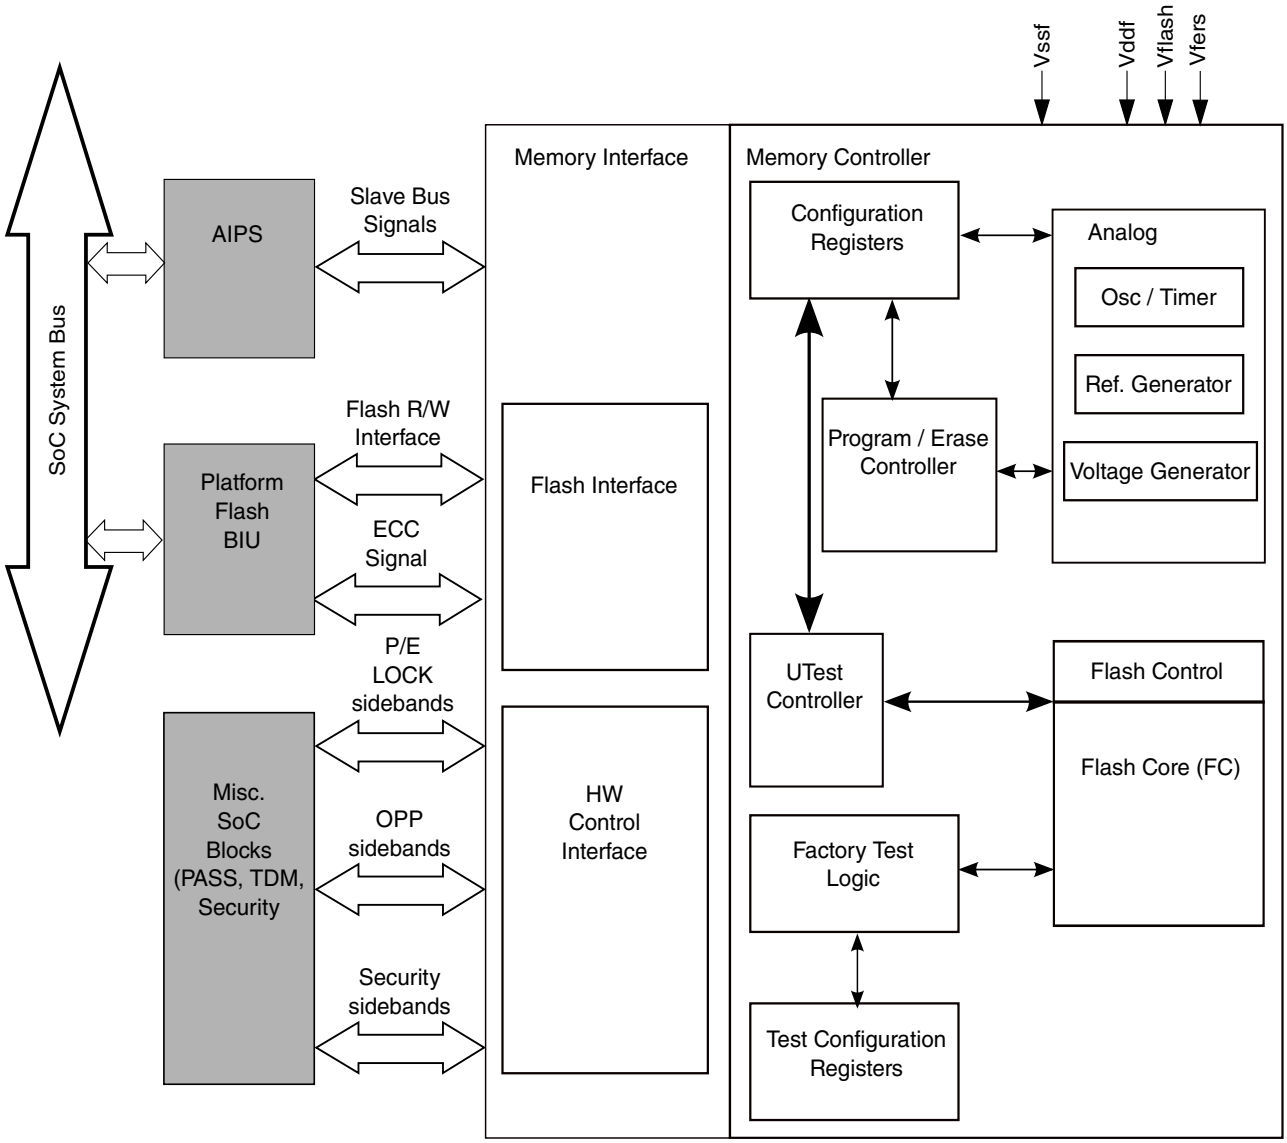

Figure 34-1. c55fmc block diagram

34.1.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see Functional Description.

34.1.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

34.1.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *Low power mode* turns off all DC current sources within the embedded flash memory on the Vflash domain, and enables VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in low power mode.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

34.2 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

34.3 Test mode disable seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the Utest block becomes OTP (Erase Locked, and Over Program Protection enabled). The Utest Block also is not accessible in Test Mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

Utest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and Single Bit Corrections and Double Bit Detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A . Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written. UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to let two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 34-1. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

34.4 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks..

34.4.1 Module Configuration Register (C55FMC_MCR)

NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description.
2. See Functional Description for information about simultaneous MCR writes, and priority levels.

Address: 0h base + 0h offset = 0h

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations(and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE:** This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. **NOTE:** 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24 FERS	Factory Erase and Program FERS is used for erase and program operations to enable a faster operation. Factory Erase must be done following “Initial Factory Conditions All Temps” with respect to voltage conditions, write/erase cycling, and temperature which can be from -40 °C to 150 °C;. After setting the ERS or PGM bit, but prior to setting EHV, FERS may be set to enable a Factory Erase or Program. FERS can be written only when ERS or PGM are high, but EHV is still low. Factory Erase may also be disabled by writing a location in the UTest NVM space. Address 0x0020 in the UTest NVM space will be checked at reset, and if programmed with data that contains at least one zero, a factory erase is not allowed, and FERS is locked. Writes attempted that violate the above cases will result in FERS remaining cleared. FERS is cleared on reset. 0 Factor Erase is disabled. 1 Factory Erase is enabled.
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within Tesus of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. **NOTE:** Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

34.4.2 Alternate Module Configuration Register (C55FMC_MCRA)

NOTE

1. This is an alternate interface register. It may be mapped to a different address than shown. See the Chip Configuration Chapter for details.
2. A number of Alternate Module Configuration Register (MCRA) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description .
3. See Functional Description for information about simultaneous MCRA register writes, and priority levels.
4. Reset values are dependent on chip configuration. See the Chip Configuration chapter for specifics.

Address: 0h base + 4h offset = 4h

C55FMC_MCRA field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEASa	Program Access Space PEASa is used to indicate which space is valid for program operations, either main array space or UTest NVM space for the Alternate program and erase interface. It should be noted that erase is not allowed to the UTest NVM space (even if unsealed with the Test Mode Disable Seal) through the alternate interface. If an interlock write is done to the UTest NVM space with ERSa set, PEASa will remain 0. See PEAS definition in the MCR. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONEa	State Machine Status DONEa indicates if the embedded flash memory is performing a high-voltage operation for the Alternate program and erase interface. See DONE definition in the MCR for more information. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEGa	Program/Erase Good The PEGa bit indicates the completion status of the last flash memory program or erase sequence for which high-voltage operations were initiated for the Alternate program and erase interface. See PEG definition in the MCR for more information. It should be noted that in the event of a error on the alternate interface PEGa will clear, but the ADR will not be updated with the failing location. The ADR is only valid for main interface program or erase fails, and other fails noted in the ADR. 0 Program or erase operation failed. 1 Program or erase operation successful.
23–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGMa	Program PGMa is used to set up embedded flash memory for a program operation for the Alternate program and erase interface. See PGM definition in the MCR register for more information. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUSa	Program Suspend PSUSa is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state for the Alternate program and erase interface. See PSUS definition in the MCR register for more information. Erase ERSa is used to set up embedded flash memory for an erase operation for the Alternate program and erase interface. See ERS definition in the MCR register for more information. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERSa	Erase Suspend

Table continues on the next page...

C55FMC_MCRA field descriptions (continued)

Field	Description
	ERSa is used to set up embedded flash memory for an erase operation for the Alternate program and erase interface. See ERS definition in the MCR register for more information. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUSa	Erase Suspend ESUSa is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state for the Alternate program and erase interface. See ESUS definition in the MCR register for more information. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHVa	Enable High Voltage The EHVa bit enables the embedded flash memory for a high-voltage program/erase operation for the Alternate program and erase interface. See EHV definition in the MCR register for more information. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

34.4.3 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:

- The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no factory erase or or margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. 1 165 °C maximum operating temperature with reduced performance.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total). 00101 Ten 256 KB blocks (2.5 MB total). 00110 Twelve 256 KB blocks (3 MB total). 00111 Fourteen 256 KB blocks (3.5 MB total). 01000 Sixteen 256 KB blocks (4 MB total). 01001 Eighteen 256 KB blocks (4.5 MB total). 01010 Twenty 256 KB blocks (5 MB total). 01011 Twenty-two 256 KB blocks (5.5 MB total). 01100 Twenty-four 256 KB blocks (6 MB total). 01101 Twenty-six 256 KB blocks (6.5 MB total). 01110 Twenty-eight 256 KB blocks (7 MB total). 01111 Thirty 256 KB blocks (7.5 MB total). 10000 Thirty-two 256 KB blocks (8 MB total). 10001 Reserved 10010 Reserved 10011 Reserved 10100 Reserved 10101 Reserved 10110 Reserved 10111 Reserved 11000 Forty-eight 256 KB blocks (12 MB total). 11001 Reserved. 11010 Reserved. 11011 Reserved. 11100 Reserved. 11101 Reserved. 11110 Reserved. 11111 Reserved.
8–10 n64Kh	Number of 64 KB blocks in partitions 4 and 5. This field is read only.

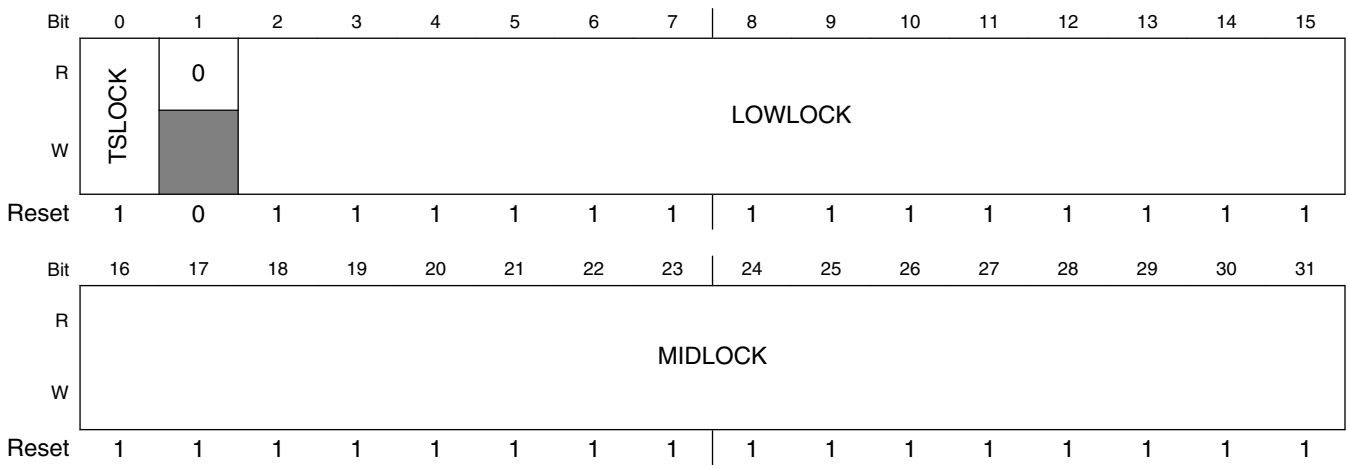
34.4.4 Lock 0 register (C55FMC_LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

Address: 0h base + 10h offset = 10h



C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended. 0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended.

Table continues on the next page...

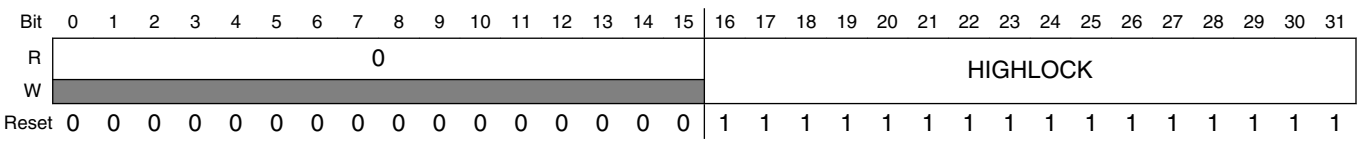
C55FMC_LOCK0 field descriptions (continued)

Field	Description
	The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

34.4.5 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h



C55FMC_LOCK1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. HIGH Blocks exist in partitions 4 and 5. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

34.4.6 Lock 2 register (C55FMC_LOCK2)

The Lock 2 (LOCK2) register provides a means to protect blocks from being modified.

Address: 0h base + 18h offset = 18h

The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect.

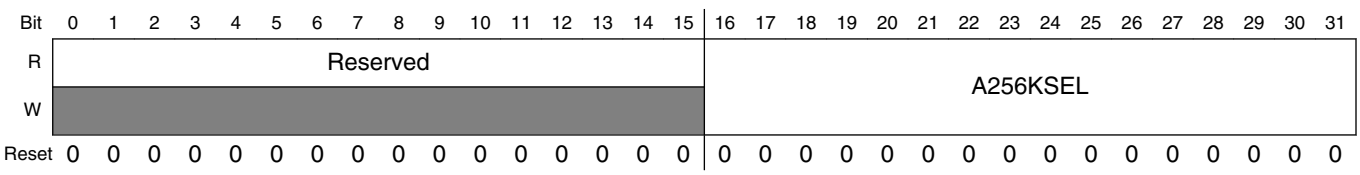
C55FMC_SEL2 field descriptions (continued)

Field	Description
	0 The block is not selected 1 The block is selected for erase

34.4.13 Select 3 register (C55FMC_SEL3)

The Select 3 (SEL3) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 44h offset = 44h



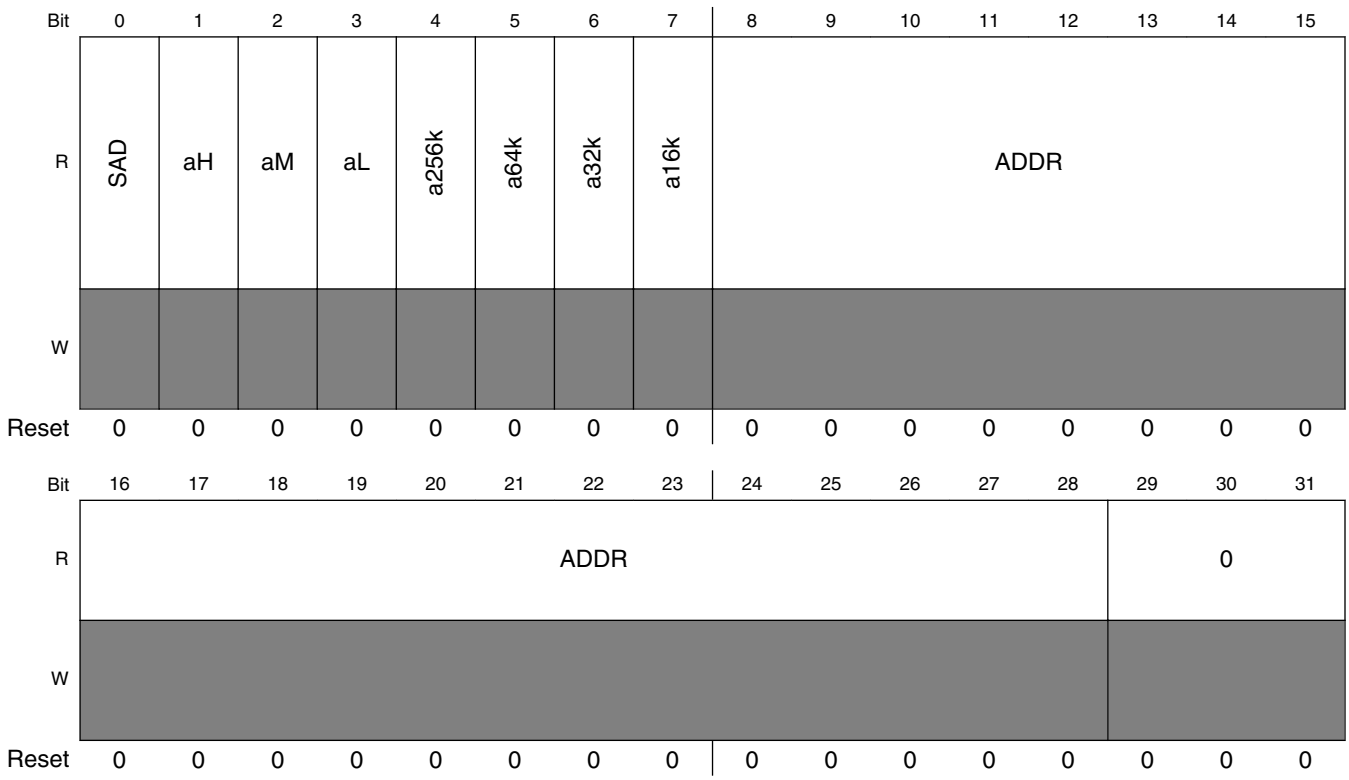
C55FMC_SEL3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

34.4.14 Address register (C55FMC_ADR)

The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h



C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...

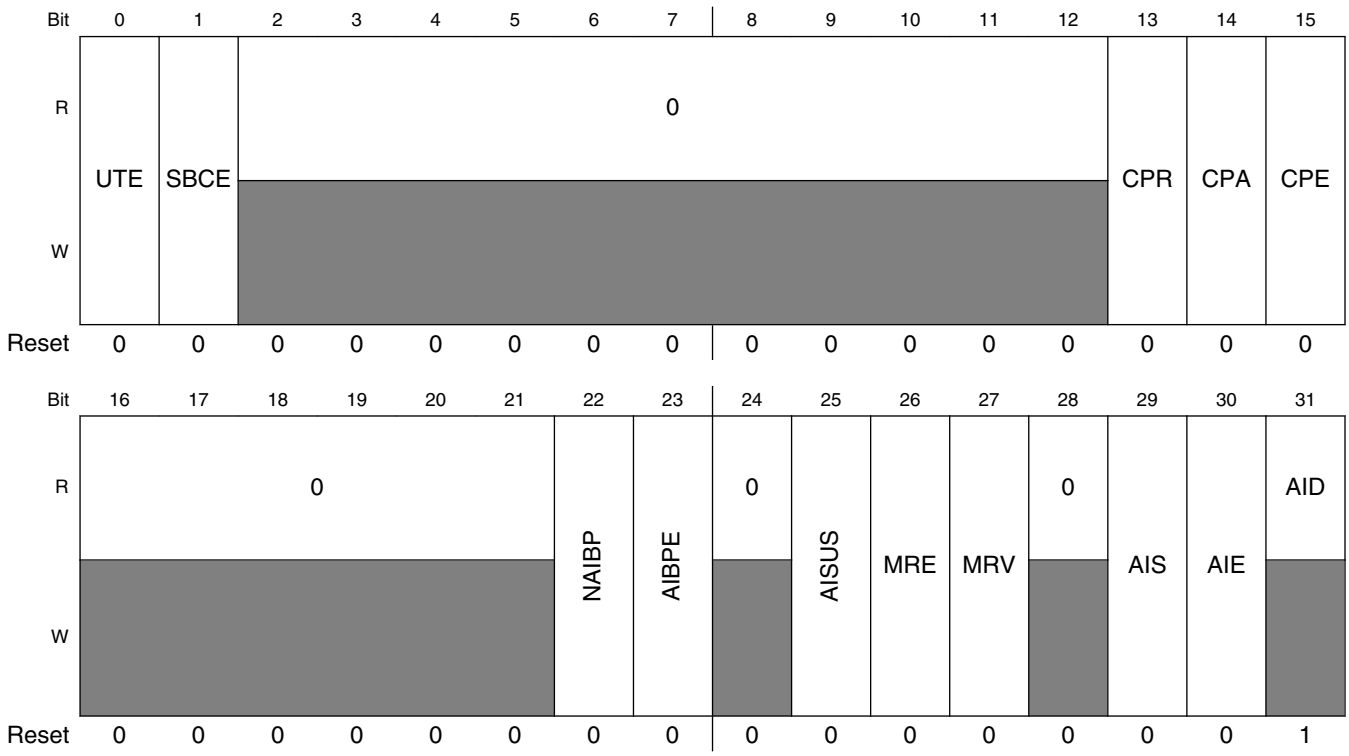
C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.4.15 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h



C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

34.4.16 UMISR register (C55FMC_UM*n*)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MISR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_UM*n* field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

34.4.17 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W

C55FMC_UM9 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MISR	MISR[288]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained

34.4.18 Over-Program Protection 0 register (C55FMC_OPP0)

The Over-Program Protection 0 (OPP0) register provides a means to protect blocks from being over-programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

C55FMC_OPP0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWOPP	Low Block Over-Program Protection[13:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Low Blocks starts at LOWOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The LOWOPP register is not writable, and is status only. The default value of the LOWOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.
16–31 MIDOPP	Mid Block Over-Program Protection[15:0]. A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Mid Blocks starts at MIDOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The MIDOPP register is not writable, and is status only.

Table continues on the next page...

C55FMC_OPP0 field descriptions (continued)

Field	Description
	The default value of the MIDOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming. 0 The corresponding block is available to be over-programmed.

34.4.19 Over-Program Protection 1 register (C55FMC_OPP1)

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 84h offset = 84h

Field	Description
0–31 PWD	Password challenge

34.5 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register (C55FMC_MCR). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 34-2. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- Low Power mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

34.5.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

34.5.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read, except when the embedded flash memory is in low power mode. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] =0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

34.5.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

   NOTE

   Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as

a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.

3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

34.5.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

34.5.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

34.5.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency in not limited, enabling at least 20uS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

34.5.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

34.5.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset. This feature is valid for programs done on the main interface, and not valid for programs done on the alternate interface.

34.5.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored(except for alternate erase interface). The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

34.5.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see Program software locking.

34.5.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

34.5.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

Warning

In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.

Warning

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency is not limited, enabling at least 5mS between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

34.5.1.4 Alternate program and erase interface

A second interface is provided on the flash for program and erase operations. The intent is that a dedicated master can have private access to blocks through this interface.

The alternate interface includes an alternate MCR register and alternate lock registers. Any block in low, mid, or high address space may be accessible through the alternate interface. The UTest NVM Block is also accessible for program through the alternate interface. 256 KB sized blocks are not accessible through this interface.

The alternate interface supports programming of data sizes from one doubleword (64 bits) to four doublewords within a single page (256 bits). Within a page, up to eight words may be altered in a single program operation. It is recommended that programming operations through the alternate interface be from 64 bits to 256 bits, and be 64-bit aligned.

The alternate interface supports erasing a single block at a time with each erase operation.

As with the main interface, erase suspend, program suspend, and erase-suspended programs are supported.

Program and Erase times for the alternate interface are the same as the main interface when programs and erases are done in isolation. If main interface and alternate interface are being utilized simultaneously, bandwidth sharing is utilized.

NOTE

It is possible for the UTest NVM block to exist in both the main program interface and alternate program interface. In the event of a conflict the first interface to do the program to an address will get priority, and all other attempts after this will result in an OTP over-program failure (MCR[PEG] or MCRA[PEGa] being set to 0).

34.5.1.4.1 Alternate program interface

The programming procedure follows exactly the same flow as the main interface, except that only page programming is allowed. See section Program for more information on programming.

The alternate interface program is done at lower priority compared to the main interface. Based on the size of programming allowed, the main interface has a 4:1 ratio advantage over the alternate interface. Program operations are allowed to finish on the active interface prior to allowing the inactive interface to execute its operation. Suspends done on the active interface enable the inactive interface to begin its operation.

NOTE

For alternate program while erase, there could be a latency of up to 5 ms in the program operation.

For more information on interaction between the alternate program interface and the main interface, see Alternate interface performance.

If the alternate interface is the only interface active, then normal program times may be expected.

34.5.1.4.2 Alternate erase interface

For erases done thru the alternate interface, the single block to be erased is selected based on the address that is received during the erase interlock write. Thus the Select registers are not valid for the alternate interface (step 2 of the erase flow in section Erase), and the interlock write address is used (step 3 of the erase flow in section Erase). All other features of the main interface apply to the alternate erase interface. The erase procedure is exactly the same as for the main interface. See section Erase for more information on erase.

The alternate interface erase is done at lower priority compared to the main interface. The time-slice ratio between the two interfaces is 10:1, with 50 ms of time given to the main erase for every 5 ms of alternate interface. Suspends done on the active interface enable the inactive interface to begin its operation.

For alternate erase while program, there can be a latency of up to 5 ms in the main program time. Once the alternate erase is interrupted, it will remain interrupted for main programs for a fixed time of 50 ms, at which time the alternate erase will restart. It should be noted that multiple interruptions of the alternate erase will significantly increase the total erase time.

For alternate erase while erase, the main erase has priority and receives 50 ms of erase for every 5 ms of alternate erase. This may result in a significant increase in the erase time for the alternate interface, and a minor increase in erase time for the main interface.

For more information on interaction between the alternate erase interface and the main interface, see Alternate interface performance

If the alternate interface is the only interface active, then normal erase times may be expected.

34.5.1.4.3 Alternate interface performance

Table 34-3 highlights the interactions between the alternate interface and the main interface for program, erase, suspend, and idle conditions.

Table 34-3. Alternate program and erase characteristics

Alt PGM/ERS interface request	Main PGM/ERS interface request	Alt interface result on memory array	Main interface result on memory array
IDLE	IDLE	IDLE	IDLE
IDLE/SUS	PGM/ERS	IDLE/SUS	PGM/ERS
PGM/ERS	IDLE/SUS	PGM/ERS	IDLE/SUS
PGM	PGM	PGM	Priority PGM (up to 4:1)
PGM	ERS	PGM with latency of 5 ms	ERS (possible minimal increase to total ERS time)
ERS	PGM	ERS (significant increase in total ERS time expected)	Priority PGM (possible latency of 5 ms) Once PGM is granted, 50 ms time slice available for more programs
ERS	ERS	ERS (significant increase in total ERS time expected)	Priority ERS (10:1) (possible minor increase to total ERS time) 50 ms Main ERS for every 5 mS alternate ERS

34.5.2 Low Power mode

In Low Power mode, the embedded flash memory enables VDDF power gating, and disables circuits on the VFLASH domain. No reads from or writes to the embedded flash memory are possible when in Low Power mode.

Prior to entering Low Power Mode, it is required that all program, erase, and UTest operations be stopped prior to entering the mode. If Low Power mode is entered while an operation is suspended, entering Low Power mode will have the same effect as a reset during suspend.

When in Low Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

34.5.3 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

34.5.3.1 Array integrity self check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks. The data to be read is customer-specific - user code may be programmed into the flash memory and the correct MISR signature is calculated based on that code. Any random or nonrandom code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the system frequency being used. The array integrity check consists of the following sequence of events:

1. Enable UTest mode.
2. Select the block or blocks to be receive the array integrity check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for array integrity check do not need to be unlocked.

NOTE

Unselected blocks are still read as part of the array integrity sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

NOTE

Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks will not be captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

NOTE

For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that AIS be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, ensure that UT0[SBCE] is set.
6. Set the UT0[AIE] bit.
   a. If desired, the array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and then continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers will contain a signature for the portion of the operation that was completed prior to the abort, and will not be deterministic. Prior to doing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
   b. If desired, the array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After

the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the flash may be done. Once [AID] goes high, UT0[AISUS] may be cleared to resume the array integrity sequence.

NOTE

User mode array reads requested during the array integrity test will be ignored, to ensure that the array integrity operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until the UT0[AID] bit goes high.
8. If breakpoints were enabled, check UT0[NAIBP], and if this is set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear MCR[SBC] or MCR[EER] bits. Then the operation may be resumed by clearing UT0[NAIBP]. Continue to wait until the UT0[AID] bit goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit.

34.5.3.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin reads are done at a read margin level checking for erased bits or programmed bits encroaching on the nominal read level. User margin read is a self-timed event, and is independent of system clocks or wait states selected. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific, and user code may be programmed into the flash memory. Any random or non-random code is valid. Once the operation is completed, the margin read results can be checked by reading the MCR[EER] bit and the MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode.
2. Select the block or blocks to receive margin read check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for margin read do not need to be unlocked.

NOTE

Unselected blocks are still read as part of the margin read sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks will not result in a faster margin read execution time.

NOTE

Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks will not be captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

NOTE

It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

NOTE

For margin read checks of the flash memory, sequential addressing is recommended. Setting AIS to 0 is possible for Margin Reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. Ensure that the MCR[EER] and MCR[SBC] bits are cleared.
6. If you want to detect single bits during margin read, set UT0[SBCE] to 1.

7. Set the UTO[MRE] bit.
8. Set the UT0[MRV] bit to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Set the UT0[AIE] bit.

NOTE

User mode array reads requested during the margin read test will be ignored, to ensure that the margin read operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

NOTE

During Margin Read operations, with AID low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

10. Wait until the UT0[AID] bit goes high.
    a. If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Array integrity self check for more information.
11. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

12. Write a logic 0 to the UT0[AIE] bit.

34.6 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash

memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 35
Decorated Storage Memory Controller (DSMC)

35.1 Introduction

This section details the hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rB,rA` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rB,rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `"x"` mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in the following figure.

Table 35-1. Power Architecture decorated load and store instruction formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
lbdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	0	0	0	0	1	1	/
lhdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	1	0	0	0	1	1	/
lwdx	0	1	1	1	1	1	rT						rA				rB				1	0	0		1	0	0	0	0	1	1	/
lbdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	0	0	0	0	1	0	/
lhdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		0	1	0	0	0	1	0	/
lwdcbx	0	1	1	1	1	1	rT						rA				rB				1	0	0		1	0	0	0	0	1	0	/
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
stbdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	0	0	0	0	1	1	/
sthdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	1	0	0	0	1	1	/
stwdx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		1	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		0	1	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1	**r**S						**r**A				**r**B				1	0	1		1	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit "decoration". The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

35.2 Decorated stores: `st[b,h,w]d{cb}x rS,rA,rB`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA

- accessAddress = rB
- wdata = rS

35.2.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container

Table 35-2. Decoration format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT			0	0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	0	BFW				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read
if bfw == 0
         then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp  & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
```

```
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

35.2.1.1 Compare-and-Store (CAST)

Table 35-3. Decoration format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8							
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16															
cast.w	1	0	0	1	CD28																											

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size]  // memory read

if (size == 8)             // define compare_operand
    compare_operand = CD8
else if (size == 16)
         compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand) // compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

35.2.1.1.1 Logical AND (AND)

Table 35-4. Decoration format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table continues on the next page...

Table 35-4. Decoration format: AND (continued)

and.{b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata      // modify
mem[accessAddress, size] = tmp// memory write
```

35.2.1.1.2 Logical OR (OR)

Table 35-5. Decoration format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or.{b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata          // modify
mem[accessAddress, size] = tmp// memory write
```

35.2.1.1.3 Logical Exclusive-OR (XOR)

Table 35-6. Decoration format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor.{b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata          // modify
mem[accessAddress, size] = tmp// memory write
```

35.2.1.2 Decorated Loads: `l[b,h,w]d{cb}x rT,rA,rB`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an "extract") operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

35.2.1.2.1 Simple Load (SLD)

Table 35-7. Decoration format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld.{b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

35.2.1.2.2 Registers-and-memory exchange (SWAP)

Table 35-8. Decoration format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
swap.b	0	1	0	1	-	-	**-**	-	-	-	-	**-**	-	-	-	-	**-**	-	-	-	-	-	-	-	WD8							
swap.h	0	1	0	1	-	-	-	-	-	-	-	**-**	-	-	-	-	**WD16**															
swap.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)             // store_operand - "modify"
    store_operand = WD8
else if (size == 16)
           store_operand = WD16
    else store_operand = {0x0, WD28} // zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

35.2.1.2.3 Load-and-Set-1(Bit) (LAS1)

Table 35-9. Decoration format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask  = 1 << (container - bit - 1) // generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

35.3 DSMC instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

Chapter 36
Flash Memory Programming and Configuration

36.1 Introduction

This chapter provides basic guidance on activities related to configuring and programming the embedded flash memory in the MPC5777M microcontroller.

Multiple layers of protection are available to prevent unintended updates to flash contents and unauthorized reads and writes to flash contents. The protection mechanisms range from simple write-protect bits for individual flash blocks to four levels of 256-bit password read and/or write protection and configuration of flash memory blocks as One Time Programmable (OTP).

Additionally, the MPC5777M microcontroller includes a tamper detection feature, debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

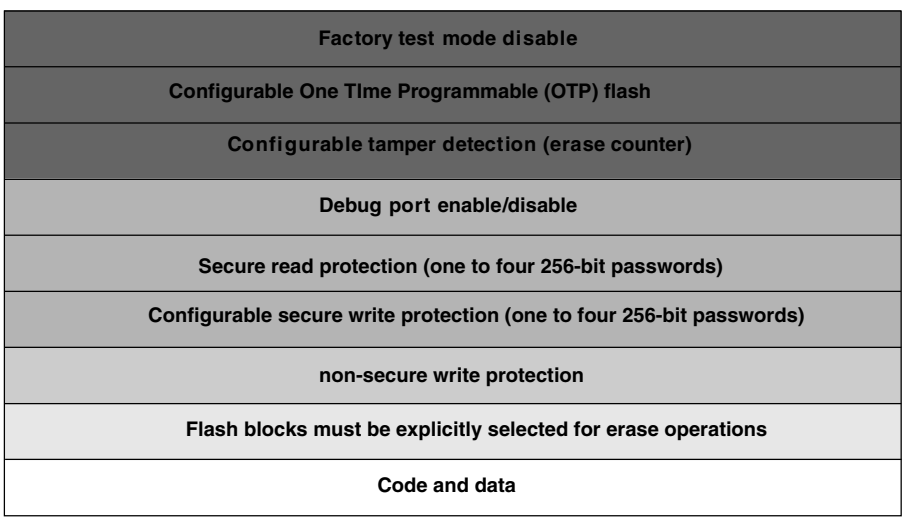

Figure 36-1. Flash memory protection layers

At the lowest layer of protection, all flash erase operations require the explicit selection of one or more blocks of flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The MPC5777M microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection region if desired.

Another protection feature related to tamper detection is the ability to configure any flash block as one-time programmable (OTP).

Finally, the microcontroller includes a feature that allows the customer to disable the ability to place the device in factory test mode.

The remainder of the chapter provides details regarding these protection mechanisms and gives a brief overview of security configuration planning.

Note

Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the flash protection features work and relate to each other, please read the chapter in sequence from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection and tamper detection applied to groups of flash memory blocks), i.e., a custom level of access protection can be provided for each flash memory block. This is accomplished

through the use of registers containing bits that are mapped to individual flash blocks. Understanding the mapping is key to understanding the implementation and use of the MPC5777M microcontroller's flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in Selection of flash memory blocks for erase. It is important to understand the topic before proceeding to other sections.

36.2 Selection of flash memory blocks for erase

The registers used for selecting flash blocks for erase operations are the flash control registers named LOCK0, LOCK1, and LOCK2. There is also a LOCK3 register, but no flash blocks are mapped to it.

The LOCK0–2 registers are 32-bit registers containing fields associated with specific address spaces: low, mid, high, and 256 KB. Each non-reserved bit in the fields is mapped to a specific flash block.

For example, Figure 36-2 shows the Select 0 (SEL0) register for the flash module. This register provides a way of selecting blocks in the low and mid address spaces for erase operations.

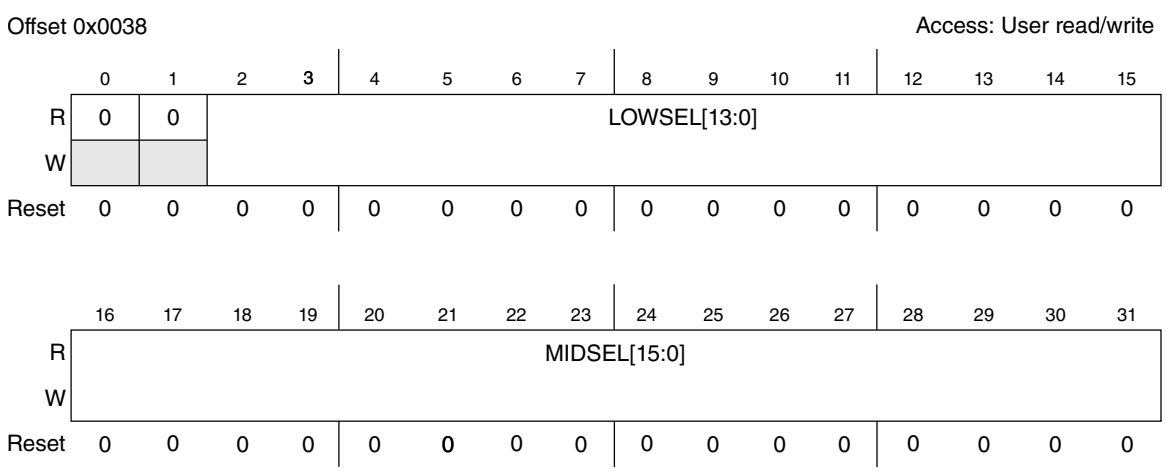

Figure 36-2. SEL0 flash control register

Table 36-1 shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual flash blocks[1]. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–11 (register bits 15–4,[2]) and

1. The table lists the LOWLOCK register field but the structure is identical to the LOWSEL field in Figure 36-2.
2. Register bits in Power Architecture-based microcontrollers are numbered with the most significant bit as 0. This is not necessarily the case with register field bit numbering. The field bit numbering shown in the figure has the least significant bit numbered as 0.

MIDSEL bits 0–2 are mapped. Before any mapped block can be erased, it must be selected by writing a '1' to its corresponding bit in one of the SEL*n* registers. See the device configuration chapter for the complete mapping.

Note

Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 36-2, all bits are reset to '0'. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Table 36-1. Sample low and mid address space flash block bit mapping

Start Address	End Address	Size (KB)	Partition	LOCK*n*[1] Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit[2]	Read Lock group[3]	Block No.	Description
0x0040_4000	0x0040_7FFF	16	0	LOCK0	LOWLOCK[0]	16	—	0	BAF[4]
0x00FC_0000	0x00FC_3FFF	16	0	LOCK0	LOWLOCK[1]	17	1	1	Code Flash[5]
0x00FC_4000	0x00FC_7FFF	16	0	LOCK0	LOWLOCK[2]	18	1	2	Code Flash[4]
0x00FC_8000	0x00FC_BFFF	16	1	LOCK0	LOWLOCK[3]	19	1	3	Code Flash[4]
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash[4]
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code
0x00FD_0000	0x00FD_7FFF	32	0	LOCK0	LOWLOCK[6]	22	1	6	Code Flash
0x00FD_8000	0x00FD_FFFF	32	1	LOCK0	LOWLOCK[7]	23	1	7	Code Flash
0x00FE_0000	0x00FE_FFFF	64	0	LOCK0	LOWLOCK[8]	24	1	8	Code Flash
0x00FF_0000	0x00FF_FFFF	64	0	LOCK0	LOWLOCK[9]	25	1	9	Code Flash
0x0061_0000	0x0061_FFFF	64	1	LOCK0	LOWLOCK[10]	26	3	10	Secure Code
0x0062_0000	0x0062_FFFF	64	1	LOCK0	LOWLOCK[11]	27	3	11	Secure Code
0x0068_0000	0x0068_3FFF	16	2	LOCK0	MIDLOCK[0]	0	4	12	Secure Data
0x0068_4000	0x0068_7FFF	16	3	LOCK0	MIDLOCK[1]	1	4	13	Secure Data
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST[6]

1. There are multiple sets of LOCK*n* registers, i.e., the flash module's LOCK0–-3 registers and PASS module's PASS_LOCK0–3_PG0–3, but all use the same mapping of register bits to flash blocks. The same mapping applies the the flash module's SEL0–3 registers.
2. The DCF record DATA bit refers to the DATA[31:0] field contained in DCF records created during OEM configuration activities. The DCF records related to flash blocks are used to implement password-secured write protection, password-secured read protection, tamper detection, and debug port enable/disable as a permanent part of the device configuration.
3. The Read Lock group pertains to protecting code and data blocks from being read by debuggers. This type of protection is implemented using DCF records and the PASS_LOCK3_PG0–3 registers.
4. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.
5. This block is searched to determine the boot location (if it contains the boot header).
6. One time programmable.

Example: 36.2.1 Selecting blocks for erase

Selecting blocks for erase

Referring to Table 36-1, writing the value 0x0030_0000 to the SEL0 register (Figure 36-2) selects the following blocks for erase:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash[4]
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

Note

The mappings of SEL*n* register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the MPC5777M microcontroller.

36.3 Non-secure write protection

Non-secure write protection refers to the chip's ability to lock individual flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip's modules. The non-secure write protection feature detailed here applies only to embedded flash memory.

Implementing non-secure write protection is almost identical to selecting specific flash blocks for an erase operation—the only difference is the register used. To provide non-secure write protection for a block, write a '1' to the corresponding mapped bit found in one of the LOCK0–2 flash control registers.

Note

As indicated by the reset values shown in Figure 36-3, after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

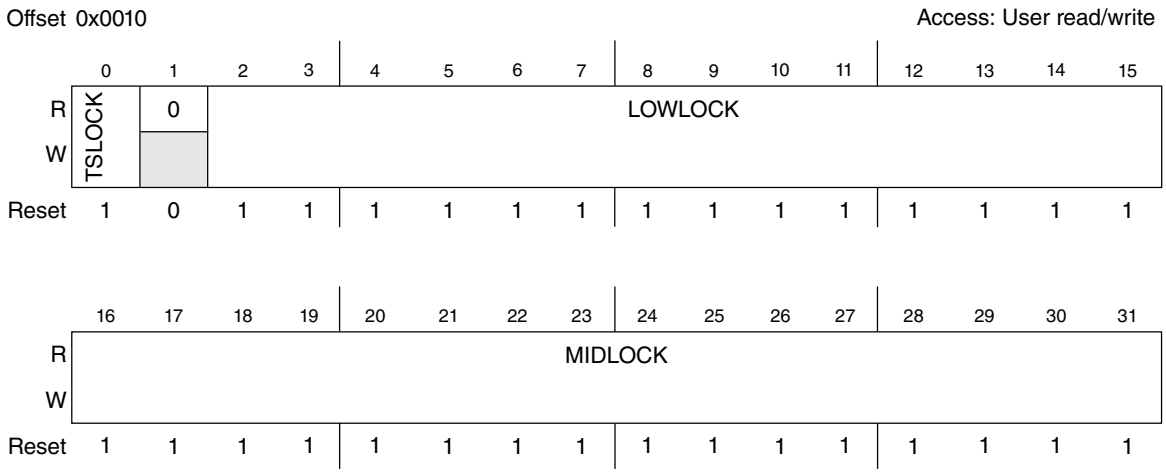

Figure 36-3. LOCK0 flash control register

Example: 36.3.1 Selecting

Selecting

Referring to Table 36-2, writing the value 0x0030_0000 (same value used in Selecting blocks for erase) to the LOCK0 register (Figure 36-3) locks the following blocks (same blocks selected in Selecting blocks for erase) so they cannot be programmed or erased, even if selected for erase:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash[4]
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in Secure write protection). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to '0'.

36.4 Secure write protection

Secure write protection refers to the chip's ability to implement up to four levels of 256-bit password-secured *write* protection for individual flash blocks. Use of this feature is optional but the default behavior of the MPC5777M microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records.

Note that the *secure* write protection settings override the non-secure write protection detailed in Non-secure write protection.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each flash block. The DCF records use a bit mapping scheme identical to the mapping in the flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module—they distinguished by the PG*n* suffix. The PG*n* (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding flash block.

Each set of registers contains the same mapping of bits to flash blocks as the flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one

PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

Figure 36-4 shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

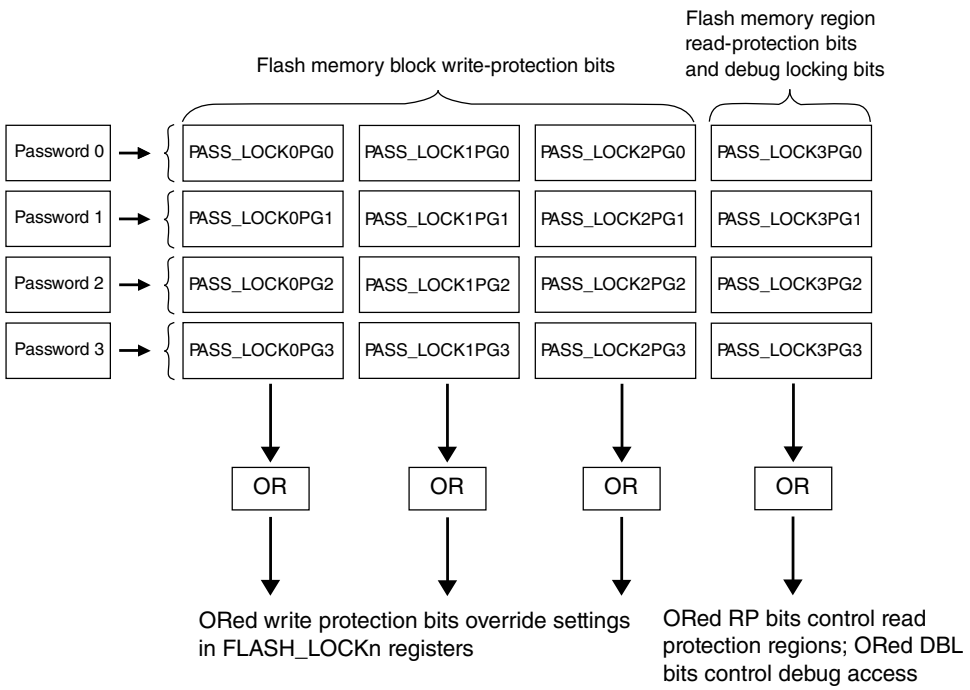

Figure 36-4. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

36.4.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers[3]. The DCF records have a structure that includes the same mapping of bits to flash memory blocks as

3. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

the flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers.

See Device Configuration Format (DCF) Records for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to flash memory blocks is identical to the mapping used for selecting flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

CAUTION

Careful planning is required before writing DCF records. They are created in a write-once area of flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table (Table 9-6 in Device Configuration Format (DCF) Records). Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory. The structure of a DCF Record is shown in Figure 36-5.

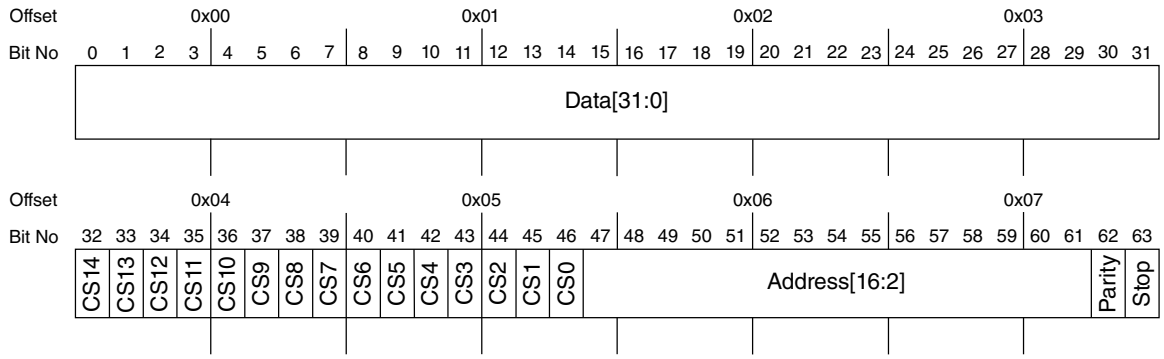

Figure 36-5. DCF record structure

Note

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0–3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase.
3. The PASS_LOCK*x*PG*n* bits take effect when the life cycle is matured to "OEM Production" or older.

Example: 36.4.1.1 Implementing secure write protection

Implementing secure write protection

Implementation of secure write protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device flash called UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n* –PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers.
2. DCF records must be created to define which flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2, determine the reset values of the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group:

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash[4]
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

From the PASS section of Table 9-6 in Device Configuration Format (DCF) Records :

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to Figure 36-5, the values for the DCF record are:

- Data[31:0] is 0x0030_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (see footnotes in Figure 36-6.

The following DCF record provides secure write protection for the blocks in Table 36-1 by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	x^1	x^2

Figure 36-6. Sample DCF record for secure write protection

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to flash blocks 4 and 5 set to '1'.

CAUTION

The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

See the PASS section of DCF client list table (Table 9-6 in Device Configuration Format (DCF) Records).

36.4.2 Overriding secure write protection

The "PG*n*" (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the flash module's SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCK*x*PG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

Figure 36-7 shows the PASS_LOCK0_PG*n* register. As you can see, it has the same structure as the flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCK*x*_PG*n* registers and the flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

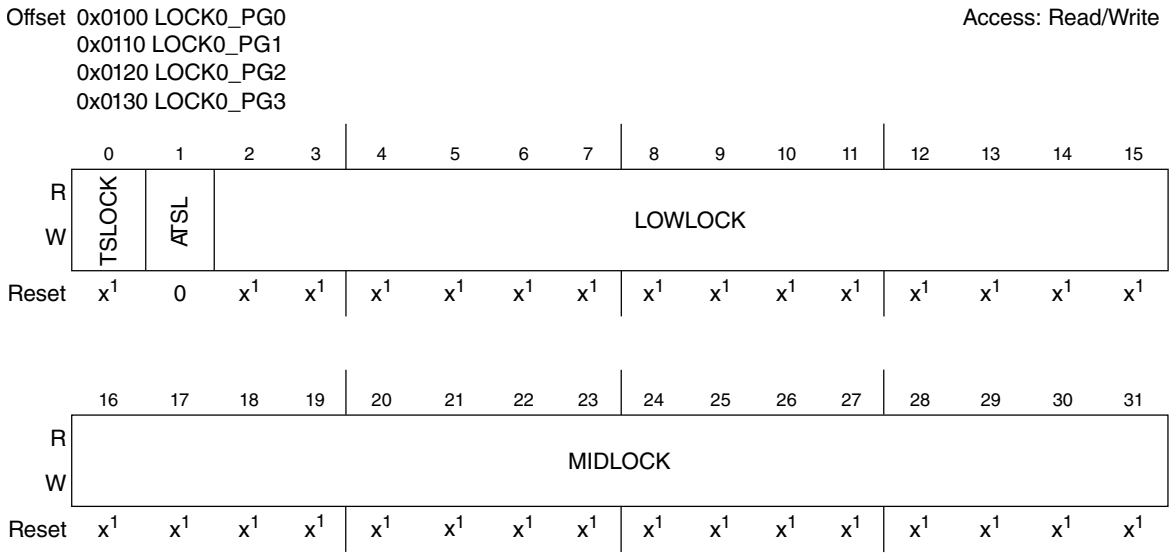

Figure 36-7. LOCK0_PG*n* register

Note

1. The values in the PASS_LOCK*x*PG*n* registers override the settings in the flash module's LOCK0–3 registers.
2. Values written to the PASS_LOCK*x*PG*n* registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.
3. The PASS_LOCK*x*PG*n* bits take effect after the life cycle is matured to "OEM Production" or older.

Example: 36.4.2.1 Overriding secure write protection

Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the flash module's LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

Just as in previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash[4]
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

36.5 Secure read protection

Read Protection is ability of the flash controller to block read accesses to the flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool

- DMA reads
- SIPI reads
- All other types of bus master reads

When secure read protection is active, the affected flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a flash read protected region terminates with a bus error.

Most instances of flash memory read protection in the MPC5777M microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTEST flash memory. Password-based read protection *is* customer-configurable[4] and is similar to the password-based write protection mechanism detailed in Secure write protection.

There are two significant differences between password-based read protection and password-based write protection in the MPC5777M microcontroller.

1. Read protection can only be applied to pre-defined groups of flash memory blocks. These groups, called "Read Lock groups", cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to "Failure Analysis".

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

4. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

Note

The mappings of PASS_LOCK3_PG*n* register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the MPC5777M microcontroller.

The next sections discuss implementing secure read protection and overriding secure write protection.

36.5.1 Implementing secure read protection

Implementation of secure read protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device flash named UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n* –PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers.

   Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.

   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in Figure 36-8. The fields relevant to implementing secure read protection are RL4–RL0.

Offset 0x010C LOCK3_PG0
0x011C LOCK3_PG1

Table 36-2. Sample low and mid address space flash block bit mapping (continued)

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x0068_0000	0x0068_3FFF	16	2	LOCK0	MIDLOCK[0]	0	4	12	Secure Data
0x0068_4000	0x0068_7FFF	16	3	LOCK0	MIDLOCK[1]	1	4	13	Secure Data
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST

To provide two level of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL*n* bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of Table 9-6 in Device Configuration Format (DCF) Records.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to Figure 36-5, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)

    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.
- For LOCK3_PG2
    - Data[31:0] is 0x0000_0000 (bits 0–31)
    - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
    - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.
- For LOCK3_PG3
    - Data[31:0] is 0x0000_0000 (bits 0–31)
    - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
    - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)
    - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
    - Preferred Stop value is 0.

36.5.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG*n* registers (see Figure 36-8) contain five read protection fields, RP0–RP4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to '1', causing the blocks associated with each read group to be read locked.

Example: 36.5.2.1 Overriding secure read protection

Overriding secure read protection

Building on Implementing secure read protection, where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to '0' in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

36.6 Debug port enable/disable

The mechanism for temporarily enabling the MPC5777M debug port after it has been locked by its life cycle state is similar to the flash memory read protection mechanism detailed in Secure read protection. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RP0–RP4 fields.

36.7 Tamper detection

The Tamper Detection Module (TDM) provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual flash memory blocks to be selected for tamper detection.

See Tamper Detection Module (TDM) for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, e.g., a flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of DCF client list table (Table 9-6 in Device Configuration Format (DCF) Records) gives the CS and Address value combinations that correspond to groups of LOCK0–LOCK3 registers, similar to the flash module's LOCK0–LOCK3 registers.

The mapping of individual flash blocks to TDM DCF record data field bits is shown in included in the detailed flash block map in the flash section of the Device Configuration chapter.

36.7.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections

36.7.2 Creating the tamper detect diary

Tamper detection in the MPC5777M microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called "tamper detect regions", or TDRs, within the flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the flash module's SEL*n* and LOCK*n* registers, which contain bits matched to specific flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a "diary" that tracks flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes.

Note

The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for MPC5777M) multiplied by 2 KB, the portion of the diary allotted to records associated with each TDR.

Since the minimum flash programming operation size is 8 bytes, the maximum number of tamper detect records for a given TDR is 256 8-byte entries.

The diary can be placed within any flash block in the flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section)
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be '0'

Warning

The tamper detect diary base address DCF record is a "write once" record. All subsequent tamper detect diary base address DCF records created are ignored.

Example: 36.7.2.1 Creating the tamper detect diary

Creating the tamper detect diary

If the total space required for a diary is 12 KB (as in the case of 6 TDRs), any flash block can be used because the smallest flash blocks in the MPC5777M microcontroller are 16 KB. Since the diary base address must be on a 4 KB, boundary, though, if the diary base address is within a 16 KB flash block, it can only be assigned to the base address of the block or the address given by the base address plus 4 KB.

If the base address of the 16 KB block is 0x00FC4000, the base address of the diary is given by:

0b0000_0000_1111_1100_0000_0000_0000_0000 (16 KB base address)
or
0b0000_0000_1111_1100_0001_0000_0000_0000 (16 KB base address + 4 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of Table 9-6 in Device Configuration Format (DCF) Records.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to Figure 36-5, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x00FC4000 (the base address)
  - CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0000_0000 (bits 47–61)
  - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
  - Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table (Table 9-6 in Device Configuration Format (DCF) Records) for details.

Note

User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in Overriding tamper detection.

36.7.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDR*x*_LOCK*n* DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDR*x*LOCK*n* DCF records mapped in exactly the same way as the flash module's SEL*n* and LOCK*n* registers (see the detailed flash block map in the flash section of the Device Configuration chapter for the mapping).

In the TDR*x*LOCK*n* DCF records:

- A bit set to '1' means the corresponding flash block is assigned to this TDR
- A bit set to '0' means the corresponding flash block is NOT assigned to this TDR

The default state (no TDRs defined) is defined as 'Block NOT assigned to the TDR'.

36.7.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in Figure 36-9.

warning

Bits in this DCF record is writable from 0 to 1only. Attempted writes of bits from 1 to 0 are ignored.

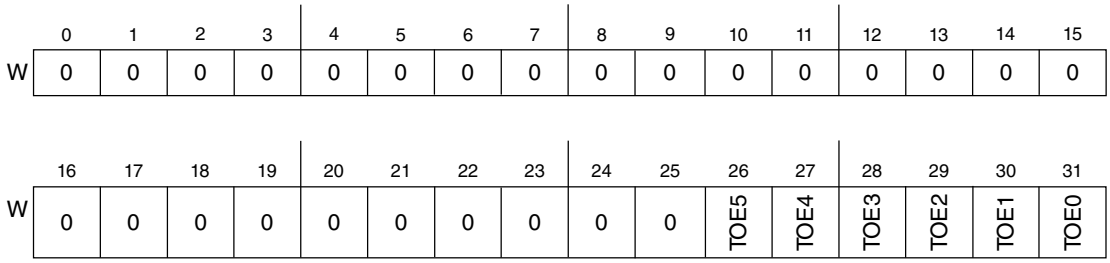

Figure 36-9. Data portion of Tamper Region Override (TO) DCF record

Example: 36.7.4.1 Implementing secure write protection

Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of Table 9-6 in Device Configuration Format (DCF) Records.

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to Figure 36-5, the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3)
- CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
- Address[16:2] is 0b000_0000_0000_0001 (bits 47–61)
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table (Table 9-6 in Device Configuration Format (DCF) Records) for details.

36.8 Implementing OTP

Any flash block within the flash array can be assigned, at any time, to be OTP. OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

warning

After a flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in Table 9-6 in Device Configuration Format (DCF) Records. See the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

36.9 Implementing test mode disable

The MPC5777M flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

36.9.1 Unconditional test mode disable seal

Warning

This process is not reversible. After completing these steps the MPC5777M microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note

1. Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.
2. The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.9.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note

1. Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.
2. The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.9.3 Selecting flash memory blocks for test mode disable seal

Selecting flash memory blocks for test mode disable seal protection is similar to selecting blocks for tamper detection in that it involves writing to non-register flash locations. In the case of the test mode disable seal function, there are two areas of UTEST flash memory that have identical mapping to flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

CAUTION

1. The mapping of bits to blocks for this function is different from the mapping used for other functions. See the table in the device configuration chapter for the map.
2. Selecting a block for test mode disable requires a '0' in the mapped bit—not a '1' as with other functions.

The mapping of individual flash blocks to Test Mode Disable Block Select bits is shown in Table 36-3.

Table 36-3. Mapping of Test Mode Disable Block Select bitsto flash blocks

36.10 Security configuration planning

At minimum, designing the flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

In devices containing a Hardware Security Module (HSM), significant planning must go into the implementation of HSM functions. The HSM is an independent software platform within the microcontroller. It is intended to be used to implement advanced security functions that are defined by customer software.

Note

Details of advanced security features, including the advanced security architecture and the Hardware Security Module (HSM) are contained in the *MPC5777M Microcontroller Security Reference Manual*. Distribution of the document is restricted to qualified customers.

The basic security features available in the MPC5777M microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) flash memory block assignment
- Factory test mode disable

36.10.1 Hardware Security Module (HSM)

Details of the HSM are included in the *MPC5777M Microcontroller Security Reference Manual*. It is mentioned here because the flash memory module includes blocks that can be configured for exclusive access by the HSM. If the HSM is to be used in an application it is advisable to protect HSM code by configuring it for exclusive access by the HSM. The blocks configurable for exclusive access by the HSM appear in Figure 3-3 in Embedded Memories. They are labeled as secure code flash or secure EEPROM emulation blocks. They are not configured for HSM-exclusive access by default, though —they are available to act as secure flash areas but must be explicitly configured for that purpose. See the *MPC5777M Microcontroller Security Reference Manual* for details.

36.10.2 Creating password groups

Most basic security features in the MPC5777M microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTEST memory map (Table 5-6) in Memory Map.

The UTEST memory map fields to be written are:

- PASS Password Group 0

- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Warning

The password fields are in OTP UTEST flash, so they can only be written once.

36.10.3 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user flash are write protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in Implementing secure write protection and Table 9-6 in Device Configuration Format (DCF) Records.

36.10.4 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user flash are read protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in Implementing secure read protection and Table 9-6 in Device Configuration Format (DCF) Records.

36.10.5 Planning debug port enable/disable

Please see Debug port enable/disable and Table 9-6 in Device Configuration Format (DCF) Records.

36.10.6 Planning OTP flash memory block assignment

Any block of user flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a flash block as OTP is not reversible.

Before creating DCF records to implemented OTP flash blocks, please thoroughly review the implementation steps detailed in Implementing OTP and Table 9-6 in Device Configuration Format (DCF) Records.

36.10.7 Planning factory test mode disable

Please see Implementing test mode disable and Table 9-6 in Device Configuration Format (DCF) Records.

Chapter 37
External Bus Interface (EBI)

37.1 Introduction

This section contains an overview, list of features and modes of operation for the External Bus Interface (EBI).

37.1.1 Overview

The External Bus Interface (EBI) handles the transfer of information between the internal busses and the memories or peripherals in the external address space. The EBI includes a memory controller that generates interface signals to support a variety of external memories. This includes Single Data Rate (SDR) burst mode flash, SRAM, and asynchronous memories. It supports 3 regions (via chip selects), each with its own programmed attributes.

37.1.2 Features

- 32-Bit Address bus with transfer size indication
- 32-Bit Data bus (16-bit Data Bus Mode also supported)
- Memory controller with support for various memory types:
- synchronous burst SDR flash and SRAM
- asynchronous/legacy flash and SRAM
- Burst support (wrapped only)
- Port size configuration per chip select (16 or 32 bits)
- Support for Dynamic Calibration with up to 3 chip-selects

- Four Write/Byte Enable ($\overline{WE}$[0:3]/$\overline{BE}$ [0:3]) signals
- Slower-speed clock modes
- Stop and Module Disable Modes for power savings
- Optional automatic CLKOUT gating to save power and reduce EMI
- Misaligned access support
- Compatible with MPC5xx external bus (with some limitations)

37.1.3 Modes of Operation

The mode of the EBI is determined by the MDIS and DBM bits in the EBI_MCR, and the AD_MUX bit in the EBI_BR0-EBI_BR2. See Module Configuration Register (EBI_MCR) and Base Register Bank (EBI_BR*n*) for details. Slower-speed modes, Debug Mode, Stop Mode, and Factory Test Mode are modes that the MCU may enter, in parallel to the EBI being configured in one of its block-specific modes.

37.1.3.1 Single Master Mode

In Single Master Mode, the EBI responds to internal requests matching one of its regions, but ignores all externally-initiated bus requests. The MCU is the only master allowed to initiate transactions on the external bus in this mode; therefore, it acts as a parked master and does not have to arbitrate for the bus before starting each cycle. Single Master Mode is entered when MDIS=0 in the EBI_MCR.

37.1.3.2 Module Disable Mode

The Module Disable Mode is used for MCU power management. The clock to the non-memory-mapped logic in the EBI is stopped while in Module Disable Mode. Logic on the MCU external to the EBI is used to fully implement the Module Disable Mode (to shut off the clock). Module Disable Mode is entered when MDIS=1 in the EBI_MCR.

37.1.3.3 Stop Mode

When a request is made to enter Stop Mode (controlled in device logic outside EBI), the EBI block completes any pending bus transactions and acknowledges the stop request. After the acknowledgement, the system clock input may be shut off by the clock driver on the MCU. While the clocks are shut off, the EBI is not accessible.

37.1.3.4 EBI Clock Frequency

The maximum clock frequency for the EBI is one third the platform clock frequency, or 66.6 MHz, whichever is less. The EBI clock (CLKOUT) frequency is determined by a divider in the MC_CGM. See MC_CGM chapter for more information.

37.1.3.5 16-Bit Data Bus Mode

For MCUs that have only 16 data bus signals pinned out, or for systems where the use of a different multiplexed function (e.g. GPIO) is desired on 16 of the 32 data pins, the EBI supports a 16-bit Data Bus Mode. In this mode, only 16 data signals are used by the EBI. The user can select which 16 data signals are used (DATA[0:15] or DATA[16:31]) by writing the D16_31 bit in the EBI_MCR.

For EBI-mastered accesses, the operation in 16-bit Data Bus Mode (DBM=1, PS=x) is similar to a chip-select access to a 16-bit port in 32-bit Data Bus Mode (DBM=0, PS=1).

16-bit Data Bus Mode is entered when DBM=1 in the EBI_MCR.

Note

Since there is not an external TA pin, non-chip-select accesses are not supported.

37.1.3.6 Debug Mode

When the MCU is in Debug Mode, the EBI behavior is unaffected and remains dictated by the mode of the EBI.

37.2 External Signal Description

This section lists the external pins and describes the external signals of the EBI.

37.2.1 Overview

The following table lists the external pins used by the EBI. Not all signals listed here are available external to the chip.

Table 37-1. Signal Properties

Name	I/O Type	Function	Pull[1]
ADDR[8:31] ADDR[8:11]_WE[3:0]/BE[3:0]	I/O	Address bus	-
$\overline{\text{BDIP}}$	Output	Burst Data in Progress	Up
CLKOUT[2]	Output	Clockout	-
$\overline{\text{CS}}$[0:2]	Output	Chip Selects	-
DATA[0:31]	I/O	Data bus[3]	-
OE	Output	Output Enable	Up
RD_$\overline{\text{WR}}$	I/O	Read_Write	Up
TS	I/O	Transfer Start	Up

1. This column shows which signals require a weak pullup or pulldown. The EBI block does not contain these pullup/pulldown devices within the block. They are assumed to be in another module of the MCU (for example; pads module).
2. The CLKOUT signal is driven by the System Clock Block outside the EBI.
3. In Address/Data multiplexing modes, Data will also show the address during the address phase.

37.2.2 Detailed Signal Descriptions

This section describes the superset of signals for the EBI.

37.2.2.1 ADDR[8:31] — Address Lines 8-31

The ADDR[8:31] signals specify the physical address of the bus transaction.

The upper address lines ADDR[8:11] are shared with the WE[0:3]/BE[0:3] signals. The msb mapping is reversed to allow maximum address lines for a 16-bit memory, since only WE[0:1]/BE[0:1] are used in this case.

The address lines can be adjusted to the memory port size (8/16/32) via the EBI_OR[APS] bit on a per chip select basis. This allows a larger address space for wider memories.

Write enables are used to enable program operations to a particular memory. These signals can also be used as byte enables for read and write operation by setting the WEBS bit in the appropriate Base Register. $\overline{\text{WE}}$[0:3]/BE[0:3] are only asserted for chip-select accesses.

For chip-select accesses to a 16-bit port, only $\overline{\text{WE}}$ [0:1]/$\overline{\text{BE}}$[0:1] are used by the EBI, regardless of which half of the DATA bus is selected via the D16_31 bit in the EBI_MCR.

See Four Write/Byte Enable ($\overline{\text{WE}}$/$\overline{\text{BE}}$) Signals for more details on $\overline{\text{WE}}$[0:3]/$\overline{\text{BE}}$[0:3] functionality.

37.2.2.2 CLKOUT — Clockout

CLKOUT is a general-purpose clock output signal to connect to the clock input of SDR external memories.

37.2.2.3 $\overline{\text{CS}}$ [0:2] — Chip Selects 0-2

$\overline{\text{CS}}$x is asserted by the master to indicate that this transaction is targeted for a particular memory bank on the Primary external bus.

$\overline{\text{CS}}$ is driven in the same clock as the assertion of $\overline{\text{TS}}$ and valid address, and is kept valid until the cycle is terminated. See Memory Controller with Support for Various Memory Types for details on chip-select operation.The port size for the least significant address line, and the write/byte enable select is configurable for each chip select.

37.2.2.4 DATA [0:31] — Data Lines 0-31

The DATA[0:31] signals contain the data to be transferred for the current transaction.

DATA[0:31] is driven by the EBI when it owns the external bus and it initiates a write transaction to an external device.

DATA[0:31] is driven by an external device during a read transaction from the EBI.

For 8-bit and 16-bit transactions, the byte lanes not selected for the transfer do not supply valid data.

DATA[0:31] is driven by the EBI in the address phase with the ADDR value if the Address on Data multiplexing mode is enabled.

In 16-bit Data Bus Mode, (or for chip-select accesses to a 16-bit port), only DATA[0:15] or DATA[16:31] are used by the EBI, depending on the setting of the D16_31 bit in the EBI_MCR. See 16-Bit Data Bus Mode.

37.2.2.5 $\overline{\text{OE}}$ — Output Enable

$\overline{\text{OE}}$ is used to indicate when an external memory is permitted to drive back read data. External memories must have their data output buffers off when $\overline{\text{OE}}$ is negated. $\overline{\text{OE}}$ is only asserted for chip-select accesses.

For read cycles, $\overline{\text{OE}}$ is asserted one clock after $\overline{\text{TS}}$ assertion (by default with EBI_BR[EOE]=0b00) and held until the termination of the transfer. For write cycles, $\overline{\text{OE}}$ is negated throughout the cycle.

37.2.2.6 RD_$\overline{\text{WR}}$ — Read / Write

RD_$\overline{\text{WR}}$ indicates whether the current transaction is a read access or a write access.

RD_$\overline{\text{WR}}$ is driven in the same clock as the assertion of $\overline{\text{TS}}$ and valid address, and is kept valid until the cycle is terminated.

37.2.2.7 $\overline{\text{TS}}$ — Transfer Start

$\overline{\text{TS}}$ is asserted by the current bus owner to indicate the start of a transaction on the external bus.

$\overline{\text{TS}}$ is only asserted for the first clock cycle of the transaction, and is negated in the successive clock cycles until the end of the transaction.

37.2.2.8 $\overline{\text{WE}}$ [0:3] / $\overline{\text{BE}}$ [0:3] — Write/Byte Enables 0-3

Write enables are used to enable program operations to a particular memory. These signals can also be used as byte enables for read and write operation by setting the WEBS bit in the appropriate Base Register. $\overline{\text{WE}}$[0:3]/BE[0:3] are only asserted for chip-select accesses.

For chip-select accesses to a 16-bit port, only $\overline{\text{WE}}$ [0:1]/$\overline{\text{BE}}$[0:1] are used by the EBI, regardless of which half of the DATA bus is selected via the D16_31 bit in the EBI_MCR.

See Four Write/Byte Enable ($\overline{WE}$/$\overline{BE}$) Signals for more details on $\overline{WE}$[0:3]/$\overline{BE}$[0:3] functionality.

37.3 Memory Map/Register Definition

NOTE

The EBI registers must not be written while a transaction to the EBI (from internal or external master) is in progress (or within 2 CLKOUT cycles after a transaction has just completed, to allow internal state machines to go IDLE) In those cases, the behavior is undefined.

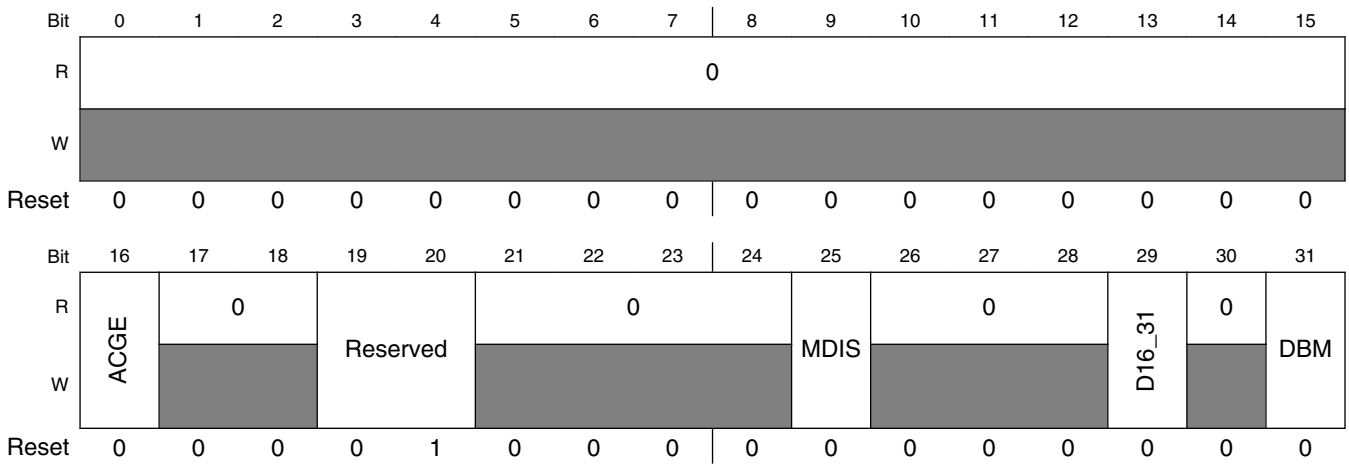
EBI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (EBI_MCR)	32	R/W	0000_0800h	37.3.1/1410
10	Base Register Bank (EBI_BR0)	32	R/W	2000_0002h	37.3.2/1411
14	Option Register Bank (EBI_OR0)	32	R/W	E000_0000h	37.3.3/1413
18	Base Register Bank (EBI_BR1)	32	R/W	2000_0002h	37.3.2/1411
1C	Option Register Bank (EBI_OR1)	32	R/W	E000_0000h	37.3.3/1413
20	Base Register Bank (EBI_BR2)	32	R/W	2000_0002h	37.3.2/1411
24	Option Register Bank (EBI_OR2)	32	R/W	E000_0000h	37.3.3/1413

37.3.1 Module Configuration Register (EBI_MCR)

The EBI Module Configuration Register contains bits which configure various attributes associated with EBI operation.

Address: 0h base + 0h offset = 0h



EBI_MCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ACGE	Automatic CLKOUT Gating Enable The ACGE bit enables the EBI feature of turning off CLKOUT (holding it high) during idle periods in-between external bus accesses. 0 Automatic CLKOUT Gating is disabled 1 Automatic CLKOUT Gating is enabled
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–20 Reserved	This field is reserved.
21–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 MDIS	Module Disable Mode The MDIS bit controls an internal EBI "enable clk" signal which can be used (if MCU logic supports) to control the clocks to the EBI. The MDIS bit allows the clock to be stopped to the non-memory mapped logic in the EBI, effectively putting the EBI in a software controlled power-saving state. See Module Disable Mode for more information. No external bus accesses can be performed when the EBI is in Module Disable Mode (MDIS=1). 0 Module Disable Mode is inactive (assert "enable clk" signal) 1 Module Disable Mode is active (negate "enable clk" signal)

Table continues on the next page...

EBI_MCR field descriptions (continued)

Field	Description
26–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 D16_31	Data Bus 16_31 Select The D16_31 bit controls whether the EBI uses the DATA[0:15] or DATA[16:31] signals, when in 16-bit Data Bus Mode (DBM=1) or for chip-select accesses to a 16-bit port (PS=1). **NOTE:** There is one usage case where D16_31=0 cannot be used. For systems that are using both a 32-bit non-chip-select device AND a 16-bit device (chip-select or non-chip-select), the user must set D16_31=1. Otherwise (if D16_31=0 is used), when an access to the 16-bit device is performed, the 32-bit non-chip-select device may decode the wrong upper address bits and may respond to that access, causing contention on the shared address/data lines going to both devices. This is due to the 32-bit device expecting address 8:15 on DATA[8:15] pins, whereas D16_31=0 has address 24:31 on those pins. This contention case is avoided when D16_31=1, because the shared address/data pins have the same functions for both the 16-bit and 32-bit memory accesses (address 16:31 on DATA[16:31] pins). This contention case is also avoided when only chip-select devices are used, since the devices ignore accesses when their corresponding chip-select is not asserted. 0 DATA[0:15] signals are used for 16-bit port accesses 1 DATA[16:31] signals are used for 16-bit port accesses
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 DBM	Data Bus Mode The DBM bit controls whether the EBI is in 32-bit or 16-bit Data Bus Mode. 0 32-bit Data Bus Mode is used 1 16-bit Data Bus Mode is used

37.3.2 Base Register Bank (EBI_BR*n*)

The EBI Base Registers are used to define the base address and other attributes for the corresponding chip select.

NOTE

The upper bits of the BA field [0:2] are tied to a fixed value of "001", in which case the reset value is this fixed value and not zero.

Address: 0h base + 10h offset + (8d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BA															
W																
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

R	BA	0		LWRN	PS	EOE		SBL	AD_MUX	BL	WEBS	TBDIP	GCSN	0	BI	V
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

EBI_BR*n* field descriptions

Field	Description
0–16 BA	Base Address These bits are compared to the corresponding unmasked address signals among ADDR[0:16] of the internal address bus to determine if a memory bank controlled by the memory controller is being accessed by an internal bus master. **NOTE:** An MCU has some of the upper bits of the BA field [0:2] tied to a fixed value of "001" internally in order to restrict the address range of the EBI for that MCU. Tied-off bits can be read but not written. These bits are ignored by the EBI during the chip-select address comparison. However, the internal bridge of the MCU most likely requires that the chip-select banks be located in memory regions corresponding to the fixed values chosen.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 LWRN	Late RD_$\overline{WR}$ Negation The LWRN bit determines the timing of RD_WR signal negation for a write transfer. 0 Negate RD_$\overline{WR}$ one cycle earlier than $\overline{CS}$ negation. See Figure 37-9. 1 Negate RD_$\overline{WR}$ the same cycle as $\overline{CS}$ negation. See Figure 37-12.
20 PS	Port Size The PS bit determines the data bus width of transactions to this chip-select bank. **NOTE:** In the case where the DBM bit in EBI_MCR is set for 16-bit Data Bus Mode, the PS bit value is ignored and is always treated as a '1'(16-bit port). 0 32-bit port 1 16-bit port
21–22 EOE	Early $\overline{OE}$ The EOE field determines the timing of $\overline{OE}$ signal assertion for a read transfer. When EBI_BR[ADMUX]=1, the EOE value is ignored and treated as 0b00 (in order to avoid contention on shared address/data bus for muxed transfers).
23 SBL	Short Burst Length The SBL bit provides support for a 2-word external burst (see Figure 37-31 in Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1. 0 When SBL=0, the number of beats in a burst is determined by the BL bit. See Table 37-2 under BL bit description for SBL and BL encodings. 1 When SBL=1, the number of beats in a burst is automatically determined by the EBI to be 2 or 4 according to the Port Size (PS bit), regardless of BL bit value.
24 AD_MUX	Address on Data Bus Multiplexing The AD_MUX bit controls whether accesses for this chip select have the address driven on the data bus in the address phase of a cycle.

Table continues on the next page...

EBI_BR*n* field descriptions (continued)

Field	Description
	0 Address on Data Multiplexing Mode is disabled for this chip select. 1 Address on Data Multiplexing Mode is enabled for this chip select.
25 BL	Burst Length The BL bit (along with SBL bit) determines the amount of data transferredin a burst for this chip select, measured in 32-bit words. 0 When SBL=0, the number of beats in a burst is automatically determined by the EBI to be 4, 8, or 16 according tothe Port Size (PS bit) so that the burst fetches the number of words chosen by BL. For internal AMBA data bus width of 32-bits, the BL bit is ignored (treated as 1). 1 When SBL=1, the BL bit value is a don't care. See Table 37-2 for SBL and BL encodings.
26 WEBS	Write Enable / Byte Select This bit controls the functionality of the $\overline{WE}$[0:3]/$\overline{BE}$[0:3] signals. 0 The $\overline{WE}$[0:3]/$\overline{BE}$[0:3] signals function as $\overline{WE}$[0:3] 1 The $\overline{WE}$[0:3]/$\overline{BE}$[0:3] signals function as BE[0:3]
27 TBDIP	This bit determines how long the BDIP signal is asserted for each data beat in a burst cycle. 0 Assert $\overline{BDIP}$ throughout the burst cycle, regardless of wait state configuration 1 Only assert $\overline{BDIP}$ (BSCY+1) external cycles before expecting subsequent burst data beats
28 GCSN	Guarantee $\overline{CS}$ Negation The GCSN bit allows support for guaranteeing that the EBI will negate $\overline{CS}$ between all back-to-back transfer cases (even those that are part of a set of Small Accesses). See Figure 37-17. 0 Default operation ($\overline{CS}$ may or may not negate between transfers, depending on the particular back-to-back case). 1 Negate $\overline{CS}$ between all external transfers. This adds an extra dead cycle for some back-to-back cases.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BI	Burst Inhibit This bit determines whether or not burst read accesses are allowed for this chip-select bank. 0 Enable burst accesses for this bank 1 Disable burst accesses for this bank. This is the default value out of reset.
31 V	Valid bit The user writes this bit to indicate that the contents of this Base Register and Option Register pair are valid. The appropriate $\overline{CS}$ signal does not assert unless the corresponding V-bit is set. 0 This bank is not valid 1 This bank is valid

37.3.3 Option Register Bank (EBI_OR*n*)

The EBI Option Registers are used to define the address mask and other attributes for the corresponding chip select.

NOTE

Some upper bits [0:2] of the AM field are tied to a fixed value of "111", in which case the reset value is this fixed value and not zero. Tied-off bits can be read but not written. See the corresponding Note for the Base Register BA field for more details.

Address: 0h base + 14h offset + (8d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	AM	0		APS	0	AWE	0		SCY				0	BSCY		0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EBI_OR*n* field descriptions

Field	Description
0–16 AM	Address Mask This field allows masking of any corresponding bits in the associated Base Register. Masking the address independently allows external devices of different size address ranges to be used. Any clear bit masks the corresponding address bit. . Any set bit causes the corresponding address bit to be used in comparison with the address pins. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map. This field can be read or written at any time. **NOTE:** An MCU has some of the upper bits [0:2] of the AM field tied to a fixed value of "111" internally in order to restrict the address range of the EBI for that MCU. See the corresponding Note for the Base Register BA field for more details. Tied-off bits can be read but not written.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 APS	Address by Port Size The user writes this bit to cause the EBI to shift the address it drives out for accesses to this chip-select, such that the lowest address bit addresses an element of data that matches the port size specified in the corresponding EBI_BR[PS] field. APS=0, PS=X Default Byte Addressing APS=1, PS=0 Word Addressing: EBI drives internal address 6:29 to ADDR[8:31] APS=1, PS=1 Half-Word Addressing: EBI drives internal address 7:30 to ADDR[8:31] See Address by Port Size for additional details.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 AWE	Address / Write Enable Select The user writes this bit to cause the EBI to drive its internal WE[0:3] onto the upper 4 address bus signals (such as in systems where upper 4 address bus signals are not needed and separate WE[0;3] pins are not available). AWE has no effect on the other address bits besides the upper 4. For example, for an SoC using a 24-bit address bus, the upper 4 bits are ADDR[8:11]. See Address / Write Enable Multiplexing for additional details.

Table continues on the next page...

EBI_OR*n* field descriptions (continued)

Field	Description
	0 Default address function driven on 4 upper address bus signals 1 WE[0:3] driven into 4 upper address bus signals
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 SCY	Cycle length in clocks This field represents the number of wait states (external cycles) inserted after the address phase in the single transfer case, or in the first beat of a burst, when the memory controller handles the external memory access. Values range from 0 to 15. This is the main parameter for determining the length of the cycle. The total cycle length for the first beat (including the $\overline{TS}$ cycle) = (2+SCY) external clock cycles . See Example Wait State Calculation for related application information.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 BSCY	Burst beats length in clocks This field determines the number of wait states (external cycles) inserted in all burst beats except the first, when the memory controller starts handling the external memory access and thus is using SCY[0:3] to determine the length of the first beat. The total memory access length for each beat is (1 + BSCY) external clock cycles. The total cycle length (including the TS cycle) = (2+SCY) + (#beats-1) * (BSCY+1). #beats is the number of beats (4,8,16) determined by BL and PS bits in Base Register. 00 0 - clock cycle wait states (1 clock per data beat) 01 1 - clock cycle wait states (2 clocks per data beat) 10 2 - clock cycle wait states (3 clocks per data beat) 11 0 - clock cycle wait states (4 clocks per data beat)
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

37.4 Functional Description

The following sections describe the EBI functionality.

37.4.1 External Bus Interface Features

37.4.1.1 32-Bit Data Bus (16-bit Data Bus Mode also supported)

The entire 32-bit data bus is available for external memory accesses. There is also a 16-bit Data Bus Mode available via the DBM bit in EBI_MCR. See 16-Bit Data Bus Mode.

37.4.1.2 Memory Controller with Support for Various Memory Types

The EBI contains a memory controller that supports a variety of memory types, including synchronous burst mode flash and SRAM, and asynchronous/legacy flash and SRAM with a compatible interface.

Each $\overline{CS}$ bank is configured via its own pair of Base and Option Registers. Each time an internal to external bus cycle access is requested, the internal address is compared with the base address of each valid Base Register (with 17 bits having mask). See Figure 37-1. If a match is found, the attributes defined for this bank in its BR and OR are used to control the memory access. If a match is found in more than one bank, the lowest bank matched handles the memory access (for example; bank 0 is selected over bank 1).

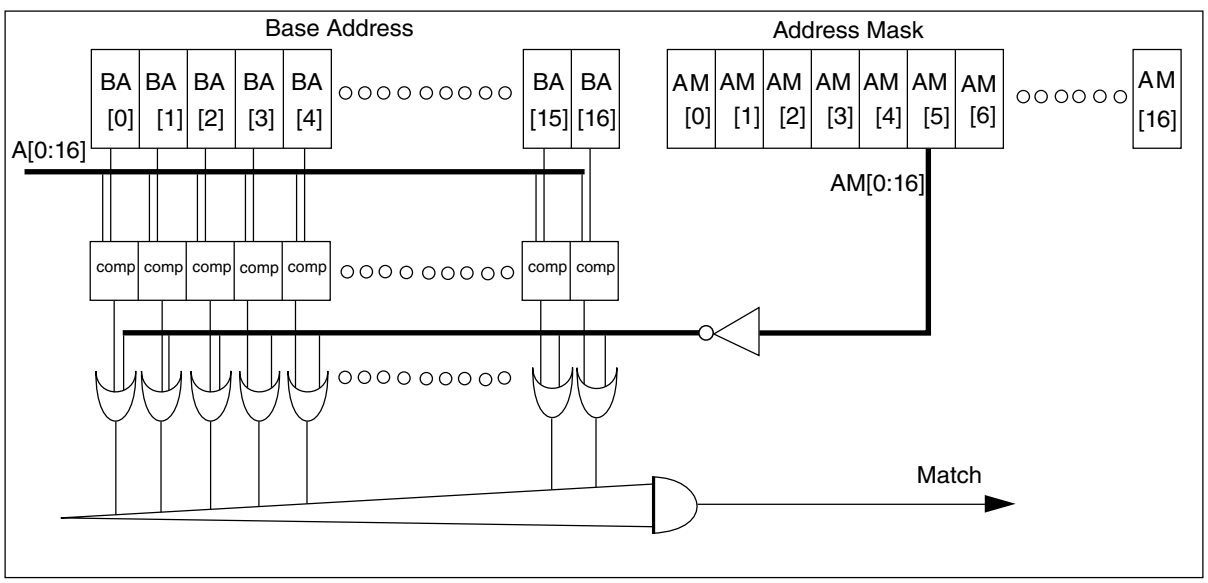

Figure 37-1. Bank Base Address and Match Structure

When a match is found on one of the chip-select banks, all its attributes (from the appropriate Base and Option Registers) are selected for the functional operation of the external memory access, such as:

- Number of wait states for a single memory access, and for any beat in a burst access
- Burst enable
- Port size for the external accessed device

See Module Configuration Register (EBI_MCR) and Base Register Bank (EBI_BR*n*) for a full description of all chip-select attributes.

When no match is found on any of the chip-select banks, the default transfer attributes shown in Table 37-2 are used.

Table 37-2. Default Attributes for Non-Chip-Select Transfers

CS Attribute	Default Value	Comment
PS	0	32-bit port size
BL	0	burst length is don't care since burst is disabled
WEBS	0	write enables
BI	1	burst inhibited
SCY	0	Cycle length in clocks
BSCY	0	Burst beats length in clocks

37.4.1.3 Burst Support (wrapped only)

The EBI supports burst read accesses of external burstable memory. To enable bursts to a particular memory region, clear the BI (Burst Inhibit) bit in the appropriate Base Register. External burst lengths of 2, 4 and 8 words are supported. Burst length is configured for each chip select by using the BL and SBL bits in the appropriate Base Register. See Burst Transfer for more details on burst operation.

Burst writes are not supported. Internal requests to write >32 bits (such as a cache line) externally are broken up into separate 32-bit or 16-bit external transactions according to the port size. See Small Accesses (Small Port Size and Short Burst Length) for more detail on these cases.

37.4.1.4 Port Size Configuration per Chip Select (16 or 32 bits)

The EBI supports memories with data widths of 16 or 32 bits. The port size for a particular chip select is configured by writing the PS bit in the corresponding Base Register.

37.4.1.5 Configurable Wait States

From 0 to 15 wait states can be programmed for any cycle that the memory controller generates, via the SCY bits in the appropriate Option Register. From 0 to 3 wait states between burst beats can be programmed using the BSCY bits in the appropriate Option Register.

37.4.1.6 Four Write/Byte Enable ($\overline{WE}$/$\overline{BE}$) Signals

The functionality of the $\overline{WE}$[0:3]/$\overline{BE}$ [0:3] signals depends on the value of the WEBS bit in the corresponding Base Register. Setting WEBS to 1 configures these pins as $\overline{BE}$[0:3], while resetting it to 0 configures them as $\overline{WE}$ [0:3]. The WE[0:3]/BE[0:3] signals are mapped to the address lines and are independently enabled for each chip select. $\overline{WE}$[0:3] are asserted only during write accesses, while $\overline{BE}$ [0:3] is asserted for both read and write accesses. The timing of the $\overline{WE}$[0:3]/$\overline{BE}$[0:3] signals remains the same in either case.

The upper Write/Byte Enable ($\overline{WE0}$/$\overline{BE0}$) indicates that the upper eight bits of the data bus (DATA[0:7]) contain valid data during a write/read cycle. The upper middle Write/Byte Enable ($\overline{WE1}$/$\overline{BE1}$) indicates that the upper middle eight bits of the data bus (DATA[8:15]) contain valid data during a write/read cycle. The lower middle Write/Byte Enable ($\overline{WE2}$/$\overline{BE2}$) indicates that the lower middle eight bits of the data bus (DATA[16:23]) contain valid data during a write/read cycle. The lower Write/Byte Enable ($\overline{WE3}$/$\overline{BE3}$) indicates that the lower eight bits of the data bus (DATA[24:31]) contain valid data during a write/read cycle.

Note

The exception to the preceding $\overline{WE}$/$\overline{BE}$ description is that for 16-bit port transfers (DBM=1 or PS=1), only the $\overline{WE}$[0:1]/$\overline{BE}$[0:1] signals are used, regardless of whether DATA[0:15] or DATA[16:31] are selected (via the D16_31 bit in the EBI_MCR). This means for the case where DATA[16:31] are selected, that $\overline{WE0}$ indicates that DATA[16:23] contains valid data, and $\overline{WE1}$ indicates that DATA[24:31] contains valid data.

The Write/Byte Enable lines affected in a transaction for a 32-bit port (PS = 0) and a 16-bit port (PS=1) are shown in Table 37-3. Only Big Endian byte ordering is supported by the EBI.

The following table applies to aligned internal master transfers only. In the case of a misaligned internal master transfer that is split into multiple aligned external transfers, not all of the write enables X'd in the table will necessarily assert. See Misaligned Access Support.

Table 37-3. Write/Byte Enable Signals Function

Transfer Size	EBI_MCR[SIZE]	Address		32-Bit Port Size				16-Bit Port Size[1]			
		A30	A31	$\overline{WE0}$/ $\overline{BE0}$	$\overline{WE1}$/ $\overline{BE1}$	$\overline{WE2}$ /$\overline{BE2}$	$\overline{WE3}$ /$\overline{BE3}$	$\overline{WE0}$ /$\overline{BE0}$	$\overline{WE1}$/ $\overline{BE1}$	$\overline{WE2}$ /$\overline{BE2}$	$\overline{WE3}$ /$\overline{BE3}$
Byte	01	0	0	X				X			

Table continues on the next page...

Table 37-3. Write/Byte Enable Signals Function (continued)

Transfer Size	EBI_MCR[SIZE]	Address		32-Bit Port Size				16-Bit Port Size[1]			
		A30	A31	WE0/ BE0	WE1/ BE1	WE2 /BE2	WE3 /BE3	WE0 /BE0	WE1/ BE1	WE2 /BE2	WE3 /BE3
	01	0	1		X				X		
	01	1	0			X		X			
	01	1	1				X		X		
16-bit	10	0	0	X	X			X	X		
	10	1	0			X	X	X	X		
32-bit	00	0	0	X	X	X	X	X[2]	X[2]		
Burst	00	0	0	X	X	X	X	X	X		

1. Also applies when DBM=1 for 16-bit data bus mode.
2. This case consists of two 16-bit external transactions, but for both transactions the $\overline{WE}$[0:1]/$\overline{BE}$[0:1] signals are the only $\overline{WE}$/$\overline{BE}$ signals affected.

37.4.1.7 Slower-Speed Clock Modes

For memories that cannot run with a full-speed external bus, the EBI supports slower-speed clock modes. See MC_CGM chapter for adjusting the CLKOUT and external bus frequency.

37.4.1.8 Stop and Module Disable Modes for Power Savings

See Modes of Operation for a description of the power saving modes.

37.4.1.9 Optional Automatic CLKOUT Gating

The EBI has the ability to hold the external CLKOUT pin high when the EBI's internal master state machine is idle and no requests are pending. The EBI outputs a signal to the pads logic in the MCU to disable CLKOUT. This feature is disabled out of reset, and can be enabled or disabled by the ACGE bit in the EBI_MCR.

Note

This feature must be disabled for multi-master systems. In those cases, one master is getting its clock source from the other master and needs it to stay valid continuously.

37.4.1.10 Misaligned Access Support

The EBI has limited misaligned access support. Misaligned non-burst chip-select transfers from internal masters are supported. The EBI aligns the accesses when it sends them out to the external bus (splitting them into multiple aligned accesses if necessary), so that external devices are not required to support misaligned accesses. Burst accesses (internal master) must match the internal bus size (64-bit aligned). See Misaligned Access Support for more details.

37.4.2 External Bus Operations

The following sections provide a functional description of the external bus, the bus cycles provided for data transfer operations and error conditions.

37.4.2.1 External Clocking

The CLKOUT signal sets the frequency of operation for the bus interface directly. Internally, the MCU uses a phase-locked loop (PLL) circuit to generate a master clock for all of the MCU circuitry (including the EBI) that is phase-locked to the CLKOUT signal. In general, all signals for the EBI are specified with respect to the rising-edge of the CLKOUT signal, and they are guaranteed to be sampled as inputs or changed as outputs with respect to that edge.

37.4.2.2 Reset

Upon detection of internal reset assertion, the EBI immediately ends all transactions (abruptly, not through normal termination protocol), and ignores any transaction requests that take place while reset is asserted.

37.4.2.3 Basic Transfer Protocol

The basic transfer protocol defines the sequence of actions that must occur on the external bus to perform a complete bus transaction. A simplified scheme of the basic transfer protocol is shown in Figure 37-2.

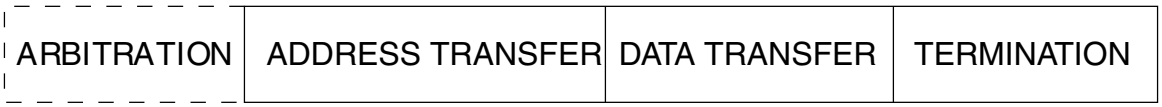

Figure 37-2. Basic Transfer Protocol

The arbitration phase is where bus ownership is requested and granted. This phase is not needed in Single Master Mode because the EBI is the permanent bus owner in this mode.

The address transfer phase specifies the address for the transaction and the transfer attributes that describe the transaction. The signals related to the address transfer phase are $\overline{TS}$, ADDR (or DATA if Address/Data multiplexing is used), $\overline{CS}$ [0:2] and RD_$\overline{WR}$. The address and its related signals (with the exception of $\overline{TS}$) are driven on the bus with the assertion of the $\overline{TS}$ signal, and kept valid until the bus master receives $\overline{TA}$ asserted (the EBI holds them one cycle beyond $\overline{TA}$ for writes). Writes with internal $\overline{TA}$, RD_$\overline{WR}$ are not held one cycle past $\overline{TA}$.

The data transfer phase performs the transfer of data, from master to slave (in write cycles) or from slave to master (on read cycles), if any is to be transferred. The data phase may transfer a single beat of data (1-4 bytes) for non-burst operations or a 2-beat, 4-beat, 8-beat, or 16-beat burst of data (2 or 4 bytes per beat depending on Port Size) when burst is enabled. On a write cycle, the master must not drive write data until after the address transfer phase is complete. This is to avoid electrical contentions when switching between drivers. The master must start driving write data one cycle after the address transfer cycle. The master can stop driving the data bus as soon as it samples the $\overline{TA}$ line asserted on the rising edge of CLKOUT. To facilitate asynchronous write support, the EBI keeps driving valid write data on the data bus until 1 clock after the rising edge where RD_$\overline{WR}$ and $\overline{WE}$ are negated. See Figure 37-9 for an example of write timing. On a read cycle, the master accepts the data bus contents as valid on the rising edge of the CLKOUT in which the $\overline{TA}$ signal is sampled asserted. See Figure 37-4 for an example of read timing.

The termination phase is where the cycle is terminated according to the values in the EBI Base Registers. Termination is discussed in detail in Termination Signals Protocol.

Note

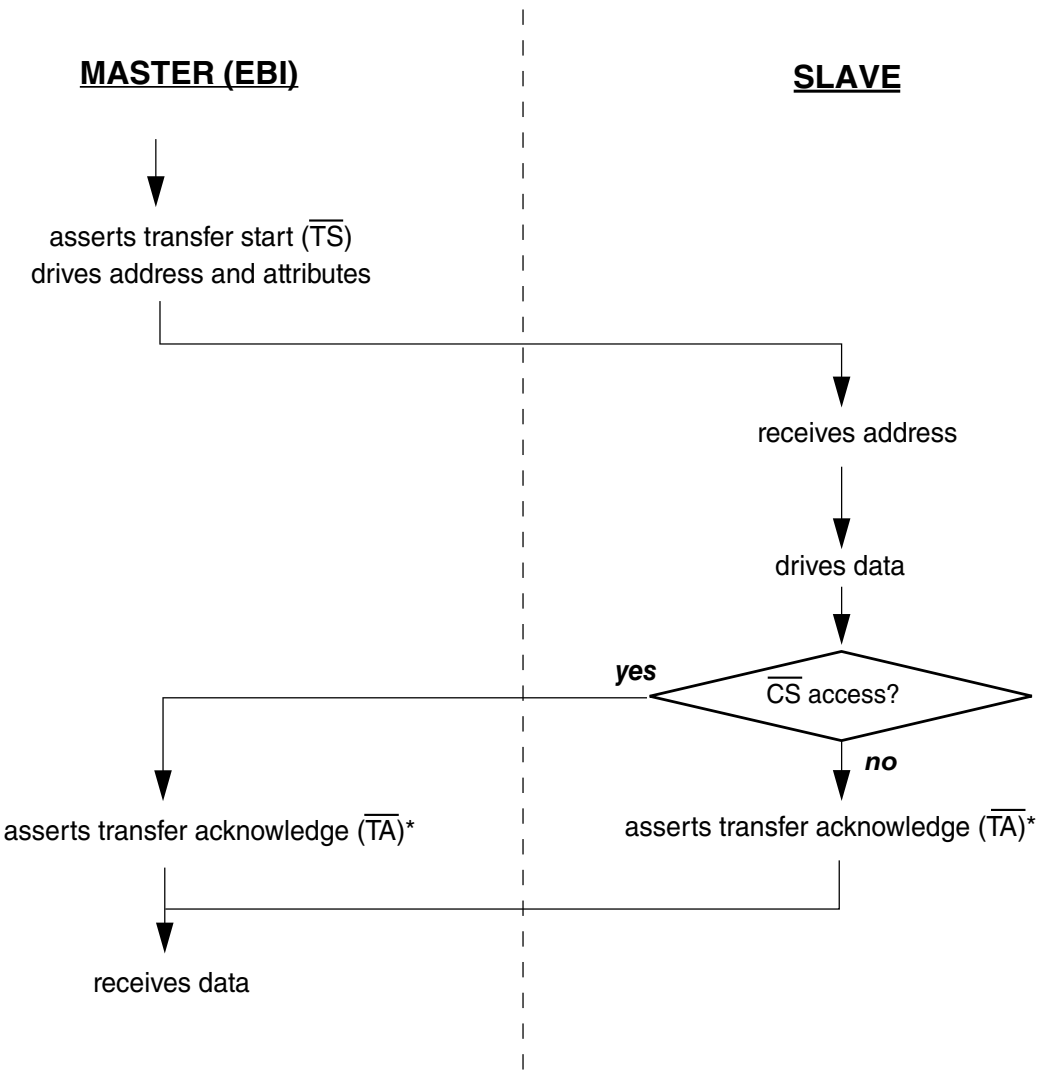
In the timing diagrams in this document, asynchronous relationships between signals that switch in the same CLKOUT cycle are not guaranteed. For example, in Figure 37-9, $\overline{WE}$ and write DATA change during the same CLKOUT cycle. There is no guarantee that DATA will be stable before $\overline{WE}$ assertion. External devices should not be latching write DATA on $\overline{WE}$ assertion, but instead must use a signal edge that takes place in a later CLKOUT cycle, such as $\overline{WE}$ negation.

37.4.2.4 Single Beat Transfer

The flow and timing diagrams in this section assume that the EBI is configured in Single Master Mode. Therefore, arbitration is not needed and is not shown in these diagrams

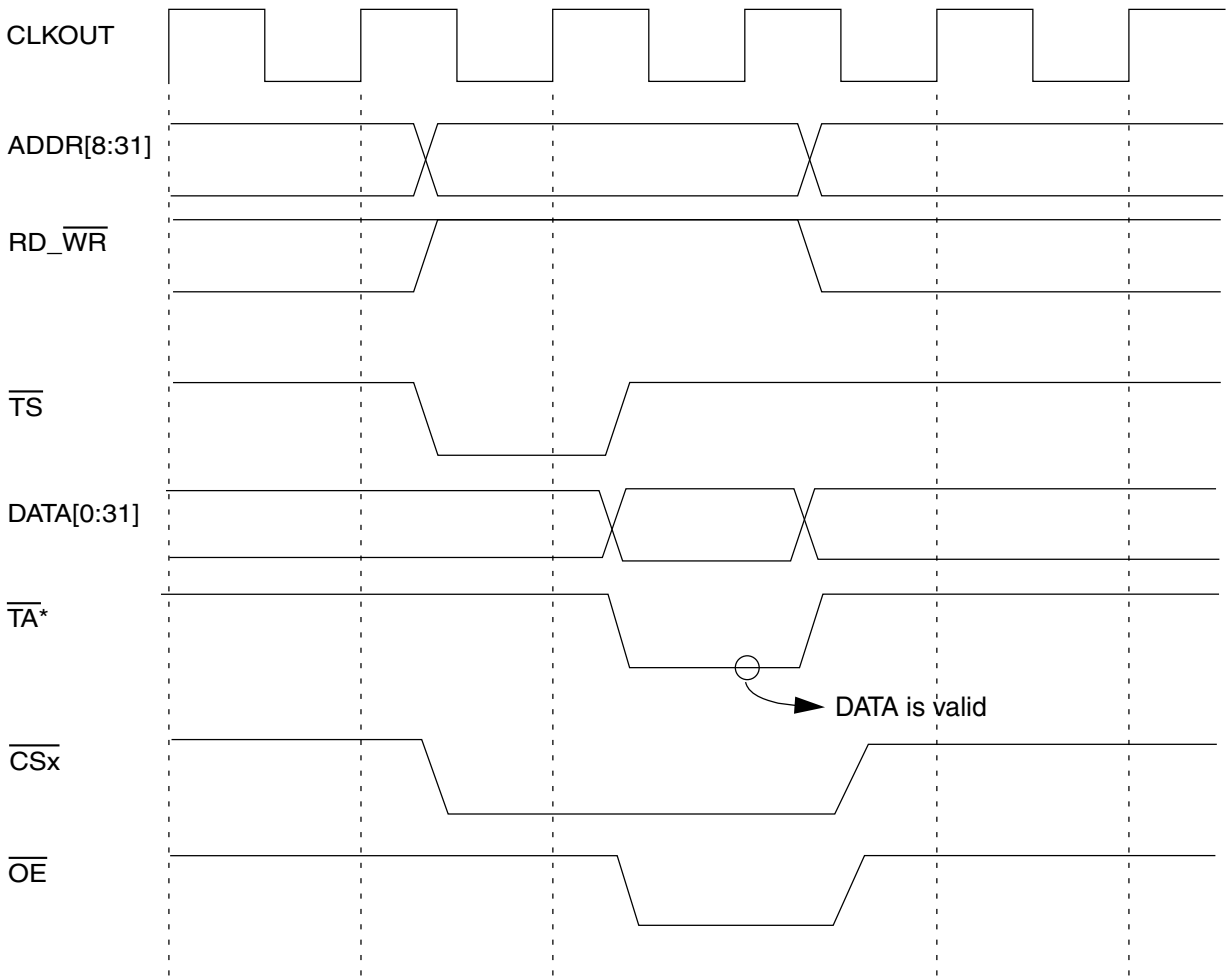
37.4.2.4.1 Single Beat Read Flow

The handshakes for a single beat read cycle are illustrated in the following flow and timing diagrams.



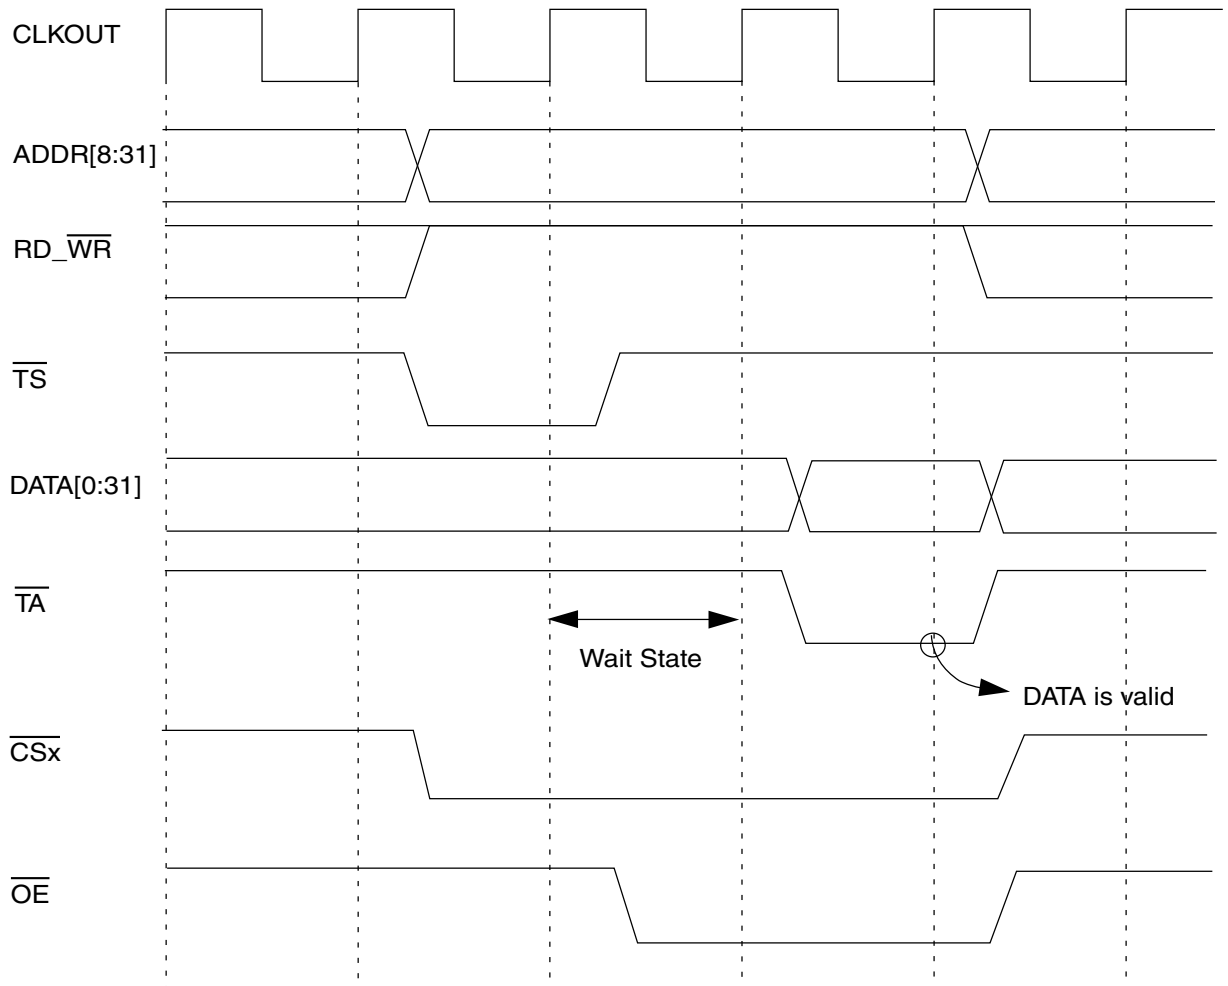
* There is no external $\overline{TA}$ signal. The $\overline{TA}$ signal is generated internally.

Figure 37-3. Basic Flow Diagram of a Single Beat Read Cycle



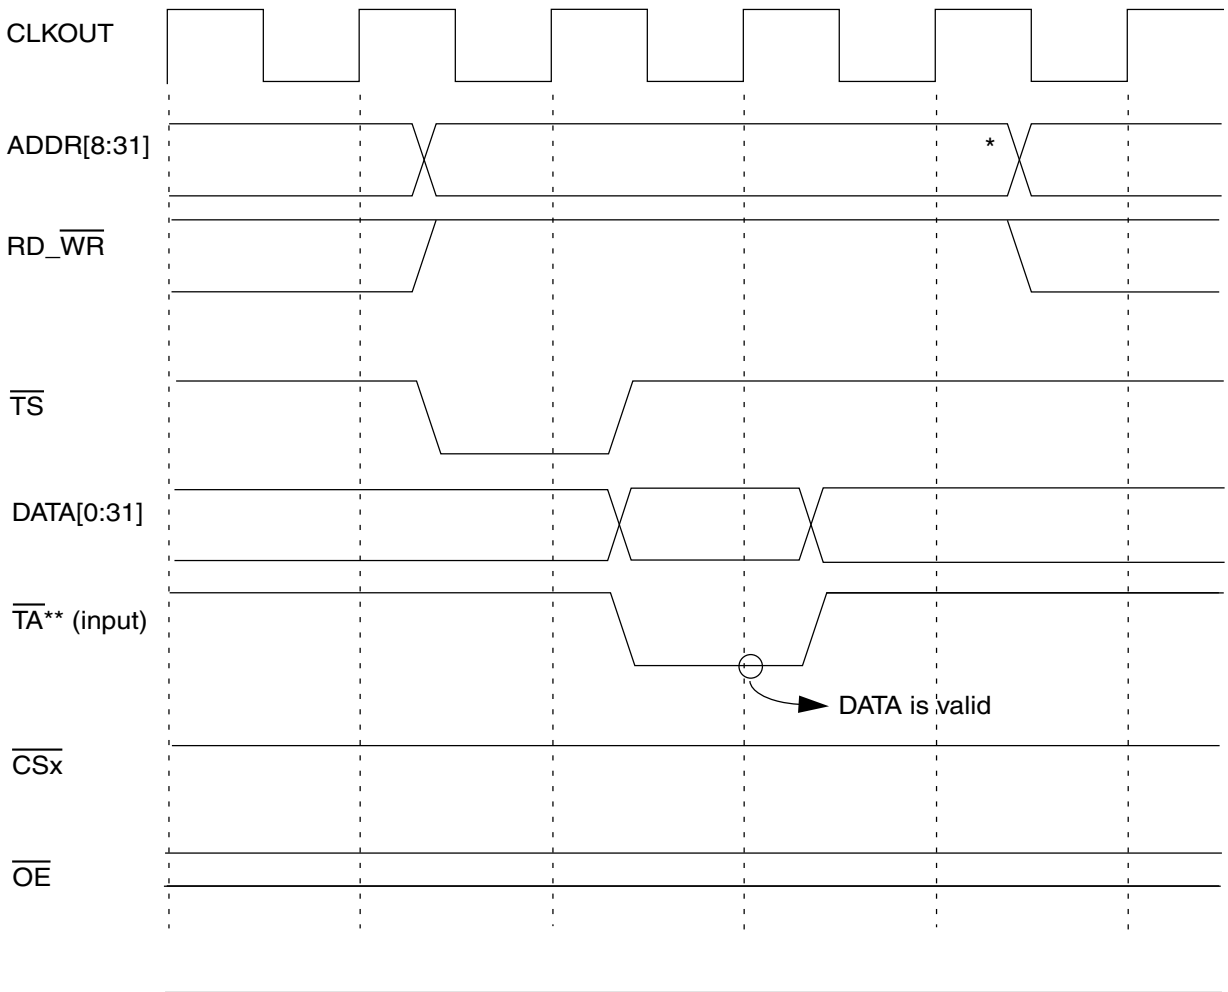
* There is no external TA signal. The TA signal is generated internally.

Figure 37-4. Single Beat 32-bit Read Cycle, CS Access, Zero Wait States



* There is no external TA signal. The TA signal is generated internally.

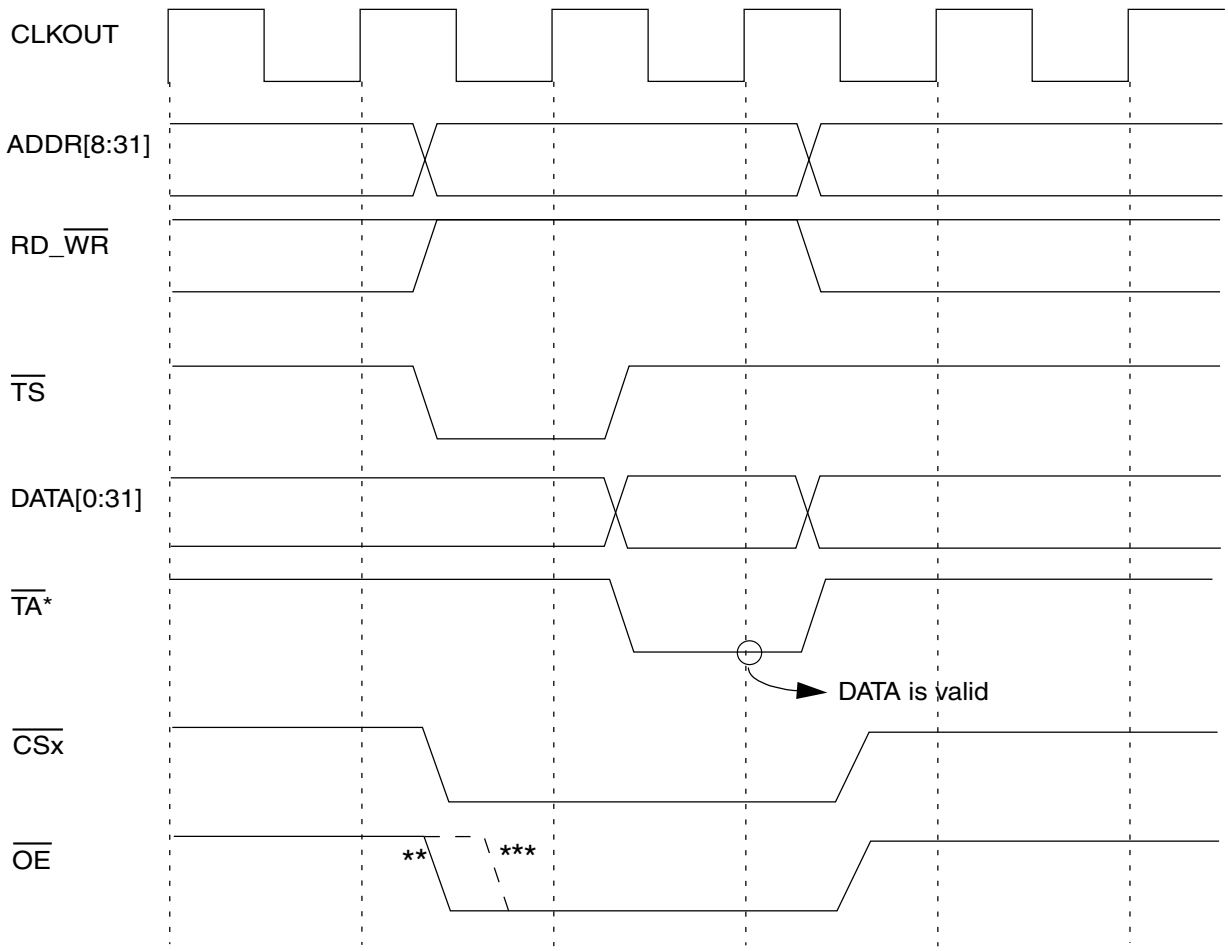
Figure 37-5. Single Beat 32-bit Read Cycle, CS Access, One Wait State



* The EBI drives address and control signals an extra cycle because it uses a latched version of the TA (1 cycle delayed) to terminate the cycle.

** There is no external TA signal. The TA signal is generated internally.

Figure 37-6. Single Beat 32-bit Read Cycle, Non-CS Access, Zero Wait States



* There is no external TA signal. The TA signal is generated internally.

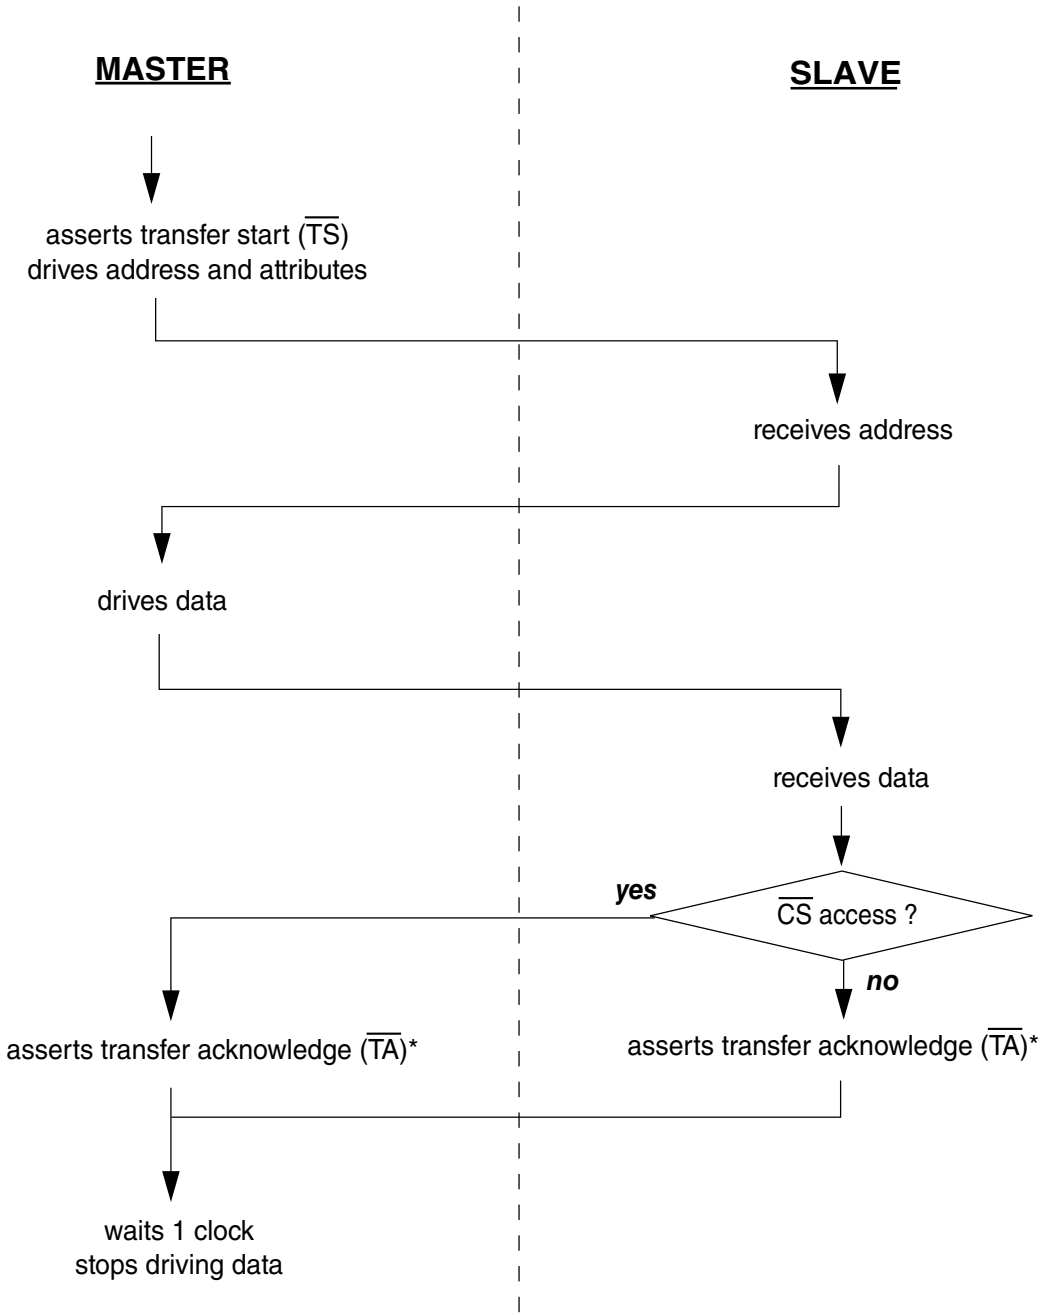
** When EBI_BR[EOE]=0b01 (or 0b10 in 1:1 bus speed mode), OE asserts around the same time as TS (could be slightly before or after TS, order of TS/OE assertion is not guaranteed).

*** When EBI_BR[EOE]=0b10 (and not in 1:1 bus speed mode), OE asserts 1 internal system clock (partial CLKOUT cycle) later as compared to TS.

Figure 37-7. Single Beat 32-bit Read Cycle, CS Access, Zero Wait States (EOE=0b01, 0b10)

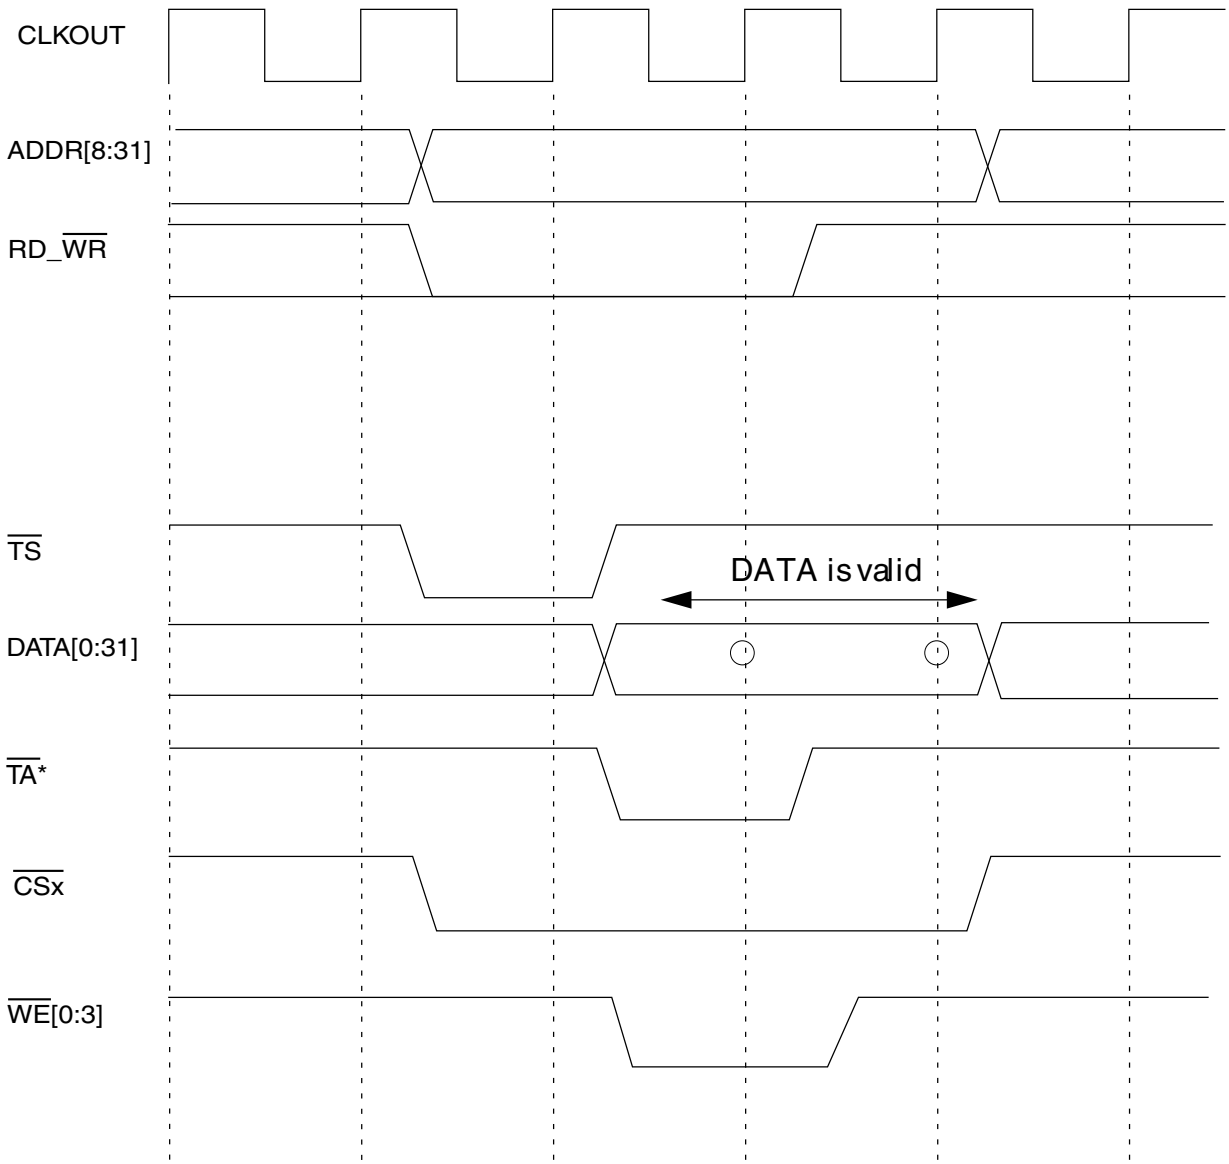
37.4.2.4.2 Single Beat Write Flow

The handshakes for a single beat write cycle are illustrated in the following flow and timing diagrams.



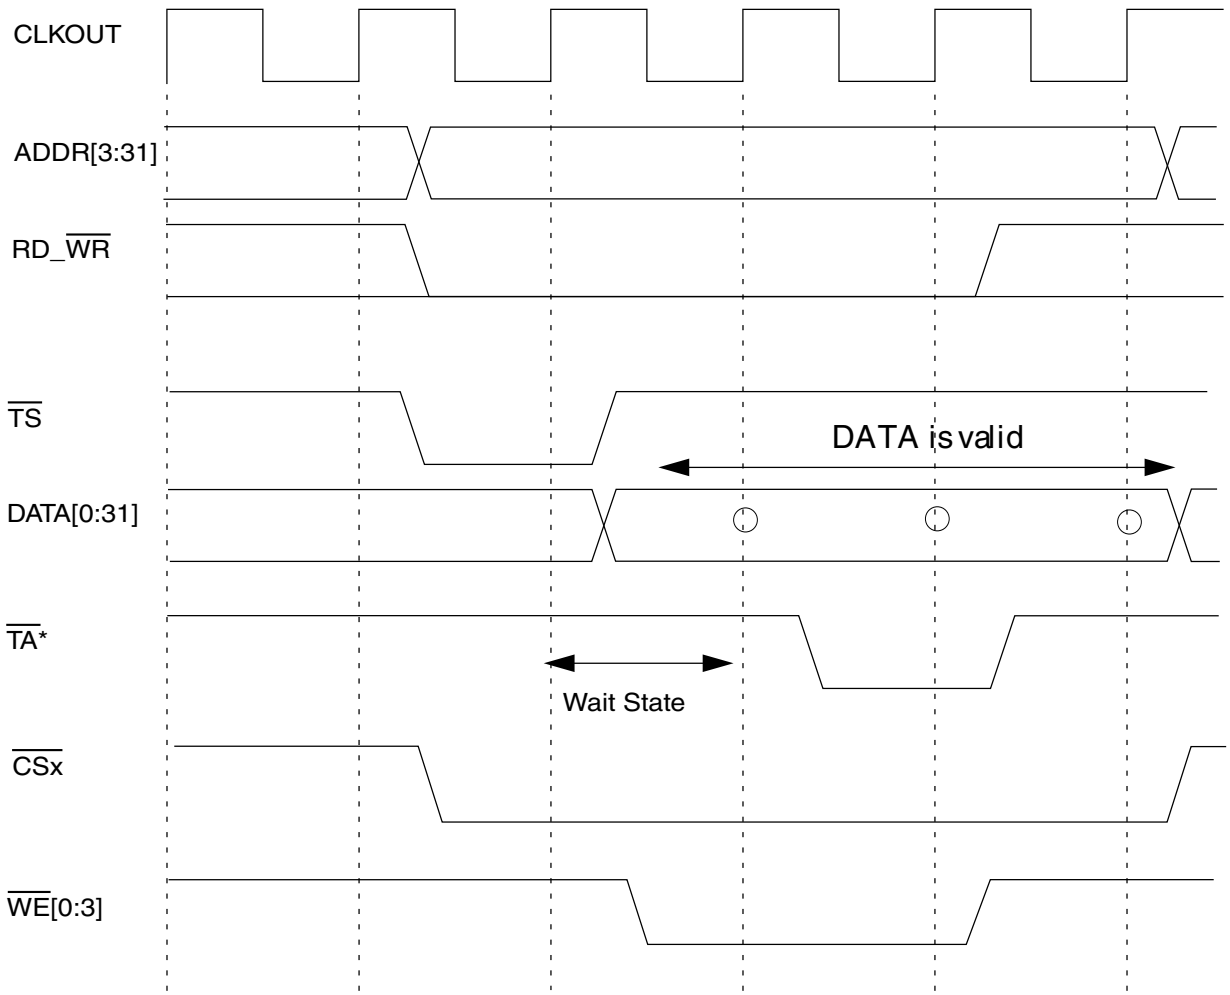
* There is no external TA signal. The TA signal is generated internally.

Figure 37-8. Basic Flow Diagram of a Single Beat Write Cycle



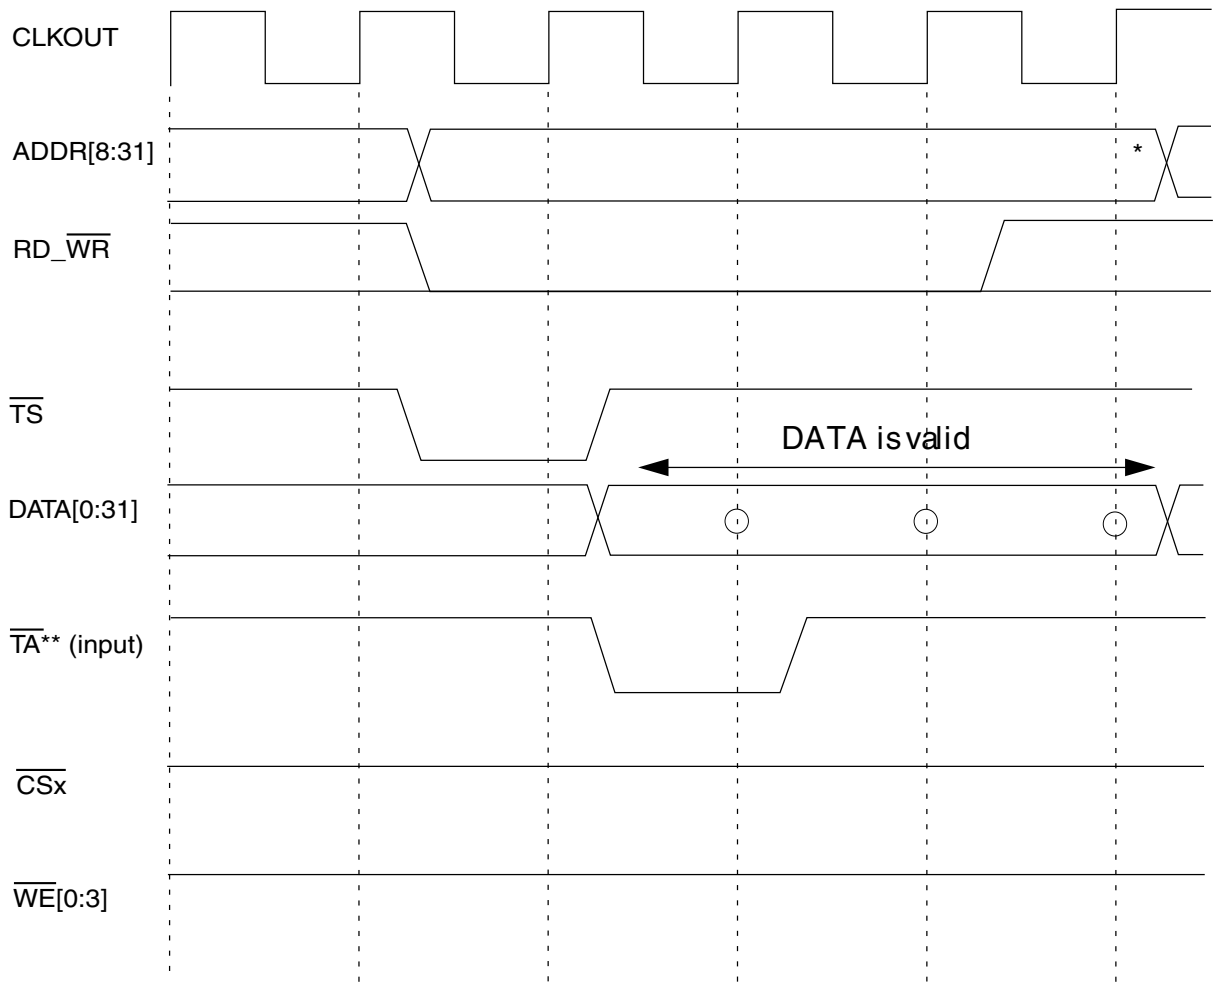
There is no external TA signal. The TA signal is generated internally.

Figure 37-9. Single Beat 32-bit Write Cycle, CS Access, Zero Wait States



* There is no external TA signal. The TA signal is generated internally.

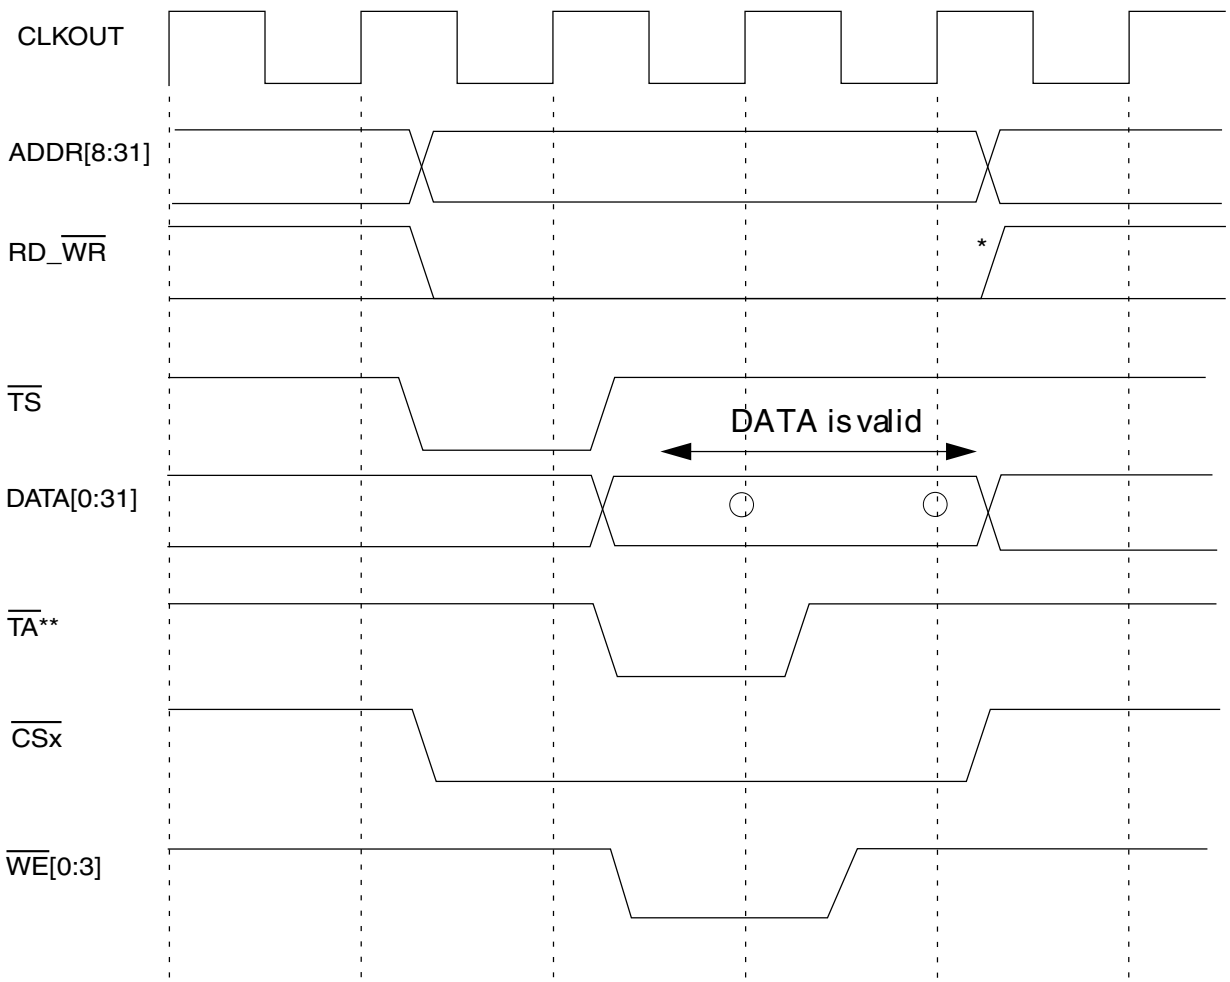
Figure 37-10. Single Beat 32-bit Write Cycle, CS Access, One Wait State



* The EBI drives address and control signals an extra cycle because it uses a latched version of the external TA (1 cycle delayed) to terminate the cycle.

** There is no external TA signal. The TA signal is generated internally.

Figure 37-11. Single Beat 32-bit Write Cycle, Non-CS Access, Zero Wait States



* Negation of RD_$\overline{WR}$ signal is delayed by 1 cycle (as shown) when EBI_BR[LWRN]=1.

** There is no external $\overline{TA}$ signal. The $\overline{TA}$ signal is generated internally.

Figure 37-12. Single Beat 32-bit Write Cycle, $\overline{CS}$ Access, Zero Wait States, LWRN=1

37.4.2.4.3 Back-to-Back Accesses

Due to internal bus protocol, one dead cycle is necessary between back-to-back external bus accesses that are not part of a set of small accesses (see Small Accesses (Small Port Size and Short Burst Length) for small access timing). A dead cycle refers to a cycle between the $\overline{TA}$ of a previous transfer and the $\overline{TS}$ of the next transfer.

Note

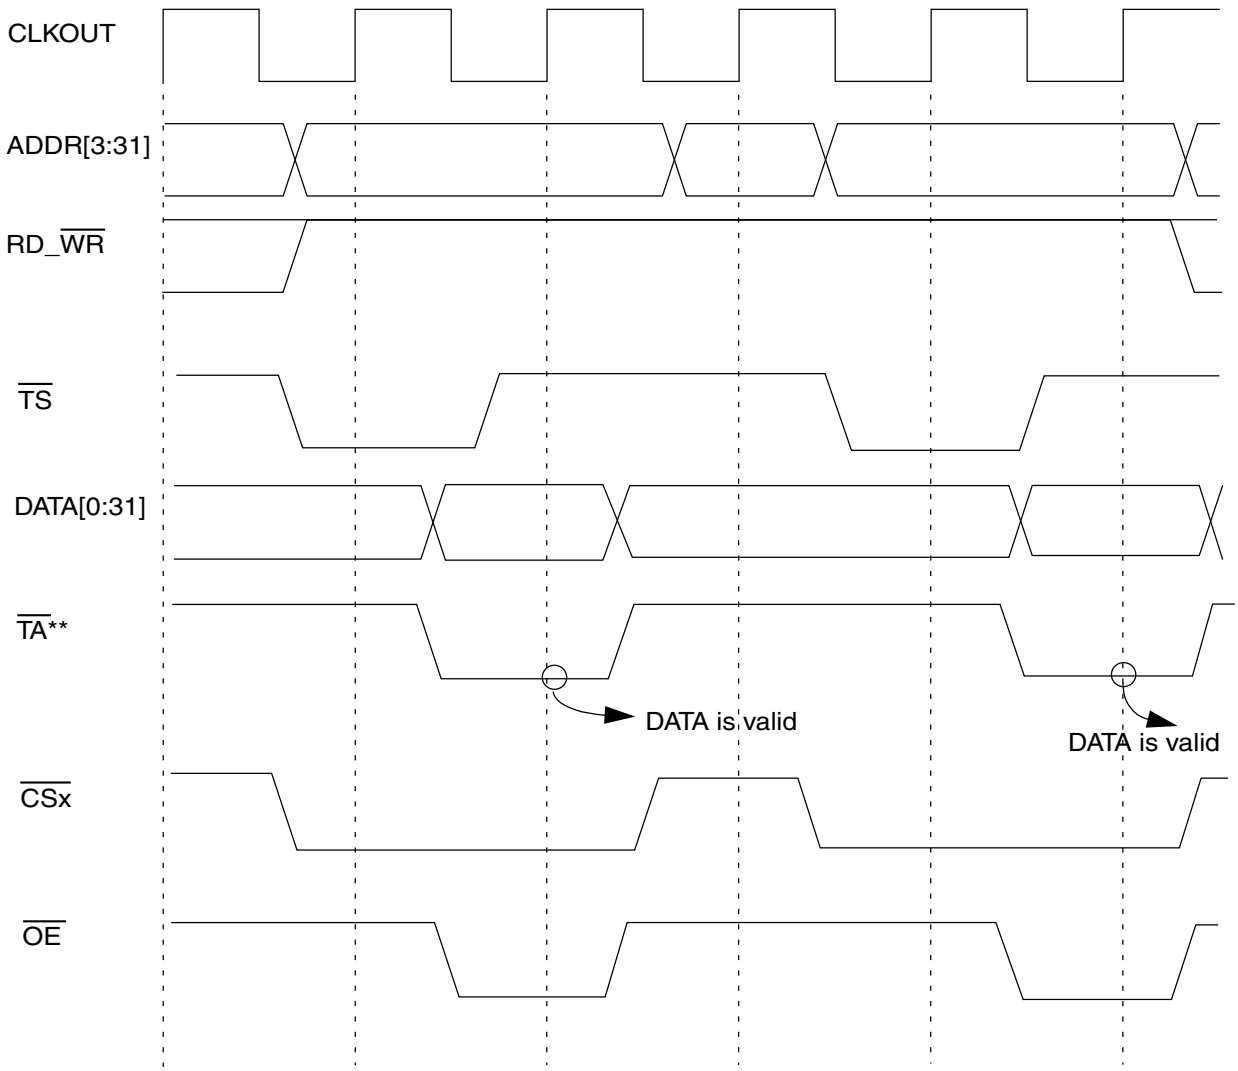
In some cases, $\overline{CS}$ remains asserted during this dead cycle, such as the cases of back-to-back writes or read-after-write to the same chip-select (with EBI_BR[GCSN]=0). See Figure 37-16 and Figure 37-18. However, if EBI_BR[GCSN]=1 for the first

access (see Figure 37-17 and Figure 37-19), then the EBI inserts an extra dead cycle between the accesses for these cases in order to guarantee $\overline{CS}$ negation between accesses.

Besides this dead cycle, in most cases, back-to-back accesses on the external bus do not cause any change in the timing from that shown in the previous diagrams, and the two transactions are independent of each other. The only exceptions to this are listed below:

- 4-word burst transfers (using 64-bit AMBA bus) whose starting address is not 0x20 aligned. In these cases, an extra cycle is required between the end of the 2nd 4-word burst access and the $\overline{TS}$ assertion of a subsequent access. See Figure 37-29.

The following diagrams show a few examples of back-to-back accesses on the external bus.



* This timing diagram is unaffected by EBI_BR[GCSN].

** There is no external TA signal. The TA signal is generated internally.

Figure 37-22. Read After Write to Different $\overline{CS}$ Banks

37.4.2.5 Burst Transfer

The EBI supports wrapping 32-byte critical-doubleword-first burst transfers. Bursting is supported only for internally-requested (e.g. core, dma, etc.) cache-line size (32-byte) read accesses to external devices that use the chip selects.

Note

In the case where the internal AMBA data bus width is 32 bits (instead of 64), the EBI supports a 16-byte critical-word-first burst transfer (instead of 32-byte critical-doubleword-first). In general, this document assumes the default case of 64-bit AMBA bus, 32-byte burst transfer.

Accesses to devices operating without a chip select are always single beat. If an internal request to the EBI indicates a size of less than 32 bytes, the request is fulfilled by running one or more single-beat external transfers, not by an external burst transfer.

An 8-word wrapping burst reads eight 32-bit words by supplying a starting address that points to one of the words (doubleword aligned) and requiring the memory device to sequentially drive each word on the data bus. The selected slave device must internally increment ADDR[27:29] (also ADDR30 in the case of a 16-bit port size device) of the supplied address for each transfer, until the address reaches an 8-word boundary, and then wrap the address to the beginning of the 8-word boundary. The address and transfer attributes supplied by the EBI remain stable during the transfers. Termination of each beat transfer occurs by the EBI asserting $\overline{\text{TA}}$. The EBI requires that addresses be aligned to a doubleword boundary on all burst cycles.

Table 37-4 shows the burst order of beats returned for an 8-word burst to a 32-bit port.

Table 37-4. Wrap Bursts Order

Burst Starting Address ADDR[27:28]	Burst Order (Assuming 32-bit Port Size)
00	word0 -> word1 -> word2 -> word3 -> word4 -> word5 -> word6 -> word7
01	word2 -> word3 -> word4 -> word5 -> word6 -> word7 -> word0 -> word1
10	word4 -> word5 -> word6 -> word7 -> word0 -> word1 -> word2 -> word3
11	word6 -> word7 -> word0 -> word1 -> word2 -> word3 -> word4 -> word5

The general case of burst transfers assumes that the external memory has 32-bit port size and 8-word burst length (SBL=0, BL=0). The EBI can also burst from 16-bit port size memories, taking twice as many external beats to fetch the data as compared to a 32-bit port with the same burst length. The EBI can also burst from 16-bit or 32-bit memories that have a 4-word burst length (SBL=0, BL=1 in the appropriate Base Register). In this case, two external 4-word burst transfers (wrapping on 4-word boundary) are performed

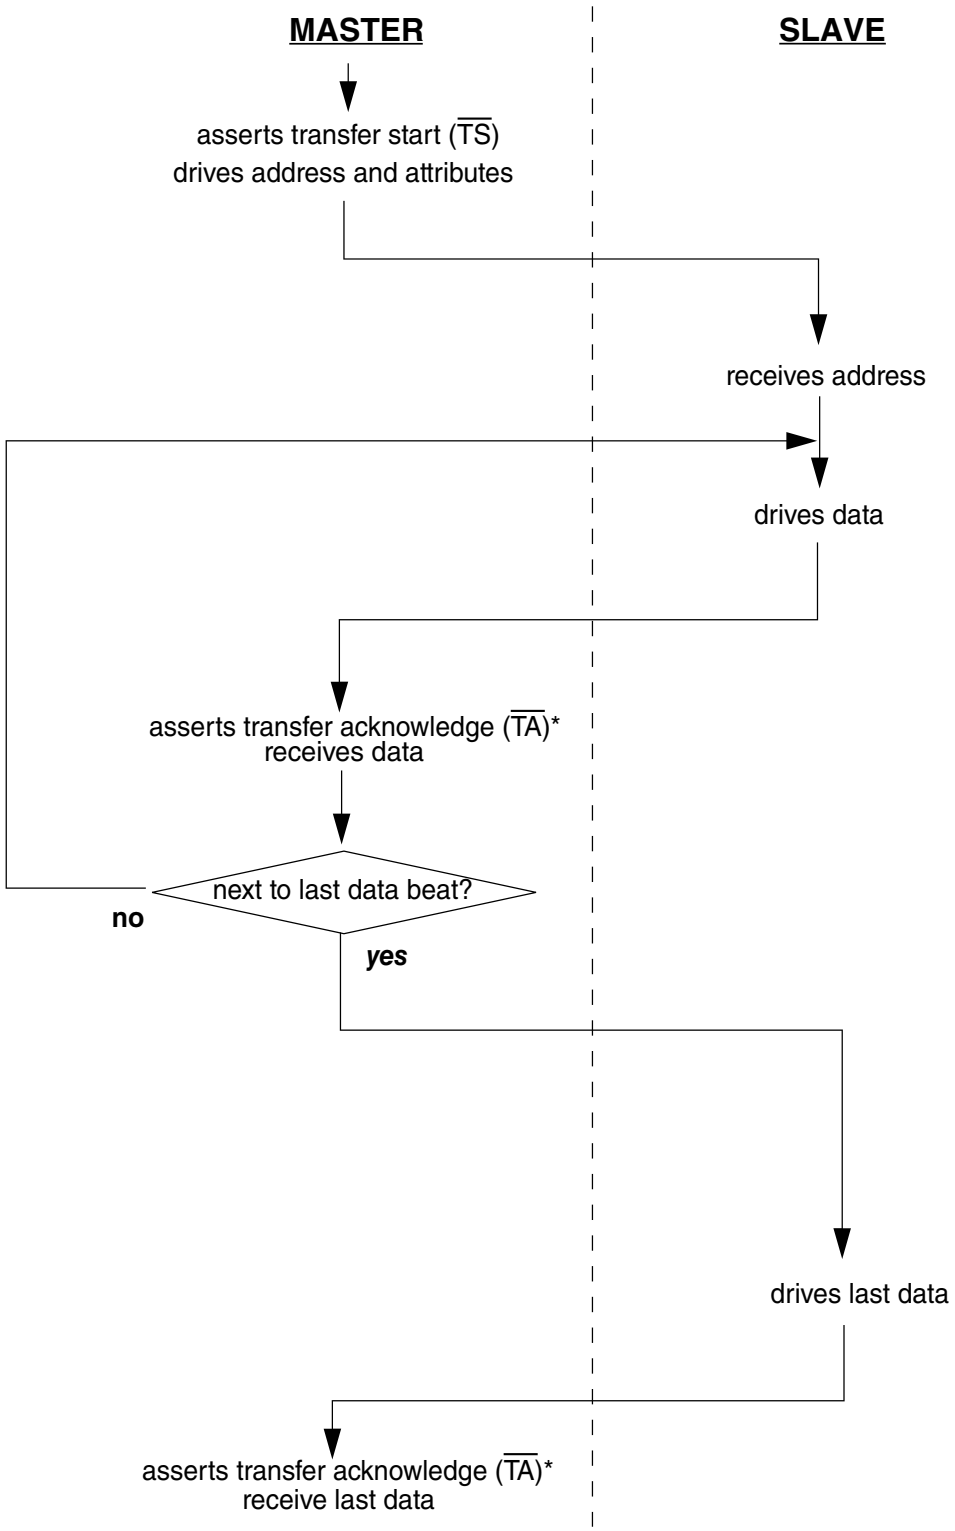
to fulfill the internal 8-word request[1]. This operation is considered atomic by the EBI, so the EBI does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. For more details and a timing diagram, see Small Access Example #3: 32-byte Read to 32-bit Port with BL=1.

The EBI can also burst from 16-bit or 32-bit memories that have a 2-word burst length (SBL=1, BL=X in the appropriate Base Register). In this case, four[2] external 2-word burst transfers (wrapping on 2-word boundary) are performed to fulfill the internal 8-word request. This operation is considered atomic by the EBI, so the EBI does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. For more details and a timing diagram, see Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1.

During burst cycles, the $\overline{\text{BDIP}}$ (Burst Data In Progress) signal is used to indicate the duration of the burst data. During the data phase of a burst read cycle, the EBI receives data from the addressed slave. If the EBI needs more than one data, it asserts the $\overline{\text{BDIP}}$ signal. Upon receiving the data prior to the last data, the EBI negates $\overline{\text{BDIP}}$. Thus, the slave stops driving new data after it receives the negation of $\overline{\text{BDIP}}$ on the rising edge of the clock. Some slave devices have their burst length and timing configurable internally and thus may not support connecting to a BDIP pin. In this case, $\overline{\text{BDIP}}$ is driven by the EBI normally, but the output is ignored by the memory and the burst data behavior is determined by the internal configuration of the EBI and slave device. When the TBDIP bit is set in the appropriate Base Register, the timing for $\overline{\text{BDIP}}$ is altered. See TBDIP Effect on Burst Transfer for this timing.

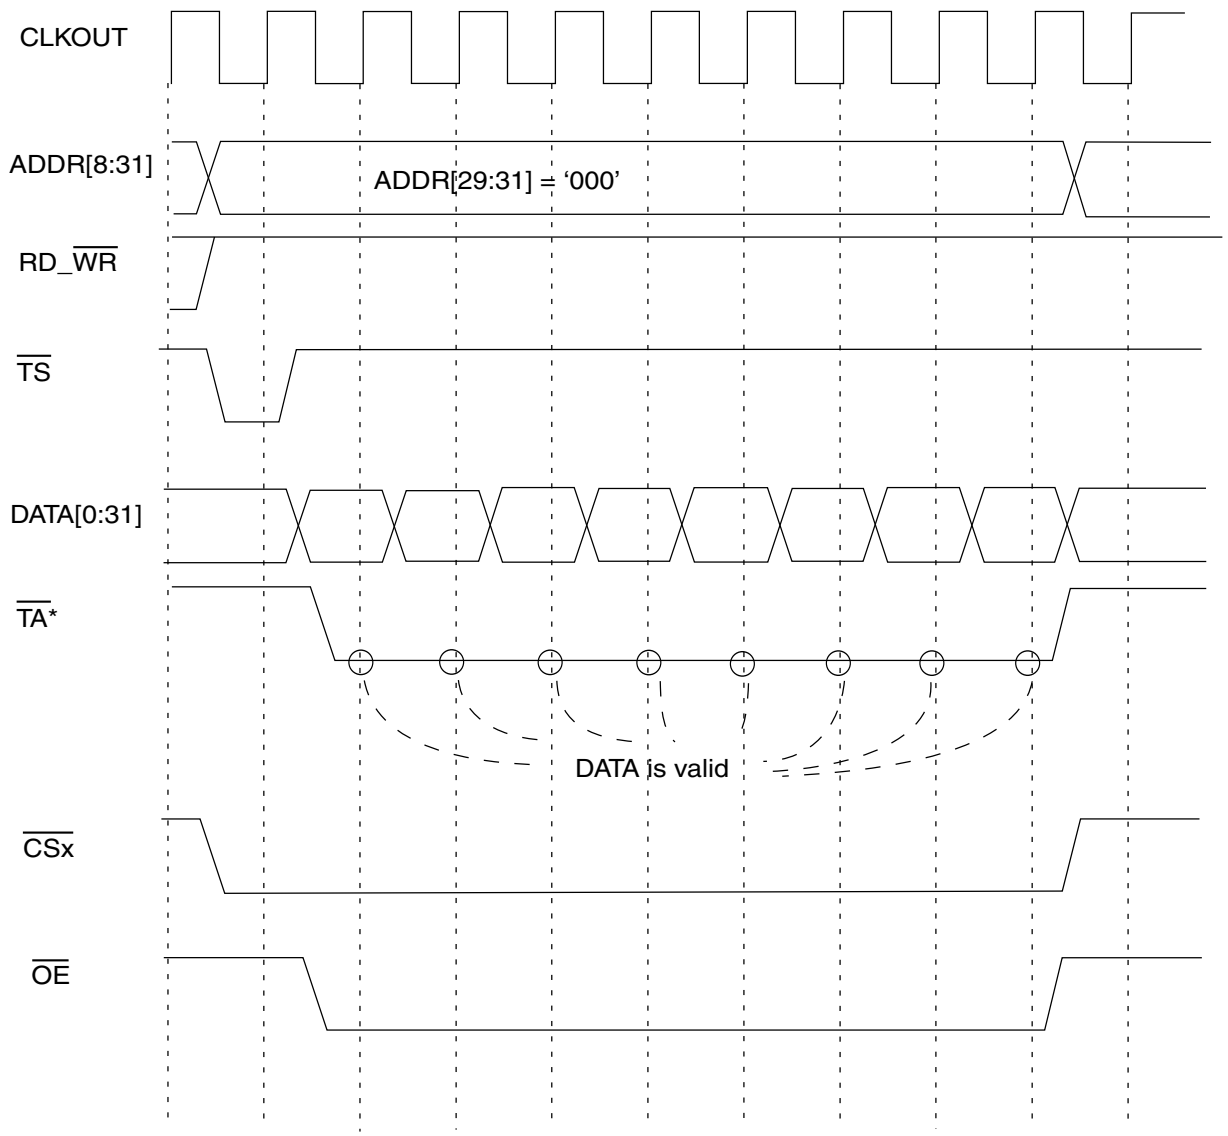
Since burst writes are not supported by the EBI, the EBI negates $\overline{\text{BDIP}}$ during write cycles.

1. This case (of 2 external 4-word burst transfers being required) applies only to AMBA data bus width of 64 bits.
2. Applies to 64-bit AMBA data bus width. For 32-bit AMBA data bus width, only two transfers are performed.



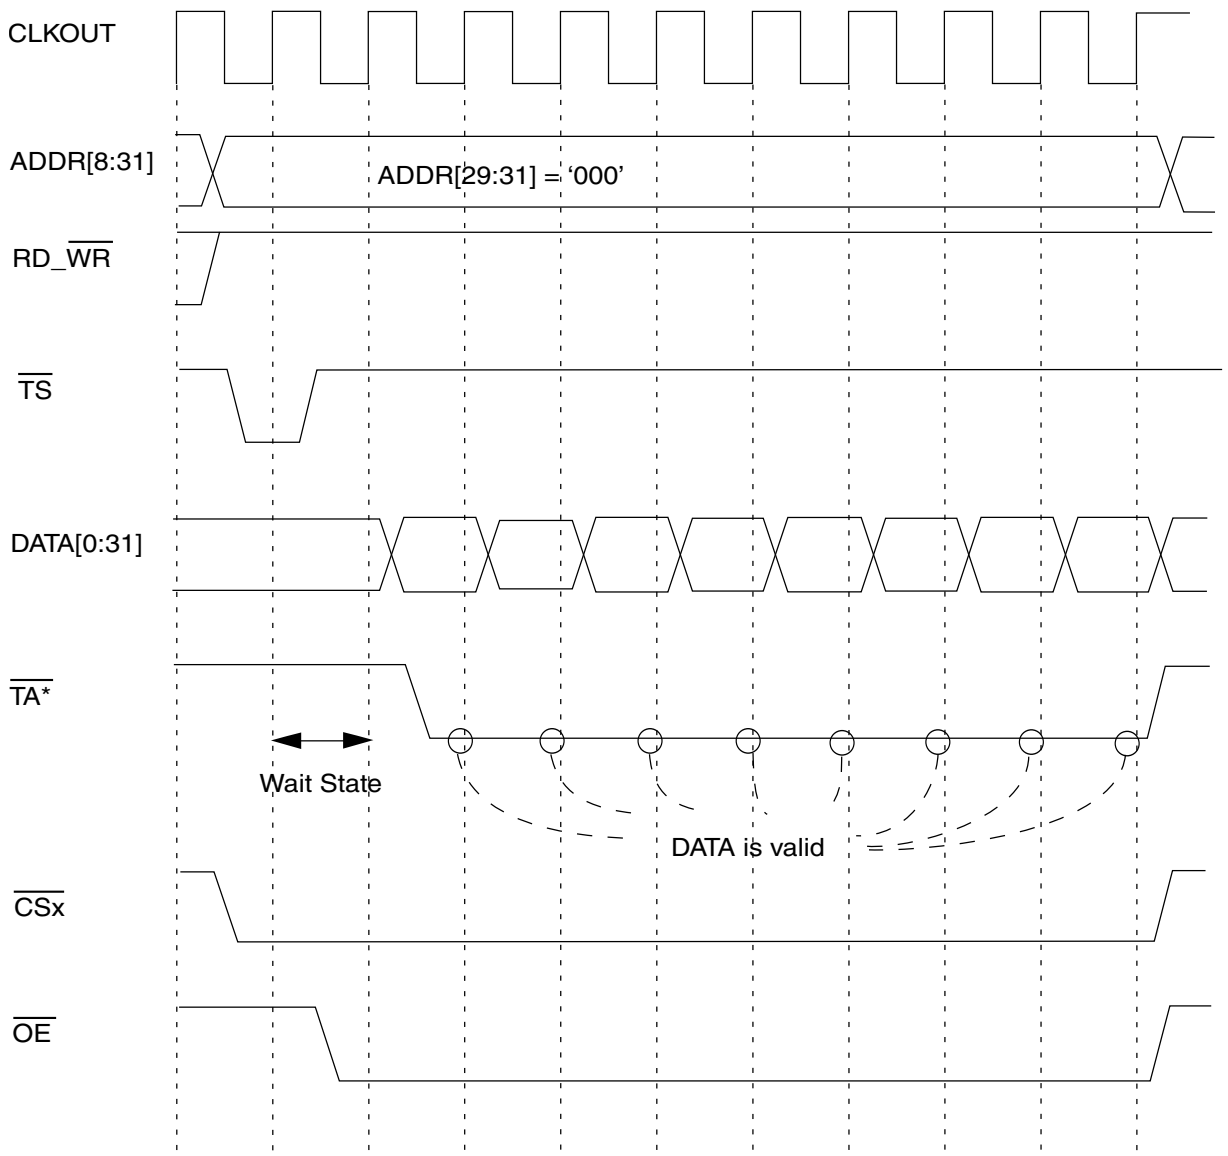
*There is no external TA signal. The TA signal is generated internally.

Figure 37-23. Basic Flow Diagram of a Burst Read Cycle



* There is no external $\overline{TA}$ signal. The $\overline{TA}$ signal is generated internally.

Figure 37-24. Burst 32-bit Read Cycle, Zero Wait States

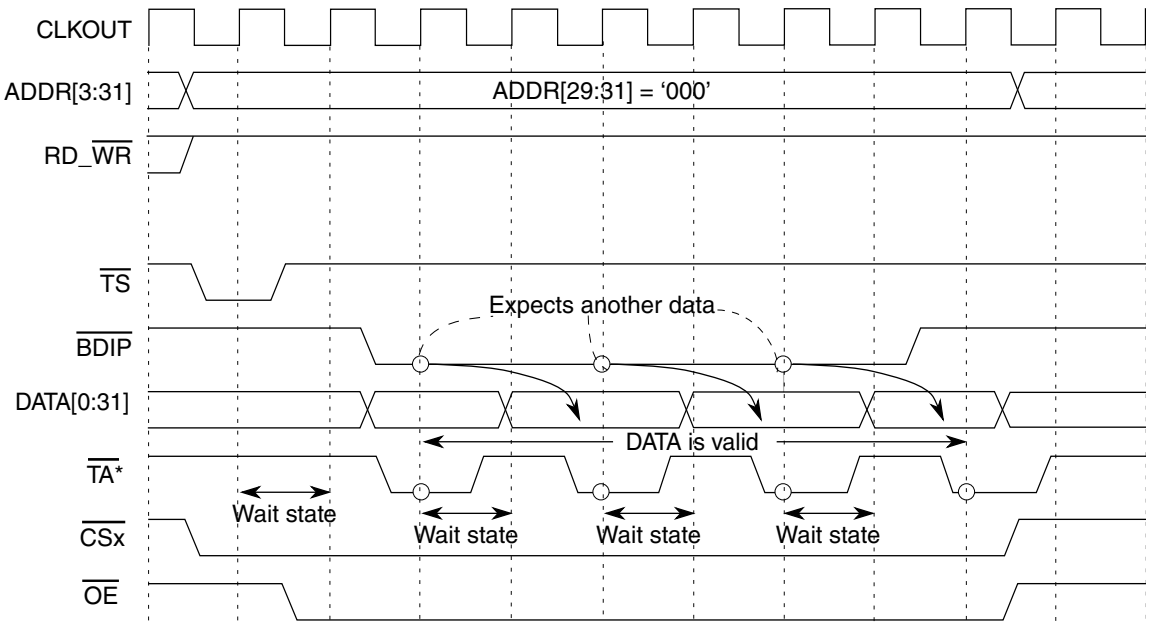


* There is no external TA signal. The TA signal is generated internally.

Figure 37-25. Burst 32-bit Read Cycle, One Initial Wait State

37.4.2.5.1 TBDIP Effect on Burst Transfer

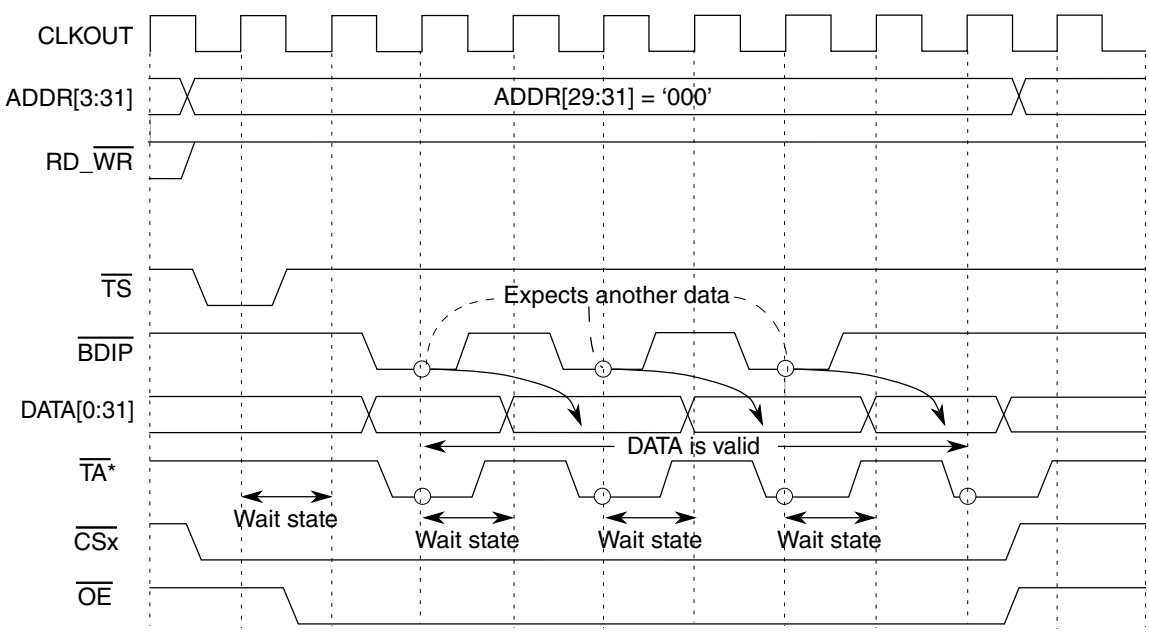
Some memories require different timing on the BDIP signal than the default to run burst cycles. Using the default value of TBDIP=0 in the appropriate EBI Base Register results in BDIP being asserted (SCY+1) cycles after the address transfer phase, and being held asserted throughout the cycle regardless of the wait states between beats (BSCY). Figure 37-26 shows an example of the TBDIP=0 timing for a 4-beat burst with BSCY=1.



*There is no external TA signal. The TA signal is generated internally.

Figure 37-26. Burst 32-bit Read Cycle, One Wait State between Beats, TBDIP=0

When using TBDIP=1, the BDIP behavior changes to toggle between every beat when BSCY is a non-zero value. Figure 37-27 shows an example of the TBDIP=1 timing for the same 4-beat burst shown in Figure 37-26.



*There is no external TA signal. The TA signal is generated internally.

Figure 37-27. Burst 32-bit Read Cycle, One Wait State between Beats, TBDIP=1

37.4.2.6 Small Accesses (Small Port Size and Short Burst Length)

In this context, a *small access* refers to an access whose burst length and port size (SBL, BL, PS bits in Base Register for chip-select access or default burst disabled, 32-bit port for non-chip-select access) are such that the number of bytes requested by the internal master cannot all be fetched (or written) in one external transaction. If this is the case, the EBI initiates multiple transactions until all the requested data is transferred. It should be noted that all the transactions initiated to complete the data transfer are considered as an atomic transaction, so the EBI does not allow other unrelated master accesses to intervene between the transfers.

Table 37-5 shows all the combinations of burst length, port size, and requested byte count that cause the EBI to run multiple external transactions to fulfill the request.

Table 37-5. Small Access Cases

Byte Count Requested by internal master	Burst Length	Port Size	# External Accesses to Fulfill Request
Non-Burstable Chip-Select Banks (BI=1)			
4	1 beat	16-bit	2
8	1 beat	32-bit	2
8	1 beat	16-bit	4
16[1]	1 beat	32-bit	4
16[1]	1 beat	16-bit	8
32[2]	1 beat	32-bit	8
32[2]	1 beat	16-bit	16
Burstable Chip-Select Banks (BI=0)			
32[2]	4 words	16-bit (8 beats), 32-bit (4 beats)	2
32[3]	2 words	16-bit (4 beats), 32-bit (2 beats)	4

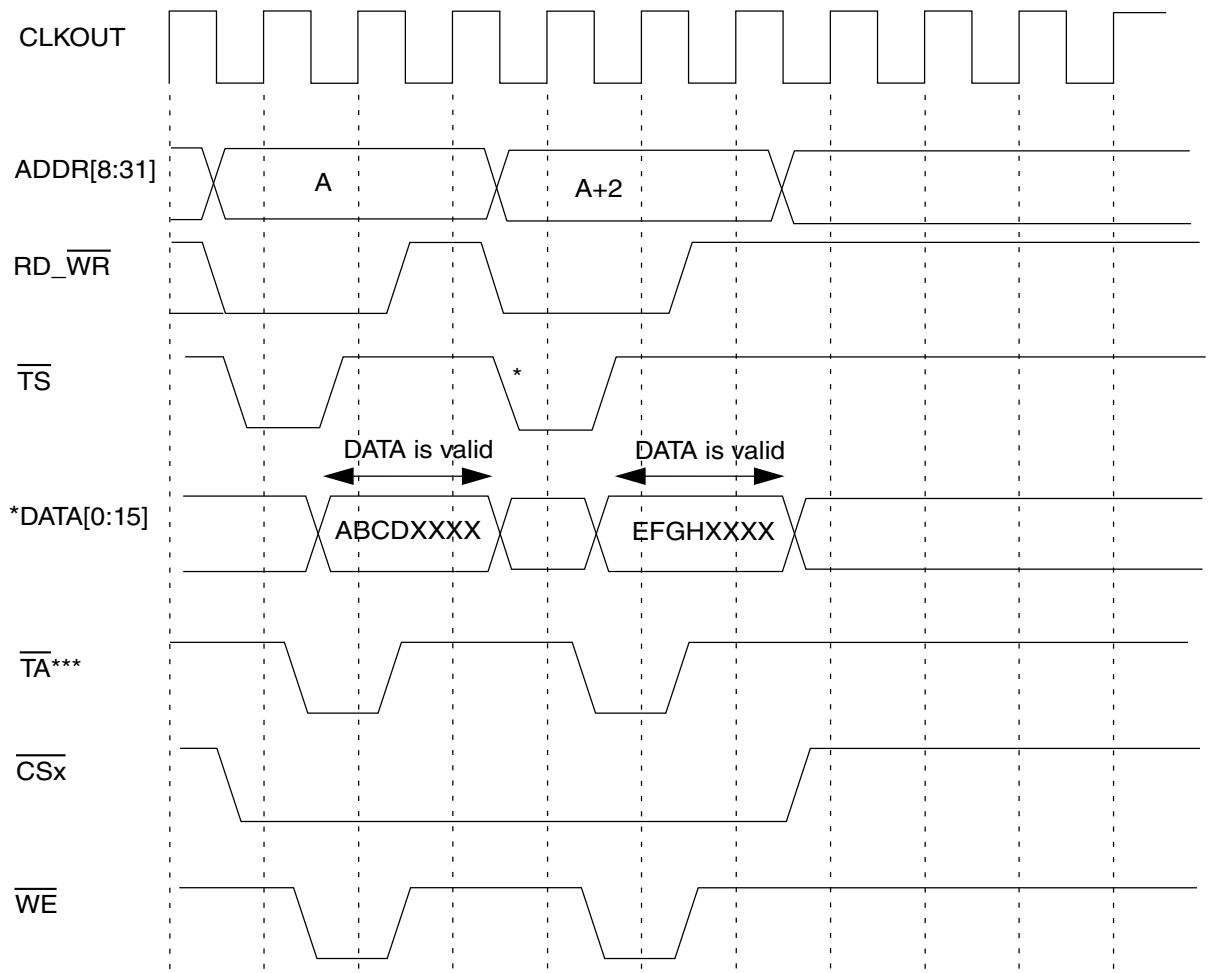
1. Only supported for case of 32-bit internal AMBA data bus.
2. Only supported for case of 64-bit internal AMBA data bus.
3. SBL=1 (2-word burst case).

In most cases, the timing for small accesses is the same as for normal single-beat and burst accesses, except that multiple back-to-back external transfers are executed for each internal request. These transfers have no additional dead cycles in-between that are not present for back-to-back stand-alone transfers except for the case of writes with an internal request size of >64 bits.

The following sections show a few examples of small accesses. The timing for the remaining cases in Table 37-5 can be extrapolated from these and the other timing diagrams in this document.

37.4.2.6.1 Small Access Example #1: 32-bit Write to 16-bit Port

Figure 37-28 shows an example of a 32-bit write to a 16-bit port, requiring two 16-bit external transactions.



* Or DATA[16:31], based on D16_31 bit in EBI_MCR.

** Timing shown applies when EBI_BR[GCSN]=0. When EBI_BR[GCSN]=1, the 2nd TS assertion is delayed by 1 cycle and CS negates between the two transfers..

*** There is no external TA signal. The TA signal is generated internally.

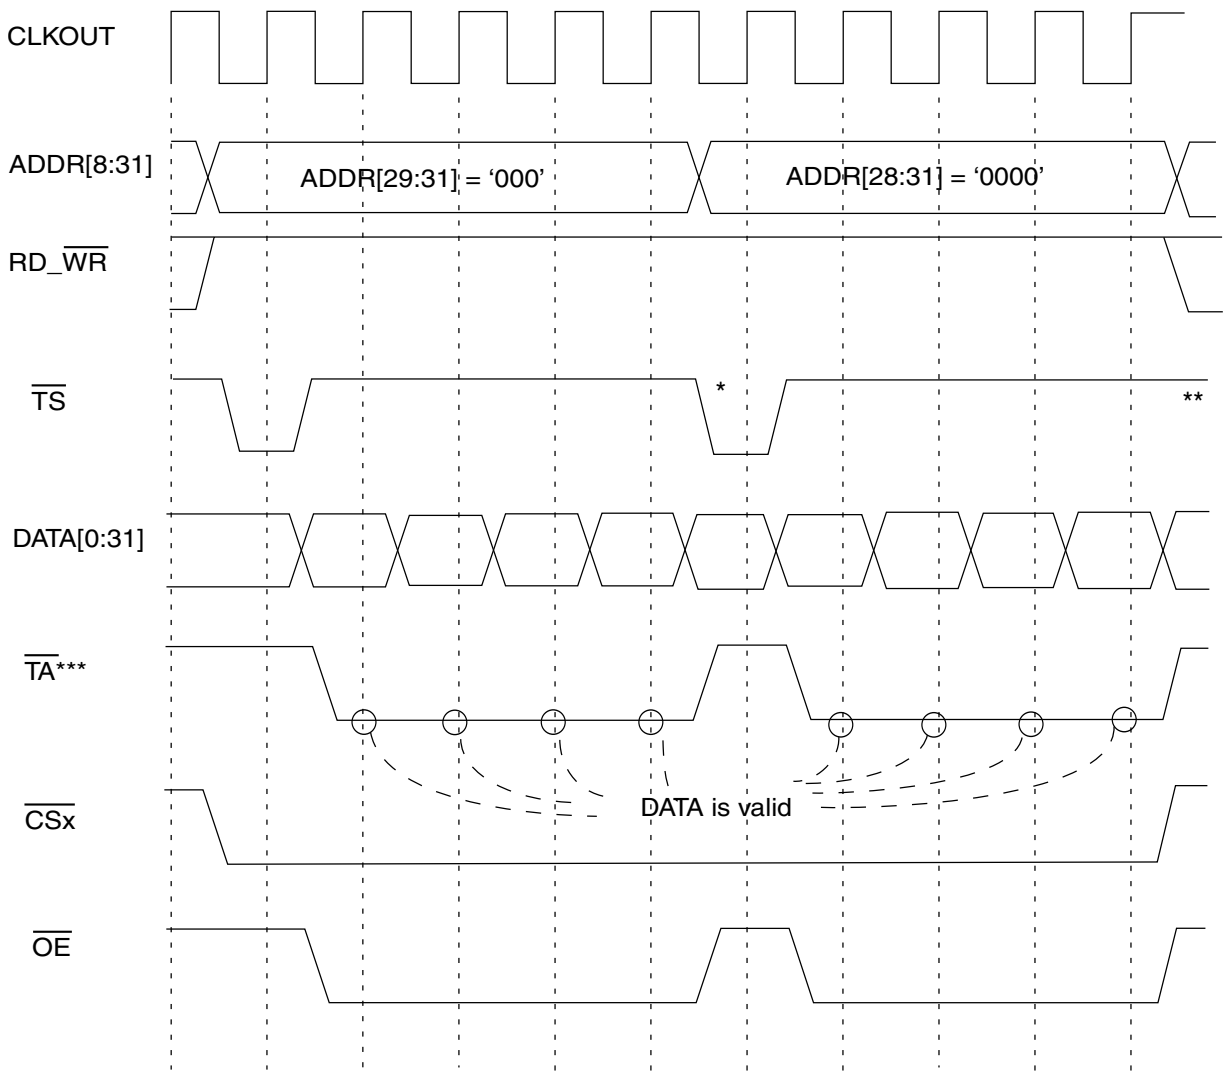
Figure 37-28. Single Beat 32-bit Write Cycle, 16-bit Port Size, Basic Timing

37.4.2.6.2 Small Access Example #3: 32-byte Read to 32-bit Port with BL=1

Figure 37-29 shows an example of a 32-byte read to a 32-bit burst enabled port with burst length of 4 words, requiring two 4-word (16-byte) external transactions. For this case, the address for the 2nd 4-word burst access is calculated by adding 0x10 to the lower 5 bits of the 1st address (no carry), and then masking out the lower 4 bits to fix them at zero.

Table 37-6. Examples of 4-word Burst Addresses

1st Address	Lower 5 bits of 1st Address + 0x10 (no carry)	Final 2nd Address (After Masking Lower 4 Bits)
0x000	0x10	0x10
0x008	0x18	0x10
0x010	0x00	0x00
0x018	0x08	0x00
0x020	0x30	0x30
0x028	0x38	0x30
0x030	0x20	0x20
0x038	0x28	0x20



* Timing shown applies when EBI_BR[GCSN]=0. When EBI_BR[GCSN]=1, the 2nd TS assertion is delayed by 1 cycle and CS negates between the two transfers.

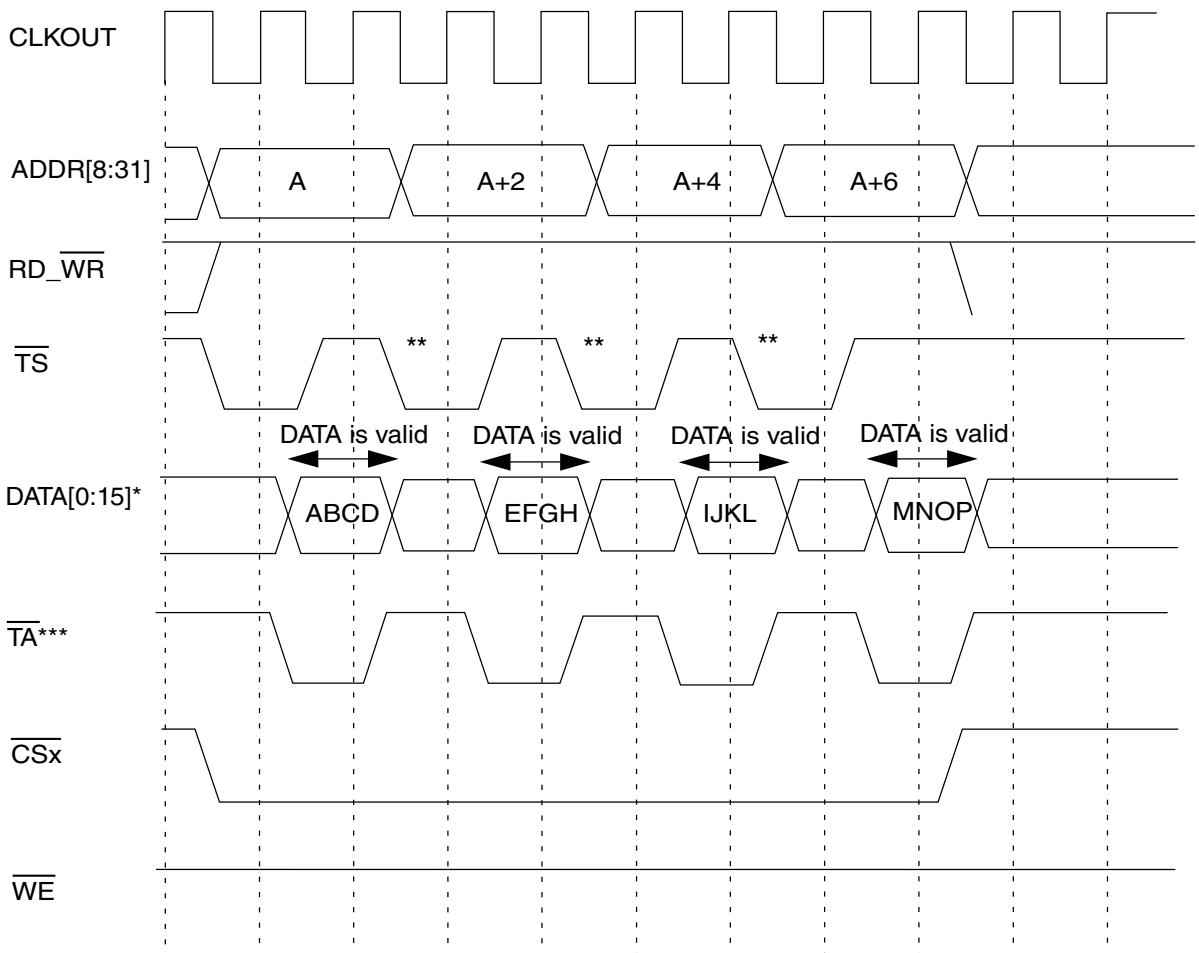
** For the case where the starting address for 4-word burst is not 0x20 aligned, the start of a subsequent back-to-back transfer is delayed by 1 cycle.

*** There is no external TA signal. The TA signal is generated internally.

Figure 37-29. 32-Byte Read with B-T-B 4-Word Bursts to 32-bit Port, Zero Wait States

37.4.2.6.3 Small Access Example #4: 64-bit Read to 16-bit Port

Figure 37-30 shows an example of a 64-bit read to a 16-bit port, requiring four 16-bit external transactions.



* Or DATA[16:31], based on D16_31 bit in EBI_MCR.

** Timing shown applies when EBI_BR[GCSN]=0. When EBI_BR[GCSN]=1, the 2nd-4th $\overline{TS}$ assertions are each delayed by 1 cycle and $\overline{CS}$ negates between each transfer.

*** There is no external $\overline{TA}$ signal. The $\overline{TA}$ signal is generated internally.

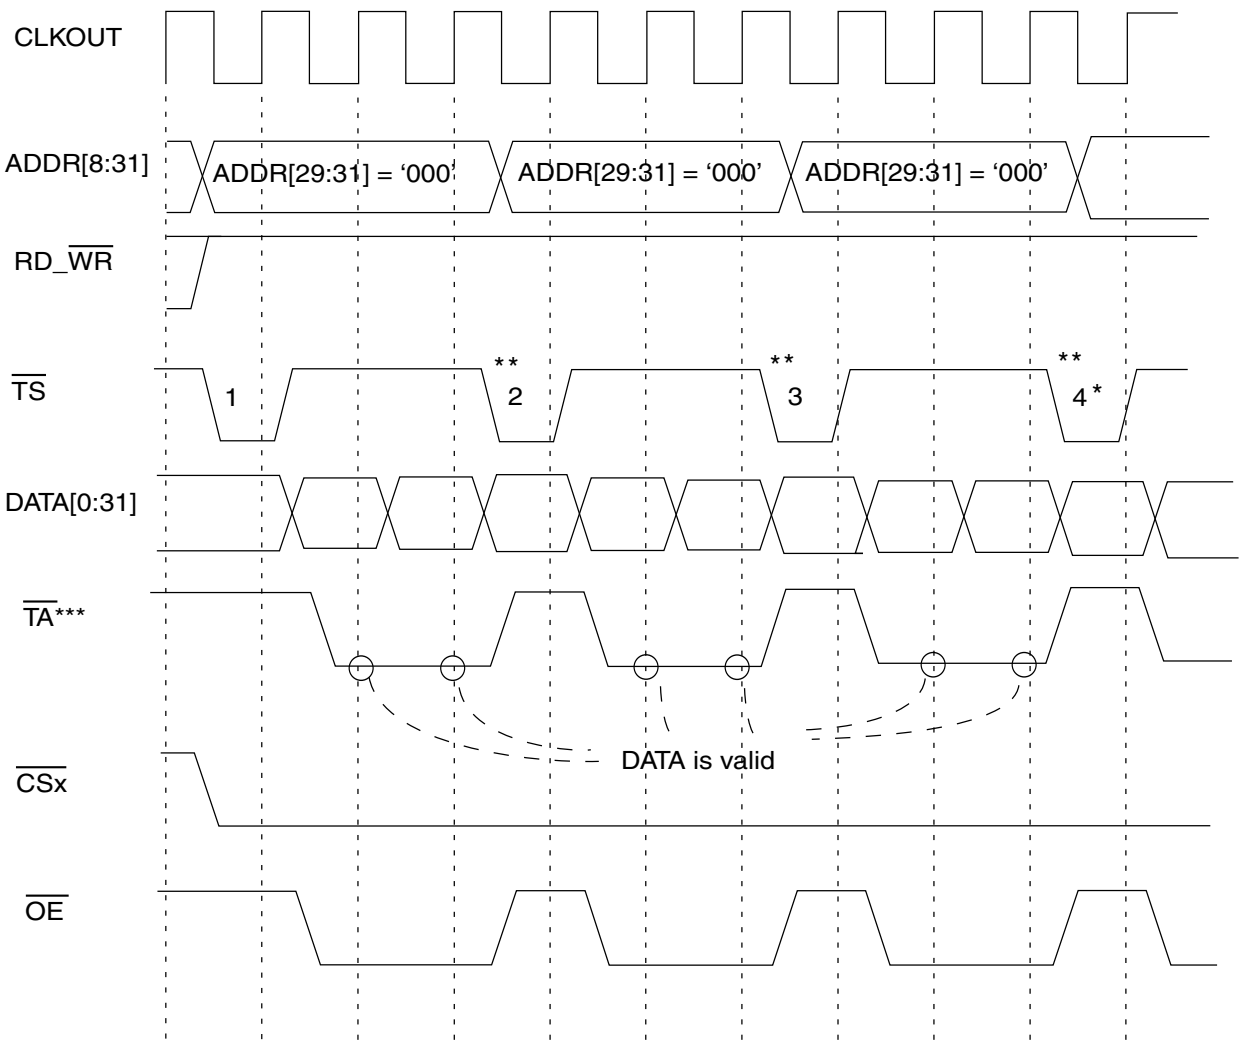
Figure 37-30. Single Beat 64-bit Read Cycle, 16-bit Port Size, Basic Timing

37.4.2.6.4 Small Access Example #5: 32-byte Read to 32-bit Port with SBL=1

Figure 37-29 shows an example of a 32-byte read to a 32-bit burst enabled port with burst length of 2 words, requiring four 8-byte external transactions. For this case, the address for the 2nd-4th 2-word burst accesses is calculated by adding 0x08 to the lower 5 bits of the 1st address (no carry), and then masking out the lower 3 bits to fix them at zero.

Table 37-7. Examples of 2-word Burst Addresses

1st Address	Lower 5 bits of 1st Address + 0x08 (no carry)	Final 2nd-4th Addresses (After Masking Lower 3 Bits)
0x000	0x08	0x08, 0x10, 0x18
0x008	0x10	0x10, 0x18, 0x00
0x010	0x18	0x18, 0x00, 0x08
0x018	0x00	0x00, 0x8, 0x10
0x020	0x28	0x28, 0x30, 0x38
0x028	0x30	0x30, 0x38, 0x20
0x030	0x38	0x38, 0x20, 0x28
0x038	0x20	0x20, 0x28, 0x30



* For space reasons, the rest of the 4th external access is not shown, but the behavior is identical to the previous 3 burst accesses. Strobe negation timing at end of 4th access is the same as seen in other burst diagrams.

** Timing shown applies when EBI_BR[GCSN]=0. When EBI_BR[GCSN]=1, the subsequent $\overline{TS}$ assertions after the 1st are delayed by 1 cycle each and $\overline{CS}$ negates between each transfer.

*** There is no external $\overline{TA}$ signal. The $\overline{TA}$ signal is generated internally.

Figure 37-31. 32-Byte Read with 4 B-T-B 2-Word Bursts to 32-bit Port, Zero Wait States (SBL=1)

37.4.2.7 Size, Alignment and Packaging on Transfers

Table 37-8 shows the allowed sizes that an internal master can request from the EBI. The behavior of the EBI for request sizes not shown below is undefined. No error signal is asserted for these erroneous cases.

Table 37-8. Transaction Sizes Supported by EBI

# Bytes (internal master)	# Bytes (external master)
1	1
2	2
4	4
3[1]	
8	
16[2]	
32[3]	

1. Some misaligned access cases may result in 3-byte writes. These cases are treated as power-of-2 sized requests by the EBI, using $\overline{\text{WE\_BE}}$ [0:3] to make sure only the appropriate 3 bytes get written.
2. Only supported for case of 32-bit internal AMBA data bus.
3. Only supported for case of 64-bit internal AMBA data bus.

Even though misaligned non-burst transfers from internal masters are supported, the EBI naturally aligns the accesses when it sends them out to the external bus, splitting them into multiple aligned accesses if necessary. See Misaligned Access Support for these cases.

Natural alignment for the EBI means:

- Byte access can have any address
- 16-bit access, address bit 31 must be 0
- 32-bit access, address bits 30-31 must be 0
- For burst accesses of any size, address bits 29-31 must be 0

The EBI never generates a misaligned external access. In the erroneous case that an externally-initiated misaligned access does occur, the EBI errors the access (by asserting $\overline{\text{TEA}}$ externally) and does not initiate the access on the internal bus.

The EBI requires that the portion of the data bus used for a transfer to/from a particular port size be fixed. A 32-bit port must reside on data bus bits 0-31,and a 16-bit port must reside on bits 0-15.

In the following figures and tables the following convention is adopted:

- The most significant byte of a 32-bit operand is OP0, and OP3 is the least significant byte.

- The two bytes of a 16-bit operand are OP0 (most significant) and OP1, or OP2 (most significant) and OP3, depending on the address of the access.
- The single byte of a byte-length operand is OP0, OP1, OP2, or OP3, depending on the address of the access.

This can be seen in Figure 37-32.

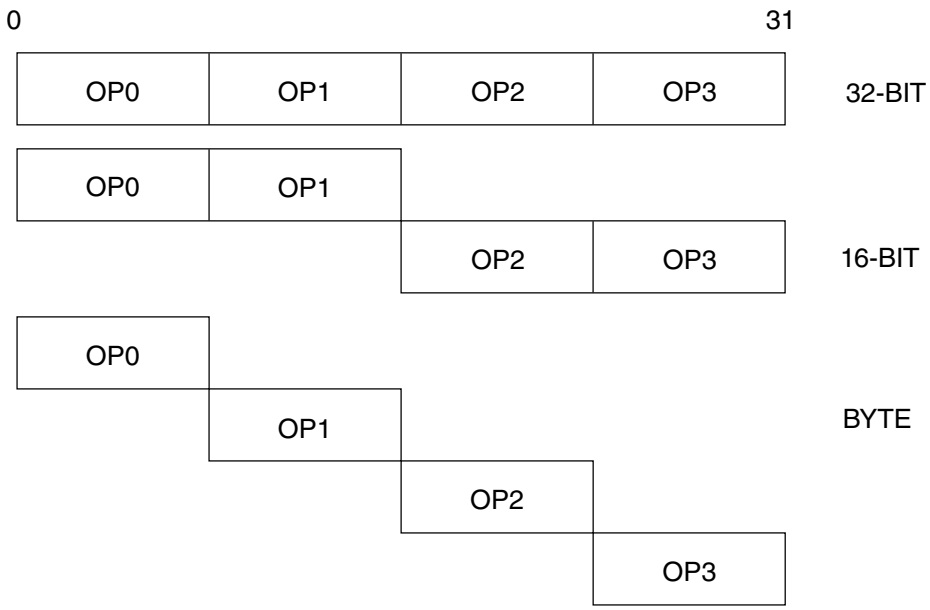


Figure 37-32. Internal Operand Representation

Figure 37-33 shows the device connections on the DATA[0:31] bus.

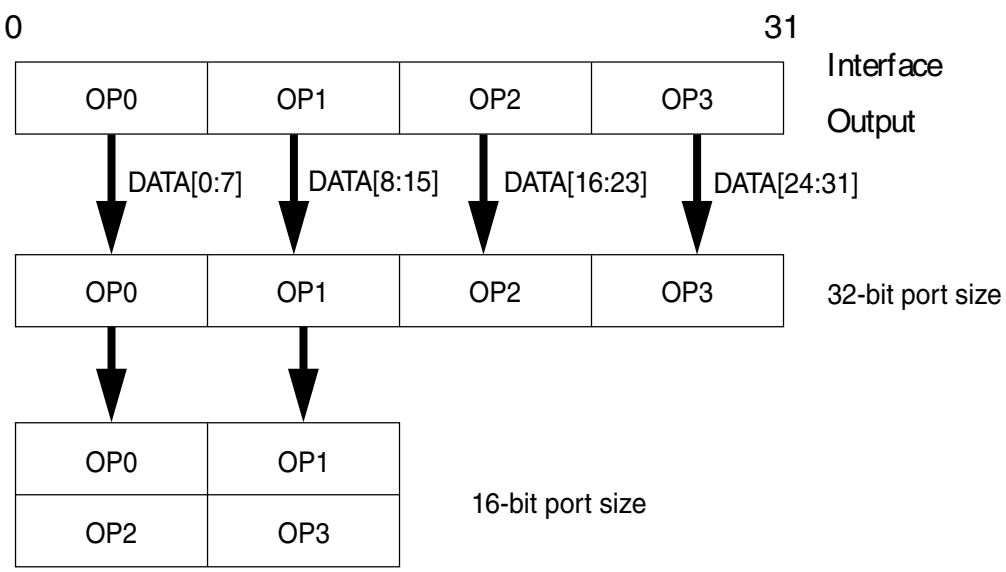

Figure 37-33. Interface to Different Port Size Devices

Table 37-9 lists the bytes required on the data bus for read cycles. The bytes indicated as '-' are not required during that read cycle.

Table 37-10 lists the patterns of the data transfer for write cycles when accesses are initiated by the MCU. The bytes indicated as '-' are not driven during that write cycle.

Table 37-9. Data Bus Requirements for Read Cycles

Transfer Size	EBI_MCR [SIZE]	Address		32-Bit Port Size				16-Bit Port Size[1]	
		A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7[2]	D8:D15[3]
Byte	01	0	0	OP0	-	-	-	OP0	-
	01	0	1	-	OP1	-	-	-	OP1
	01	1	0	-	-	OP2	-	OP2	-
	01	1	1	-	-	-	OP3	-	OP3
16-bit	10	0	0	OP0	OP1	-	-	OP0	OP1
	10	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2[4]	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].
4. This case consists of two 16-bit external transactions, the first writing OP0 and OP1, the second writing OP2 and OP3.

Table 37-10. Data Bus Contents for Write Cycles

Transfer Size	EBI_MCR [SIZE]	Address		32-Bit Port Size				16-Bit Port Size[1]	
		A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7[2]	D8:D15[3]
Byte	01	0	0	OP0	-	-	-	OP0	-
	01	0	1	-	OP1	-	-	-	OP1
	01	1	0	-	-	OP2	-	OP2	-
	01	1	1	-	-	-	OP3	-	OP3
16-bit	10	0	0	OP0	OP1	-	-	OP0	OP1
	10	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2[4]	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].
4. This case consists of two 16-bit external transactions, the first writing OP0 and OP1, the second writing OP2 and OP3.

37.4.2.8 Termination Signals Protocol

The termination signals protocol was defined in order to avoid electrical contention on lines that can be driven by various sources. In order to do that, a slave must not drive signals associated with the data transfer until the address phase is completed and it

recognizes the address as its own. The slave must disconnect from signals immediately after it acknowledges the cycle and not later than the termination of the next address phase cycle.

37.4.2.9 Misaligned Access Support

This section describes all the misaligned cases supported by the EBI. These cases are a subset of the full set of cases allowed by the AMBA AHB V6 specification. The EBI works under the assumption that all internal masters on the device do not produce any misaligned access cases (to the EBI) other than the ones below.

37.4.2.9.1 Misaligned Access Support (64 bit AMBA)

Table 37-11 shows all the misaligned access cases supported by the EBI (using a 64-bit AMBA implementation), as seen on the internal master AMBA bus. All other misaligned cases are not supported. If an unsupported misaligned access to the EBI is attempted (such as non-chip-select or burst misaligned access), the EBI errors the access on the internal bus and does not start the access externally.

27	(2 AHB transfers)	000	1111_1110	11	1

1. Misaligned case number. Only transfers where HUNALIGN=1 are numbered as misaligned cases.
2. Address on internal master AHB bus, not necessarily address on external ADDR pins.
3. Internal byte strobe signals on AHB bus. Shown with Big-Endian byte ordering in this table, even though internal master AHB bus uses Little-Endian byte-ordering (EBI flips order internally).
4. Internal signal on AHB bus; 00=8-bits, 01=16 bits, 10=32 bits,11=64-bits. HSIZE is driven according to the smallest aligned container that contains all the requested bytes. This results in extra EBI external transfers in some cases.
5. Internal signal on AHB bus that indicates that this transfer is misaligned (when 1).
6. For this case, the EBI internally treats HSIZE as 10 (4-byte access), if PS=1 (16-bit port).
7. For this case, the EBI internally treats HSIZE as 00(1-byte access).
8. For this case, the EBI internally treats HSIZE as 01 (2-byte access).
9. For this case, the EBI internally treats HSIZE as 10 (4-byte access).

Table 37-12 shows which external transfers are generated by the EBI for the misaligned access cases in Table 37-11, for each port size.

The number of external transfers for each internal AHB master request is determined by the HSIZE value for that request relative to the port size. For example, a half-word write to @011 (misaligned case #2) with 16-bit port size results in 4 external 16-bit transfers because the HSIZE is 64-bits. For cases where two or more external transfers are required for one internal transfer request, these external accesses are considered part of a "small access" set, as described in Small Accesses (Small Port Size and Short Burst Length).

Since all transfers are aligned on the external bus, normal timing diagrams and protocol apply.

			010	0011
			100	0011
			110	0111

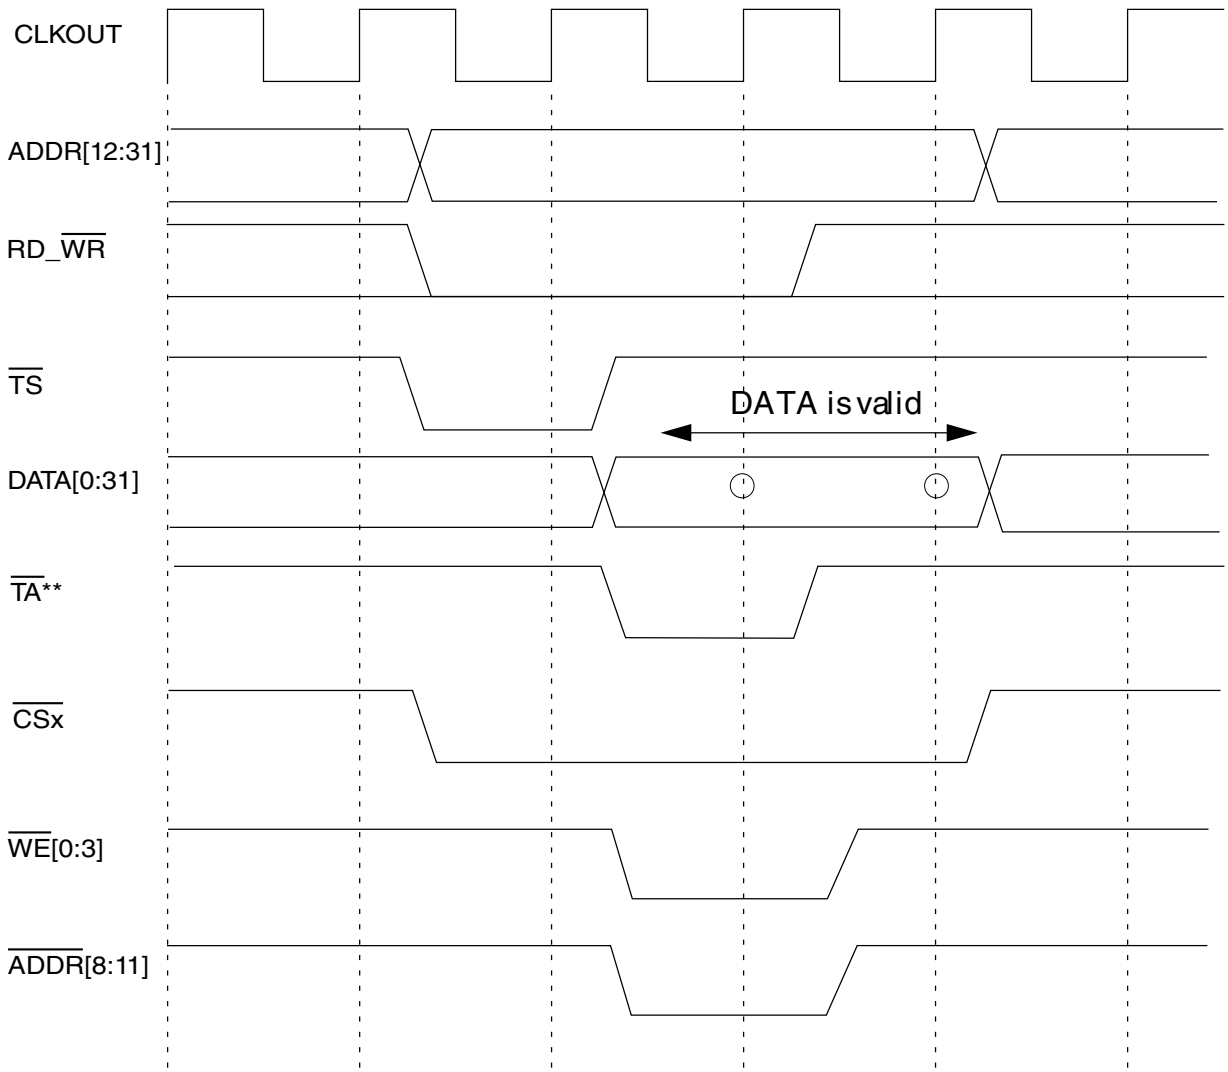
1. Misaligned case number, from Table 1.
2. Misaligned case number, from Table 1.
3. Port size; 0=32 bits, 1=16 bits.
4. External ADDR pins, not necessarily the address on internal master AHB bus.
5. External $\overline{\text{WE\_BE}}$ pins. Note that these pins have negative polarity, opposite of the internal byte strobes in Table 1.

37.4.2.10 Address / Write Enable Multiplexing

Address/Write Enable multiplexing enables the design of a system with reduced pin count (saves 4 pins). The typical usage is the case where the SoC is connected to an external chip-select device that requires write-enable functionality, but does not require the full address bus width. In such a system, the user can set EBI_OR[AWE]=1 to cause the EBI to drive its internal WE[0:3] signals onto the upper 4 ADDR pins, instead of relying on separate WE[0:3] pins (which may not be present on some SoCs).

In general, timing diagrams using ADDR/WE multiplexing (EBI_OR[AWE]=1) are very similar to other diagrams in this document, except for the behavior of the upper 4 ADDR signals, which can be seen in Figure 37-34.



* The upper 4 address bits just mirror WE[0:3].
** There is no external TA signal. The TA signal is generated internally

Figure 37-34. Single Beat 32-bit Write Cycle, CS Access, Zero Wait States, AWE=1

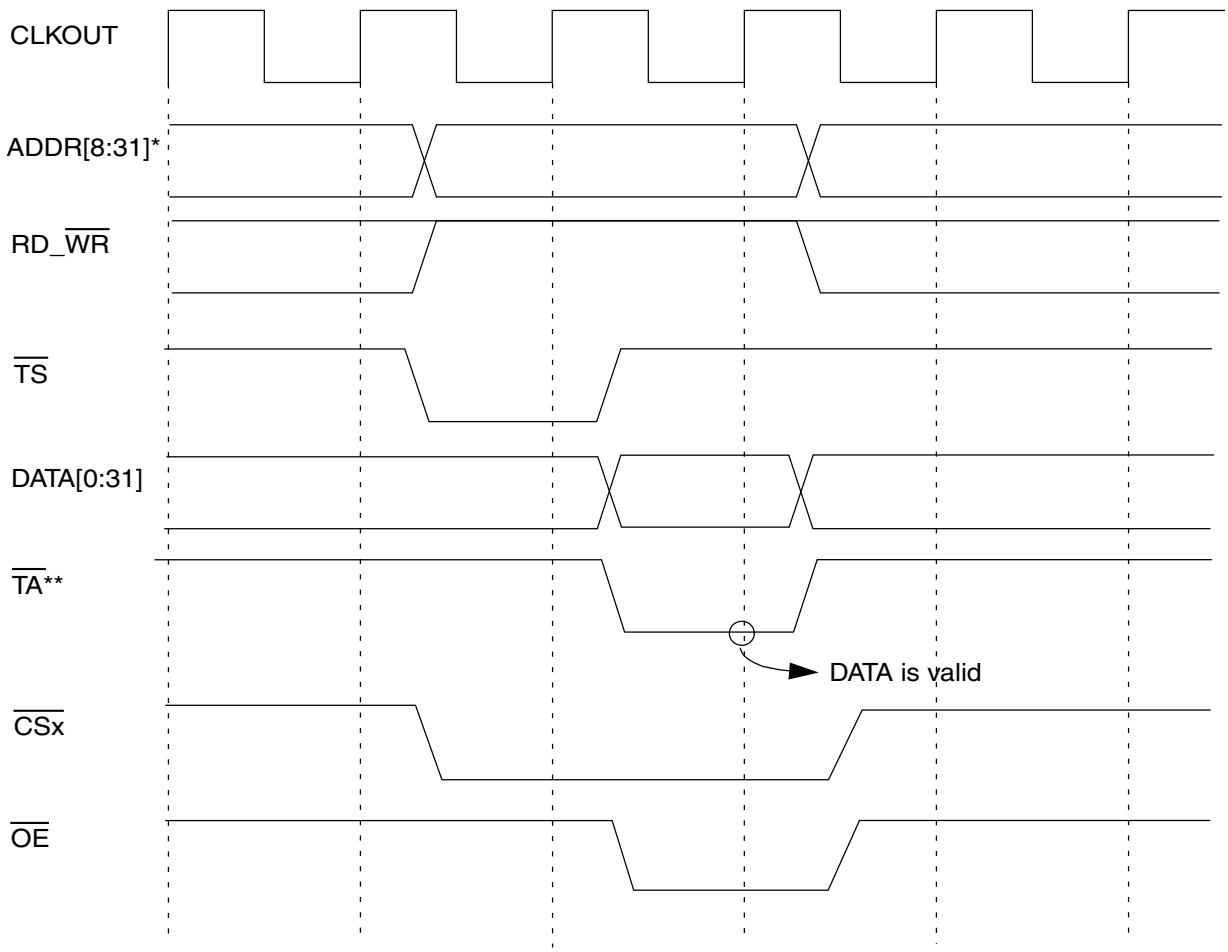
37.4.2.11 Address by Port Size

Address by Port Size (EBI_OR[APS]=1) provides a way to increase the memory size supported by the EBI for external chip-select devices with 16 or 32-bit port size.

For example, consider an SoC that has ADDR[8:31] pinned out and connects to an external 32-bit chip-select memory:

- If APS=0, then ADDR[31] is not connected to the memory and thus only 22 address lines (ADDR[8:29]) are left to connect to the memory.
- If APS=1, then the EBI drives internal address 6:29 to external ADDR[8:31], thus giving the user a 24-bit address range to access the 16-bit memory.

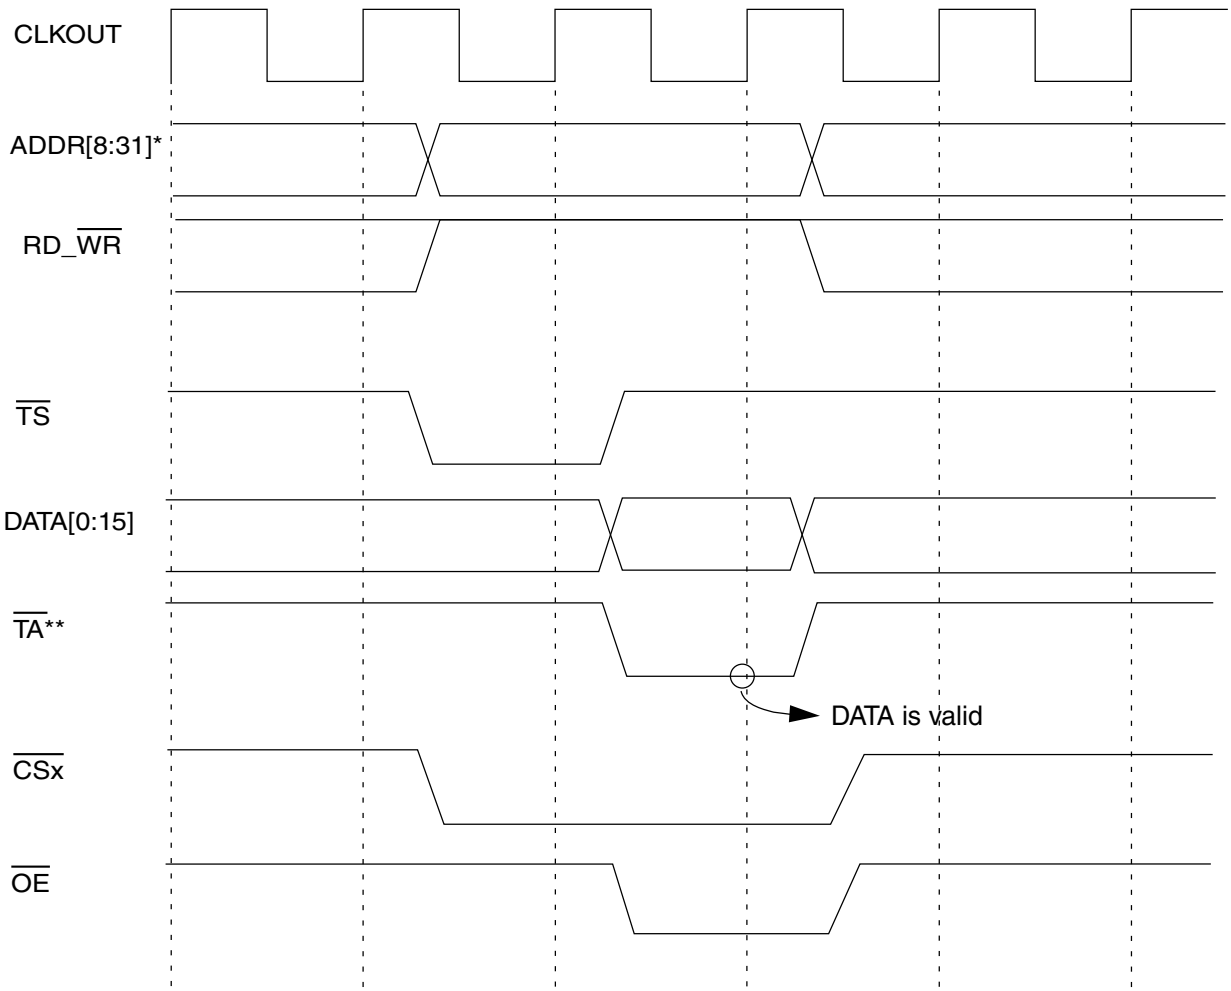
In general, timing diagrams using APS=1 are very similar to other diagrams in this document, except for the shifting of the ADDR signals, which can be seen in Figure 37-35 and Figure 37-36.



* Only difference from APS=0 timing is ADDR[8:31] is driven by internal address 6:29 for this case. If the full ADDR[3:31] bus is being pinned out, then the EBI drives ADDR[3:31] with internal address 1:29

**There is no external TA signal. The TA signal is generated internally.

Figure 37-35. Single Beat 32-bit Read Cycle, CS Access, Zero Wait States, APS=1, PS=0



* Only difference from APS=0 timing is ADDR[8:31] is driven by internal address 7:30 in this case. If the full ADDR[3:31] range is being used, then the EBI drives ADDR[3:31] with internal address 2:30

**There is no external TA signal. The TA signal is generated internally.

Figure 37-36. Single Beat 16-bit Read Cycle, CS Access, Zero Wait States, APS=1, PS=1

37.4.2.12 32-bit AMBA Burst on 64-bit AMBA Case

This section only applies for those SoC's that use the EBI with an AMBA bus width of 64 bits. This section is N/A for those SoC's that use the EBI in a 32-bit AMBA configuration (determined by SoC parameter).

On some SoCs that use this EBI, the internal AMBA master is capable of requesting a WRAP4 32-bit burst even with a 64-bit AMBA bus width. This case is supported by the AMBA standard, but is rarely used on SoCs, since normally the full AMBA width is used

when bursting (for optimum performance). A scenario where this case occurs is when there is a 32-bit AMBA master connecting through a 32->64 bit gasket that drives requests to the EBI's 64-bit AMBA bus.

In the 32-bit burst on 64-bit AMBA case, the EBI returns data on the appropriate half of the 64-bit AMBA bus, based on the address of the transfer (address bit 2 using N:0 numbering), and then alternates halves on each AMBA burst beat. Examples below are based on AMBA data bus numbering 63:0.

- For a burst starting at address 0x0 (or 0x8, 0x10, etc.), the 4 beats of data are returned on hrdata [63:32], [31:0], [63:32], [31:0].
- For a burst starting at address 0x4 (or 0xC, 0x14, etc.), the 4 beats of data are returned on hrdata [31:0], [63:32], [31:0], [63:32]

Note

For the case of a 32-bit burst on 64-bit AMBA where EBI_BR[BL]=0 and EBI_BR[SBL]=0, the external burst size (8 words) is mismatched to the internal burst size (4 words). In this case, to avoid erroneous data due to different wrapping boundaries, the EBI disables external burst for that access and splits the internal burst request to multiple single external accesses.

37.4.2.13 Internal AMBA Master Burst Read Abort Case

On some SoCs that use this EBI, the internal AMBA master has the capability to abort the AMBA burst read early, without performing the 4 requests that are normally part of an AMBA WRAP4 burst sequence. For example, instead of the usual htrans=NSEQ, SEQ, SEQ, SEQ, the master might do 1 of these cases:

- htrans=NSEQ (with hburst=WRAP4), SEQ (0-2 times), NSEQ (2nd NSEQ aborts prior burst)
- htrans=NSEQ (with hburst=WRAP4), SEQ (0-2 times), IDLE (IDLE aborts prior burst)

In these cases, the EBI has already started the burst externally, but will abort it early (without asserting internal hresp), and only returns the beats of data on the internal AMBA bus corresponding to the AMBA NSEQ/SEQ requests received. In a subset of

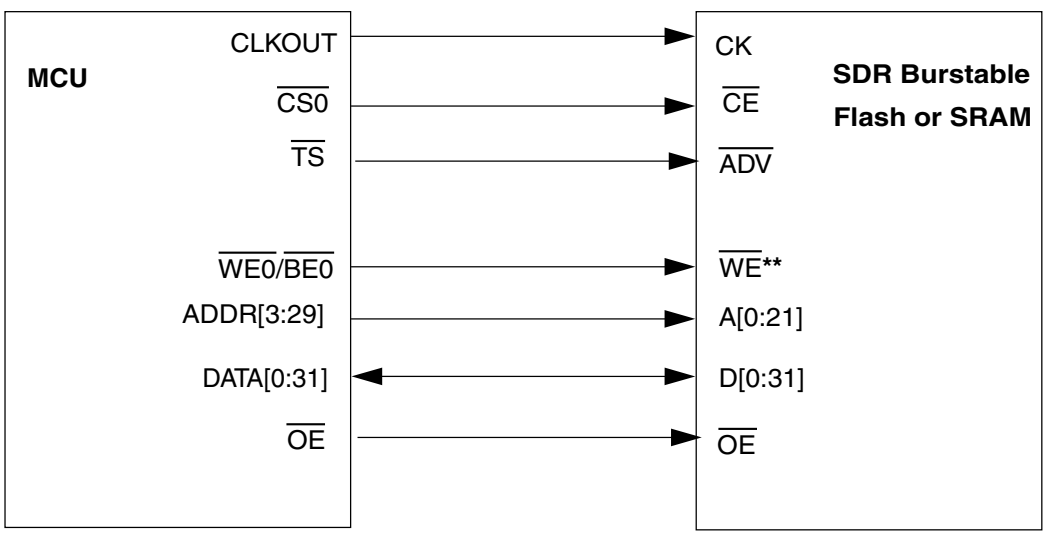
these master burst abort cases, there may be extra $\overline{TS}$ /$\overline{TA}$ transfers on the external bus after the internal AMBA master has aborted (e.g. finishing a "small access" set of transfers). These extra read accesses are extraneous and can just be ignored.

This feature is not part of the AMBA standard, but is implemented in some AMBA masters for performance reasons. The master burst abort feature applies to reads only. The behavior of the EBI for an aborted AMBA burst write is undefined.

37.5 Initialization/Application Information

37.5.1 Running with SDR (Single Data Rate) Burst Memories

This includes FLASH and SRAM memories with a compatible burst interface. Figure 37-37 shows a block diagram of an MCU connected to a 32-bit SDR burst memory.



* May or may not be connected, depending on the memory used.

** Flash memories typically use one $\overline{WE}$ signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 37-37. MCU Connected to SDR Burst Memory

Refer to Figure 37-24 for an example of the timing of a typical Burst Read operation to an SDR burst memory. Refer to Figure 37-9 for an example of the timing of a typical Single Write operation to SDR memory.

37.5.2 Running with Asynchronous Memories

The EBI also supports asynchronous memories. In this case, the CLKOUT and $\overline{TS}$ pins are not used by the memory and bursting is not supported. However, the EBI still drives these outputs, and always drives and latches all signals at posedge CLKOUT (i.e., there is no "asynchronous mode" for the EBI). The data timing is controlled by setting the SCY bits in the appropriate Option Register to the proper number of wait states to work with the access time of the asynchronous memory, just as done for a synchronous memory.

37.5.2.1 Example Wait State Calculation

This example applies to any chip-select memory, synchronous or asynchronous.

As an example, say we have a memory with 50ns access time, and we are running the external bus @ 66 MHz (CLKOUT period: 15.2ns). Assume the input data spec for the MCU is 4ns.

number of wait states = (access time) / (CLKOUT period) + (0 or 1) (depending on setup time)

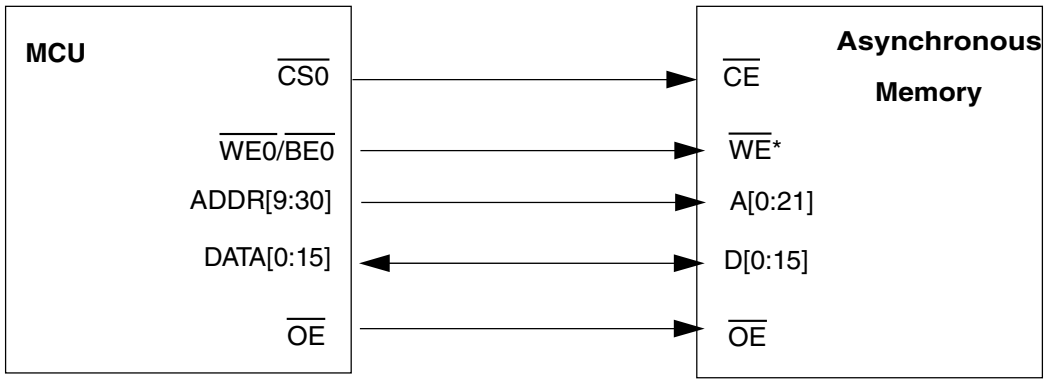
50/15.2 = 3 with 4.4ns remaining (so we need at least 3 wait states, now check setup time)

15.2-4.4=10.8ns (this is the achieved input data setup time)

Since actual input setup (10.8ns) is greater than the input setup spec (4.0ns), 3 wait states is sufficient. If the actual input setup was less than 4.0ns, we would have to use 4 wait states instead.

37.5.2.2 Timing and Connections for Asynchronous Memories

The connections to an asynchronous memory are the same as for a synchronous memory, except that the CLKOUT and $\overline{TS}$ signals are not used. Figure 37-38 shows a block diagram of an MCU connected to an asynchronous memory.

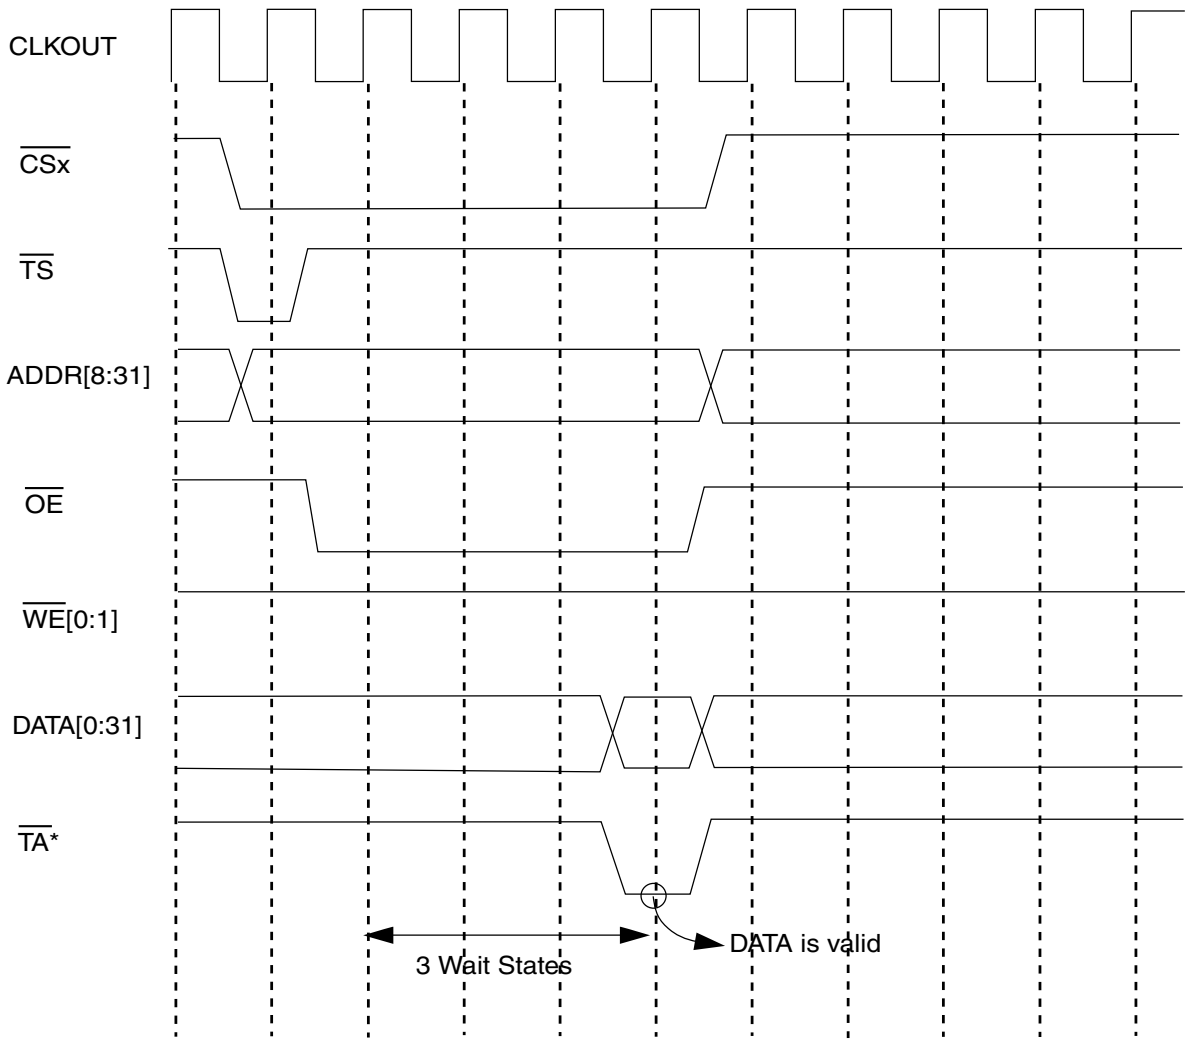


* Flash memories typically use one WE signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 37-38. MCU Connected to Asynchronous Memory

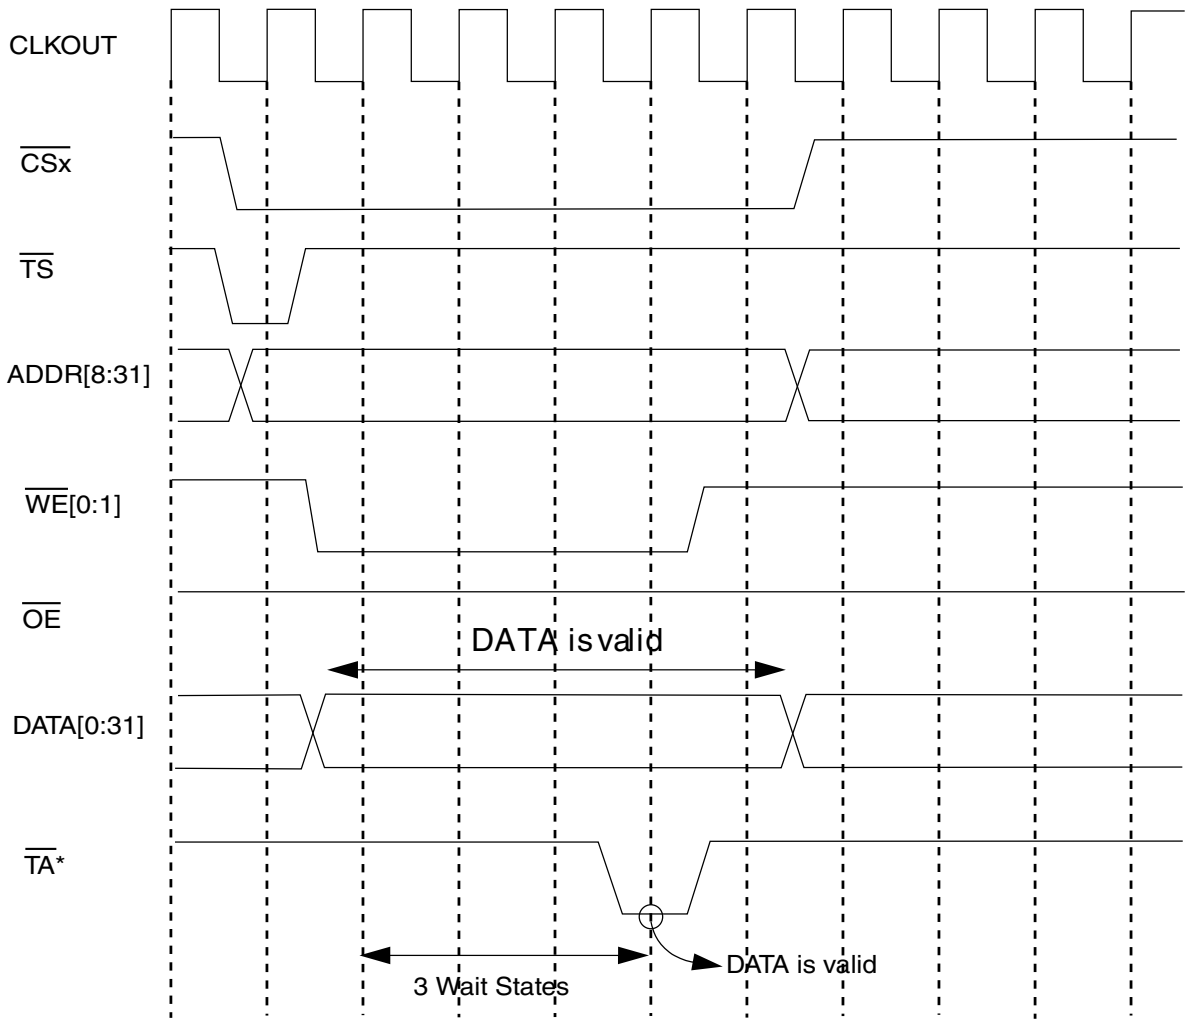
Figure 37-39 shows a timing diagram of a read operation to a 16-bit asynchronous memory using 3 wait states.

Figure 37-40 shows a timing diagram of a write operation to a 16-bit asynchronous memory using 3 wait states.



*There is no external TA signal. The TA signal is generated internally.

Figure 37-39. Read Operation to Asynchronous Memory, Three Initial Wait States



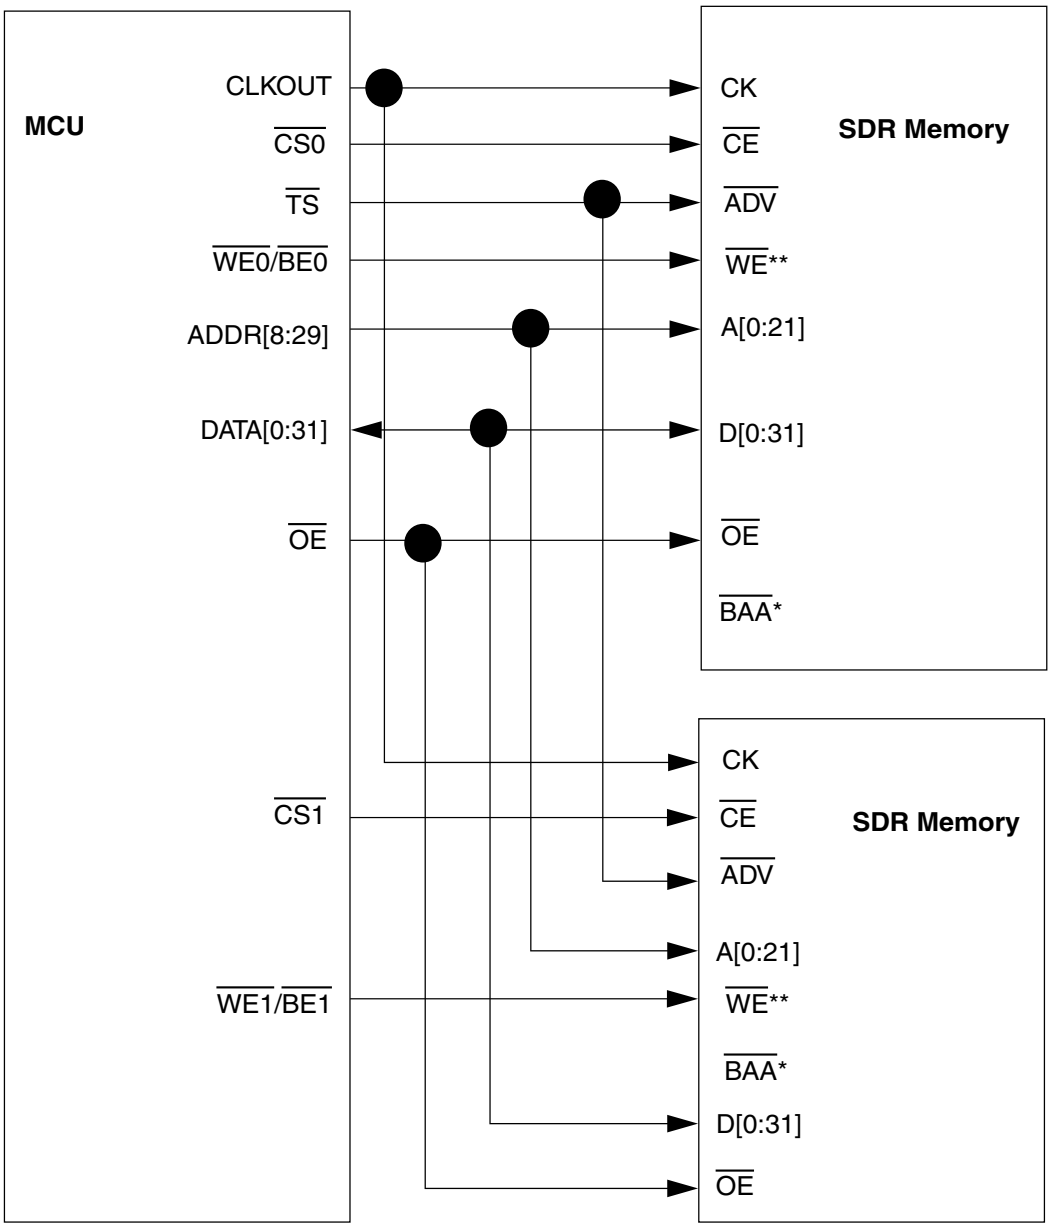
*There is no external TA signal. The TA signal is generated internally.

Figure 37-40. Write Operation to Asynchronous Memory, Three Initial Wait States

37.5.3 Connecting an MCU to Multiple Memories

The MCU can be connected to more than one memory at a time.

Figure 37-41 shows an example of how two memories could be connected to one MCU.



* May or may not be connected, depending on the memory used.

** Flash memories typically use one $\overline{WE}$ signal as shown, RAMs use 2 or 4 (16-bit or 32-bit)

Figure 37-41. MCU Connected to Multiple Memories

Chapter 38
Analog-to-Digital Converters (ADC) Configuration

38.1 ADC overview

This chapter is organized into the following sections:

- ADC overview
  - ADC subsystem block diagram
  - Analog input pin multiplexing
- Configuration of ADC modules
  - Sigma-Delta Analog-to-Digital Converter (SDADC)
  - Successive Approximation Register Analog-to-Digital Converter (SARADC)

MPC5777M contains the following analog-to-digital converters (ADCs):

- 12 independent 12-bit Successive Approximation Register Analog-to-Digital Converters (SARADCs)
- 10 independent 16-bit Sigma-Delta Analog-to-Digital Converters (Sigma-Delta, or SDADCs)

These ADCs interface to external analog input pins:

Number of external analog input pins	Package
60	416 BGA
84	512 BGA

Each ADC instance, whether SAR or Sigma-Delta, has independent analog input pin multiplexing, register interface, trigger and clock inputs, independent interrupt, and DMA capability. Each SAR and Sigma-Delta ADC has a dedicated peripheral bridge (PBRIDGE) interface for CPU access to the registers.

The 416/512 BGA packages have separate supply and ground pins for the SAR and the Sigma-Delta ADCs:

- VDD_HV_ADV_S/VSS_HV_ADV_S for SAR
- VDD_HV_ADV_D/VSS_HV_ADV_D for Sigma-Delta

The SARADCs on the device are referred to as SARADC_B (84:1 input mux), SARADC_0–SARADC_10 (maximum 8:1 input mux for each).

38.1.1 ADC subsystem block diagram

The following figure gives the block diagram for the high-level integration of the ADC sub-system for MPC5777M. The primary intent of the diagram is to show that each ADC, whether SAR or Sigma-Delta, have independent register interfaces, interrupt/DMA requests, and trigger source selection.

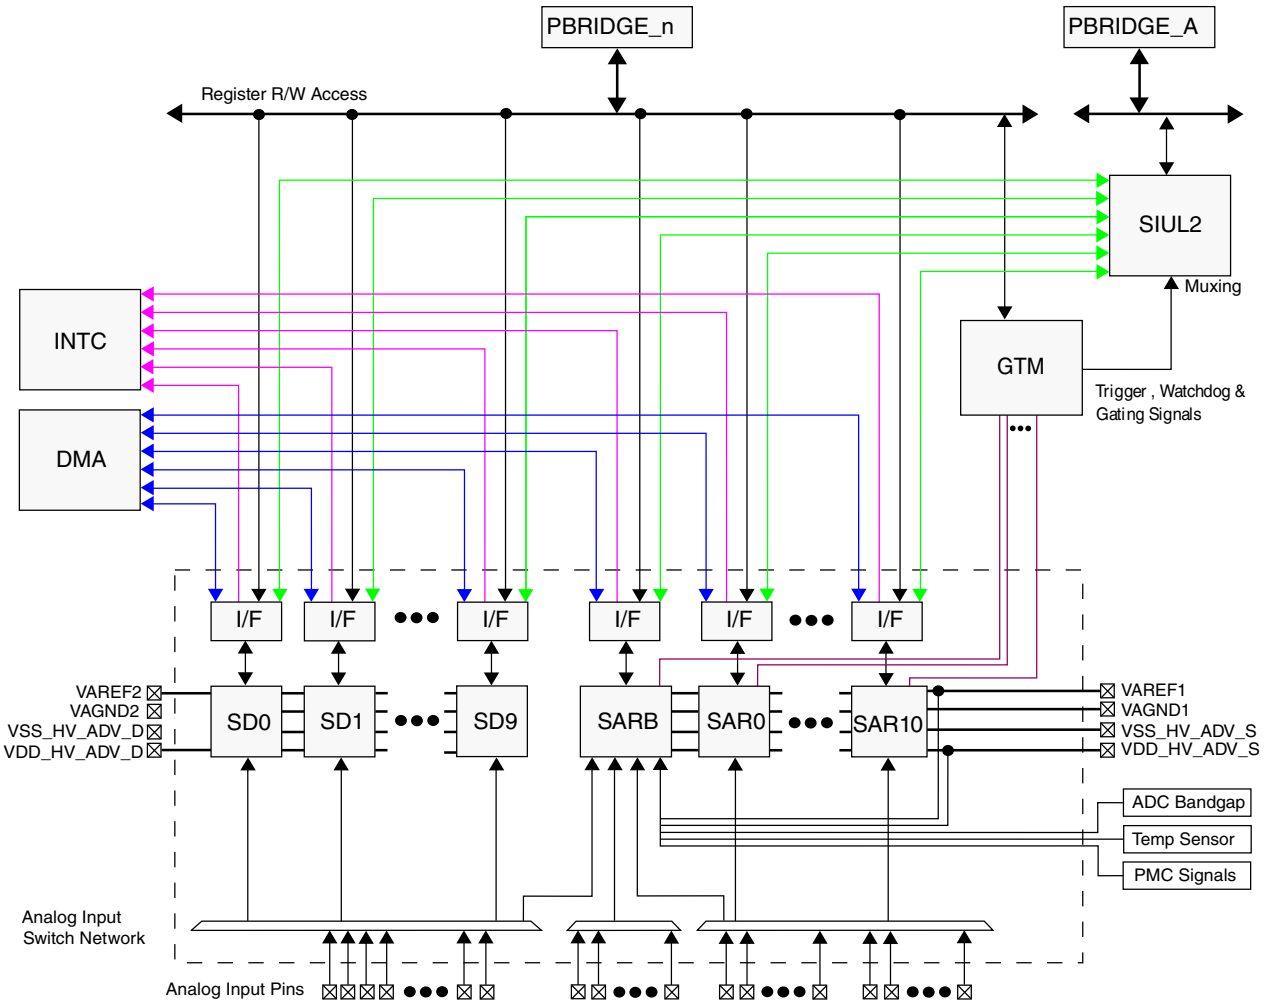


Figure 38-1. MPC5777M ADC subsystem

38.1.2 Analog input pin multiplexing

There are 60 external analog input pins in the 416 BGA package for MPC5777M, and 84 in the 512 BGA package. All analog input pins in either package are readable by SARADC_B. In addition to SARADC_B, all analog input pins are routed to either the Sigma-Delta or SARADCs, but never both. The following table gives the analog input pin assignment for the packages.

Table 38-1. MPC5777M analog input pin multiplexing

ADC instance	416 BGA		512 BGA	
	Analog input pins	Mux input[1]	Analog input pins	Mux input[1]
SARADC_B	AN0:AN11, AN16:AN21, AN24:AN29, AN32:AN33, AN36:AN37, AN40:AN43, AN48:AN53, AN56:AN61, AN64:AN65, AN68:AN73,	0:11, 16:21, 24:29, 32:33, 36:37, 40:43, 48:65, 68:73,	AN0:AN87	87

Table continues on the next page...

Table 38-1. MPC5777M analog input pin multiplexing (continued)

SDADC_9	AN86:AN87	AN[0]:AN[1]	AN86:AN87	AN[0]:AN[1]

1. For the Sigma-Delta mux inputs, even channel numbers (0,2,4,6) correspond to the positive terminal of the differential input, and odd channel numbers (1,3,5,7) correspond to the negative terminal.

38.2 Configuration of ADC modules

The following sections describe device-specific details for the following modules:

- Sigma-Delta Analog-to-Digital Converter (SDADC)
- Successive Approximation Register Analog-to-Digital Converter (SARADC)

38.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC)

There are ten independent Sigma-Delta ADCs on MPC5777M. Refer to Figure 38-1 for the ADC subsystem block diagram.

The following sections describe configuration details:

- Sigma-Delta ADC integration diagram
- Sigma-Delta ADC analog input multiplexing
- Sigma-Delta ADC clock sources
- Sigma-Delta ADC starting/triggering
- Sigma-Delta ADC external modulator
- Conversion result interrupt/DMA
- Sigma-Delta ADC analog input channel selection

For detailed module information, refer to the Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface chapter.

38.2.1.1 Sigma-Delta ADC integration diagram

The following figure shows the block diagram of the Sigma-Delta ADC integration on MPC5777M. Note in the diagram that any unused Sigma-Delta ADC input can be read by SARADC_B. This is true for the unused input in single-ended operation.

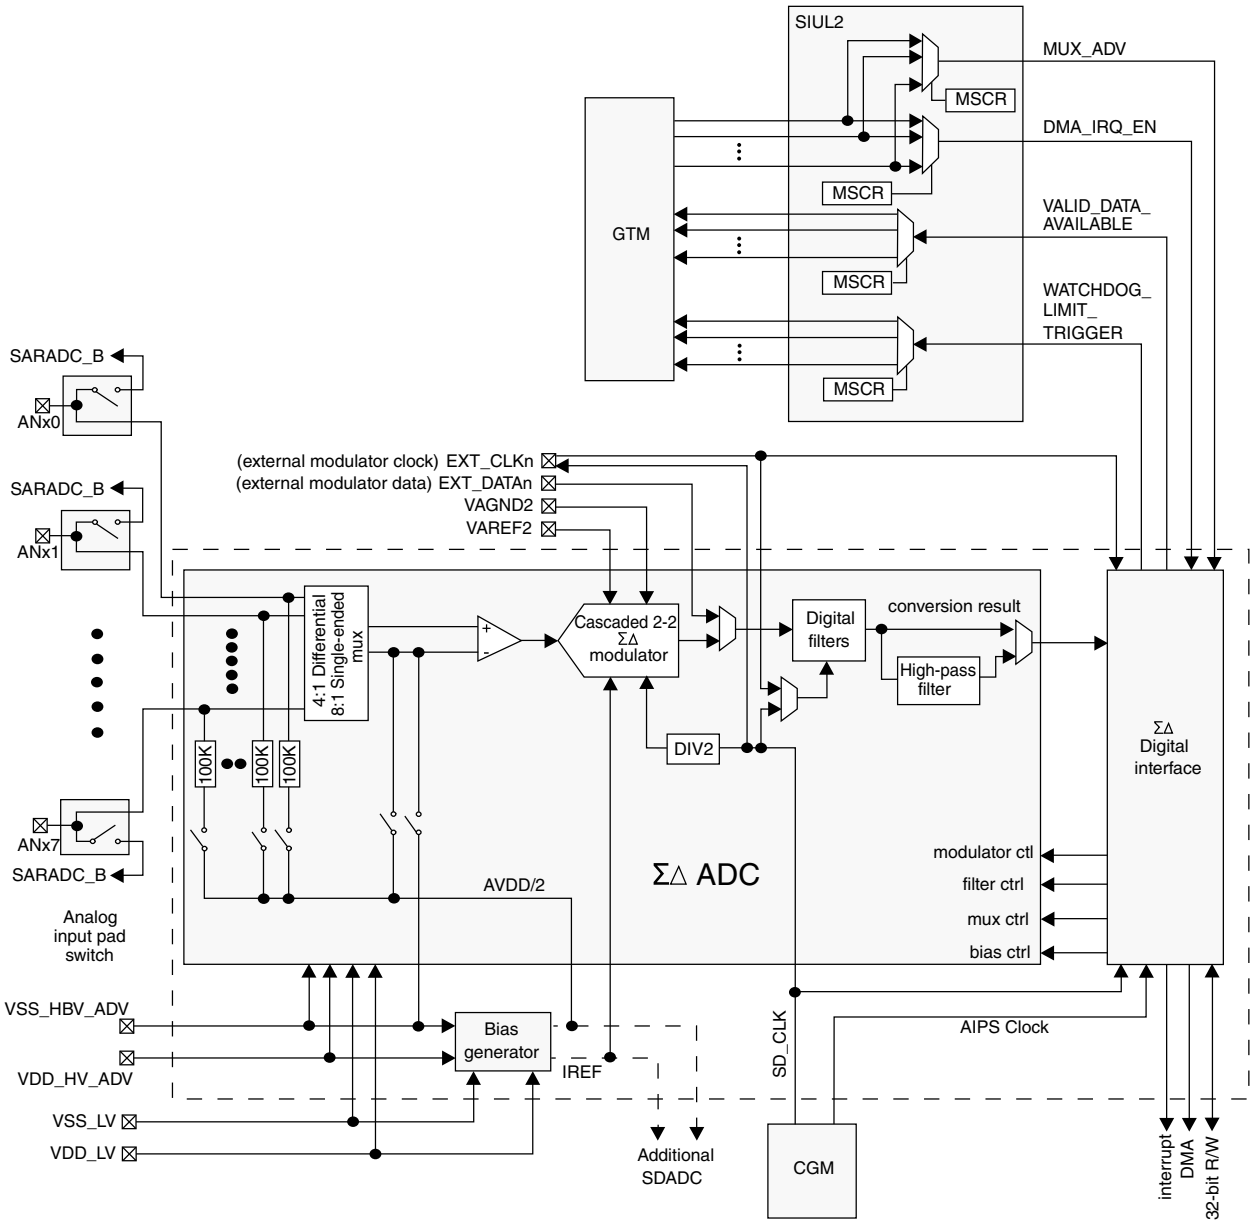

Figure 38-2. Sigma-Delta ADC integration diagram

38.2.1.2 Sigma-Delta ADC analog input multiplexing

The analog input multiplexing switches are contained within the Sigma-Delta ADCs. A single analog switch pad cell is used for the Sigma-Delta analog input pins in order to share the pin with SARADC_B. The connection to the Sigma-Delta ADC inputs is made to the pad pin through the analog switch pad cell, shown in Figure 38-2, and is controlled as follows:

- SARADC_B analog inputs are switchable by the SIUL2_MSCRn[APC] bit.
- SDADC analog inputs have no SIUL2_MSCRn[APC] bit control, but are directly connected to the pad.

The mapping of analog input pins to the Sigma-Delta converters is given in Table 38-1.

38.2.1.3 Sigma-Delta ADC clock sources

Each Sigma-Delta ADC digital interface on the MPC5777M has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE*n*_CLK. The module clock is sourced by the modulator clock (SD_CLK). The input clock for the Sigma-Delta modulator is the SD_CLK. The following figure gives a block diagram of the required Sigma-Delta ADC clock architecture. See the clocking chapter, Sigma-Delta ADC clocking, for more detail on the clock sources.

The frequency range for the SD_CLK is 4–16 MHz. Both the analog and digital blocks of the ADC contain an internal clock mux for external modulator mode. The external modulator clock (EXT_CLK) can be input to the device, or generated from SD_CLK from the CGM. The pad input/output settings in the corresponding SIUL2 MSCR pad control registers determine the external modulator clock source to the ADC blocks. The EXT_CLK pins are multiplexed on multiple external pins on the device. Selection of the EXT_CLK pin to use for the external modulator clock for each ADC is done in the SIUL2 MSCR input multiplexing registers. Each Sigma-Delta ADC has three external pins to select from for an external modulator clock.

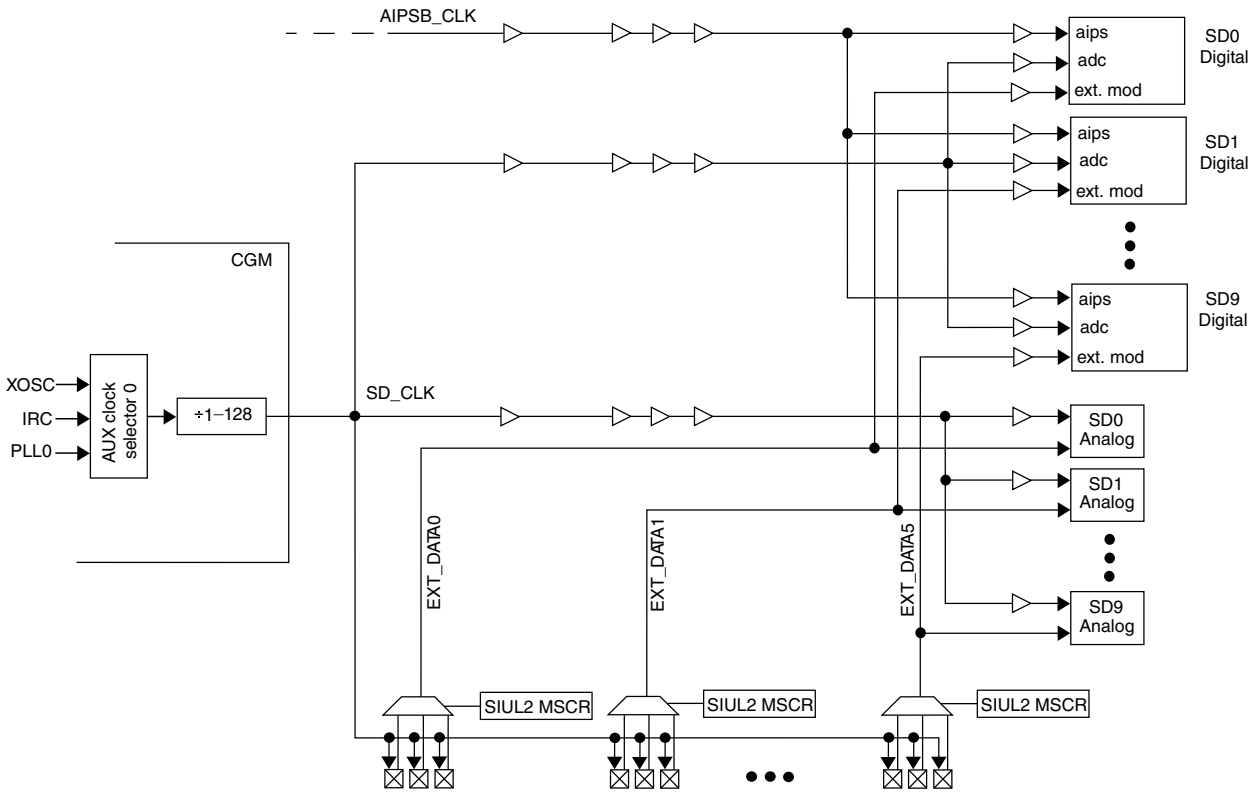

Figure 38-3. Sigma-Delta ADC clock diagram

38.2.1.3.1 Clock Skew

To avoid crosstalk issues, all Sigma-Delta ADCs run at the same clock frequency. Independent programmable oversampling rates are provided to support the varying bandwidths of interest on each ADC in the application. Therefore, all Sigma-Delta analog blocks are clocked from the output of a single divider of the peripheral clock at the chip level.

38.2.1.4 Sigma-Delta ADC starting/triggering

Each Sigma-Delta ADC on MPC5777M supports starting the converter with a software write to an enable bit in a register in the digital interface.

38.2.1.4.1 Simultaneous start of multiple Sigma-Delta converters

A method to start multiple Sigma-Delta converters simultaneously by a single software write to a control register is available on the device. Simultaneously in this case means that all selected converters start sampling their inputs on the same SD_CLK clock edge.

The digital interface of the Sigma-Delta ADC contains the control register for simultaneous start of the ADCs. When the register is written to start multiple converters, an output from the digital interface is asserted. The hardware trigger input of each Sigma-Delta ADC is connected to this simultaneous start output. This way the user controls which ADCs are selected by enabling the hardware trigger of desired ADCs before writing to the starting simultaneous converters.

The connections for the simultaneous start of the converters is given in the following figure.

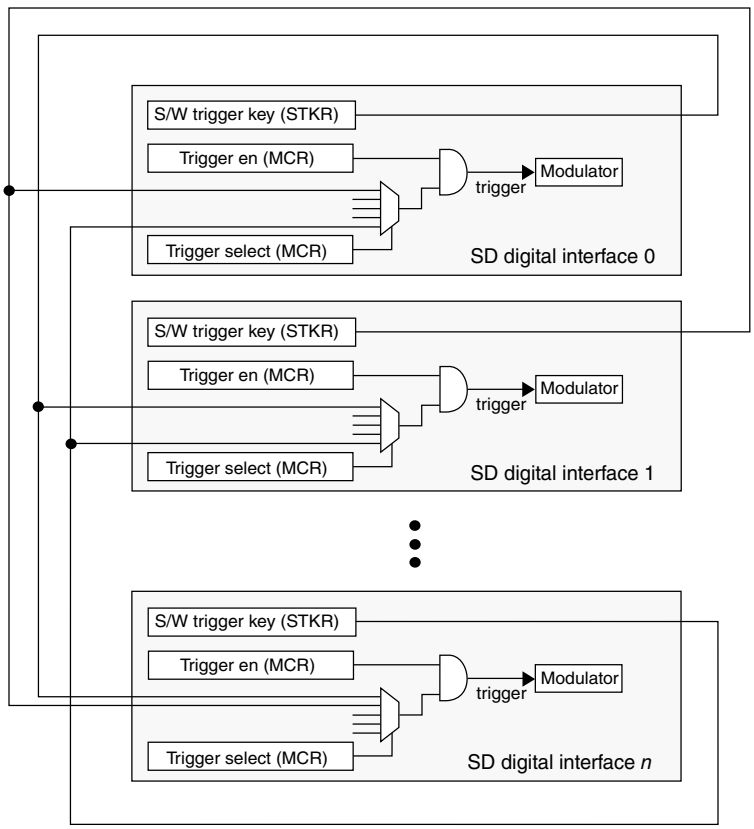

Figure 38-4. Sigma-Delta ADC simultaneous start connectivity

38.2.1.4.2 Sigma-Delta mux input advance and wraparound

The mux wraparound feature is enabled and controlled in the digital interface of the Sigma-Delta ADC. The advancing of the mux can be controlled in the interface by software or by external GTM channels. The mapping of GTM output channels to the mux advance input for each Sigma-Delta ADC for each device is given in the SIUL2 MSCR registers.

38.2.1.5 Sigma-Delta ADC external modulator

38.2.1.5.1 External modulators

The Sigma-Delta ADC supports an interface to external Sigma-Delta modulators. In this mode, the Sigma-Delta ADC internal modulator is disabled, and a serial bit stream from an external modulator is clocked into the back-end digital filters of the on-chip Sigma-Delta ADC. Currently, the AMC1203 external modulator is supported by the Sigma-Delta ADC. It is possible that other external 2nd order modulators with clock rates less than 10 MHz and a compatible electrical interface (see MPC5777M Data Sheet) could be supported.

The external modulator interface for each Sigma-Delta ADC on MPC5777M is shown in the following figure.

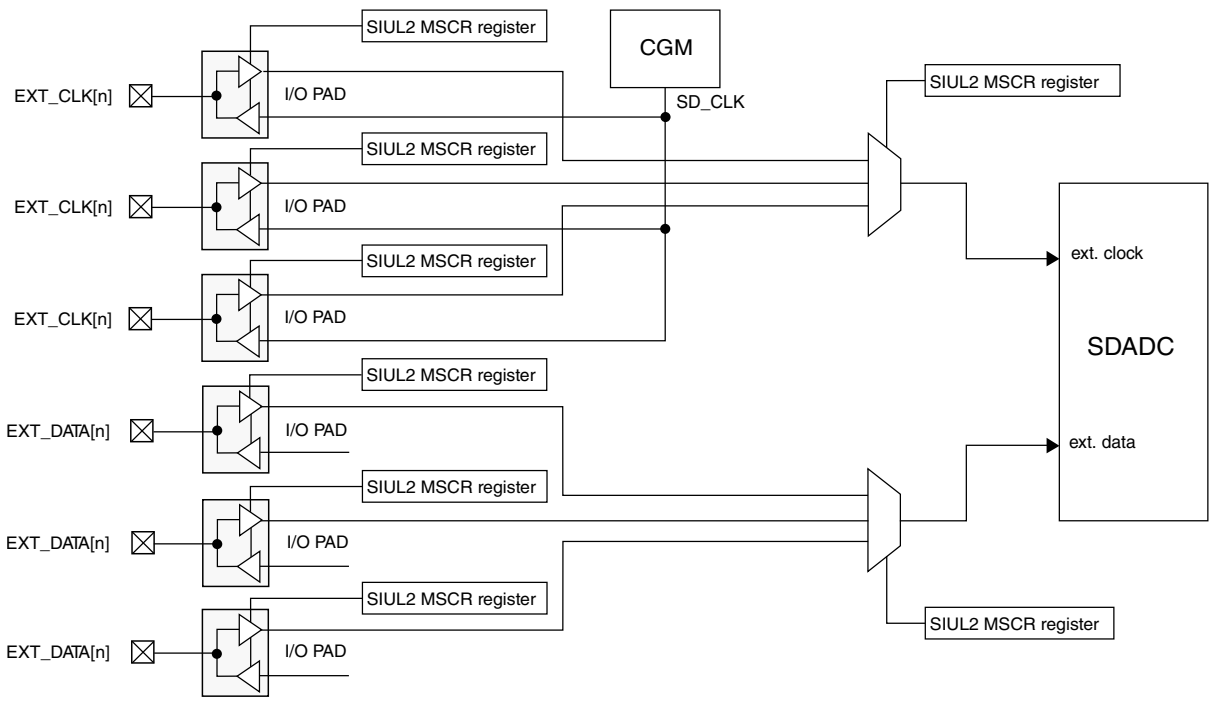

Figure 38-5. Sigma-Delta ADC external modulator interface

38.2.1.5.2 External modulator clock/data inputs

Two external pins are required for each Sigma-Delta ADC to support an external modulator, an input data pin EXT_DATA (bitstream data), and an input/output clock pin EXT_CLK (bitstream clock). When the external modulator is used, the clock and data inputs to the Sigma-Delta ADC digital filters come from the EXT_CLK and EXT_DATA pins, instead of the internal modulator as shown in Figure 38-12. External modulator operation is enabled in the ADC digital interface registers. The internal modulator is

disabled. The EXT_CLK and EXT_DATA inputs are multiplexed on port input pins. For each Sigma-Delta ADC, there are three sets of EXT_CLK/EXT_DATA pins, and selection of those pins for each ADC is done in the SIUL2 MSCR registers.

38.2.1.5.3 External modulator clock output

MPC5777M provides an option for an output clock from the device to the external modulator. When providing an output clock, the SD_CLK from the CGM is connected to the EXT_CLK output pin. Both the input and output buffer of the EXT_CLK pin must be enabled in the corresponding SIUL2 MSCR register, in order for both the external modulator and internal filters to be clocked from the SD_CLK. This is shown in Figure 38-5.

38.2.1.6 Conversion result interrupt/DMA

A DMA or interrupt can be generated for each conversion for each ADC. The Sigma-Delta ADC has an 8-deep result FIFO.

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input signal is connected to outputs from the GTM timer block. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the signal from the GTM is asserted, no interrupt or DMA request is generated for any conversion results. The polarity of the gating signal is such that when the signal is high, interrupt and DMA requests are passed. When the gating signal is low, interrupt and DMA requests are blocked.

The gating signal for each ADC is driven by several GTM channels. See the System Integration Unit Lite2 (SIUL2) chapter for the specific mapping of GTM channels to Sigma-Delta interrupt/DMA gating signals.

38.2.1.7 Conversion Limit Watchdog Output to GTM

Each Sigma-Delta ADC provides an optional conversion limit check for upper and lower bounds. The enable bit and the two 16-bit limit registers for the feature are included in the SDADC wrapper. If a conversion result exceeds one of the limits, a flag bit is asserted in a status register in the SDADC wrapper. The flag bit is output to the GTM for each SDADC. The mapping of conversion limit watchdog outputs to GTM channels is defined in the SIUL2 MSCR registers.

38.2.1.8 SDADC_MCR[TRIGSEL] definitions

For this chip, the following input triggers apply:

Table 38-2. Input triggers for this chip

TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware-triggered conversions. 0000 SDADC_0 0001 SDADC_1 0010 SDADC_2 0011 SDADC_3 0100 SDADC_4 0101 SDADC_5 0110 SDADC_6 0111 SDADC_7 1000 SDADC_8 1001 SDADC_9 1010 – 1110 Reserved 1111 MUX_ADV **Note:** Selecting the input trigger source to be from the output trigger of the same SDADC is not prohibited by hardware, but is not supported, and will result in the SDADC never responding to the input trigger.

38.2.1.9 Sigma-Delta ADC analog input channel selection

For the Sigma-Delta mux inputs AN[x], the positive and negative input terminals are selected in the Sigma-Delta ADC digital interface Channel Selection Register (CSR).

This section shows analog channel selections for each combination of Module Configuration Register (MCR) field values MCR_MODE and MCR_VCOMSEL. The following table provides a quick reference key to the MCR fields used in the SD ADC analog input selection tables that follow it.

Table 38-3. Register fields for SD ADC analog input channel selection

Field	Description
MCR_VCOMSEL	Common Voltage Bias Selection

Table continues on the next page...

Table 38-3. Register fields for SD ADC analog input channel selection (continued)

Field	Description
	This bit selects the common voltage bias for the negative input terminal of SDADC during single-ended mode (MODE=1). 0 Negative input terminal is biased with VREFN. 1 Negative input terminal is biased with VREFP/2 (half scale bias).
MCR_MODE	Mode selection 0 Differential input mode is selected. 1 Single-ended input mode is selected.
CSR_ANCHSEL	Analog Channel Selection Based on single-ended or differential mode of operation (MODE bit of MCR), common mode voltage selection (VCOMSEL bit of MCR), this bit-field defines the connectivity of analog inputs to either positive or negative polarity terminals of Sigma-Delta ADC, as shown in the following tables: • Table 38-4 for SDADC_0 • Table 38-5 for SDADC_1 • Table 38-6 for SDADC_2 • Table 38-7 for SDADC_3 • Table 38-8 for SDADC_4 • Table 38-9 for SDADC_5 • Table 38-10 for SDADC_6 • Table 38-11 for SDADC_7 • Table 38-12 for SDADC_8 • Table 38-13 for SDADC_9

38.2.2 Successive Approximation Register Analog-to-Digital Converter (SARADC)

There are twelve independent SARADCs on MPC5777M. Refer to Figure 38-1 for the ADC sub-system block diagram.

The following sections describe configuration details:

- SAR ADC integration diagram
- SAR ADC analog input pin multiplexing
- SAR ADC clock sources
- SAR ADC triggering
- SAR ADC alternate reference
- SAR absolute voltage reference
- SAR ADC diagnostic
- SARADC channel assignment
- SAR ADC register definitions

For detailed module information, refer to the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

38.2.2.1 SAR ADC integration diagram

The following figure shows the block diagram of the integration of the twelve ADCs on MPC5777M.

SARADC_B implements a bias generator converting the VDD_HV_ADR_S, 1/3 VDD_HV_ADR_S, 2/3 VDD_HV_ADR_S, and VSS_HV_ADR_S reference points through the internal 20 kΩ source impedance. See the SARADC block diagram in the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

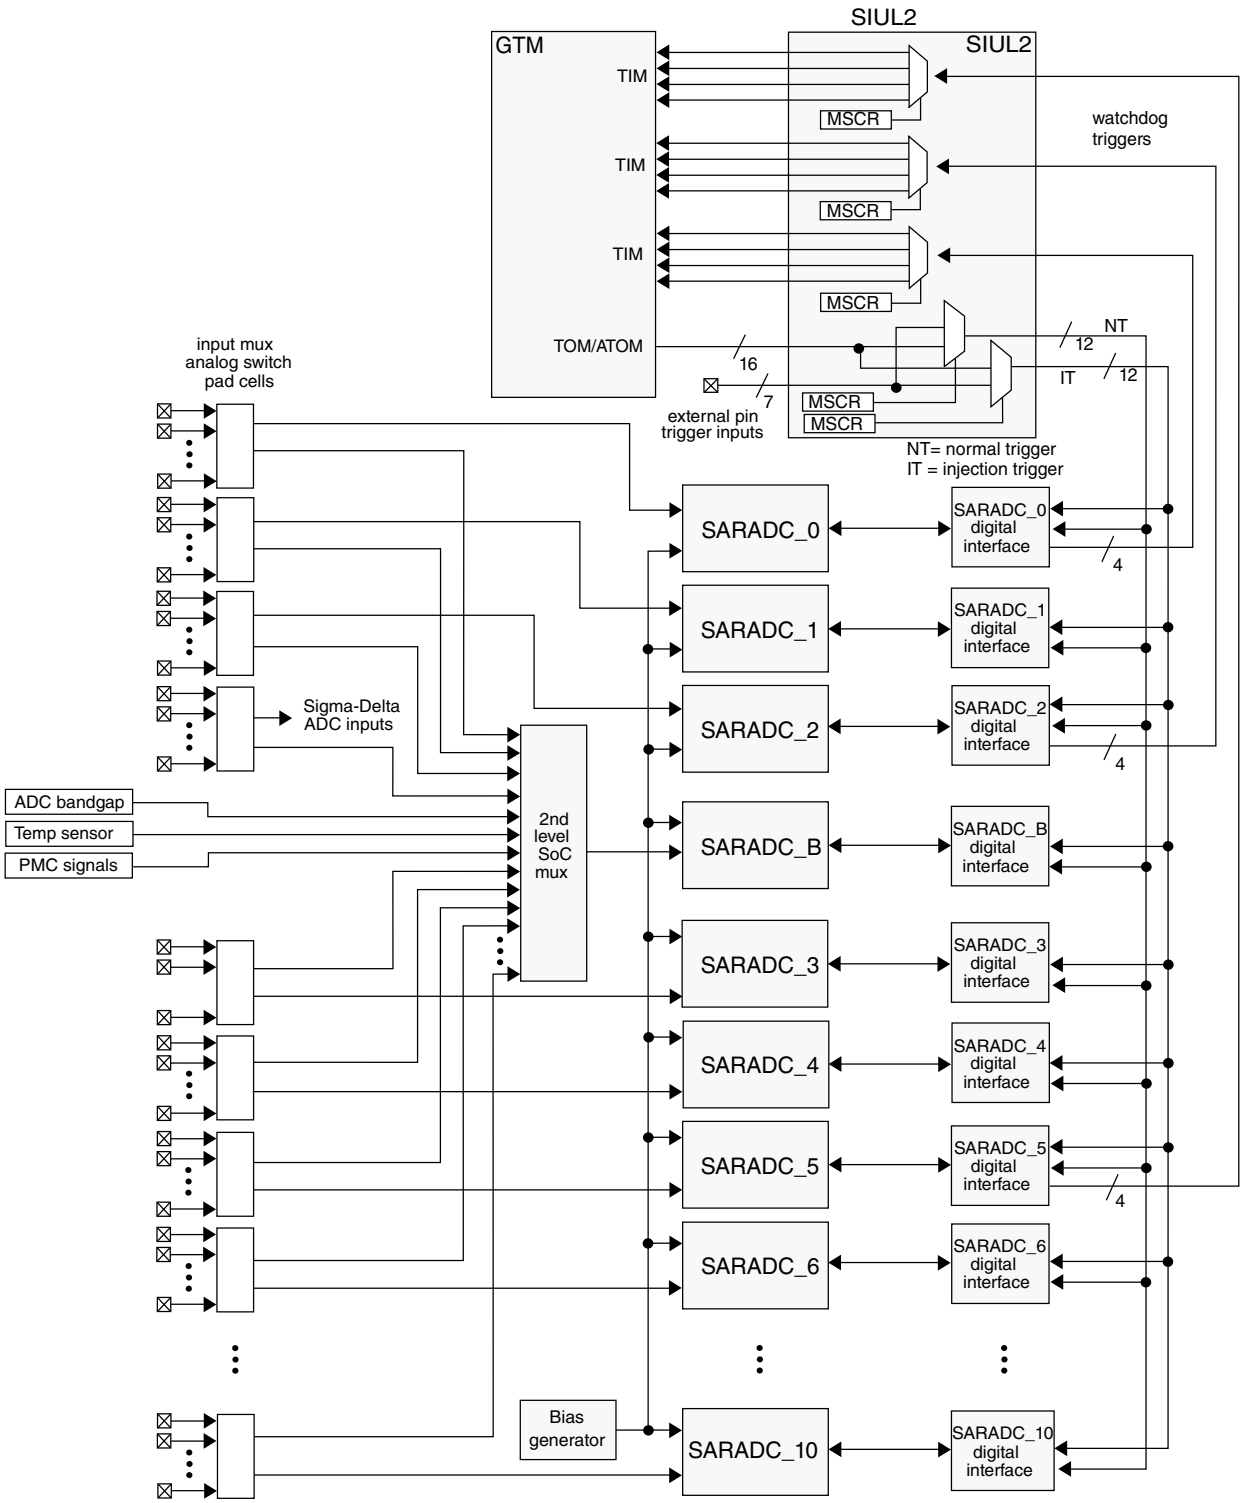

Figure 38-6. SAR ADC integration diagram

38.2.2.2 SAR ADC analog input pin multiplexing

All analog input pins routed to SARADC_B and another fast SAR ADC are multiplexed with a dual analog input switch pad cell. Analog input pins that only connect to SARADC_B use a single analog switch pad cell.

Note

Simultaneous sampling of two ADCs on same analog input is not allowed.

A second level of multiplexing is required for SARADC_B to reduce the parasitic capacitance on the analog input due to the 84:1 input mux. The second level muxing is done in an SoC level IP block so that it can be optimally placed for routing. The analog switches in the second level mux block are controlled by the SAR ADC digital interface block.

The mapping of analog input pins to the SAR converters is given in Table 38-1.

38.2.2.3 SAR ADC clock sources

Each SAR ADC digital interface on MPC5777M has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE*n*_CLK. The module clock is sourced by the ADC clock (SAR_CLK). See Clock generation for more detail on the clock sources.

The input clock for the SAR ADC analog blocks is clocked by the SAR_CLK. The following figure shows a block diagram of the SAR ADC clock architecture. The maximum frequency for the clock input to the converter is 14.6 MHz.

To avoid crosstalk issues, all SAR ADCs run at the same clock frequency. The SAR digital interface is clocked from the PBRIDGE*n*_CLK clock. All SAR analog blocks are clocked from the output of a single divider of the SAR_CLK at the device level.

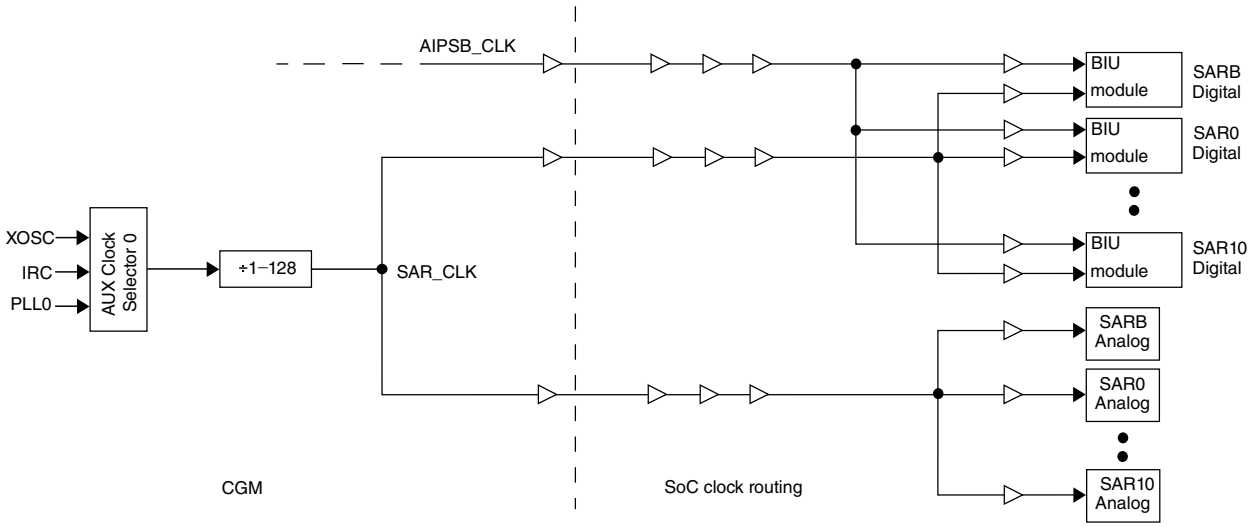

Figure 38-7. SAR ADC clock diagram

38.2.2.4 SAR ADC triggering

Each SAR ADC has 16 independent trigger inputs for starting conversion on an analog input. Selection from the 16 trigger inputs is done inside the SAR ADC digital wrapper. Each SAR ADC on the device has an independent set of trigger inputs, but the same sources are used for each SAR ADC, so only one trigger input is required for each SAR ADC.

The trigger sources for each SAR ADC on the device are either external input pins or GTM channels. Each external input can selectively trigger any of the SAR ADCs on the device. The synchronization to the PBRIDGE clock and digital filtering of the external input pin triggers is done in the system integration logic.

Each trigger input supports software selectable options for rising edge, falling edge, rising and falling edge, or level-based trigger assertion. The trigger selection for each SAR ADC and edge/level selection is located in the SIUL2. The MPC5777M SoC diagram for the SAR ADC trigger inputs is given in the following figure.

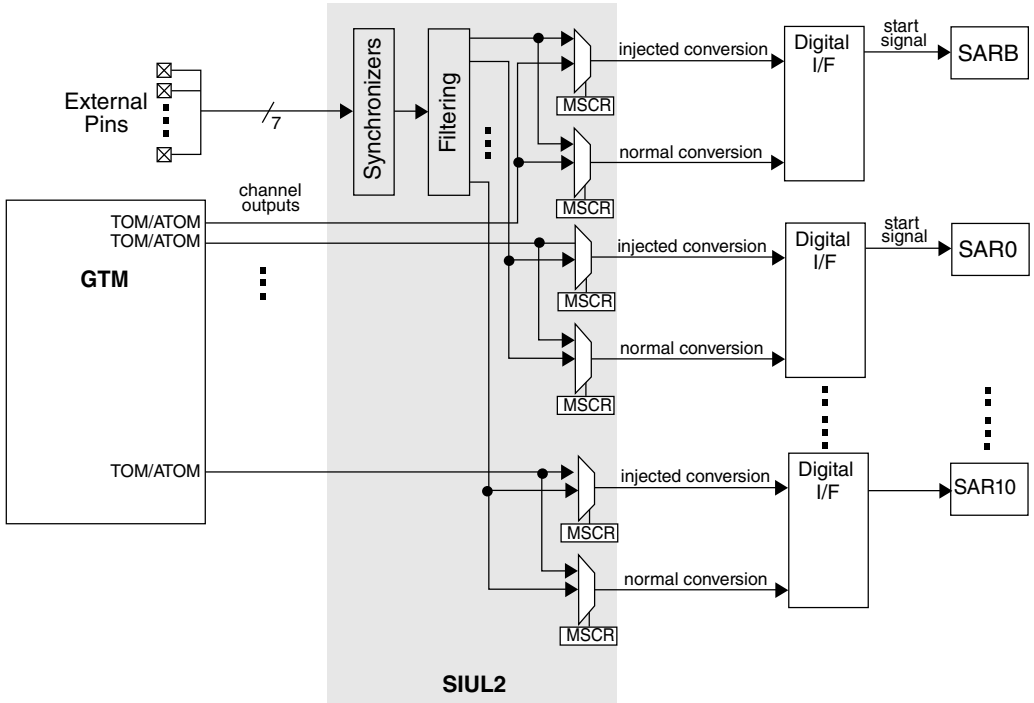

Figure 38-8. SARADC input trigger diagram

Trigger source selection for each SAR ADC is given in the SIUL2 chapter of this document.

38.2.2.5 SAR ADC alternate reference

The SAR ADCs support connection to more than one conversion reference. The alternate references are muxed with analog input pins on MPC5777M. The analog input pins used as alternate references to the respective SAR ADCs are given in the following table.

Table 38-14. SARADC alternate references

SARADC	Alternate reference pin
SARADC_B	AN[8]
SARADC_2	AN[16]

To meet safety requirements, the reference for specific SAR analog inputs cannot be changed. For MPC5777M, these are SARADC_B channels 4–7 and 35, and all other SAR analog inputs. For these SAR ADC instances that do not enable an alternate reference, ICDR*n*[REFSEL] is a read-only bit. There is no option to connect these pins as analog references for the device for safety considerations.

Alternate reference selection is enabled only for the following channels, for which ICDR*n*[REFSEL] is read-write bit:

- SARADC_B channels (0–3, 8–34, 36–95): See Table 38-20, SAR ADC register definitions.
- All SAR2 channels (16–19, 22–23): See Table 38-25, SAR ADC register definitions.

38.2.2.6 SAR absolute voltage reference

MPC5777M provides an internal, absolute voltage reference that can be read by SARADC_B. The ADC conversion channel number for the absolute reference, ADC Bandgap Reference, is given in Table 38-16.

38.2.2.7 SAR ADC diagnostic

38.2.2.7.1 Self Test features

Following are the Self Test features:

- The ADCBIAS provides four different voltage levels defined as GND, $V_{ref}/3$, $2*V_{ref}/3$ and V_{ref}. The self test internal reference voltage precision is provided in the SARn ADC electrical specification table of the device datasheet.
- The impedance requirement has been satisfied putting a physical poly resistor R_{out} = 20 kΩ typical characterized by a process and temperature variation of ±30%.
- The impedance of the switches that are connecting the different references to the ADC input has not been considered in the impedance calculation.
- The impedance of the switches from the reference generation to the ADC input has been matched with the one of the switches that are connecting the device pin to the ADC input.
- The sampling time of SARADC_B needs to be extended to 2.2 ms due to long settling time induced by the high impedance of the source (20 kΩ).
- The SAR ADC Digital Interface provides the necessary control to select the required switches S1–S7 (shown in the following figure) to perform the Self Test.

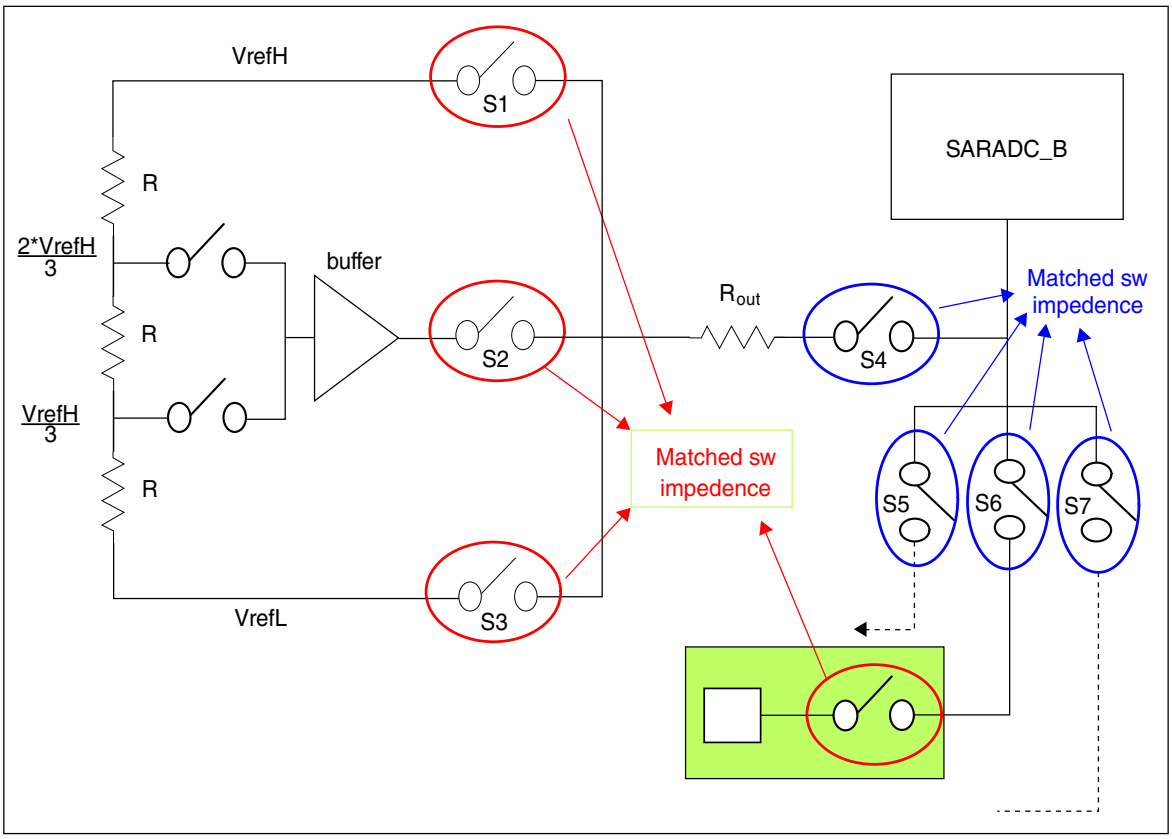

Figure 38-9. Self Test implementation

38.2.2.7.2 Internal reference

The SARB ADC provides the ability to sample and convert four internal voltages through a 20 kΩ source impedance. These voltages are as follows:

- $V_{DD\_HV\_ADR\_S}$
- 1/3 $V_{DD\_HV\_ADR\_S}$
- 2/3 $V_{DD\_HV\_ADR\_S}$
- $V_{SS\_HV\_ADR\_S}$

Conversion of an internal reference voltage works the same as that for a normal conversion, with the exception of the conversion time. Due to the 20 kΩ source impedance, the sampling time is much higher than the normal time.

Enabling the sampling and selection of an internal reference is independent of input channel selection for SARADC_B.

38.2.2.7.3 Analog input pin programmable pullup/pulldown

An open or short circuit condition is detectable within the device for analog input pins. There is a programmable pullup/pulldown pad cell at the input pad. This allows for application testing of the mux input logic. The analog input pin diagram with the pullup/pulldown is shown in the following figure. The pullup/pulldown is included inside the analog input pad cell. The pullup/pulldown is also included in the single switch analog input pad cell.

Control of the pullup/pulldown is independently done in the SIUL2 MSCR registers for each analog input pin.

Only the analog input pins specified in Table 38-1 have the pullup/pulldown feature.

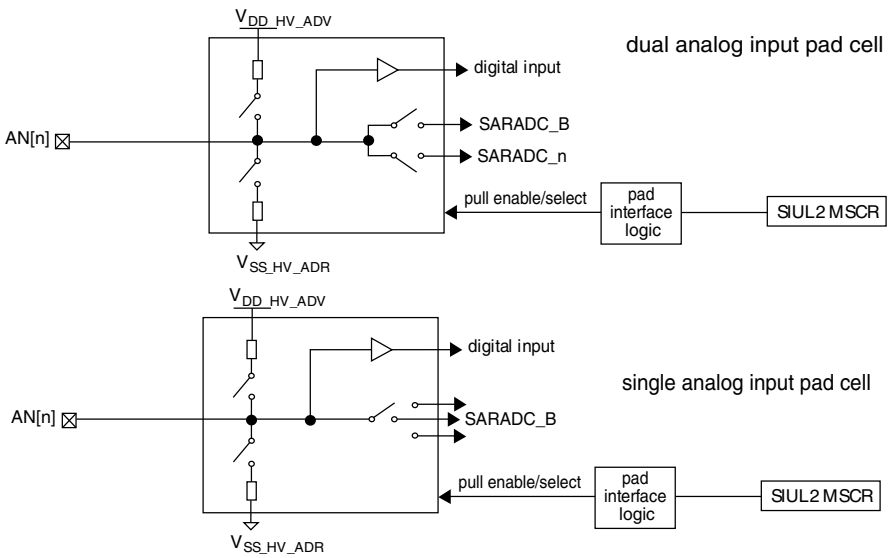

Figure 38-10. Analog input pin pullup/pulldown pad cell

38.2.2.7.4 Analog input pin switch to $V_{SS\_HV\_ADV}$

Two analog input pins on MPC5777M have a programmable switch to $V_{SS\_HV\_ADV}$ to discharge the input. This switch is implemented on analog input pins AN7 and AN35 for MPC5777M. The analog input diagram for AN35 is given in the following figure. The default state of the switch for both inputs is OFF.

Figure 38-11. Analog input AN35 — discharge switch to AVSS

The ground switches for AN7/AN35 are controlled independently from the input switch to the ADC. The ground switch for AN7/AN35 is controlled in input multiplexing MSCR registers (MSCR[WPDE]) in the SIUL2. The MSCR register provides selection between open or closed switch, with open being the default state.

The ground switches can be used to periodically discharge the associated channels.

38.2.2.8 SARADC channel assignment

The input multiplexer channel assignments for the SARADCs is provided in Table 38-15.

38.2.2.8.1 Internal voltage monitor channel assignments

Each internal voltage monitor has a unique channel assignment, and is treated by software like any other A/D conversion. Access to the internal monitor channels is required for SARADC_B only. The internal voltage monitor channel assignments for SARADC_B are given in Table 38-16.

Table 38-15. SAR analog input channel assignment

Analog input pin	SARADC_B input channel	Fast SAR	Fast SAR channel	Description

Table continues on the next page...

Table 38-16. SARADC_B analog test channel assignment (continued)

SARADC_B input channel	Fast SAR	Fast SAR channel	Description
125	—	—	SAR BIAS 1 — 1/3 (VDD_HV_ADR_S - VSS_HV_ADR_S) through 20 KΩ source impedance
126	—	—	SAR BIAS 2 — 2/3 (VDD_HV_ADR_S - VSS_HV_ADR_S) through 20 KΩ source impedance
127	—	—	SAR BIAS 3 — (VDD_HV_ADR_S - VSS_HV_ADR_S) through 20 KΩ source impedance

1. When doing conversions on this channel, it is recommended to mask the corresponding HVD/LVD from generating a reset for the duration of the conversion when this channel is enabled.
2. Channels 122 and 123 are reserved for factory use only.

38.2.2.8.2 SARADC_B interface to PMC

The connection of the PMC to SARADC_B ADC is shown in the following figure. SARADC_B ADC channel 110 connects to the PMC. The PMC contains an analog mux that passes internal voltage nodes in addition to those given in Table 38-16. The PMC mux is programmed in a register in the PMC digital interface. To convert an internal PMC voltage, the user programs the PMC analog mux selection, and then programs SARADC_B to convert PMC channel 110. See the Power Management chapter of this document for more info on additional internal voltages that can be read by the SARADC_B ADC.

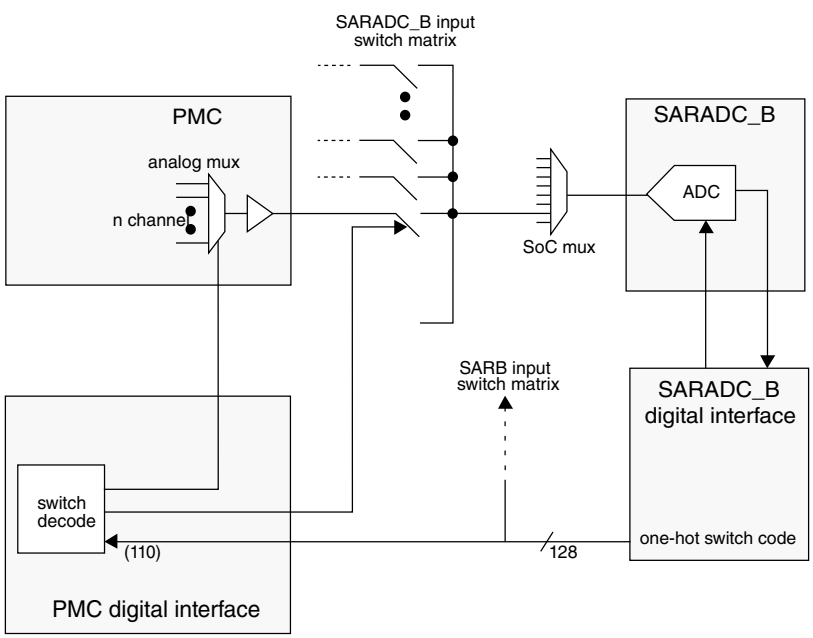

Figure 38-12. SARADC_B ADC read of internal PMC voltages

38.2.2.9 SAR ADC register definitions

Each of the following sections shows register definitions for one SAR ADC instance:

- SARADC_B register definitions
- SARADC_0 register definitions
- SARADC_1 register definitions
- SARADC_2 register definitions
- SARADC_3 register definitions
- SARADC_4 register definitions
- SARADC_5 register definitions
- SARADC_6 register definitions
- SARADC_7 register definitions
- SARADC_8 register definitions
- SARADC_9 register definitions
- SARADC_10 register definitions

The following tables provide a key for the register definition tables. Test channels and external channels are only used for SARADC_B.

Chapter 39
Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface

39.1 Introduction

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides accurate conversion data for a wide range of applications.

39.2 Overview

The SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, high-pass filter enable, etc. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. It also provides external modulator support and keeps the internal modulator in low consumption mode. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

The following figure depicts the block diagram of an SDADC and its digital control block.

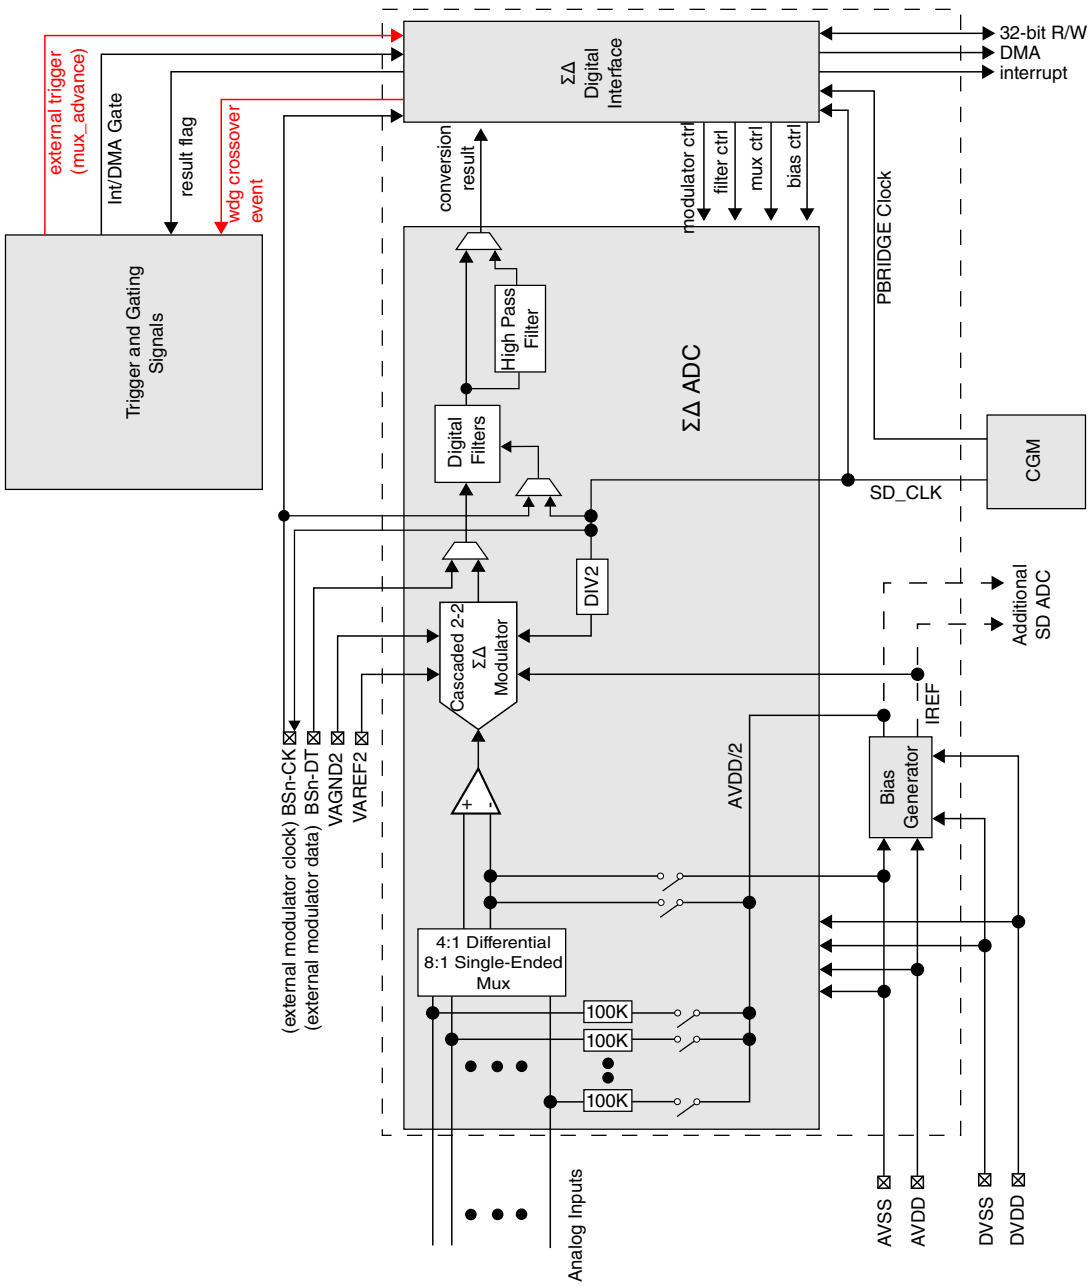

Figure 39-1. SDADC block diagram

39.3 Features

The features of the SDADC are as follows:

- 16-bit data resolution output
- Single-ended input or differential input mode of operation
- Programmable wraparound mechanism for both modes of operation

    - Configurable trigger sources: hardware or software
    - Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single-ended mode
- Gain and offset calibration support using fixed bias for input terminals
- Programmable decimation rate
- Programmable gain for analog inputs
- Optional external modulator support
- Optional high-pass filter for pure AC application
- Hardware trigger support for synchronous operation of multiple SDADC blocks
- Trigger event output generation by software
- Programmable FIFO structure for storing up to 16 datawords of 16-bit converted data
- Interrupt/DMA request generation based on various conditions:
    - Data buffer above threshold
    - Data buffer overrun
    - Watchdog (WDG) crossover event
- Programmable threshold range watchdog support
- Low consumption mode
- Optional conversion process halt mechanism on SoC debug request

39.4 Modes of operation

This section describes the different operation modes of the SDADC. When exiting reset, the mode of operation is determined by the Module Configuration Register (MCR).

39.4.1 Differential input mode

This mode is entered by negating the MCR[MODE] bit. In this mode, a pair of analog inputs are connected to positive and negative terminals of ADC modulator. In order to support gain and offset calibration for diagnostics, it is possible in this mode to select fixed bias voltages to both input terminals.

39.4.2 Single-ended input mode

This mode is entered by asserting the MCR[MODE] bit. In this mode, the negative input terminal is biased with a fixed voltage based on selection information in MCR, and the other analog input is connected to the selected external analog channel.

39.4.3 External modulator mode

This mode is entered by asserting the MCR[EMSEL] bit. In this mode, the data stream and clock outputs from the external modulator available on EMDATA/EMCLK input pins are routed directly to the SDADC block. The internal modulator is bypassed in this mode. Only the digital filters of the SDADC will be used for result calculation. The source for the external modulator clock can be the internal on-chip clock source or the direct clock output coming from the external modulator. The external pin function control for these pins must be configured in the integration logic on a device, and is not included in the SDADC digital interface.

39.5 External signal description

The following table shows the list of signals driven by external pins. See the chip-specific details about SDADC signals and package pinouts for information about signal muxing and availability external to the chip.

Table 39-1. Signal properties

Name	Function	I/O	Reset	Pull-up
AN[0:7]	Single-ended analog inputs or Differential pairs of analog inputs	I	—	—
EMDATA	External modulator data input	I	0	—
EMCLK	External modulator clock input	I	0	—
VREFP	Voltage reference for SDADC	I	—	—
VREFN	Ground reference for SDADC	I	—	—
AVDD	Analog voltage supply for SDADC	I	—	—
AVSS	Analog ground supply for SDADC	I	—	—
DVDD	Digital voltage supply for SDADC	I	—	—
DVSS	Digital ground supply for SDADC	I	—	—

39.6 Memory map and register definition

This section provides the memory map for the SDADC block.

SDADC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (SDADC_MCR)	32	R/W	0000_0000h	39.6.1/1561

Table continues on the next page...

SDADC_MCR field descriptions (continued)

Field	Description
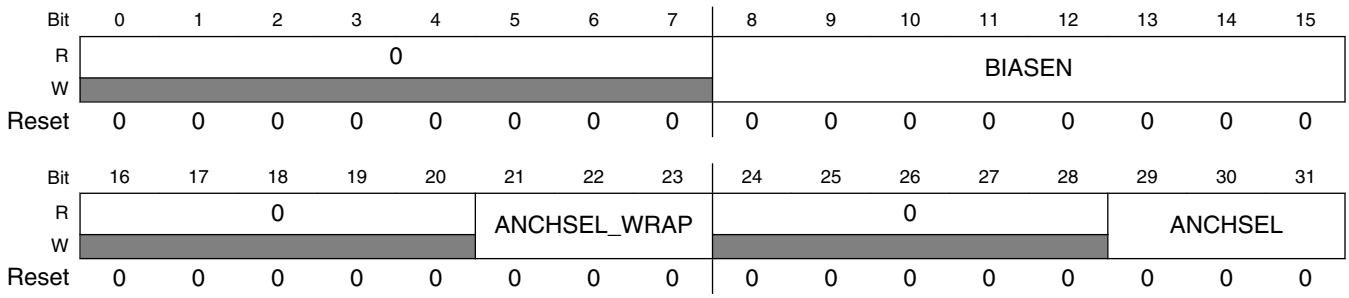
24 FRZ	Freeze This field enables stopping the SDADC conversions at the end of the current channel conversion when the chip enters debug mode. When the chip enters debug mode, further conversions by the SDADC analog block will be stopped, and converted data output from the SDADC analog block are ignored. The ongoing channel conversion will be completed and the converted data is stored. When the chip exits debug mode, SDADC resumes the job that was left before halting the conversions. 0 Conversions are not stopped 1 Conversions are stopped
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 VCOMSEL	Common Voltage Bias Selection This field selects the common voltage bias for the negative input terminal of the SDADC during single-ended mode (MODE = 1). 0 Negative input terminal is biased with VREFN 1 Negative input terminal is biased with VREFP/2 (half-scale bias)
28 WRMODE	Wrap-Around Mode This bit selects the wraparound mechanism for conversion of programmed sequence of channels. 0 Wraparound mechanism disabled (in this case the default software control mechanism will be enabled) 1 Wraparound mechanism enabled
29 GECEN	Accurate Gain Error Mode Enable This bit selects the accurate gain error mode, and must be set during gain error calibration as well as during conversions requiring accurate gain error mode. It can be kept '0' if gain error calibration mode is not needed. 0 Gain error calibration mode disabled 1 Gain error calibration mode enabled
30 MODE	Mode selection 0 Differential input mode selected 1 Single-ended input mode selected
31 EN	Enable for SDADC block 0 SDADC internal modulator placed in low consumption mode 1 SDADC internal modulator enabled

39.6.2 Channel Selection Register (SDADC_CSR)

The Channel Selection Register (CSR) selects analog inputs AN[0:7] to be connected to positive and negative terminals of the SDADC and controls the biasing of analog inputs to half-scale bias through 100 kOhm resistance.

Address: 0h base + 4h offset = 4h



SDADC_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 BIASEN	Bias enable If BIASEN[i] = 1, analog input AN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 kOhm resistor.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 ANCHSEL_ WRAP	Analog Channel Selection Wraparound Value (ANCHSEL_WRAP) When in wraparound mode, this field indicates the maximum value of the wraparound counter, after which it will wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1).
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 ANCHSEL	Analog Channel Selection(ANCHSEL) Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of the SDADC according to the following table. Wraparound Mode: • This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter will start incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[WRMODE] = 1)). • If this field is written any time during wraparound mode (when MCR[WRMODE] = 1), the present value of the wraparound counter will be updated with the value of ANCHSEL - the next trigger will act on the updated channel, and the next increment will be on the updated channel. Here, the value of ANCHSEL chosen should be < ANCHSEL_WRAP; otherwise it will be ignored by hardware. • Wraparound will always be from initial counter value 000.

Table continues on the next page...

			111	VREFN	VREFP

39.6.3 Reset Key Register (SDADC_RKR)

The Reset Key Register (RKR) is the target for a predefined key write operation used to reset the SDADC to start a fresh conversion.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																RESET_KEY															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1

SDADC_RKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 RESET_KEY	Reset Key This field, when written with 5AF0h, is used to generate the reset for the SDADC block and to reload the internal counterwith the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access will always return the inverted key.

39.6.4 Status Flag Register (SDADC_SFR)

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing a '0' to a flag has no effect.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													ANCHSEL_CNT

R	0							DFEF	0			WTHH	WTHL	CDVF	DFORF	DFFF
W												w1c	w1c		w1c	w1c
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

SDADC_SFR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 ANCHSEL_CNT	Analog Channel Selection Counter(ANCHSEL_CNT) This field reflects the current value of the internal Analog Channel Selection Counter. It indicates the present number of the channel selected through the analog multiplexer.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 DFEF	Data FIFO Empty Flag This field is asserted when there is no dataword in the FIFO. 0 Data FIFO is not empty 1 Data FIFO is empty
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 WTHH	Watchdog Upper Threshold Cross Over Event This field is set when Converted Data crosses Upper Threshold of WDG. It can be cleared by software writing '1' to clear. **NOTE:** This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: • SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog upper threshold cross over event, a request is generated) • SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) • SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Upper Threshold Cross Over Event did not occur 1 Watchdog Upper Threshold Cross Over Event occurred
28 WTHL	Watchdog Lower Threshold Cross Over Event This field is set when Converted Data crosses Lower Threshold of WDG. It can be cleared by software writing '1' to clear. **NOTE:** This bit is also cleared by an acknowledgement from the DMA module when all of the following conditions are met: • SDADC_RSER[WTHDIRE]=1 (When this field is set by the occurrence of a watchdog lower threshold cross over event, a request is generated) • SDADC_SFR[WTHDIRS]=1 (The request generated when this field is set is a DMA request) • SDADC_RSER[GDIGE]=0 OR, if SDADC_RSER[GDIGE]=1, the external gating signal is asserted 0 Watchdog Lower Threshold Cross Over Event did not occur 1 Watchdog Lower Threshold Cross Over Event occurred
29 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the SDADC block. The converted data is not valid or is corrupted whenever there is a change in configuration settings determined by MCR, channel selection programmed in CSR. Any write access to the registers MCR and CSR will reset this flag. This flag is set automatically after an internal timer counts a number of output clock fd clock cycles specified by the value of SDADC_OSDR[OSD].

Table continues on the next page...

SDADC_SFR field descriptions (continued)

Field	Description
	0 Data output from SDADC is not valid 1 Data output from SDADC is valid
30 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0 No overrun has occurred since the last time the flag was cleared 1 Overrun has occurred or the DFORF has not been cleared since the last overrun occurred
31 DFFF	Data FIFO Full Flag This bit is set when the number of converted datawords in the FIFO is equal to or more than the number indicated by FCR[FTHLD]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords will continue to be received until an overrun condition occurs. Datawords will not be received if the converted data is not valid (CDVF = 0). **NOTE:** Whenever MCR[EN] is cleared in order to stop the SDADC or change the channel configuration, it is necessary to also clear the RSER[DFFDIRE] bit alongwith. Similarly if DMA or software is too slow in not reading the FIFO datawords resulting in DFFF condition it is advisable to stop the SDADC by clearing the MCR[EN] followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation. 0 The number of datawords in FIFO is less than the number indicated by FCR[FTHLD] 1 The number of datawords in FIFO is equal to or greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared

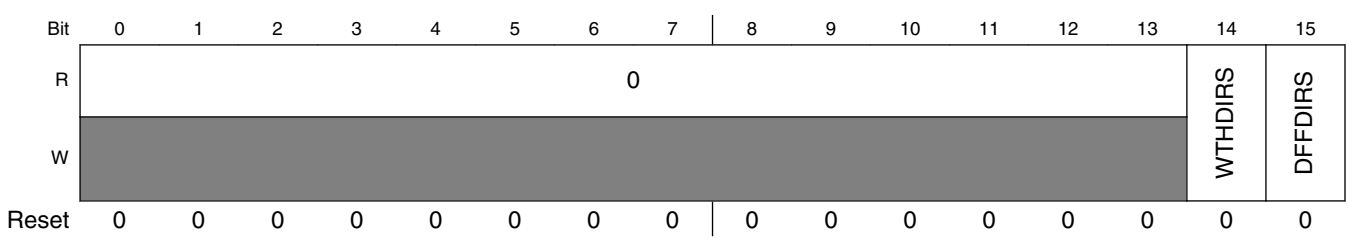
39.6.5 Request Select and Enable Register (SDADC_RSER)

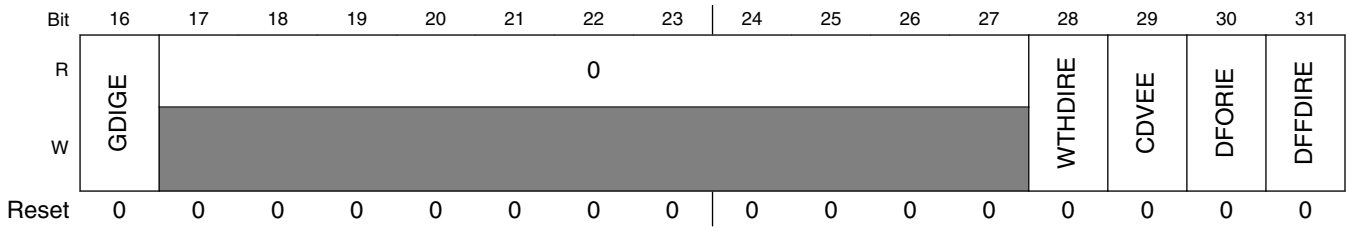
The Request Select and Enable Register (RSER) serves two purposes:

- Enables the flag bits in SFR to generate DMA requests or interrupt requests.
- Selects the type of request to generate.

Refer to the field descriptions for the type of requests that are supported.

Address: 0h base + 10h offset = 10h





SDADC_RSER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When SFR[WTHH/WTHL] and RSER[WTHDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
15 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When the SFR[DFFF] and SFR[DFFDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
16 GDIGE	Global DMA/Interrupt Gating Enable This field determines whether all module interrupts and DMA requests need to be gated by an external gating signal or not. 0 No impact of external gating signal on module DMA/interrupt requests 1 All module DMA/interrupt requests are qualified only when external gating signal is asserted
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable This field enables the SFR[WTHH/WTHL] field to generate a request. The WTHDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled on WDG Threshold Cross Over Event 1 Interrupt/DMA request is enabled on WDG Threshold Cross Over Event
29 CDVEE	Conversion Data Valid Event Enable The status of SFR[CDVF] gated with RSER[CDVEE] is passed on as an event on “conversion_flag" output port, which can be used at SoC level for indication of valid data conversion window. Once enabled, the event output will remain asserted as long as valid data conversions are ongoing. 0 Event output disabled 1 Event output assertion/deassertion based on the SFR[CDVF] field
30 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the SFR[DFORF] field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GDIGE field.

Table continues on the next page...

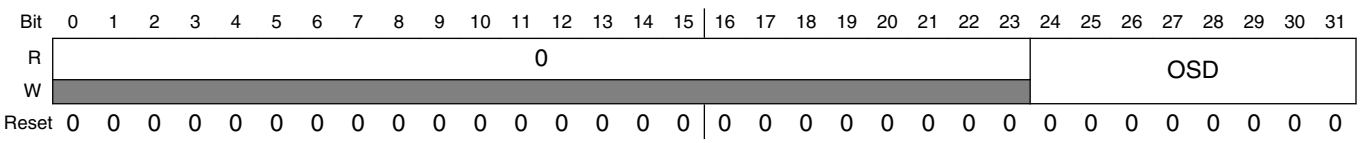
SDADC_RSER field descriptions (continued)

Field	Description
	0 Interrupt request is disabled when data FIFO overrun condition occurs 1 Interrupt request is enabled when data FIFO overrun condition occurs
31 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the SFR[DFFF] field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled when data FIFO full condition occurs 1 Interrupt/DMA request is enabled when data FIFO full condition occurs

39.6.6 Output Settling Delay Register (SDADC_OSDR)

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the SDADC.

Address: 0h base + 14h offset = 14h



SDADC_OSDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OSD	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output clock f_d until it reaches zero, and then it generates a flag which qualifies the converted data. The output clock fd is equal to f_s / (2xOSR), where f_s is the input sampling clock frequency. When external modulator is selected, the output clock is fixed to f_s / 256. See the electrical specifications for the settling delays. **NOTE:** Refer to the $t_{settling}$ and $t_{LATENCY}$ parameters in the device datasheet for the minimum allowed output settling delay values.

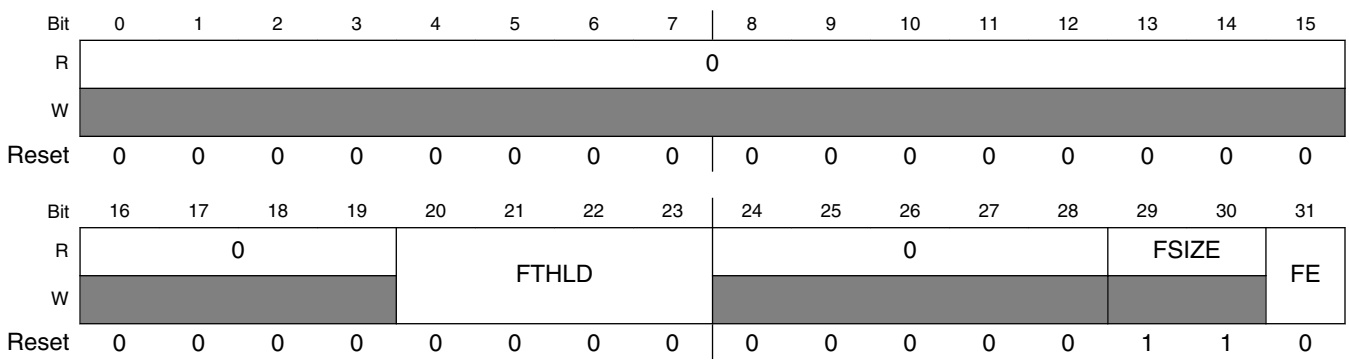
39.6.7 FIFO Control Register (SDADC_FCR)

The FIFO Control Register (FCR) provides the ability to enable or disable the FIFO functionality, and to control the amount of available FIFO depth to be used.

NOTE

1. It is important to note that the FIFO depth is set at the factory and cannot be changed but the amount of available FIFO space actually used can be set by specifying the value in the FTHLD field. The FSIZE field indicates the amount of FIFO space available. By setting the value of FTHLD to be less than the FIFO depth indicated by FSIZE, the FIFO is considered to be full when the number of data words in the FIFO is equal or greater than FTHLD.
2. This register may be read at any time, but should only be written when SDADC is disabled (MCR[EN] = 0).

Address: 0h base + 18h offset = 18h



SDADC_FCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 FTHLD	FIFO Threshold When the number of datawords in the data FIFO is greater than the value in FTHLD field, the FIFO full event is flagged. An interrupt or a DMA request will be generated as determined by DFFDIRE and DFFDIRS fields of RSER. For proper operation, the value in the FTHLD field must be set to be less than or equal to the FIFO size as indicated by FSIZE.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 FSIZE	FIFO Size

Table continues on the next page...

SDADC_FCR field descriptions (continued)

Field	Description
	The maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define the FIFO size. 00 FIFO depth = 1 dataword 01 FIFO depth = 4 datawords 10 FIFO depth = 8 datawords 11 FIFO depth = 16 datawords
31 FE	FIFO Enable When this field is set the built-in FIFO structure is enabled. The size of the FIFO structure is indicated by the FSIZE field. If this field is not set then the FIFO depth is set to one dataword regardless of the value in the FSIZE field. 0 Data FIFO is not enabled for multiple datawords; FIFO depth is one dataword 1 Data FIFO is enabled; FIFO depth is indicated by FSIZE

39.6.8 Software Trigger Key Register (SDADC_STKR)

The Software Trigger Key Register (STKR) allows generating the trigger event output by a software write operation.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SDADC_STKR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 ST_KEY	Software Trigger Key This bitfield, when written with FFFFh, is used to generate a trigger event output which can be used to trigger conversions of multiple SDADC blocks synchronously depending on the chip's implementation. Any write access to this register which is different from the predefined key is ignored. Read access will always return 0000h.

39.6.9 Converted Data Register (SDADC_CDR)

The Converted Data Register (CDR) stores the converted data in the data FIFO.

The conversion result in the CDATA word is a 16-bit, signed value.

NOTE

When SDADC_MCR[PGAN]=111b (programmable gain is 16), the least significant bit of the conversion data in SDADC_CDR[CDATA] is always 0.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SDADC_CDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CDATA	Converted Data Register (CDATA[13:0]) The converted datawords can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 15 down to 0) coming from ADC.

39.6.10 WDG Threshold Register (SDADC_WTHHLR)

This is the Converted Data Range WDG Threshold register.

NOTE

A single WDG monitor will check for lower and upper threshold crossover events.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	THRH																THRL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDADC_WTHHLR field descriptions

Field	Description
0–15 THRH	WDG Upper Threshold Value This indicates the upper threshold for the converted data on any channel, above which threshold a crossover event would be flagged through SFR[WTHH].
16–31 THRL	WDG Lower Threshold Value This indicates the lower threshold for the converted data on any channel, below which threshold cross over event would be flagged through SFR[WTHL].

39.7 Functional description

The SDADC has the following distinct available modes determined by fields in MCR:

- Differential input mode
- Single-ended input mode
- External modulator mode
- Low consumption mode

39.7.1 Differential input mode

Differential input mode is entered when the SDADC_MCR[MODE] field is set to '0' and the SDADC_MCR[EN] field is set to '1'. In differential input mode, a pair of analog inputs among AN[0:7] is connected to the input terminals of the SDADC modulator block. The module supports four differential pairs: AN[0,1], AN[2,3], AN[4,5], and AN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on the SDADC_CSR[ANCHSEL] field. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative terminal, is determined according to the Analog input AN[0:7] selection table in the Channel Selection Register description.

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

39.7.2 Single-ended input mode

Single-ended input mode is entered by setting the SDADC_MCR[MODE] and SDADC_MCR[EN] fields to '1'. In this mode, one of the analog inputs among AN[0:7] is selected via the SDADC_CSR[ANCHSEL] field and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are two internal bias voltages available: reference ground (VREFN) and half-scale bias (VREFP/2). The selection of this common mode voltage is controlled vua the SDADC_MCR[VCOMSEL] field.

39.7.3 External modulator mode

This mode is selected by asserting the MCR[EMSEL] field. When external modulator is selected, the internal modulator can be put in low consumption mode by deasserting the MCR[EN] field. In this mode, the data stream and clock outputs from the external modulator available on EMDATA/EMCLK input pins are multiplexed with internal modulator data output and input sampling clock (f_s). External modulator data must be synchronized with respect to the falling edge of EMCLK. In this mode, hardware trigger input is ignored even if it is enabled by asserting the MCR[TRIGEN] field. All other configuration settings (for example gain, decimation rate, filter, etc.) programmed in MCR have no effect on the conversion.

39.7.4 Low consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting the MCR[EN] field to enable the SDADC block. When data conversion is not required, the SDADC internal modulator can be put in low consumption mode to reduce power consumption.

39.7.5 Analog input multiplexing and bias support

The complete selection and connectivity of analog inputs AN[0:7] is based on the ANCHSEL field of CSR and the MODE and VCOMSEL bits of MCR, according to the Analog input AN[0:7] selection table in the Channel Selection Register description. Each analog input can be biased to half scale (AVDD/2) via on-chip 100 kΩ resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not.

39.7.6 Programmable gain and decimation rate

All analog inputs can be configured to have a selectable input gain as defined in the PGAN field description in MCR. This means the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

The SDADC module is provided with a fixed input sampling clock f_s. The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different passbands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by the field PDR in MCR.

39.7.7 High-pass filter support

For pure AC applications, it is useful to remove any DC component in the input signal. An optional high-pass filter is implemented which can be enabled by asserting the MCR[HPFEN] field. The –3 dB frequency of the filter is fixed (not programmable) and is specified in the device data sheet. This high-pass filter is implemented in the decimation filter logic of the SDADC and is applicable only to internal modulator mode.

39.7.8 Data conversion

The SDADC operates in a continuous conversion mode as soon as it is enabled. There is an inherent settling time required after SDADC startup before conversion data is considered valid.

NOTE

During that period, the Converted Data Valid Flag bit (SDADC_SFR[CDVF]) reads '0'.

Settling time duration depends on the latency and output settling time specifications. To account for the settling time, an internal timer is implemented that counts down from a start value determined by the value of the SDADC_OSDR[OSD] field.

The internal countdown timer is triggered by an SDADC reset, i.e., by writing the value 5AF0h to the SDADC_RKR[RESET_KEY] field.

NOTE

An SDADC reset is required any time there is a change to the SDADC configuration (via changes to the SDADC_MCR register settings), or a change to analog channel selection (via SDADC_CSR register settings).

When the timer reaches '0', the SDADC_SFR[CDVF] field is asserted and converted data is loaded into data FIFO on every rising edge of the output clock (f_d).

Any write access to the SDADC_MCR or SDADC_CSR register causes the SDADC_SFR[CDVF] flag to be cleared, indicating that data coming from SDADC is not valid. If the SDADC_SFR[CDVF] flag is '0', the following flags are blocked from becoming asserted:

- Data FIFO Full Flag (SDADC_SFR[DFFF])
- Data FIFO Overrun Flag (SDADC_SFR[DFORF])

If the SDADC_SFR[DFFF] bit is already set, the data FIFO is already full before SDADC_SFR[CDVF] deassertion.

Wraparound Control Mechanism: Here a wraparound logic includes all analog channels of the input mutiplexer from Ain("000") to Ain(CSR[ANCHSEL_WRAP]) in both Single ended and Differential ended mode in wraparound sequence triggered by hardware or software source:

- MCR[WRMODE] bit would enable or disable the wraparound mechanism. Clearing the WRMODE bit automatically switches FSM back to Software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- Wraparound Counter: An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value "000". Maximum value of the counter (wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode. The definition of ANCHSEL and ANCHSEL_WRAP is provided in the Analog input AN[0:7] selection table in the Channel Selection Register description.
- Upon entering or during wraparound mode user should take care to program ANCHSEL value less than ANCHSEL_WRAP value; otherwise hardware would reject the new ANCHSEL value.
- Possible trigger sources:
  - SOURCE1 (Software Bit): writing to STKR.ST_KEY at any time during the wraparound mode (irrespective of MCR[TRIGEN or TRIGSEL] setting) generates a trigger pulse. Each such trigger initiates a fresh conversion and advances the wraparound counter by one.

NOTE

Care should be taken while programming the TRIGEN/ TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

  - SOURCE2 (Hardware Trigger): Here external trigger output enabled by MCR[TRIGEN or TRIGEDSEL or TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger. Each such valid

trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.

- Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution. This can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value and the wraparound counter would increment from the updated value.
- Current wraparound counter value can be read from the SFR[ANCHSEL_CNT] bitfield.

39.7.9 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. The field TRIGSEL of MCR selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously for four cycles. This will ensure that SDADC starts from a fresh state when reacting to the input trigger event. The SDADC internal modulator must be enabled before enabling the trigger event — otherwise the trigger event will be ignored. A hardware trigger event is also ignored when external modulator is selected (MCR[EMSEL] = 1).

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (TRIGEN bit MCR) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSDR[OSD].

It is also possible to generate a software trigger event output by a write access of STKR with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, the skew/jitter will be less than 100 ns. It will be more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

Wraparound Control Mechanism: In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

39.7.10 Interrupt/DMA request support

The SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is equal to or greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

If RSER[GDIGE] is set, all module interrupt/DMA requests are qualified only when an external global gating signal is asserted.

39.7.11 Gain calibration support

To perform gain calibration, the following sequence needs to be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Enable gain error calibration mode by writing MCR[GECEN] to '1'.
3. Configure the mux selection ANCHSEL field of CSR to '110'. This configuration will apply VREFP on positive terminal and VREFN on negative terminal.
4. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.
5. Disable the high-pass filter by deasserting MCR[HPFEN].
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
7. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 0111_1001_1001_1001b, corresponding to full positive scale after attenuation inserted by the internal filter (1*0.95). The measurement should be repeated to reduce contribution of noise during the calibration process. D_p is the average value of attenuated positive full scale given by D_p = AVERAGE(CDR[CDATA]).
8. Change the mux selection ANCHSEL field of CSR to '111'. This configuration will apply VREFN on positive terminal and VREFP on negative terminal.
9. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.

10. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 1000_0110_0110_0110b, corresponding to full negative scale after attenuation inserted by the internal filter (-1*0.95). The measurement should be repeated to reduce contribution of noise during calibration process. D_n is the average value of attenuated negative full scale given by D_n = AVERAGE(CDR[CDATA]).
11. The SDADC calibrated gain can be calculated as:
    $Gain = (D_p - D_n) / 2^{16}$
12. The measured gain value can be used to nullify the gain errors in the digital output. For calibrated conversion, the data CDR[CDATA] provided by the SDADC should be normalized using the calculated gain: $CDATA_{norm}$ is given by $CDATA_{norm}$ = CDR[CDATA]/Gain.

Note

a. The gain error calibration should only be done with gain equal to '1' (in other words, PGAN = 000). Nevertheless, the calculated gain can be applied to normalized data also for conversion with GAIN>1.
b. MCR[GECEN] = 1 ensures the accurate gain error mode is enabled. This bit should be set both during calibration process and after calibration, for application data conversion. Application data conversion must then be normalized using the measured gain.
c. The higher the number of full-scale conversion (D_p, D_n) done, the higher the rejection of noise during the calibration. The number of conversion is dependent on application noise. It is recommended to run at least 16 conversions when calculating an average value.

39.7.12 Offset calibration support

To perform offset calibration, the following sequence must be applied.

1. Select differential mode of operation by writing SDADC_MCR[MODE] to '0'.
2. Configure the SDADC_CSR[ANCHSEL] mux selection field to '100' or '101' as required.
   a. SDADC_CSR[ANCHSEL] ='100' in case of data conversion after calibration in "single ended mode with negative input=$V_{SS\_HV\_ADR\_D}$"
   b. SDADC_CSR[ANCHSEL] ='101' in case of data conversion after calibration in "differential mode" and "single ended mode with negative input = $(V_{DD\_HV\_ADR\_D} - V_{SS\_HV\_ADR\_D}) / 2$"

3. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 00h.
4. Disable the high pass filter by deasserting SDADC_MCR[HPFEN].
5. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.
6. Read the digital output stored in FIFO after the output settling time.
7. The measured offset can be used to nullify the offset error in the digital output. Expected output is 00_0000_0000_0000b. The SDADC offset can be calculated as:
   Offset = Expected Output – Actual Output

Note

The offset must be calculated for each SDADC_MCR[PGAN] field setting since it is expected to vary with gain configuration of SDADC.

39.8 Initialization information

To initialize the SDADC registers for data conversion, the following sequence is required.

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter if required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC startup time or latency from reset exit.
6. Generate a reset event by writing 5AF0h to RESET_KEY of RKR. Otherwise, if data conversion need to be triggered by a hardware event, assert MCR[TRIGEN].
7. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

The following sequence needs to be followed when external modulator mode of SDADC is selected for data conversions.

1. Disable the SDADC internal modulator by deasserting MCR[EN].
2. Configure MCR to select the external modulator mode.
3. Select the required external pins EMDATA/EMCLK in the system integration logic (SIUL) of the device.
4. Configure OSD delay according to external modulator startup time or latency from reset exit.
5. Generate a reset event by writing 5AF0h to RESET_KEY of RKR.

6. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

39.8.1 Data conversion step

To acquire a data from SDADC, the following sequence is required:

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter is required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC required startup time or latency from reset exit.
6. Generate a reset event writing 5AF0h in RESET_KEY field of RKR register.
7. Wait till FIFO empty flag DFEF of SFR register is clear.
8. Read data by CDATA of CDR register.

Repeat steps from 6 to 8 for new acquisitions.

NOTE

The time elapsed between reset event and Read data by CDATA field of CDR register are:

- Reset event <- -> Data Valid flag(CDVS) = Output settling Time delay (OSDR has to be set at least to 16) (Refer to the $t_{settling}$ and $t_{LATENCY}$ parameters in the device datasheet for the minimum allowed output settling delay values.).
- Data Valid flag <- -> Data FIFO is not empty = 0.5*CLK_Out + 3*CLK_In
- Data FIFO is not empty <- -> read Data (safety point) = 2*CLK_In, where CLK_Out = CLK_In/(2*OSR)

Chapter 40
Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface

40.1 Introduction

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for the application. It provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has its corresponding digital interface implemented at the chip level.

40.2 Overview

The SARADC digital interface contains advanced features for normal or injected conversion modes of operation. The conversion can be triggered by software or hardware.

The digital interface can be configured to control up to 256 multiplexed analog input channels. There are three types of input channels:

- Internal channels, mapped to index ranging from 0 to 95
- Test channels, mapped to index ranging from 96 to 127
- External channels, mapped to index ranging from 128 to 255

Note

The number of input channels and their mapping varies depending on your device configuration. See the device-specific Analog-to-Digital Converters (ADC)

Configuration section (analog input pin multiplexing and SAR ADC channel assignment) for a channel mapping table.

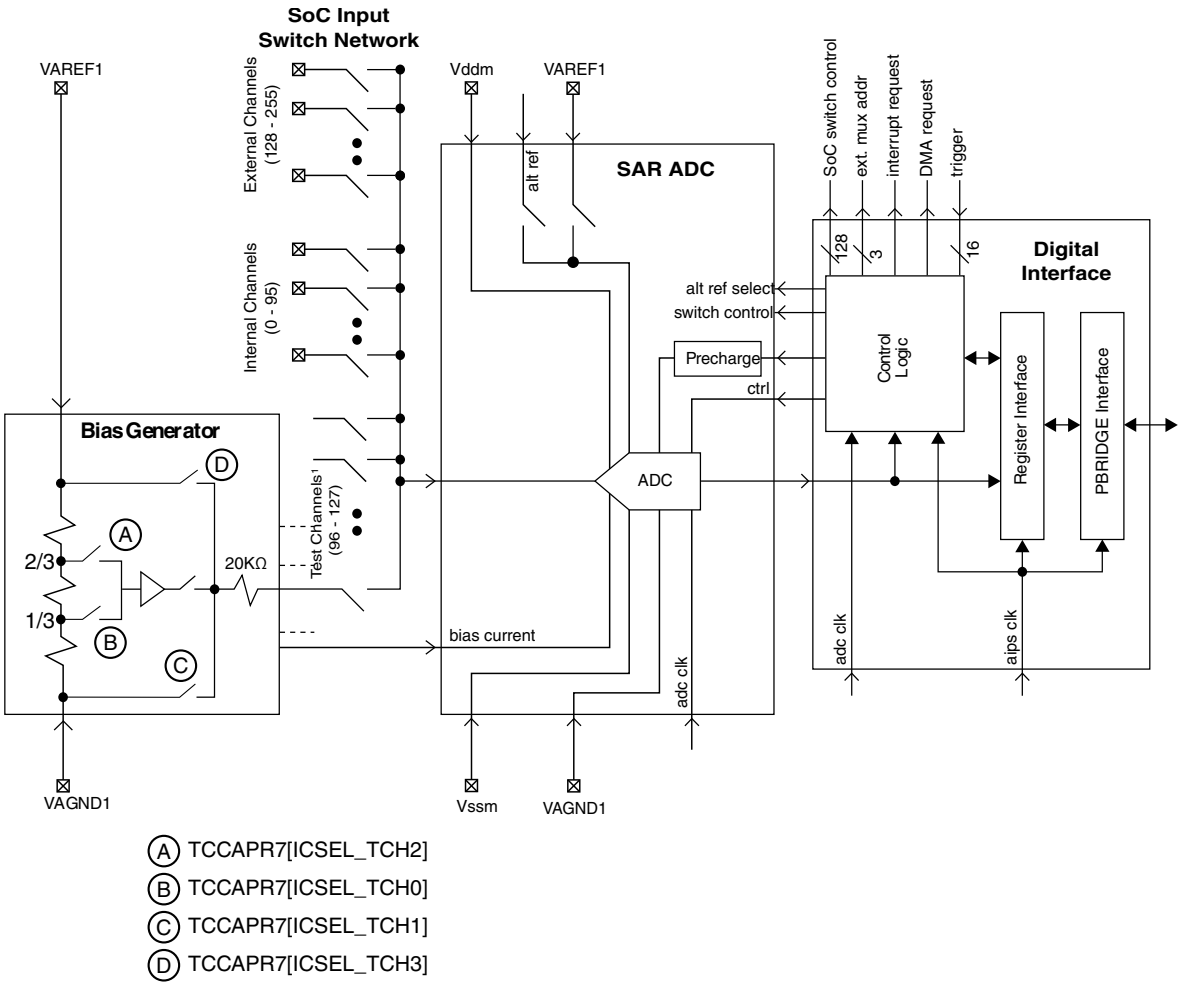
The mask registers present within the digital interface can be properly programmed to configure which channel has to be converted. External channel selection is provided through external decode signals and are available as alternate functions on GPIO. Each set of eight external channels can be mapped to any internal analog channel by static programming by software in specific registers.

Four conversion timing registers exist that allow configuration of different precharging and sampling durations, and it is possible to select one of the conversion timing registers for each channel. For each channel, it is possible to choose the voltage reference through software. Analog Watchdogs allow continuous hardware monitoring of analog input channels. The digital interface also provides for interrupt/DMA support for various conditions related to end of channel conversions.

The following figure shows the SARADC block diagram.

Note

SARADC_B implements a bias generator converting the Vddm, 1/3 Vddm, 2/3 Vddm, and Vssm reference points through the internal 20 kΩ source impedance.



[1] Test channels are mapped to internal analog channels via the SARADCB_TCCAPRx registers

Figure 40-1. SARADC block diagram

40.3 Feature description

- Selectable 10-bit or 12-bit data resolution output
- Up to 96 internal channels, 32 test channels, 128 external channels supported; variable number of analog channels of each type controlled by parameters
- 4 different conversion timing registers selectable for any channel
- Mapping of external channel to any internal channel through static programming by software
- Shorting of test channel with internal channel through static programming by software
- External decode signals (3 signals) for selection of external analog mux inputs

- Normal conversion with One Shot/Scan modes
- Injected conversion with One Shot mode
- Normal conversion with dedicated trigger input
- Injected conversion with dedicated trigger input
- 2 different abort features that allow to abort either a single channel conversion or chain conversion
- Reference selection for each channel
- Power Down Mode
- Dedicated data register for each channel, containing the following information:
  - 10-bit or 12-bit conversion result in one half-word
  - Status byte which provides some conversion information such as mode of operation (Normal, Injected), data valid, data overwritten status.
  - Control byte for reference selection, conversion timing parameter selection
- Configurable number of analog watchdogs
  - Trigger outputs on watchdog threshold crossover events
- Interrupt/DMA support for the following conditions
  - End of conversion of single channel for both normal, injected conversions
  - End of conversion chain for both normal, injected conversions
  - Watchdog thresholds crossover

40.4 Functional description

Two main conversion types are available within the SARADC digital interface:

- Normal conversion
- Injected conversion

40.4.1 Normal channel conversion

This is the normal conversion that the user programs by configuring the normal conversion mask registers (ICNCMR0-2, TCNCMR, ECNCMR0-3). Each channel can be individually enabled by setting '1' in the corresponding field of these registers. Mask registers must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends (MSR[NSTART] bit is reset).

40.4.1.1 Start of normal conversion

The normal conversion can be started as follows:

- By software
  - The normal conversion chain starts when the MCR[NSTART] bit is set. It is recommended that the normal trigger enable MCR[NTRGEN] bit is reset during conversions started by software. Once a normal conversion has started, any further write operation of the MCR[NSTART] bit will have no effect during ongoing conversion, but the conversion will be enqueued after completion of current conversion in oneshot mode.
- By normal trigger
  - A normal trigger valid edge or level is detected to start the conversion. The normal trigger is enabled by setting the NTRGEN bit in MCR and two options are available. A programmed event (rising, falling or both edges depending on NEDGESEL bitfield of MCR) on the normal trigger input starts the normal conversion. Once normal conversion has started, any further valid trigger edge will be ignored during ongoing conversion. If the trigger mode is enabled (MCR[NTRGEN] bit is set), then software can only clear the MCR[NSTART] bit for terminating the conversion process. It is not possible to software to give any conversion request.

NOTE

An appropriate gap should be maintained between any two consecutive triggers such that next trigger is received only after the completion of ongoing conversion. This gap value can calculated as a sum of total conversion time as programmed using the CTR0-3 registers for each channel in the chain.

40.4.1.2 Normal conversion operating modes

Two operating modes are available for the normal conversion:

- One Shot Mode
- Scan Mode

To enter one of these modes, it is necessary to program the MCR[MODE] bit. The first phase of the conversion process involves sampling the analog channel and the next phase involves the conversion phase when the sampled analog value is converted to digital as shown in the following figure.

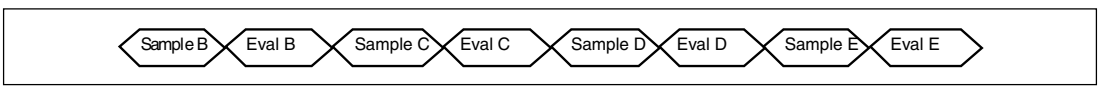


Figure 40-2. Normal conversion flow

In **One Shot Mode** (MODE = 0) a sequential conversion specified in the ICNCMR0-2, TCNCMR, ECNCMR0-3 mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored into the corresponding data register.

For Example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *One Shot Mode*. MODE = 0 is set for One Shot mode. Conversion starts from the channel B followed by conversion of channels D-E. At the end of conversion of channel E the scanning of channels stops.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time MCR[NSTART] bit is reset if the conversion is started by software.

Once the normal conversion operation starts in oneshot mode and another software conversion request is made writing the MCR[NSTART] bit and before MSR[NSTART] is cleared, one additional conversion is initiated with the same channel mask register settings after the current conversion is finished, this is called **enqueuing**. Enqueuing can help in removing the delay between two consecutive oneshot chains and uncertainty caused by metastability between MCR[NSTART] bit written at system clock and generation of start pulse on ADC clock before every chain execution.

In **Scan Mode** (MODE = 1), a sequential conversion of N channels specified in the ICNCMR0-2, TCNCMR, ECNCMR0-3 registers is continuously performed. As in the previous case, at the end of each conversion the digital result of the conversion is stored into the corresponding data register.

In this mode, the software can start conversion by writing '1' to MCR[NSTART] bit or a valid normal trigger edge is detected which also sets MCR[NSTART] bit. The MCR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One Shot Mode, the MCR[NSTART] bit is not reset. It can be reset by software when the user needs to stop scan mode. In that case, the current scan conversion is completed and MCR[NSTART] bit also is reset after the last conversion of the chain.

For Example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *Scan Mode*. MODE = 1 is set for Scan Mode. Conversion starts from the channel B followed by conversion of the channels D-E. At the end of conversion of channel E the scanning of channel B starts followed by conversion of the channels D-E. This sequence repeats itself till the MCR[NSTART] bit is reset by software.

In both the modes, at the end of each channel conversion an End Of Conversion interrupt is issued (if enabled by the corresponding mask bit) and at the end of the conversion sequence an End Of Chain interrupt is issued (if enabled by the corresponding mask bit). The End Of Chain interrupt is issued for each pass of scan mode.

40.4.2 Injected channel conversion

A conversion chain can be injected into the ongoing normal conversion configuring the injected mask registers (ICJCMR0-2, TCJCMR, ECJCMR0-3). As normal conversion, each internal, test or external channel can be individually selected. This injected conversion can only be in one-shot mode and interrupts the normal conversion. When an injected conversion is inserted, ongoing channel conversion is aborted and the injected channel request is processed. After the last channel in the injected chain is converted, normal conversion resumes from the channel at which the normal conversion was stopped as shown in the following figure.

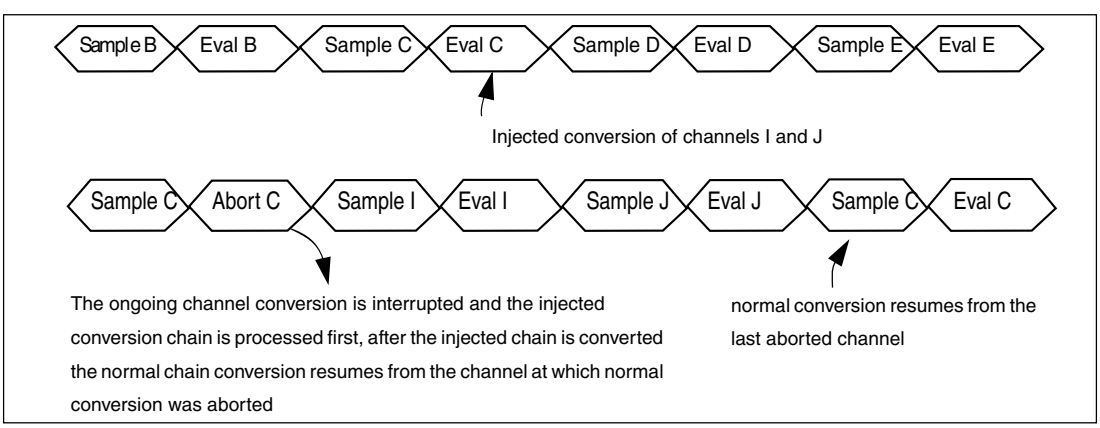

Figure 40-3. Injected sample/conversion sequence

The injected conversion can be started as follows:

- By software
  - The injected conversion chain starts when the MCR[JSTART] bit is set. The current conversion is suspended and the injected chain is converted. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed. It is recommended that the injection trigger enable MCR[JTRGEN] bit is reset during conversions started by software. Once injected conversion has started, any further write operation of MCR[JSTART] bit will not have any effect during ongoing conversion.
- By injection trigger
  - The injection trigger is enabled by setting the JTRGEN bit in MCR. A programmed event (rising, falling or both edges depending on JEDGESEL bitfield of MCR) on the injection external trigger starts the injected conversion and also sets the MSR[JSTART] bit. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed.
  - When JTRGSEQ bit is set, the injection trigger sequence feature is enabled. In this mode, each valid edge of injection trigger input will convert one analog channel. First valid edge will convert the first analog channel enabled through ICJCMR0-2, TCJCMR, ECJCMR0-3 registers. The next valid edge converts the next enabled analog input and so on. Once all the enabled channels are converted, the channel selection loops back to the first enabled channel for next trigger edge. If the JTRGSEQ is reset, the channel selection is reset again to first channel enabled through ICJCMR0-2, TCJCMR, ECJCMR0-3 registers. If JTRGSEQ is reset before completing the injected chain, the remaining channels are completed in one-shot after receiving next valid trigger edge.

NOTE

An appropriate gap should be maintained between any two consecutive injected triggers such that next injected trigger is received only after the completion of ongoing injected conversion. This gap value can calculated as a sum of total conversion time as programmed using CTR0-3 registers for each channel in the injected chain.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time MSR[JSTART] is reset if the conversion is started by software.

At the end of each injected conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit) and at the end of the sequence an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit).

40.4.3 Abort conversion

Two different abort functions are provided.

- The user can abort the ongoing conversion by setting the ABORT bit in the MCR. The current conversion is aborted and the conversion of the next channel of the chain is immediately started (generating a new start pulse to the SARADC). In the case of an abort operation, the NSTART/JSTART bit remains set and the ABORT bit is reset after the conversion of the next channel starts. The EOC corresponding to the aborted channel is not generated. This behavior is true for normal or triggered/Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported generating an ECH interrupt.
- It is also possible to abort the current chain conversion by setting the ABORTCHAIN bit in the MCR. In that case the behavior of the ADC depends on the MODE bit. In fact, if scan mode is disabled, the NSTART bit is automatically reset together with the ABORTCHAIN bit. Otherwise, if the MODE bit is set to '1', a new chain conversion is started. The EOC of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

  When a chain conversion abort is requested (ABORTCHAIN bit is set) while an injected conversion is running over a suspended Normal conversion, both injected chain and Normal conversion chain are aborted (both the NSTART and JSTART bits are also reset).

40.4.4 Analog conversion timings and reference selection

- Conversion timings
- Alternate reference selection

40.4.4.1 Conversion timings

In order to support different loadings and switching times (in particular for the external channel types) four different Conversion Timing registers are present (CTR0-3). Each conversion timing register contains PRECHG, INPSAMP bitfields to program the required duration for precharging and sampling phases. The selection of these registers for each channel is done by the SAMPSEL bitfield of corresponding channel data register.

Precharging phase allows to precharge or discharge the internal capacitor to a fixed internal voltage for duration determined by PRECHG bitfield prior to actual analog channel sampling start. This is useful for resetting information regarding the last converted data. Precharging feature can be enabled or disabled for each channel by programming the PCE bit of corresponding channel data register. If precharging is enabled for a given channel, the normal sequence of operation will be precharging, sampling followed by evaluation as shown in the following figure. Please refer to device datasheet for the minimum precharge and sample durations required.

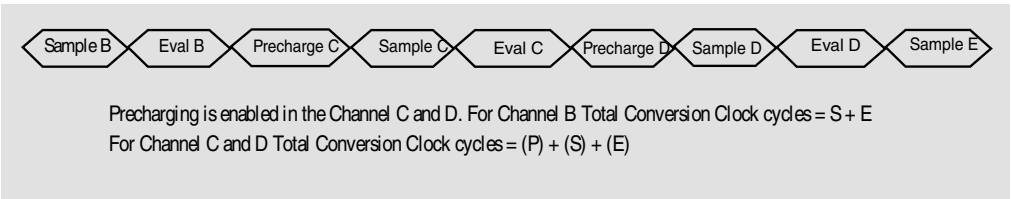

Figure 40-4. Analog conversion sequence

Bitfields PRECHG, INPSAMP are used to define the total conversion duration (t_{conv}) and in particular the partition among precharge duration (t_{prechg}), sampling phase duration (t_{sample}) and evaluation phase duration (t_{eval}).

The precharging phase duration is given by

$$t_{prechg} = PRECHG * t_{ck}$$

where PRECHG must be greater than or equal to 2 (hardware requirement) and PCE bit of channel data register is '1'. In case the value of PRECHG is found to be less than 2, it is automatically set to 2 inside SARADC. If the PCE bit is '0', the precharging phase is skipped and conversion starts with sampling phase directly.

The sampling phase duration is given by the following equation:

$$t_{sample} = INPSAMP * t_{ck}$$

where INPSAMP must be greater than or equal to 4 (hardware requirement). In case the value of INPSAMP is found to be less than 5, it is automatically set to 5 inside SARADC.

The total evaluation phase duration is given by the following equations:

$$t_{eval} = 25 * t_{ck}$$
$$t_{eval} = 21 * t_{ck} \text{ (for 10-bit conversion)}$$

In this phase, the internal sampling capacitor is disconnected from the analog channel and ADC estimates the digitized value of the sampled input using successive approximation algorithm. In the evaluation phase, all the bits are estimated sequentially to provide the conversion result.

The total conversion duration is (not including external multiplexing) is given by the following:

$t_{conv} = t_{prechg} + t_{sample} + t_{eval}$

The timings refer to the unit t_{ck} refers to reciprocal of f_{ck}, where f_{ck} = SARADC peripheral clock. Total conversion time is < 5µs.

Note

The current implementation of ADCDIG does not support hardware restriction over values of PRECHG and INPSAMP fields. As minimum values for these fields are product specific and need to be managed through software.

40.4.4.2 Alternate reference selection

In order to support different accuracy requirements, a voltage reference can be selected for each channel through REFSEL bit of the corresponding channel data register (for example, ICDR*n*). For some channels, this bit REFSEL is not software programmable and the selection configuration is fixed based on device-specific requirements.

40.4.5 Test channel connection with internal analog channel

The test channels are meant for monitoring various on-chip analog signals coming from temperature sensor, bandgap, voltage regulator and different voltage levels available on the chip. These analog signals can be interfaced to SARADC through test channels for testing purpose. Test channels are mapped from 96 to 127. Each test channel is controlled in the same way as normal internal channel.

SAR ADC Self Testing method: The test channel [127:124] is also mapped to various V_ref voltages (4 voltages) selection switches in the ADCBIAS block, the decoding of these channels to switch on and select a particular V_ref voltage in done in SoC level muxing logic. Refer to the ADC configuration for detailed mapping/control description of the Self Test feature.

It is also possible to perform test channel conversions with and without shorting the normal analog channel pin with the internal test voltage. The test channel to internal channel mapping is enabled through top level synthesis parameter testch_short_intch vector, if shorting of a particular test channel has to be disabled then parameter should be set to ‘0’ for corresponding test channel. This will result in removal of corresponding TCCAPR registers. For implemented TCCAPR registers to enable the short between test

channel and any internal analog channel, ESIC_TCHx bit of TCCAPR0-7 registers should be set. The mapping of test channel to any internal analog channel is determined by the ICSEL_TCHx bitfield of TCCAPR0-7 registers.

For analog test channel assignment, refer to the device configuration or ADC configuration section.

40.4.6 External channel mapping to internal analog channel

External channels are supposed to be used in conjunction with a given internal analog channel along with an 8:1 external mux outside the device. Each input of the external mux can be mapped to a unique channel number, thus allowing it to perform conversions like any other channel of the ADC. External channels are mapped from 128 to 255.

External channels are implemented in the multiples of 8. Each slice of eight channels can be associated to any physical internal analog channel mapped from 0 to 95. This external-to-internal channel mapping is determined by the ICSEL_ECx_x bitfield of ECMICR0-3 registers. For example, when external multiplexer is planned to be used on internal channel 5, and the external inputs need to be mapped to channels 128 to 135, then this channel number 5 must be written to the ICSEL_ECH128_135 bitfield of the ECMICR0 register. After reset, all external channels are mapped to internal analog channel 0.

40.4.7 Programmable analog watchdog

The analog watchdogs are used for determining whether the result of the conversion of a channel lies within a given guard area (as shown in the the following figure) specified by an upper and a lower threshold value named THRH and THRL respectively.

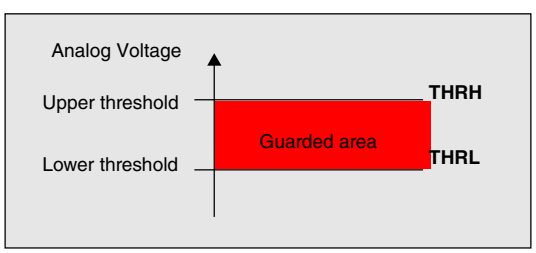

Figure 40-5. Analog watchdog guarded area

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value lies outside that guard area then corresponding threshold violation interrupts are generated. The comparison result is stored as WDGxH and WDGxL bits in the

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside that guard area, then corresponding threshold violation interrupts are generated. The comparison result is stored as WDGxH and WDGxL bits in the WTISR as explained in the following table. Depending on the MSKWDGxL and MSKWDGxH mask bits in the WTIMR, an interrupt is generated on threshold violation.

Table 40-1. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

The lower and higher threshold values for the analog watchdog are programmed using THRHLR0-15 registers. Analog watchdog functionality for each channel can be enabled independently from ICWENR0-2, TCWENR, ECWEN0-3 registers and can select the watchdog threshold registers (THRHLR0-15) to be used by programming ICWSELR0-11, TCWSELR0-3, ECWSELR0..15 registers. The threshold registers selected by WSEL_CHx field of watchdog threshold selection registers will provide the threshold values.

For example, if channel 30 is to be monitored with the threshold values in register THRHLR12, then WSEL_CH30 is programmed to select THRHLR12 register to provide threshold values. The enabling is done by setting the bit corresponding to channel 30 in ICWENR0 register.

If the converted value for a particular channel lies outside the range specified by threshold values, then corresponding bit is set in ICAWORR0-2, TCAWORR, ECAWORR0-3 registers. In this case, a set of threshold registers (THRHLR0-15) can be linked to several analog channels. The threshold values to be selected for a channel needs be programmed only once in ICWSELR, TCWSELR, ECWSELR registers.

There is an external trigger output port which provides a single clock cycle pulse to indicate WDG threshold crossover event on a particular WDG (up to 16 trigger outputs for upto 16 WDG instances).

Note

If the higher threshold for the analog watchdog is programmed lower than the lower threshold and the converted value is lesser than the lower threshold, then the WDGxL interrupt for the low threshold violation is set, else if the converted value is greater than the lower threshold (consequently also greater than the

higher threshold) then the interrupt WDGxH for high threshold violation is set. Thus the user should take care of avoiding that situation as it could lead to misinterpretation of the watchdog interrupts.

40.4.8 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel, by setting the respective masking bit in ICDSR0-2, TCDSR and ECDSR0-3 registers. The DMA masking registers must be programmed before starting any conversion. The DMA transfers can be enabled using the DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, then the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

40.4.9 Interrupts

The SARADC digital interface generates the following maskable interrupt signals:

- End Of Conversion interrupts
  - NEOC (end of normal conversion of each channel)
  - NECH (end of normal chain)
  - JEOC (end of injected conversion of each channel)
  - JECH (end of injected chain)

The EOC_CH[x] bit of interrupt pending registers (ICIPR0-2, TCIPR, ECIPR0-3) is set when channel x completes the conversion (normal or injection). This pending status is qualified when the corresponding mask bit IM_CH[x] is also set in the interrupt mask registers (ICIMR0-2, TCIMR, ECIMR0-3).

The NEOC interrupt is generated only if the following conditions are met

- ISR[NEOC] bit is set after the normal conversion completion for any channel x.
- IMR[MSKNEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The JEOC interrupt is generated only if the following conditions are met

- ISR[JEOC] bit is set after the injected conversion completion for any channel x.
- IMR[MSKJEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

It is recommended to clear the NEOC/JEOC/EOCTU bits of ISR and all the individual channel pending bits which are not masked while servicing the interrupt.

The ISR[NECH] bit is set when a normal channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

The ISR[JECH] bit is set when an injected channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

- WDGxL and WDGxH (Watchdog threshold) interrupt requests

The interrupts generated due to the analog watchdog are handled by registers WTISR and WTIMR in order to check and enable the interrupt requests to external interrupt controller module. The watchdog interrupt source sets two pending bits WDGxH and WDGxL for each channel being monitored in the WTISR. The interrupt request is generated if at least one of the following conditions are met

- WTISR[WDGxL] bit is set and the corresponding mask bit MSKWDGxL is also set in WTIMR for at least one channel.
- WTISR[WDGxH] bit is set and the corresponding mask bit MSKWDGxH is also set in WTIMR for at least one channel.

The ISR and WTISR contain the interrupt pending request status flags. In case the user wants to clear a particular interrupt event status, writing a '1' to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all other bits of the ISR must be maintained at '0'.)

The ADC module provides dedicated interrupt outputs for all interrupt sources. Also, all interrupt lines are OR-ed together to provide a single output to the external interrupt controller if a combined interrupt is required.

40.4.10 External decode signals selection and delay

The ADC provides three external decode signals used as select lines for 8:1 external mux. For each set of 8 external channels (for example [CH128:CH135], [CH136:CH143], and so on), the same 3-bit decode signals output will be used to select the inputs of external mux. These external mux select lines change in grey code sequence for each increment of channel selection. This ensures that only one line changes and avoids any current spikes or leakage if more than one line changes simultaneously.

In order to take into account the control switching time of the external analog mux, a Decode Signals Delay register is provided. Writing that register allows programming of the delay between the decoding signal selection and the actual start of conversion.

40.4.11 Power down mode

The SARADC analog block can be put in low current consumption mode by setting the PWDN bit in the MCR. This is the default mode after exiting from reset. This state must be exited before starting any operation by resetting the PWDN bit in the MCR. When in powerdown mode, no conversion can be started. Bit ADCSTATUS[0] in the MSR is set only when ADC enters Powerdown mode.

The power-down mode can be requested at any time by setting the PWDN bit in the MCR. If a conversion is ongoing, the SARADC cannot immediately enter the power-down mode. In fact, the SARADC enters power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN bit.

After the power down phase is completed the process ongoing before the power down phase must be restarted manually (by setting the appropriate START bit). Resetting PWDN bit and setting NSTART or JSTART bit during the same cycle is forbidden.

40.5 Memory map and register definition

This section provides memory map for the SARADC digital interface.

This section provides memory map for the SARADC digital interface.

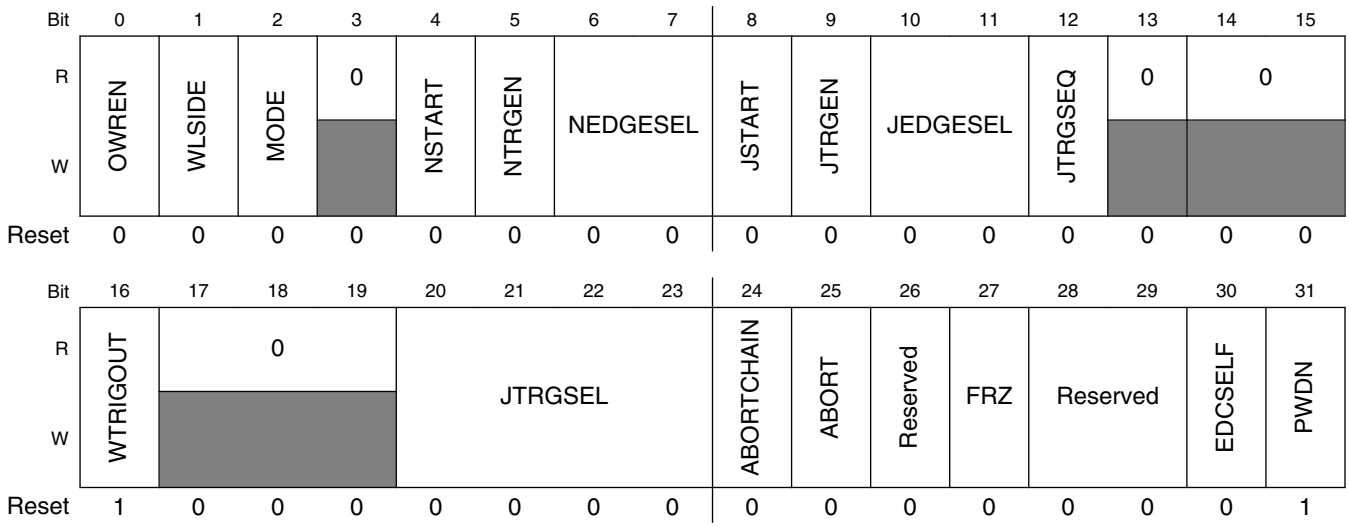
40.5.1 Main Configuration Register (SARADC_MCR)

Address: 1000h base + 0h offset = 1000h



SARADC_MCR field descriptions

Field	Description
0 OWREN	Overwrite enable This bit enables or disables the functionality to overwrite unread converted data in ICDR, TCDR, ECDR registers. 0 Prevents overwrite of unread converted data, new result is discarded 1 Enables converted data to be overwritten by a new conversion
1 WLSIDE	Write left/right-aligned 0 The conversion data in ICDR, TCDR, ECDR registers is written right-aligned. 1 Conversion data is left-aligned (from 15 to (15 - resolution + 1)).
2 MODE	One Shot/Scan 0 One Shot Mode-Configures the normal conversion of one chain. 1 Scan Mode-Configures continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 NSTART	Normal Start conversion Setting this bit starts the chain or scan conversion. Resetting this bit during scan mode causes the current chain conversion to finish, then stops the operation. 0 Causes the current chain conversion to finish and stops the operation 1 Starts the chain or scan conversion
5 NTRGEN	Normal trigger enable

Table continues on the next page...

SARADC_MCR field descriptions (continued)

Field	Description
	0 Normal trigger disabled to start a normal conversion. 1 Normal trigger enabled to start a normal conversion.
6–7 NEDGESEL	Normal trigger edge selection 00 Falling edge of normal trigger is selected. 01 Rising edge of normal trigger is selected. 10 Both rising and falling edges of normal trigger are selected. 11 Same as 10b.
8 JSTART	Injected Start conversion Setting this bit will start the configured injected analog channels to be converted by software. Resetting this bit has no effect, as the injected chain conversion cannot be interrupted. 0 Writing '0' has no effect. 1 Starts the injected chain conversion
9 JTRGEN	Injection trigger enable 0 Injection trigger disabled for channel injection (injected conversion cannot be started using an injection trigger) 1 Injection trigger enabled for channel injection
10–11 JEDGESEL	Injection trigger edge selection 00 Falling edge of injection trigger is selected. 01 Rising edge of injection trigger is selected. 10 Both rising and falling edges of injection trigger are selected. 11 Same as 10b.
12 JTRGSEQ	Injection trigger sequence enable 0 Injection trigger sequence mode is disabled. 1 Injection trigger sequence mode is enabled.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 WTRIGOUT	WDG Crossover External Trigger Output This control bit enables the Trigger on every threshold crossover event(crossing of Lower/Upper thresholds) of each WDG monitor to external trigger port(up to 16 ports for up to 16 WDGs). 0 Trigger Outputs enabled 1 Trigger Outputs disabled
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 JTRGSEL	Injection Trigger Input Selection This bitfield selects which trigger input to be selected to start injected conversion. 0000 Trigger input 0 is selected 0001 Trigger input 1 is selected 0010 Trigger input 2 is selected 0011 Trigger input 3 is selected

SARADC_MCR field descriptions (continued)

Field	Description
	0100 Trigger input 4 is selected 0101 Trigger input 5 is selected 0110 Trigger input 6 is selected 0111 Trigger input 7 is selected 1000 Trigger input 8 is selected 1001 Trigger input 9 is selected 1010 Trigger input 10 is selected 1011 Trigger input 11 is selected 1100 Trigger input 12 is selected 1101 Trigger input 13 is selected 1110 Trigger input 14 is selected 1111 Trigger input 15 is selected.
24 ABORTCHAIN	Abort Chain When this bit is set, the ongoing Chain Conversion is aborted. This bit is reset by hardware as soon as a new conversion is requested. 0 Conversion is not affected 1 Aborts the ongoing chain conversion
25 ABORT	Abort Conversion When this bit is set, the ongoing conversion is aborted and a new conversion is invoked. This bit is reset by hardware as soon as a new conversion is invoked. 0 Conversion is not affected 1 Aborts the ongoing conversion
26 Reserved	This field is reserved. Reserved
27 FRZ	Freeze This bit enables to stop the SARADC conversions at the end of current channel conversion when SoC enters debug mode. 0 Conversions are not stopped. 1 When the chip enters debug mode, further conversions by SARADC analog block will be stopped. The ongoing channel conversion will be completed and the converted data gets stored. When the SoC exits debug mode, SARADC resumes the job that was left before halting the conversions. Changing configuration registers during halted condition may cause a pending operation to fail when normal operation is resumed.
28–29 Reserved	This field is reserved. Reserved
30 EDCSELF	External Decode Channel Format Select This bit selects the format for 3-bit output port ipp_decode_extch used as select line for external decode channel 8:1 muxes. The last three bits of external channel number are passed as is (if value 0) or converted to gray code (if value 1) and passed to this port. 0 Binary format. 1 Gray Code format.
31 PWDN	Power-down enable

Table continues on the next page...

SARADC_MCR field descriptions (continued)

Field	Description
	When this bit is set, the analog module is requested to enter Power Down mode. When SARADC status is PWDN, resetting this bit starts SARADC transition to IDLE mode. 0 SARADC is in normal mode 1 SARADC has been requested to power down

40.5.2 Main Status Register (SARADC_MSR)

Address: 1000h base + 4h offset = 1004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved				NSTART	Reserved			JSTART	Reserved				JABORTCHAIN	Reserved	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CHADDR								Reserved					ADCSTATUS		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

SARADC_MSR field descriptions

Field	Description
0–3 Reserved	This field is reserved. Reserved Write of any value has no effect; read value is always 0.
4 NSTART	This status bit is used to signal that a normal conversion is ongoing. 0 Normal conversion is not taking place. 1 Normal conversion is ongoing or the normal conversion is pending due to injected conversion or CTU triggered injected conversion.
5–7 Reserved	This field is reserved. Reserved Write of any value has no effect; read value is always 0.
8 JSTART	This status bit is used to signal that a injected conversion is ongoing. 0 Injected conversion is not taking place. 1 Injected conversion is ongoing.
9–12 Reserved	This field is reserved. Reserved Write of any value has no effect; read value is always 0.
13 JABORTCHAIN	This status bit is used to signal that an Injected conversion chain has been aborted. This bit is reset when a new conversion starts. 0 Last injected conversion chain has not been aborted. 1 Last injected conversion chain has been aborted.
14 Reserved	This field is reserved. Reserved Write of any value has no effect; read value is always 0.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 CHADDR	Channel under measure address (CHADDR[7:0]) This status bit is used to signal which channel is under measure.
24–28 Reserved	This field is reserved. Reserved
29–31 ADCSTATUS	ADCSTATUS[2:0]. The value of this field depends on ADC status. While requesting an external channel conversion, the SARADC digital interface needs to wait for a fixed time determined by DSD bitfield of DSDR before proceeding to actual sampling phase. This is known as wait state. 000 IDLE 001 Power-down 010 Wait state 011 - 100 Sample 101 - 110 Conversion 111 -

40.5.3 Interrupt Status Register (SARADC_ISR)

Address: 1000h base + 10h offset = 1010h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0											0	JEOC	JECH	NEOC	NECH
W													w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SARADC_ISR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 JEOC	End of injected channel conversion interrupt flag This bit indicates the end of conversion for an injected channel. 0 End of conversion of injected channel has not occurred since the last time the flag is cleared. 1 End of conversion of injected channel has occurred or the flag has not been cleared since the last end of conversion occurrence.
29 JECH	End of injected chain conversion interrupt flag This bit indicates the end of conversion for an injected chain. 0 End of conversion of injected chain has not occurred since the last time the flag is cleared. 1 End of conversion of injected chain has occurred or the flag has not been cleared since the last end of conversion occurrence.
30 NEOC	End of normal channel conversion interrupt flag This bit indicates the end of conversion for a normal channel. 0 End of conversion of normal channel has not occurred since the last time the flag is cleared. 1 End of conversion of normal channel has occurred or the flag has not been cleared since the last end of conversion occurrence.

Table continues on the next page...

SARADC_ISR field descriptions (continued)

Field	Description
31 NECH	End of normal chain conversion interrupt flag This bit indicates the end of conversion for an normal chain. 0 End of conversion of normal chain has not occurred since the last time the flag is cleared. 1 End of conversion of normal chain has occurred or the flag has not been cleared since the last end of conversion occurrence.

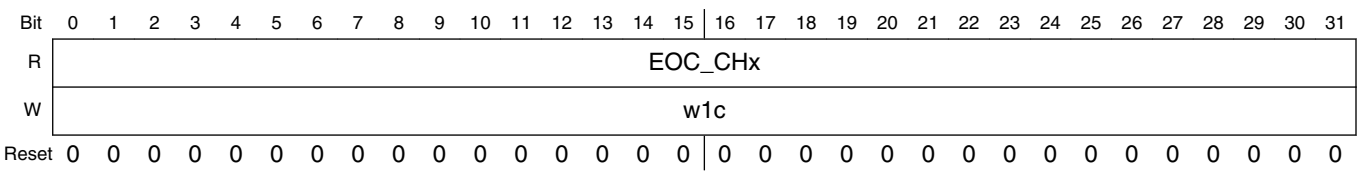
40.5.4 Internal channel Interrupt Pending Register (SARADC_ICIPR*n*)

The interrupt channel register to channel association is described below.

Table 40-2. ICIPR0-2 Registers to channel association

Register	Register Bits 0:31
ICIPR0	EOC_CH[31:0]
ICIPR1	EOC_CH[63:32]
ICIPR2	EOC_CH[95:64]

Address: 1000h base + 14h offset + (4d × i), where i=0d to 2d



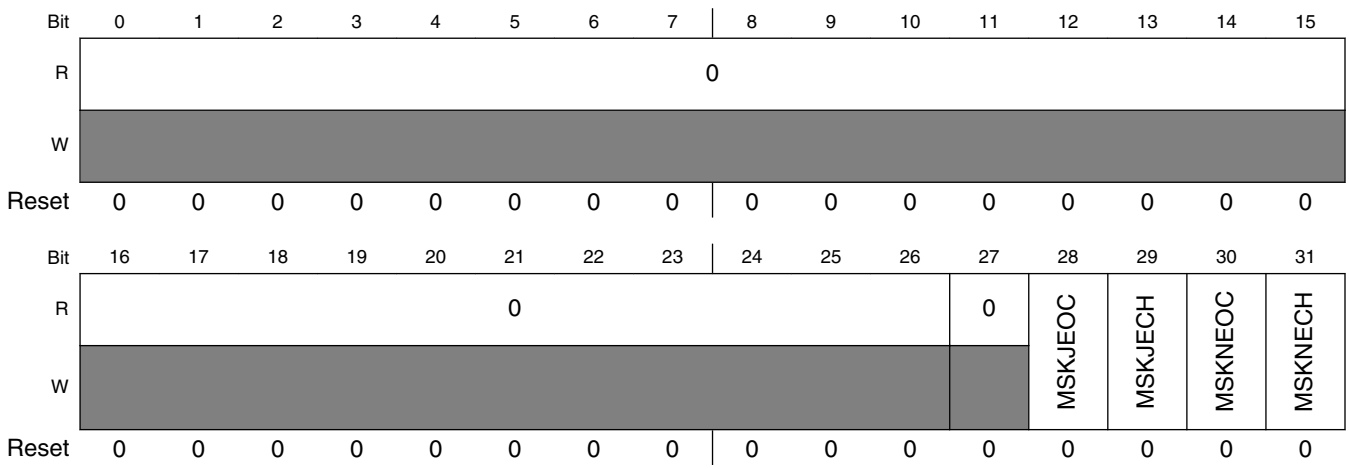
SARADC_ICIPR*n* field descriptions

Field	Description
0–31 EOC_CHx	End of conversion interrupt pending bit for channel x 0 End of conversion for CH[x] has not occurred. 1 End of conversion for CH[x] has occurred.

40.5.5 Interrupt Mask Register (SARADC_IMR)

The description of the Interrupt Mask Register is given below.

Address: 1000h base + 20h offset = 1020h



SARADC_IMR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 MSKJEOC	Mask bit for JEOC 0 JEOC interrupt is disabled. 1 JEOC interrupt is enabled.
29 MSKJECH	Mask bit for JECH 0 JECH interrupt is disabled. 1 JECH interrupt is enabled.
30 MSKNEOC	Mask bit for NEOC 0 NEOC interrupt is disabled. 1 NEOC interrupt is enabled.
31 MSKNECH	Mask bit for NECH 0 NECH interrupt is disabled. 1 NECH interrupt is enabled.

40.5.6 Internal Channel Interrupt Mask Register (SARADC_ICIMR*n*)

The interrupt mask register to channel association is described below.

Table 40-3. Interrupt Mask Registers to Channel Association

Register	Register Bits 0:31
ICIMR0	IM_CH[31:0]
ICIMR1	IM_CH[63:32]
ICIMR2	IM_CH[95:64]

Address: 1000h base + 24h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SARADC_ICIMR*n* field descriptions

Field	Description
0–31 IM_CHx	IM_CH[x]: Interrupt mask bit for channel x 0 Interrupt for CH[x] is disabled. 1 Interrupt for CH[x] is enabled.

40.5.7 Watchdog Threshold Interrupt Status Register (SARADC_WTISR)

This register gives the interrupt status information for the 16 possible upper/lower threshold limits which can be selected for each channel.

NOTE

This register is implemented only on ADCs that have analog watchdogs.

Address: 1000h base + 30h offset = 1030h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SARADC_WTISR field descriptions

Field	Description
0 WDG15H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
1 WDG15L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
2 WDG14H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
3 WDG14L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
4 WDG13H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.

Table continues on the next page...

SARADC_WTISR field descriptions (continued)

Field	Description
5 WDG13L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
6 WDG12H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
7 WDG12L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
8 WDG11H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
9 WDG11L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
10 WDG10H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
11 WDG10L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
12 WDG9H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
13 WDG9L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
14 WDG8H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.

Table continues on the next page...

SARADC_WTISR field descriptions (continued)

Field	Description
15 WDG8L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
16 WDG7H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
17 WDG7L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
18 WDG6H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
19 WDG6L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
20 WDG5H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
21 WDG5L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
22 WDG4H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
23 WDG4L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
24 WDG3H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.

Table continues on the next page...

SARADC_WTISR field descriptions (continued)

Field	Description
25 WDG3L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
26 WDG2H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
27 WDG2L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
28 WDG1H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
29 WDG1L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.
30 WDG0H	This corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Converted data is not higher than the programmed higher threshold. 1 Converted data is higher than the programmed higher threshold.
31 WDG0L	This corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Converted data is not lower than the programmed lower threshold. 1 Converted data is lower than the programmed lower threshold.

40.5.8 Watchdog Threshold Interrupt Mask Register (SARADC_WTIMR)

This register gives the interrupt mask information for the 16 possible upper/lower threshold limits which can be selected for each channel.

NOTE

This register is not implemented only on ADCs that have analog watchdogs.

Address: 1000h base + 34h offset = 1034h

29 MSKWDG1L	This corresponds to the mask bit for the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Interrupt for WDG1L is disabled. 1 Interrupt for WDG1L is enabled.
30 MSKWDG0H	This corresponds to the mask bit for the interrupt generated on the converted value being higher than the programmed higher threshold. 0 Interrupt for WDG0H is disabled. 1 Interrupt for WDG0H is enabled.
31 MSKWDG0L	This corresponds to the mask bit for the interrupt generated on the converted value being lower than the programmed lower threshold. 0 Interrupt for WDG0L is disabled. 1 Interrupt for WDG0L is enabled.

40.5.9 DMA Enable Register (SARADC_DMAE)

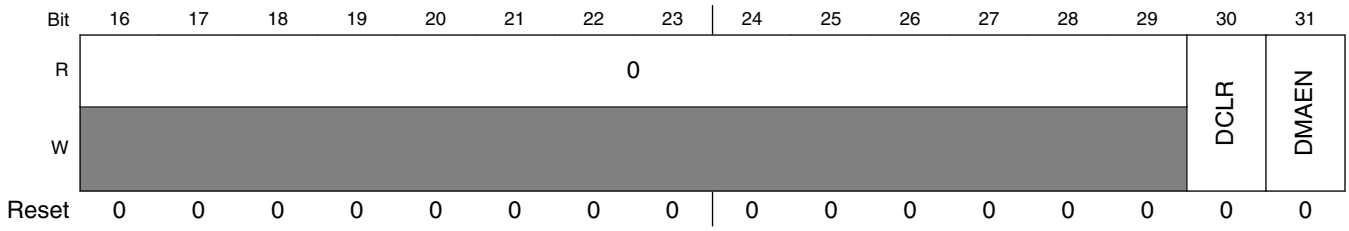
The DMA Enable (DMAE) register sets up the DMA for use with the SARADC.

NOTE

This register is implemented only for ADCs with DMA.

Address: 1000h base + 40h offset = 1040h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



SARADC_DMAE field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DCLR	DMA clear sequence enable 0 DMA request cleared by Acknowledge from DMA controller 1 DMA request cleared on read of data registers
31 DMAEN	DMA global enable 0 DMA feature disabled 1 DMA feature enabled

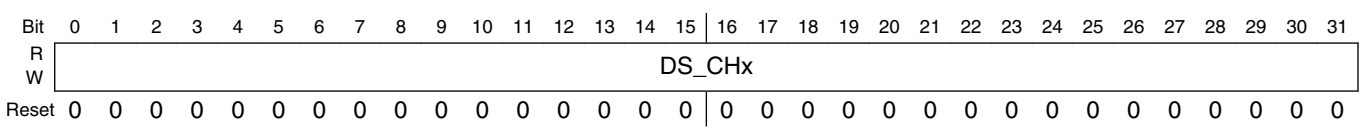
40.5.10 Internal Channel DMA Select Register (SARADC_ICDSR*n*)

The DMA select registers to channel association is described below.

Table 40-4. Internal Channel DMA Select Registers to Channel Association

Register	Register Bits 0:31
ICDSR0	DS_CH[31:0]
ICDSR1	DS_CH[63:32]
ICDSR2	DS_CH[95:64]

Address: 1000h base + 44h offset + (4d × i), where i=0d to 2d



SARADC_ICDSR*n* field descriptions

Field	Description
0–31 DS_CHx	DMA select for channel x 0 CH[x] is disabled to transfer data in DMA mode. 1 CH[x] is enabled to transfer data in DMA mode.

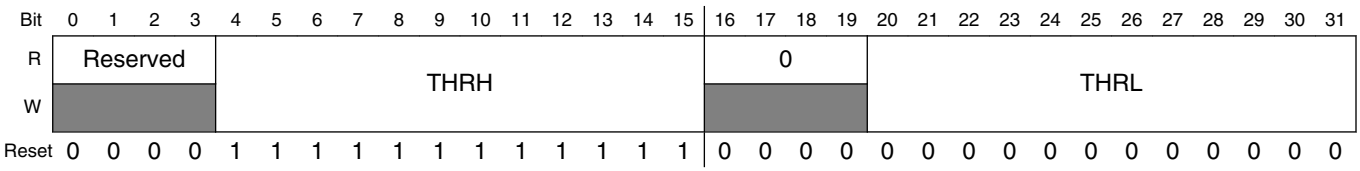
40.5.11 Watchdog Threshold Register (SARADC_WTHRHLR*n*)

NOTE

The number of WTHRHLR registers corresponds to the number of analog watchdogs implemented in the ADC module.

The length of the threshold field depends on the generic resolution.

Address: 1000h base + 60h offset + (4d × i), where i=0d to 3d

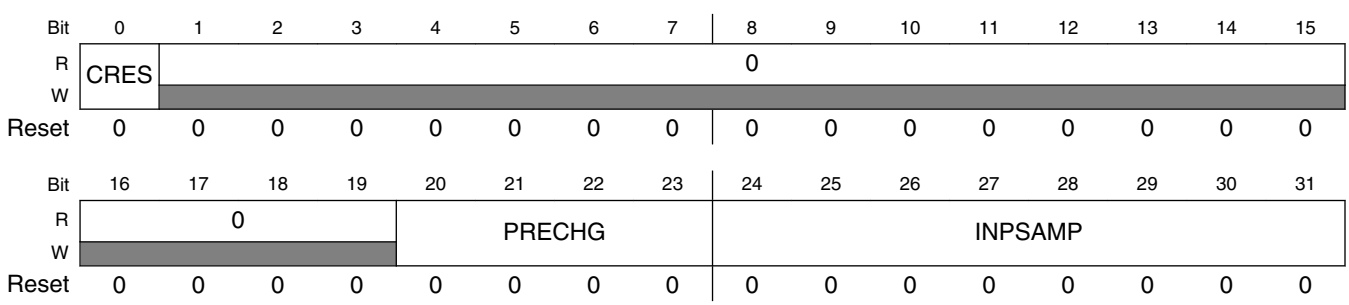


SARADC_WTHRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. Reserved Write of any value has no effect; read value is always 0.
4–15 THRH	High threshold value for channel x
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x

40.5.12 Conversion Timing Register (SARADC_CTR*n*)

Address: 1000h base + 94h offset + (4d × i), where i=0d to 3d



SARADC_CTR*n* field descriptions

Field	Description
0 CRES	Conversion Resolution select This bit selects the conversion resolution for the conversion.

Table continues on the next page...

SARADC_CTR*n* field descriptions (continued)

Field	Description
	0 12-bit resolution 1 10-bit resolution
1–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 PRECHG	Precharging phase duration This bitfield defines the precharging phase duration to be applied when this phase is enabled by PCE bit of channel data register. This duration is calculated as (PRECHG X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for precharging phase.
24–31 INPSAMP	Sampling phase duration This bitfield defines the sampling phase duration to be applied. This duration is calculated as (INPSAMP X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for sampling phase.

40.5.13 Internal Channel Normal Conversion Mask Register (SARADC_ICNCMR*n*)

The normal conversion mask registers to channel association is described below.

Table 40-5. Internal Channel Normal Conversion Mask Registers to Channel Association

Register	Register Bits 0:31
ICNCMR0	NCE_CH[31:0]
ICNCMR1	NCE_CH[63:32]
ICNCMR2	NCE_CH[95:64]

Address: 1000h base + A4h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NCE_CHx																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SARADC_ICNCMR*n* field descriptions

Field	Description
0–31 NCE_CHx	Normal conversion enable for channel x 0 Normal conversion is disabled for CH[x]. 1 Normal conversion is enabled for CH[x].

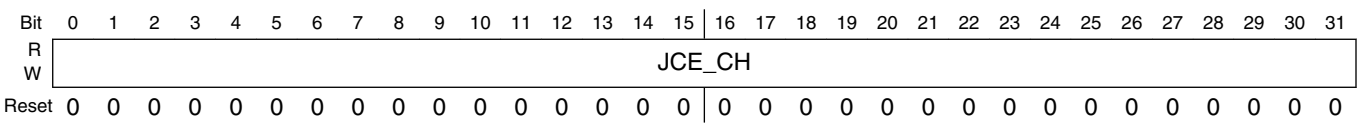
40.5.14 Internal Channel Injected Conversion Mask Register (SARADC_ICJCMR*n*)

The injected conversion mask registers to channel association is described below.

Table 40-6. Internal Channel Normal Conversion Mask Registers to Channel Association

Register	Register Bits 0:31
ICJCMR0	JCE_CH[31:0]
ICJCMR1	JCE_CH[63:32]
ICJCMR2	JCE_CH[95:64]

Address: 1000h base + B4h offset + (4d × i), where i=0d to 2d

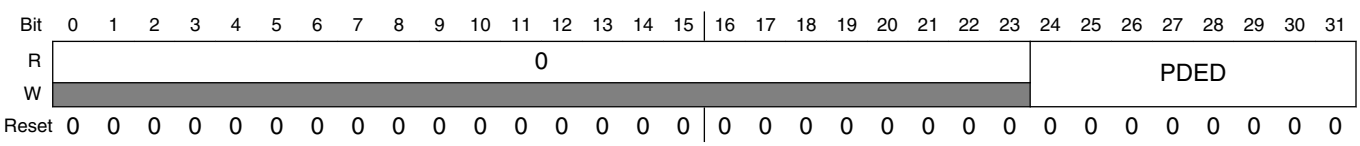


SARADC_ICJCMR*n* field descriptions

Field	Description
0–31 JCE_CH	JCE_CH[x]: Injected conversion enable for channel x 0 Injected conversion is disabled for CH[x]. 1 Injected conversion is enabled for CH[x].

40.5.15 Power Down Exit Delay Register (SARADC_PDEDR)

Address: 1000h base + C8h offset = 10C8h



SARADC_PDEDR field descriptions

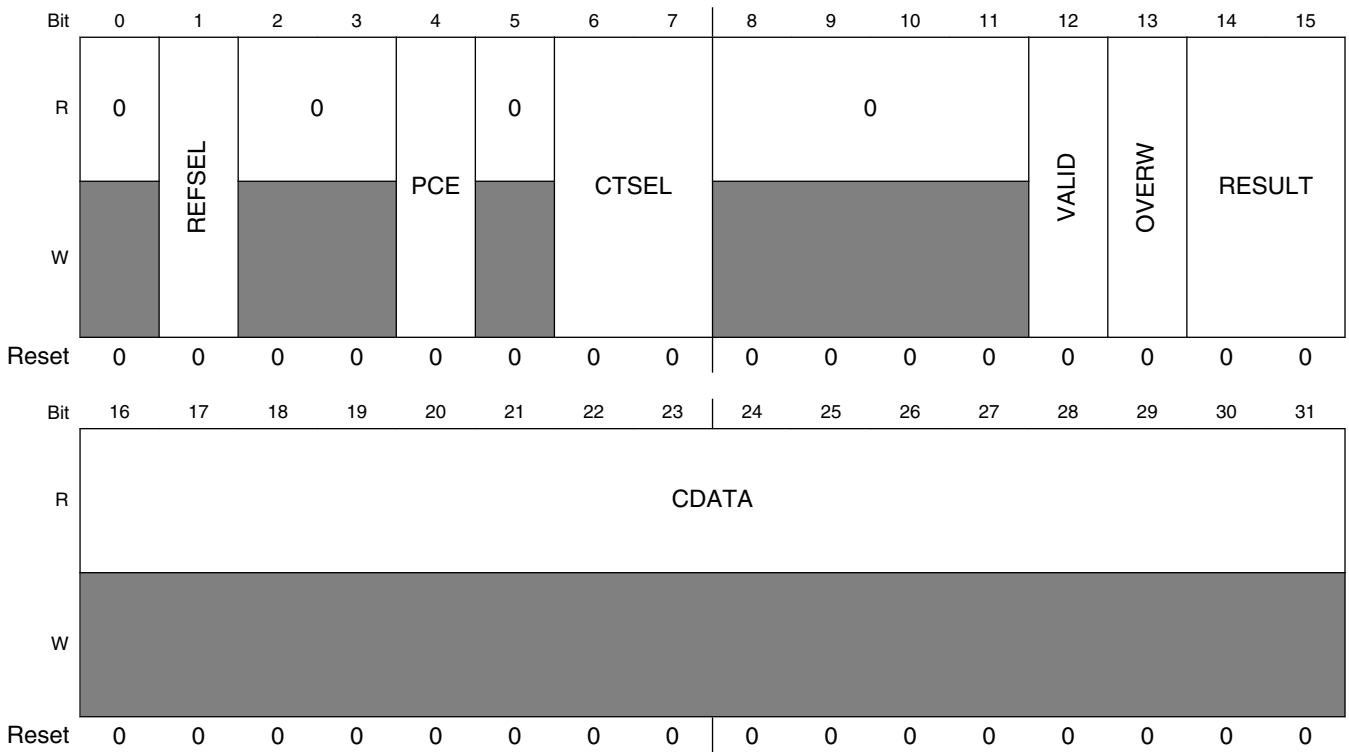
Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PDED	Power down exit delay duration. Defines the delay between the power-down bit reset and the starting of conversion. The power-down delay is calculated as [PDED x 1/(SARADC clock frequency)].

40.5.16 Internal Channel Data Register (SARADC_ICDR*n*)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid and some control information to select the required reference voltage, timing parameter selection for each channel.

This register should be accessed 32-bit R/W.

Address: 1000h base + 100h offset + (4d × i), where i=0d to 95d



SARADC_ICDR*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 REFSEL	Reference selection This bit can be used to select the reference voltage for channel conversion. 0 Selects the default reference (e.g., : 5 V) 1 Selects the alternate reference (e.g., : 2 V)
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion.

Table continues on the next page...

SARADC_ICDR*n* field descriptions (continued)

Field	Description
	0 Precharge phase is disabled 1 Precharge phase is enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: • When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. • When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14–15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–31 CDATA	Channel converted data **Note:** It is important to note that the content of the CDATA field is affected by the setting of the SARADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When SARADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When SARADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

40.5.17 Internal Channel Watchdog Selection Register (SARADC_ICWSELR*n*)

These registers contain WSEL_CHx[3:0] bitfields to select the threshold register which provides the values to be used for upper and lower bounds for channel x.

The Watchdog select registers to channel association is described below.

Table 40-7. Internal Channel Watchdog Enable Registers to Channel Association

Register	Register Bits 0:31
ICWSELRx (x = 0 to 11)	WSEL_CH[(8*x)+7] .. WSEL_CH[8*x]

Address: 1000h base + 2B0h offset + (4d × i), where i=0d to 11d

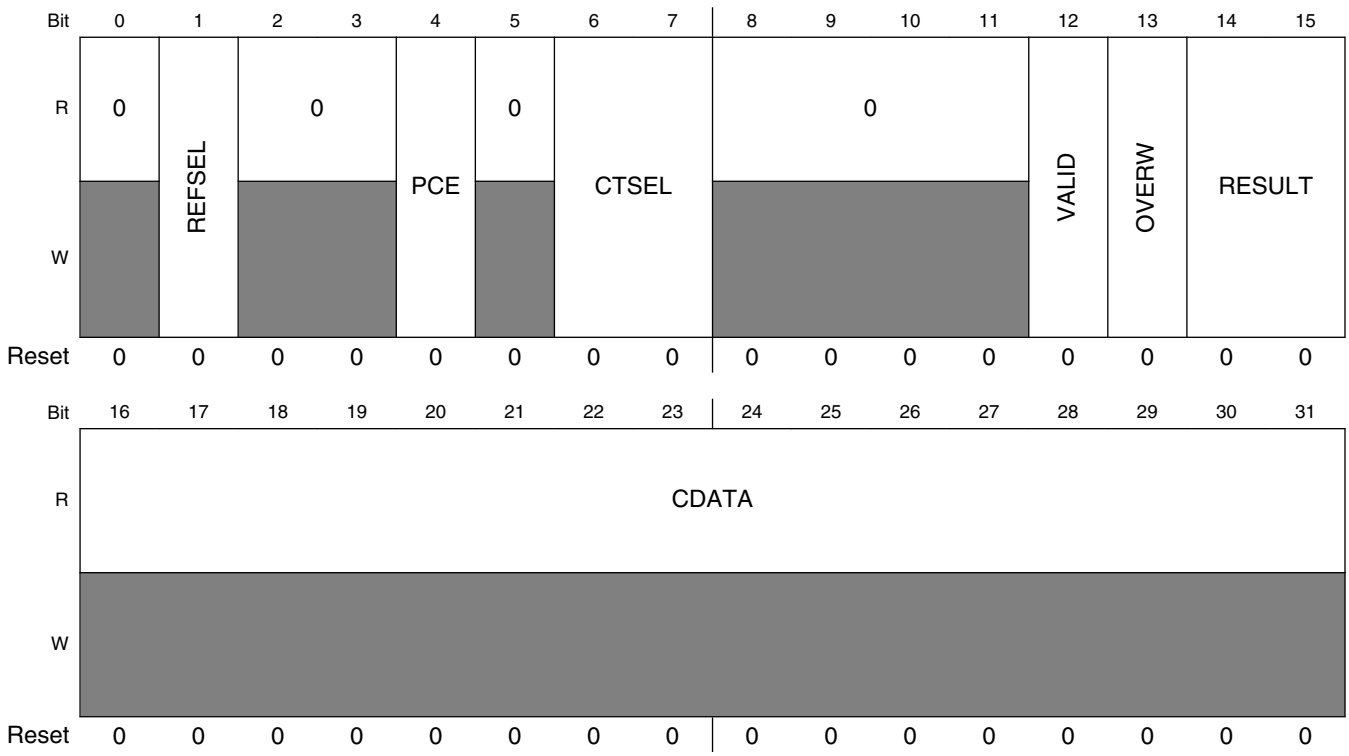
17–23 ICSEL_TCH1	Internal channel selection for short with test channel 1
24 ESIC_TCH0	Enable short with internal channel for test channel 0 0 Test channel x cannot be shorted with internal channel 1 Test channel x can be shorted with internal channel
25–31 ICSEL_TCH0	Internal channel selection for short with test channel 0

40.5.29 Test Channel Data Register (SARADC_TCDR*n*)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid and some control information to select the required reference voltage, timing parameter selection for each channel.

Address: 1000h base + 450h offset + (4d × i), where i=0d to 31d



SARADC_TCDR*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 REFSEL	Reference selection This bit can be used to select the reference voltage for channel conversion. 0 Selects the default reference (for e.g., : 5V) 1 Selects the alternate reference (for e.g., : 2V)
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 PCE	Precharge Enable This bit enables the precharging phase during channel conversion.

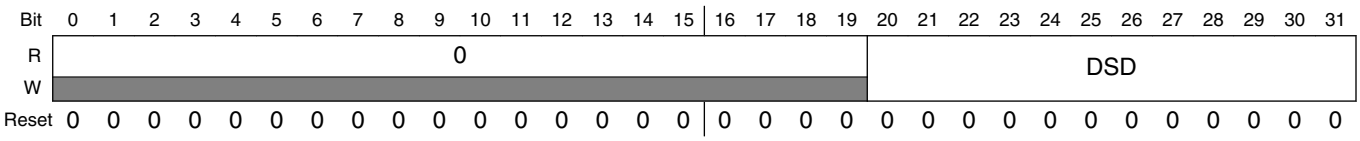
Table continues on the next page...

SARADC_TCDR*n* field descriptions (continued)

Field	Description
	0 Precharge phase is disabled 1 Precharge phase is enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: • When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. • When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14–15 RESULT	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–31 CDATA	Channel converted data **Note:** It is important to note that the content of the CDATA field is affected by the setting of the SARADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When SARADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When SARADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

40.5.30 External Channel Decode Signals Delay Register (SARADC_ECDSDR)

Address: 1000h base + 500h offset = 1500h



SARADC_ECDSDR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DSD	Decode signals delay This bitfield defines the delay between the external decode signals and the start of the sampling phase. It is used to take into account of the settling time required for the external mux. The decode signal delay is calculated as (DSD X 1/Frequency of SARADC clock).

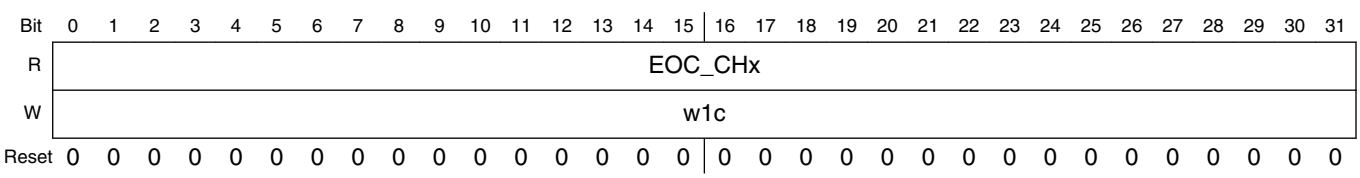
40.5.31 External Channel Interrupt Pending Register (SARADC_ECIPR*n*)

The interrupt channel register to channel association is described below.

Table 40-19. ECIPR0-3 Registers to Channel Association

Register	Register Bits 0:31
ECIPR0	EOC_CH[159:128]
ECIPR1	EOC_CH[191:160]
ECIPR2	EOC_CH[223:192]
ECIPR3	EOC_CH[255:224]

Address: 1000h base + 510h offset + (4d × i), where i=0d to 3d



SARADC_ECIPR*n* field descriptions

Field	Description
0–31 EOC_CHx	End of conversion interrupt pending bit for channel x

SARADC_ECIPR*n* field descriptions (continued)

Field	Description
	0 End of conversion for CH[x] has not occurred. 1 End of conversion for CH[x] has occurred.

40.5.32 External Channel Interrupt Mask Register (SARADC_ECIMR*n*)

The interrupt mask register to channel association is described below.

Table 40-20. External Channel Interrupt Mask Registers to Channel Association

Register	Register Bits 0:31

40.6 Start conversion pulse delay

The following table lists delays between various trigger point (initiation request for conversion) and actual issue of start pulse (adc_start) to the ADC hardmacrocell. Here each possible trigger source is described with the number of clock cycles required for different operations until trigger of adc_start.

Table 40-28. Start of conversion pulse delay

Trigger source	Register control (ipg_clk_s)	Inter domain synchronization (ipg_clk)	ADC state machine (ipg_clk_adc)	Inter domain synchronization (ipg_clk_adc)	Comments
Normal conversion triggered by	1	—	2	1-2[1]	Cumulative Delay from wen(byte_en)

Table continues on the next page...

Table 40-28. Start of conversion pulse delay (continued)

Trigger source	Register control (ipg_clk_s)	Inter domain synchronization (ipg_clk)	ADC state machine (ipg_clk_adc)	Inter domain synchronization (ipg_clk_adc)	Comments
software (setting of NSTART of MCR)					assertion to actual issue of adc_start pulse = 3-4 ipg_clk_adc cycles + 1 ipg_clk cycle.
Normal conversion triggered by external trigger (HW trigger through ipp_ind_start_trg port)	—	—	2	1–2[1]	Cumulative delay from the triggering edge (rising or falling) to the actual issue of adc_start pulse = 3–4 ipg_clk_adc cycles.
Normal conversion within a chain	—	—	0 (from EOC of previous conversion)	—	—
1 (from last_evaluation_cyc of previous conversion)	—	Delay from the EOC of last conversion, The start of next conversion is issued exactly on the same cycle when EOC is expected for previous conversion, start pulse in issued looking at last_evalution_cyc_i which is received one cycle prior to EOC.	—	—	—
Injected conversion triggered by software (setting of JSTART bit of MCR)	1	—	3	1–2[1]	Cumulative delay from wen(byte_en) assertion. Here delay for first start pulse of the injected chain execution when FSM was originally in IDLE state is considered = 4–5 ipg_clk_adc cycles + 1 ipg_clk cycle.
Injected conversion triggered by external Trigger (HW trigger through ipp_ind_injection_trg port)	—	—	3	1–2[1]	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 ipg_clk_adc cycles.

Table continues on the next page...

Table 40-28. Start of conversion pulse delay (continued)

Trigger source	Register control (ipg_clk_s)	Inter domain synchronization (ipg_clk)	ADC state machine (ipg_clk_adc)	Inter domain synchronization (ipg_clk_adc)	Comments
Injected conversion within a chain (delay between consecutive conversion of injected chain)	—	—	0 (from EOC of previous conversion)	—	—
1 (from last_evaluation_cyc of previous conversion)	—	Delay from EOC of last injected channel and adc_start pulse of next injected channel.	—	—	—
The start of next conversion is issued exactly on the same cycle when EOC is expected for previous conversion, start pulse in issued looking at last_evalution_cyc_i which is received one cycle prior to EOC					
Injected conversion over normal conversion (software injected conversion chain)	1	1–2[1]	3–5[2]	1–2[1]	Cumulative delay from wen(byte_en) assertion to actual trigger of first injected channel, when the FSM was in conversion cycle of previous normal conversion = 4–7 ipg_clk_adc cycles + 2-3 ipg_clk cycles.
Injection of conversion over normal conversion in JTRGSEQ mode	—	—	3	1–2[1]	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 ipg_clk_adc cycles.
Abort of a Normal/ Injected Channel conversion during Normal Chain/ Injected Chain execution (setting	1	1–2[1]	3–5[2]	1–2[1]	Delay from writing of ABORT bit (wen/ byte_en assertion) to actual issue of adc_start pulse for the next channel

Table 40-28. Start of conversion pulse delay

Trigger source	Register control (ipg_clk_s)	Inter domain synchronization (ipg_clk)	ADC state machine (ipg_clk_adc)	Inter domain synchronization (ipg_clk_adc)	Comments
of MCR[ABORT] bit)					conversion = 4–7 ipg_clk_adc cycles + 2–3 ipg_clk cycles.

1. The variation is due to inter domain synchronization.
2. The delay values are calculated over a range of system and ADC clock frequencies. With ipg_clk(max) = 50 MHz to ipg_clk(min) = 40 MHz and ipg_clk_adc(max) = 16 MHz to ipg_clk_adc(min) = 14 MHz. L.H.S value corresponds to max frequencies and RHS corresponds to min frequencies.

Chapter 41
Temperature Sensor

41.1 Introduction

The device includes an on-chip temperature sensor that monitors device temperature and delivers one analog output signal and three digital output signals. The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device. The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage, sampled bandgap reference voltage, which comes from another module, and calibration parameter values stored in internal flash memory. The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above one of two high temperature thresholds. These signals notify the device to take action to appropriately adjust the device temperature in response to an out of specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

41.2 Functional Description

The temperature sensor generates one analog output voltage, $V_{TSENS}(T)$, which is proportional to the absolute current junction temperature of the device, and three digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or one of two pre-set high temperature thresholds.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

41.2.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 microsecond for the digital outputs to be updated to reflect the new trimming condition.

When the temperature threshold detection feature is enabled , the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold (-40°C).
- The high temperature digital output signals if the junction temperature rises above the first high temperature threshold (150°C).

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to –40°C), and the high temperature thresholds are trimmed such that one of them matches the hot insertion test temperature (nominally equal to 150°C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on Figure 41-1.

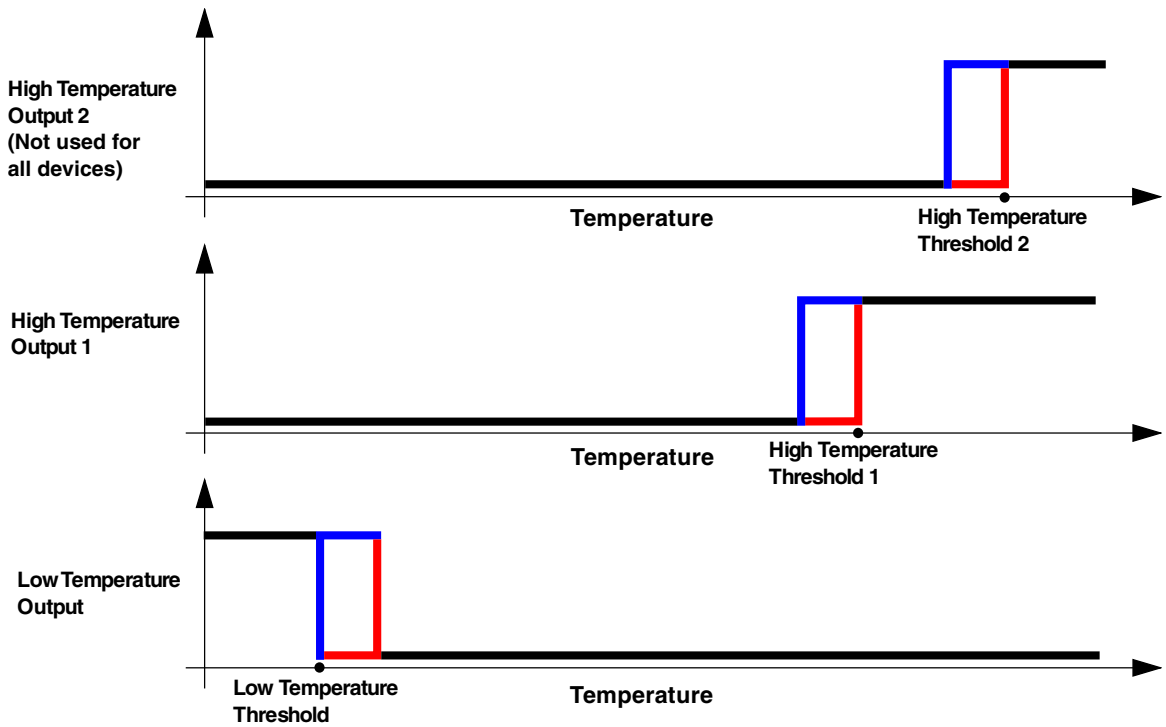

Figure 41-1. Digital output behavior with temperature

41.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

41.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in Figure 41-2 is used to calculate internal device junction temperature.

$$T = (232 + TSCA \times 2^{-6}) \times \frac{V_{TSENS\_CODE}(T)}{V_{BG\_CODE}(T)} - (273 + TSCB \times 2^{-4})\ [^{o}C]$$

Where:

$$TSCA = \left(\frac{T_{HIGH} - T_{LOW}}{V_{TSENS\_CODE}(T_{HIGH}) - V_{TSENS\_CODE}(T_{LOW})} \times V_{BG\_CODE}(T_{FINAL}) - 232 \right) \times 2^{6}$$

$$TSCB = \left(\frac{T_{HIGH} - T_{LOW}}{V_{TSENS\_CODE}(T_{HIGH}) - V_{TSENS\_CODE}(T_{LOW})} \times V_{TSENS\_CODE}(T_{LOW}) - T_{LOW} - 273 \right) \times 2^{4}$$

$$V_{TSENS\_CODE}(T_{LOW}) = \frac{V_{TSENS}(T_{LOW})}{V_{ref0}} \times 2^{12}$$

$$V_{TSENS\_CODE}(T_{HIGH}) = \frac{V_{TSENS}(T_{HIGH})}{V_{ref0}} \times 2^{12}$$

$$V_{BG\_CODE}(T_{FINAL}) = \frac{V_{BG}(T_{FINAL})}{V_{ref0}} \times 2^{12}$$

$$V_{BG\_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

$$V_{TSENS\_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12}$$

Notes:

- TSCA and TSCB are 16-bit signed integer constants stored in flash memory during factory test and calibration
- $V_{TSENS}(T)$ is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$ is the bandgap reference voltage sampled by the ADC at temperature T
- V_{ref} is the ADC reference voltage in normal usage of the device
- V_{ref0} is the ADC reference voltage during factory calibration
- T_{LOW} is the low temperature factory calibration temperature
- T_{HIGH} is the hot temperature factory calibration temperature
- T_{FINAL} is the final insertion factory calibration temperature

Figure 41-2. Temperature formula

Parameters TSCA and TSCB are 16-bit signed integer constants stored during factory test and calibration that need to be used in the temperature formula to calculate device junction temperature. The values for TSCA and TSCB translate into positive or negative shifts of the linear relation coefficients that compensate for manufacturing process variation. Figure 41-2 shows how parameters TSCA and TSCB are calculated in terms of the actual variables measured during factory calibration.

41.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate $V_{BG\_CODE}(T)$ according to the formula shown in Figure 41-2.
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate $V_{TSENS\_CODE}(T)$ according to the formula shown in Figure 41-2
3. Retrieve parameters TSCA and TSCB from flash memory.
4. Calculate T according to the formula shown in Figure 41-2.

Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

Chapter 42
System Timer Module (STM)

42.1 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

42.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

42.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

42.1.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

42.2 External signal description

The STM does not have any external interface signals.

42.3 Memory map and registers

The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

STM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STM Control Register (STM_CR)	32	R/W	0000_0000h	42.3.1/1675
4	STM Count Register (STM_CNT)	32	R/W	0000_0000h	42.3.2/1676
10	STM Channel Control Register (STM_CCR0)	32	R/W	0000_0000h	42.3.3/1676

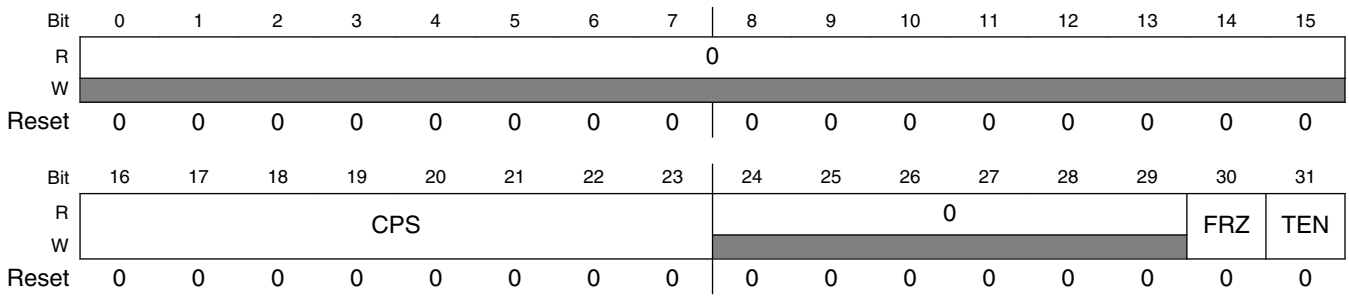
18	STM Channel Compare Register (STM_CMP0)	32	R/W	0000_0000h	42.3.5/1677
20	STM Channel Control Register (STM_CCR1)	32	R/W	0000_0000h	42.3.3/1676
24	STM Channel Interrupt Register (STM_CIR1)	32	w1c	0000_0000h	42.3.4/1677
28	STM Channel Compare Register (STM_CMP1)	32	R/W	0000_0000h	42.3.5/1677
30	STM Channel Control Register (STM_CCR2)	32	R/W	0000_0000h	42.3.3/1676
34	STM Channel Interrupt Register (STM_CIR2)	32	w1c	0000_0000h	42.3.4/1677
38	STM Channel Compare Register (STM_CMP2)	32	R/W	0000_0000h	42.3.5/1677
40	STM Channel Control Register (STM_CCR3)	32	R/W	0000_0000h	42.3.3/1676
44	STM Channel Interrupt Register (STM_CIR3)	32	w1c	0000_0000h	42.3.4/1677
48	STM Channel Compare Register (STM_CMP3)	32	R/W	0000_0000h	42.3.5/1677

42.3.1 STM Control Register (STM_CR)

The STM Control Register includes the prescale value, freeze control and timer enable bits.

Address: 0h base + 0h offset = 0h



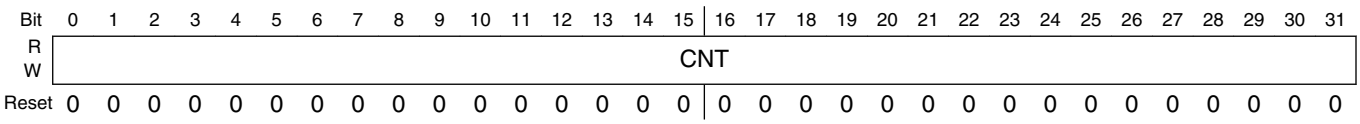
STM_CR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 CPS	Counter Prescaler. Selects the clock divide value for the prescaler (1 - 256). 0x00 Divide system clock by 1 0x01 Divide system clock by 2 ---------- 0xFF Divide system clock by 256
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FRZ	Freeze. Allows the timer counter to be stopped when the device enters debug mode. **NOTE:** When the MCU enters debug mode, the STM is notified and uses the FRZ bit to determine counter mode. 0 STM counter continues to run in debug mode. 1 STM counter is stopped in debug mode.
31 TEN	Timer counter Enabled. 0 Counter is disabled. 1 Counter is enabled.

42.3.2 STM Count Register (STM_CNT)

The STM Count Register holds the timer count value.

Address: 0h base + 4h offset = 4h



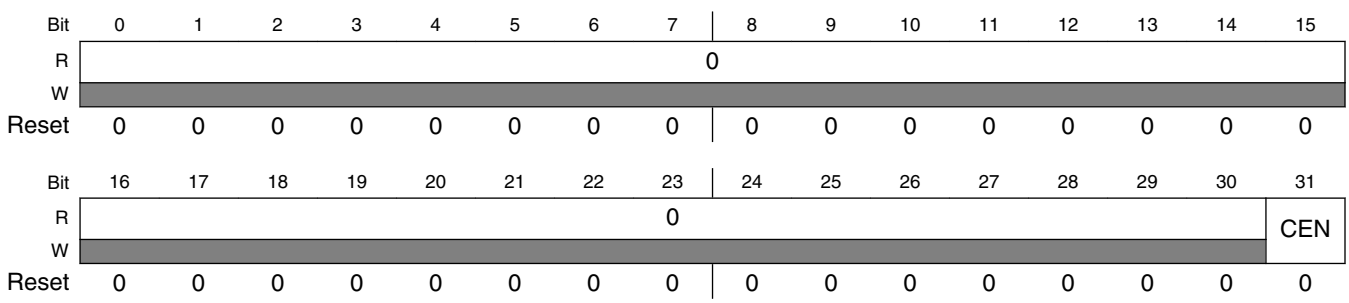
STM_CNT field descriptions

Field	Description
0–31 CNT	Timer count value used as the time base for all channels. When enabled, the counter increments at the rate of the system clock divided by the prescale value.

42.3.3 STM Channel Control Register (STM_CCR*n*)

The STM Channel Control Register (STM_CCRn) has the enable bit for channel n of the timer.

Address: 0h base + 10h offset + (16d × i), where i=0d to 3d



STM_CCR*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CEN	Channel Enable 0 The channel is disabled. 1 The channel is enabled.

42.3.4 STM Channel Interrupt Register (STM_CIR*n*)

The STM Channel Interrupt Register has the interrupt flag for channel n of the timer.

Address: 0h base + 14h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															CIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CIR*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CIF	Channel Interrupt Flag 0 No interrupt request. 1 Interrupt request due to a match on the channel.

42.3.5 STM Channel Compare Register (STM_CMP*n*)

The STM channel compare register (STM_CMPn) holds the compare value for channel n.

Address: 0h base + 18h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CMP																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CMP*n* field descriptions

Field	Description
0–31 CMP	Compare value for channel n. If the STM_CCRn[CEN] bit is set and the STM_CMPn register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIRn[CIF] bit is set.

STM_CMP*n* field descriptions (continued)

Field	Description

42.4 Functional description

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode, the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode; otherwise, it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*), and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

NOTE

The STM counter does not advance when the system clock is stopped.

Chapter 43
Software Watchdog Timer (SWT)

43.1 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

43.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

43.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

43.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

43.2 External signal description

The SWT module does not have any external interface signals.

43.3 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in the following table.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SWT Control Register (SWT_CR)	32	R/W	See section	43.3.1/1681
4	SWT Interrupt Register (SWT_IR)	32	R/W	0000_0000h	43.3.2/1684
8	SWT Time-out Register (SWT_TO)	32	R/W	See section	43.3.3/1684
C	SWT Window Register (SWT_WN)	32	R/W	0000_0000h	43.3.4/1685

14	SWT Counter Output Register (SWT_CO)	32	R	0000_0000h	43.3.6/1686
18	SWT Service Key Register (SWT_SK)	32	R/W	0000_0000h	43.3.7/1687

43.3.1 SWT Control Register (SWT_CR)

NOTE

The reset value of this register is implementation specific. See the chip-specific SWT information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

31 TIF	Time-out Interrupt Flag The flag and interrupt are cleared by writing a 1 to this bit. Writing a 0 has no effect. 0 No interrupt request 1 Interrupt request due to an initial time-out

43.3.3 SWT Time-out Register (SWT_TO)

NOTE

The reset value of this register is implementation specific. See the chip-specific SWT information.

The SWT Time-out (SWT_TO) register contains the 32-bit time-out period. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SWT_TO field descriptions

Field	Description
0–31 WTO	Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with this value or 0x100, whichever is greater, when the service sequence is written or when the SWT is enabled.

43.3.4 SWT Window Register (SWT_WN)

The SWT Window (SWT_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SWT_WN field descriptions

Field	Description
0–31 WST	Window Start Value When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

43.3.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SWT_SR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the soft lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog, see Functional description for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the soft lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

43.3.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

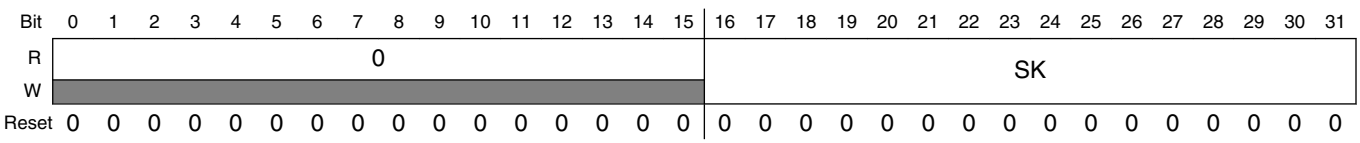
SWT_CO field descriptions

Field	Description
0–31 CNT	Watchdog Count. When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

43.3.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 18h offset = 18h



SWT_SK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^{16} .

43.4 Functional description

43.4.1 Introduction

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT_CR),
- an interrupt register (SWT_IR),
- a time-out register (SWT_TO),
- a window register (SWT_WN),
- a service register (SWT_SR),
- a counter output register (SWT_CO), and
- a service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

43.4.1.1 SWT_CR register

The SWT_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific.[3] If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

43.4.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. See the Configuration section to determine the source that is used to clock the down counter.

43.4.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

3. See the chip-specific SWT information.

43.4.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

43.4.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

43.4.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

43.4.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

43.4.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

43.4.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

43.4.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 43-1. Pseudorandom Key Generator

43.4.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

43.4.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

43.4.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to 1000, then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

43.4.5 Time-out

The interrupt-then-reset bit (SWT_CR[ITR]) controls the action taken when a time-out occurs. If the SWT_CR[ITR] bit is not set, a reset is generated immediately on a time-out. If the SWT_CR[ITR] bit is set, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period. If the service sequence is not written before the second consecutive time-out, the SWT generates a system reset. The interrupt is indicated by the time-out interrupt flag (SWT_IR[TIF]). The interrupt request is cleared by writing a one to the SWT_IR[TIF] bit.

43.4.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

Chapter 44
Periodic Interrupt Timer (PIT)

44.1 Introduction

The PIT timer module is an array of timers that can be used to raise interrupts and trigger DMA channels. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup.

Note

For the chip-specific implementation details of this module's instances see the Device Configuration chapter.

44.1.1 Block diagram

The following figure shows the PIT block diagram.

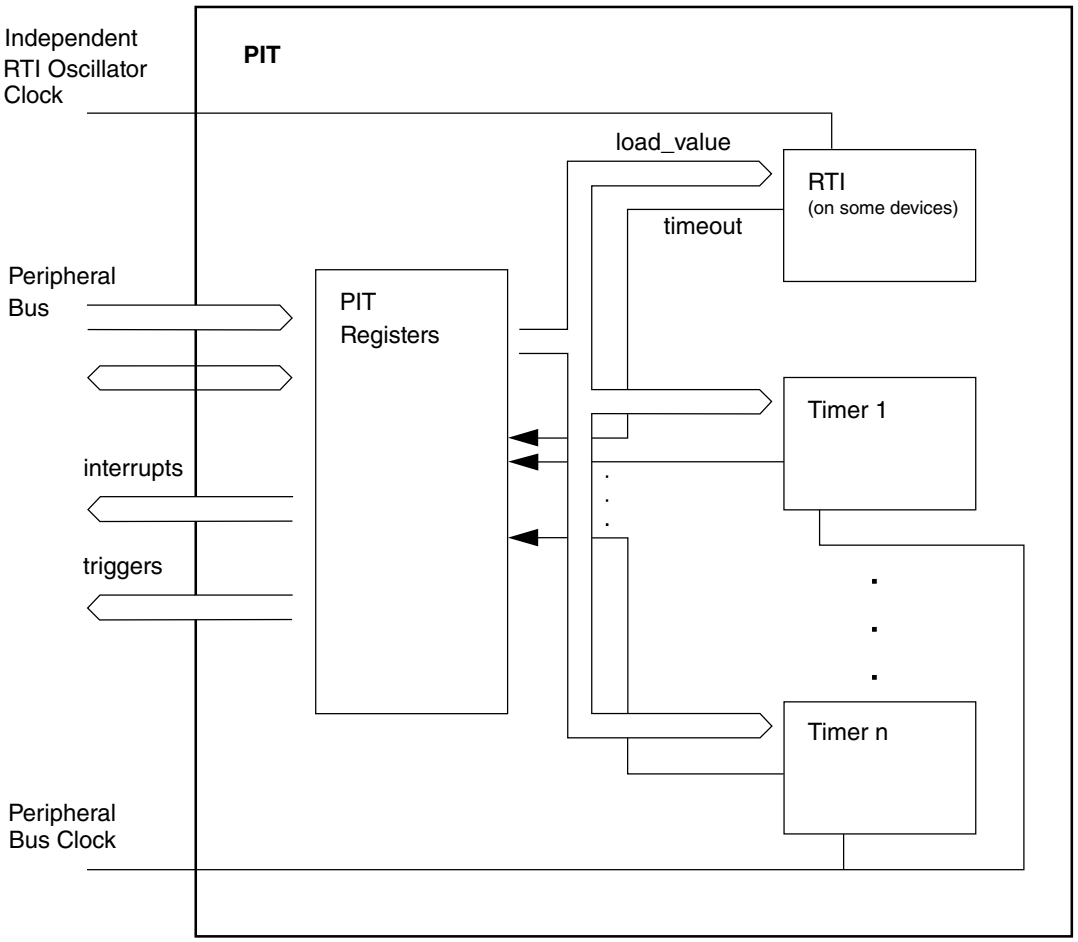


Figure 44-1. Block diagram of the PIT

Note

Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

44.1.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wake up the CPU in Stop mode
- Timers can generate DMA trigger pulses
- Timers can generate interrupts
- All interrupts are maskable
- RTI interrupt can be raised, even when the bus clock is switched off

- Power saving with a separate input clock for the RTI timer (all other timers share one common core clock)
- Independent timeout periods for each timer

44.2 Signal description

This module has no external pins.

44.3 Memory map/register description

This section provides a detailed description of all registers accessible in this module.

Note

Reserved registers will read as 0, writes will have no effect.

Note

Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

Note

The RTI registers should be programmed only when the RTI clock is running.

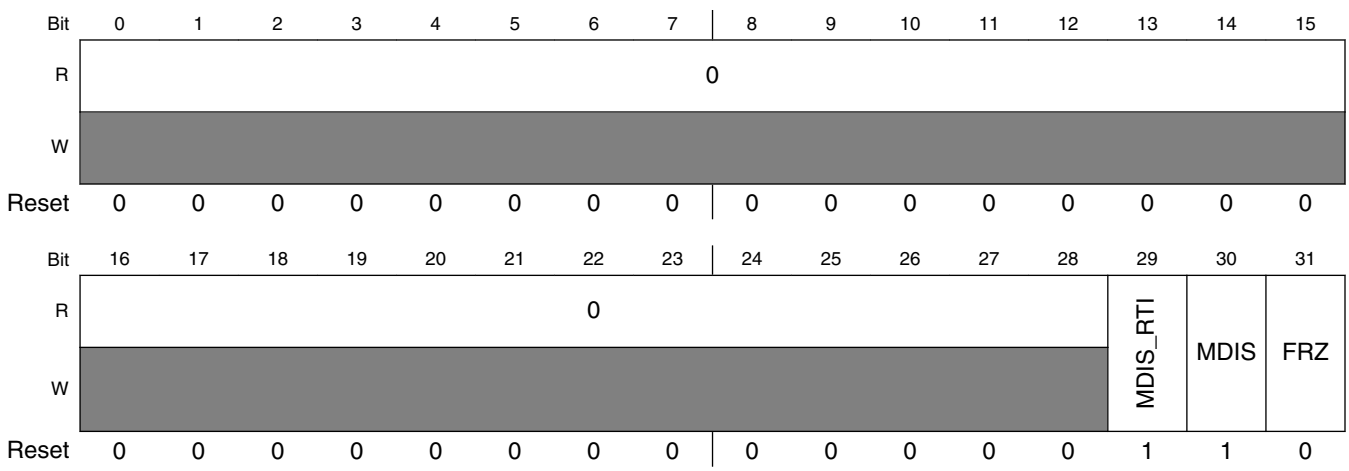
44.3.1 PIT Module Control Register (PIT_MCR)

The PIT Module Control Register (PIT*x*_MCR) controls whether the timer clocks should be enabled and whether the timers should run in debug mode.

Address: FFF8_0000h base + 0h offset = FFF8_0000h



PIT_MCR field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 MDIS_RTI	Module Disable - RTI section This is used to disable the RTI timer. This bit must be enabled before any RTI setup is done. 0 Clock for RTI timers is enabled. 1 Clock for RTI timers is disabled.
30 MDIS	Module Disable This is used to disable the module clock. The RTI timer is not affected by this bit. This bit must be enabled before any other setup is done. 0 Clock for PIT timers is enabled. 1 Clock for PIT timers is disabled.

Table continues on the next page...

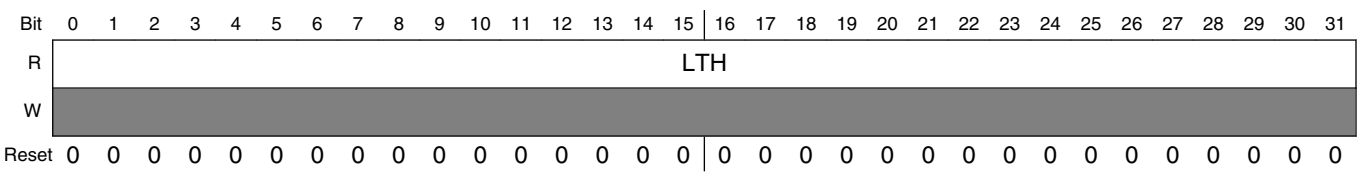
PIT_MCR field descriptions (continued)

Field	Description
31 FRZ	Freeze Allows the timers to be stopped when the device enters debug mode. 0 Timers continue to run in debug mode. 1 Timers are stopped in debug mode.

44.3.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)

The PIT Module *x* Upper Lifetime Timer Register (PIT*x*_LTMR64H) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

Address: FFF8_0000h base + E0h offset = FFF8_00E0h



PIT_LTMR64H field descriptions

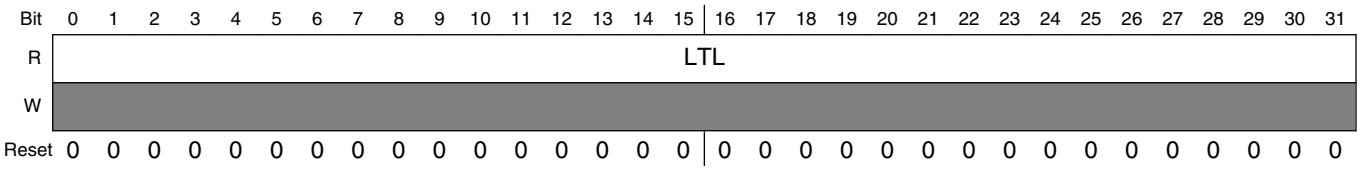
Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

44.3.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

The PIT Module *x* Lower Lifetime Timer Register (PIT*x*_LTMR64L) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Address: FFF8_0000h base + E4h offset = FFF8_00E4h



PIT_LTMR64L field descriptions

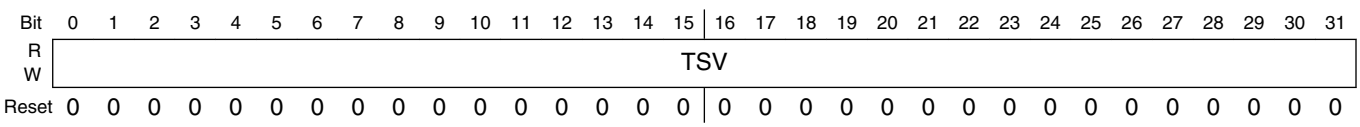
Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

44.3.4 PIT RTI Timer Load Value Register (PIT_RTI_LDVAL)

This register select the timeout period for the timer interrupts.

In the case of the RTI, it takes several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

Address: FFF8_0000h base + F0h offset = FFF8_00F0h



PIT_RTI_LDVAL field descriptions

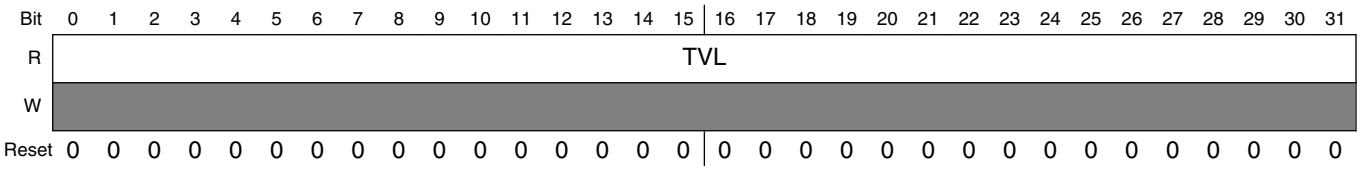
Field	Description
0–31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. **NOTE:** The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.

44.3.5 PIT RTI Current Timer Value Register (PIT_RTI_CVAL)

This register indicate the current timer position.

For the RTI timers, it shows a value which is several cycles old, since it originates from a potentially different clock domain.

Address: FFF8_0000h base + F4h offset = FFF8_00F4h



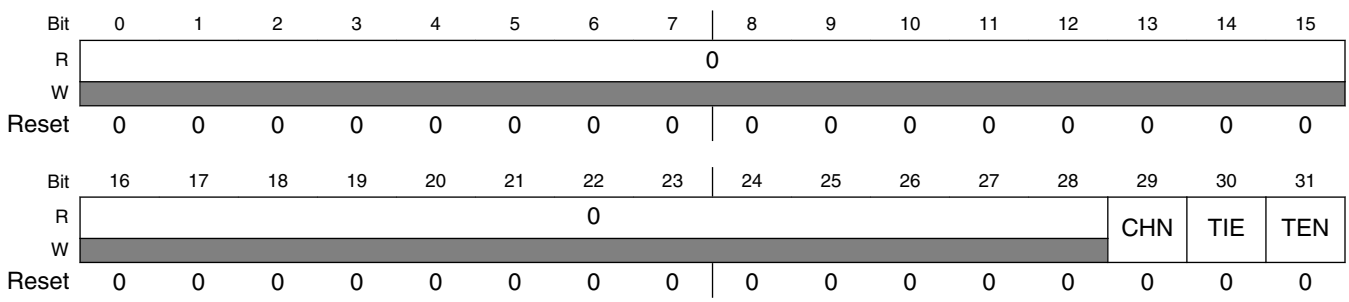
PIT_RTI_CVAL field descriptions

Field	Description
0–31 TVL	Current Timer Value If the timer is enabled, these bits represent the current timer value. If the timer is disabled, do not use this field as its value is unreliable. **NOTE:** The timer uses a down counter. The timer values are frozen in debug mode if the MCR[FRZ] bit is set.

44.3.6 PIT RTI Timer Control Register (PIT_RTI_TCTRL)

This register contain the control bits for each timer.

Address: FFF8_0000h base + F8h offset = FFF8_00F8h



PIT_RTI_TCTRL field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CHN	Chain Mode Bit When activated, timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be changed. 0 Timer is not chained. 1 Timer is chained to previous timer (example, for channel 2 if this bit is set timer 2 is chained 1).
30 TIE	Timer Interrupt Enable Bit 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set.

Table continues on the next page...

PIT_RTI_TCTRL field descriptions (continued)

Field	Description
	When an interrupt is pending (TIF set), enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TIF flag must be cleared first.
31 TEN	Timer Enable Bit This bit enables or disables the timer. 0 Timer n is disabled. 1 Timer n is active.

44.3.7 PIT RTI Timer Flag Register (PIT_RTI_TFLG)

This register holds the PIT interrupt flags.

Address: FFF8_0000h base + FCh offset = FFF8_00FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag TIF is set to 1 at the end of the timer period. This flag can be cleared only by writing it with 1. Writing 0 has no effect. If enabled (TIE = 1), TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

44.4 Functional description

This section provides the functional description of the module.

44.4.1 General

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses as well as to generate interrupts. Each interrupt is available on a separate interrupt line. Additionally the RTI timer can be used to wake up the processor.

44.4.1.1 Timers/RTI

The timers generate triggers at periodic intervals, when enabled. They load their start values, as specified in their LDVAL registers, then count down until they reach 0. Then they load their respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked (by setting the TIE bits in the TCTRL registers). A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 should be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted, by first disabling, then enabling the timer with the TEN bit (see the following figure).

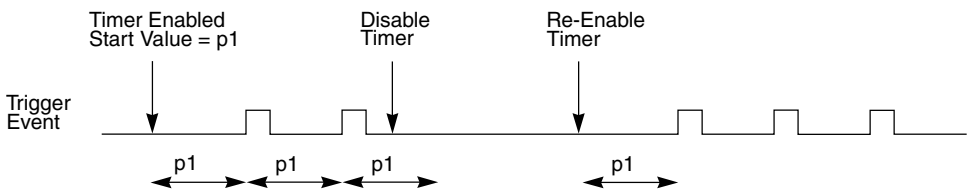

Figure 44-2. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value and then enabling the timer again (see the following figure).

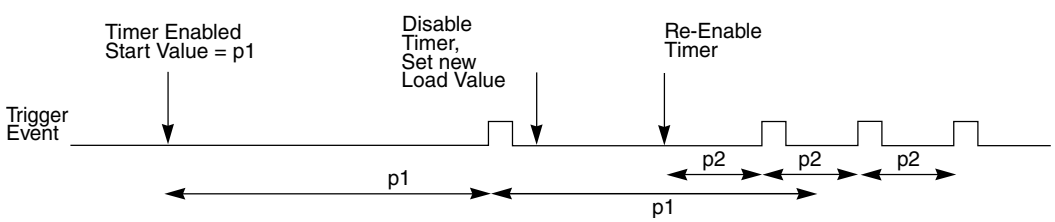

Figure 44-3. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing the LDVAL register with the new load value. This value will then be loaded after the next trigger event (see the following figure).

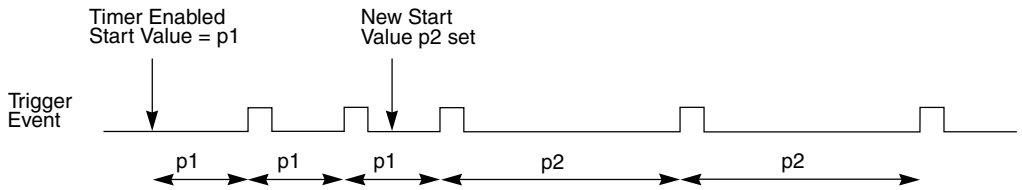

Figure 44-4. Dynamically setting a new load value

44.4.1.2 Debug mode

In debug mode, the timers will be frozen based on field PIT*x*_MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system (for example, the timer values) and then continue the operation.

44.4.2 Interrupts

All of the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. Refer to the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting the TIE bits. The timer interrupt flags (TIF) are set to 1 when a timeout occurs on the associated timer, and are cleared to '0' by writing a '1' to that TIF bit.

The PIT RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting the TIE bit to zero. The real time interrupt flag (TIF) is set to '1' when a timeout occurs, and is cleared by writing a '1' to the TIF bit. (The flag will be set regardless whether the interrupt is enabled.)

The RTI can be used for periodic wakeup from a low power mode. It can also be used to generate a general purpose interrupt.

44.4.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer *n*-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

44.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

First the PIT module must be activated by writing a 0 to field PITx_MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5000000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256000 cycles and timer 3 every 30 ms/20 ns = 1500000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) –1

This means RTI_LDVAL will be written with 004C4B3F hex, LDVAL1 should be written with 0x0003E7FF, and LDVAL3 should be written with 0x0016E35F.

To generate the wakeup interrupt, the interrupt line must be enabled by writing a '1' to bit RTI_TCTRL[TIE]. To start the RTI, bit RTI_TCTRL[TEN] must also be set.

The interrupt for Timer 1 is enabled by setting bit TCTRL1[TIE]. The timer is started by writing '1' to bit TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore Timer 3 is started by writing a '1' to bit TCTRL3[TEN]; bit TIE stays at 0.

The following example code matches the described setup:

```
                    // turn on PIT
                   PIT_MCR = 0x00;
                      // RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
  PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
           PIT_RTI_TCTRL |= PIT_TEN; // start RTI
                     // Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
       PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
```

```
                PIT_TCTRL1 |= TEN; // start Timer 1
                           // Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3for 1500000 cycles
                PIT_TCTRL3 |= TEN; // start Timer 3
```

44.6 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 hour.

First the PIT module needs to be activated by writing a '0' to field PIT*x*_MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to timer 1 and programmed to trigger every 10 times.

The value for the LDVAL register trigger is calculated as number of cycles '1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for timer 2 is enabled by setting PIT*x*_TCTRL2[TIE], the chain mode is activated by setting CHN, and the timer is started by writing a '1' to PIT*x*_TCTRL2[TEN]. In PIT*x*_TCTRL1, the TEN bit needs to be set, and CHN and TIE bits are cleared.

The following example code matches the described setup:

```
                  // turn on PIT
                PIT_CTRL = 0x00;
                   // Timer 2
PIT_LDVAL2 = 0x00000009; // setup timer 2 for 10 counts
                PIT_TCTRL2 = TIE; // enable timer 2 interrupt
                PIT_TCTRL2 |= CHN; // chain timer 2 to timer 1
                PIT_TCTRL2 |= TEN; // start timer 2
                           // Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup timer 1 for 600 000 000 cycles
                PIPIT_TCTRL1 = TEN; // start timer 1
```

44.7 Example Configuration for the Lifetime Timer

To configure the life timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a '0' to field PITx_MCR[MDIS], then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

```
                        // turn on PIT
                      PIT_CTRL = 0x00;
                        // Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
           PIT_TCTRL1 = 0x0; // disable timer 2 interrupts
            PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
                  PIT_TCTRL1 |= TEN; // start timer 1
                        // Timer 0
 PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0for maximum counting period
                PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime read first LTMR64H then LTMR64L.

$$\text{current\_uptime} = \text{PIT\_LTMR64}H << 64;$$
$$\text{current\_uptime} = \text{current uptime} + \text{PIT\_LTMR64}L$$

Equation 21. Equation for current_uptime

The timer is a down counter.

Chapter 45
GTM Integration (GTMINT) Module

45.1 About this module

45.1.1 Definition

The GTMINT integration unit is a hardware module that:

- Provides reset control, clock control, error-correcting code (ECC) functionality, interrupt and DMA control
- Provides access to GTM-IP's memory-mapped registers
- Prevents destructive read accesses into the GTM-IP registers from GTMDI

45.1.2 Features

GTMINT has the following features:

- [Covers: Saf1306][Covers: Saf1317] ECC encoder/decoder for each of 17 RAM interfaces
    - [Covers: Saf1776][Covers: Saf1311] Parity calculation using the whole word and the target memory address value
    - [Covers: Saf1309]Detection and correction of single-bit error on the read data value
    - Detection of single-bit error on address field but no need for correction
    - Double-bit error detection on data or address field without error correction
    - [Covers: Saf1771] ECC report generation for each RAM containing:
        - Address of the error in the register map

- Noncorrectable error indication (not correctable data + address ECC detected errors, or error with the RAM latched address)
- Correctable error indication (correctable data error)

- [Covers: Saf1352]RAM address error detection by comparing latched address from RAM and internal targeted RAM address
- [Covers: ADD21.004]Generation of 225 interrupt requests and or DMA requests
- [Covers: ADD21.007] Debugger access to read all GTM-IP registers through the peripheral bus even when the timer is running. The debugger can read the registers without destroying or changing their contents
- [Covers: ADD21.009] Debugger access to read all GTM-IP RAM addresses read-/writable from the peripheral bus when GTM-IP is running or halted

45.1.3 Modes of operation

GTMINT supports the following modes of operation:

Mode	Description
Normal	The clock signals to GTMINT, GTM-IP, and GTMDI are enabled. The GTM subsystem is functional, processing input timing signals and generating timed outputs.
Stop	The clock signals to GMTINT and GTM-IP are disabled. The only field you can write to is GTMMCR[MDIS].

NOTE

After reset, the mode of GTMINT is defined by the reset value of GTMMCR[MDIS].

45.1.4 Entering Normal mode

To enter Normal mode:

1. Write 0 to GTMMCR[MDIS].

   GTMMCR[STPS] is automatically cleared.

45.1.5 Entering Stop mode

To enter Stop mode:

1. Write 1 to GTMMCR[MDIS].
2. Read GTMMCR[STPS] to confirm the stop request was granted because GTMINT only requests to stop the clocks when no bus accesses to GTM-IP are pending.

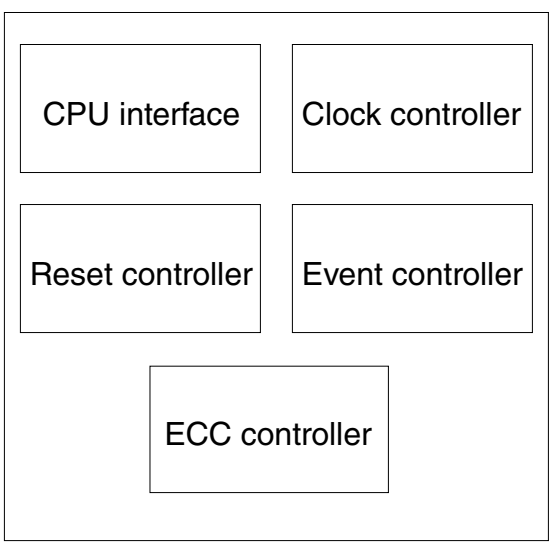
NOTE

The GTM subsystem also enters Stop mode when the chip enters Stop mode. The minimum time between Stop mode requests from the chip is 20 bus clock cycles to ensure that the previous stop mode request acknowledgement was completed by the GTM subsystem.

45.2 GTMINT

45.2.1 GTMINT block diagram

This diagram shows the components of GTMINT:



45.2.2 GTMINT components

This table describes the components of GTMINT:

Component	Function
Clock controller	Manages the clock signals. Enables and disables GTMINT and GTM-IP by gating the peripheral clocks. Clock signals come from the chips clocking module.
Event controller	Routes the GTM-IP interrupt signals to the chip's interrupt controller and DMA controller modules. Controls the interrupt flag clearing. Receives and processes the DMA_DONE_*dmaSource* signal. Does not enable or configure interrupts or DMA events.
CPU interface	Connects GTM-IP's address and data bus to the chip's address and data bus. Signals are connected externally to the chip peripheral bridge and the GTM-IP.
Reset controller	Gives GTMINT maskable software reset control for the GTM-IP to the chip interface.
ECC controller	Generates the parity bits for RAM writes and detects errors in the data read from the RAMs. Signals are connected externally to the GTM's tightly coupled RAMs and the chip's memory manager module.

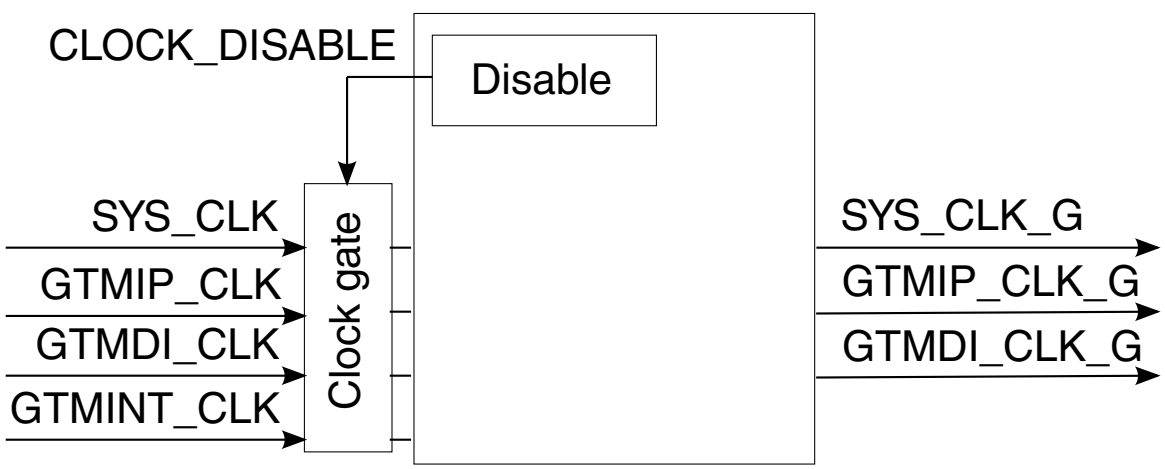
NOTE

GTM-IP is the generic name given to the GTM module used on the chip (for example, GTM104 or GTM103).

45.3 Clock controller

45.3.1 Clock controller block diagram

This diagram shows the clock controller (the clock gate is not part of the clock controller):



45.3.2 Clock controller components

This table describes the components of the clock controller:

Component	Function
Disable	Opens and closes the clock gate (located in the GTMMCR register), which places GTMINT and GTM-IP in Normal mode and Stop mode.
Clock gate	Gates clocks outside the clock controller but is controlled by Disable (GTMMCR[MDIS]).

45.3.3 Clock controller signals

This table describes the clock controller signals:

Signal	I/O	Max. frequency	Function
Clock control			
CLOCK_DISABLE	O	—	Disables the clock gate. This signal is asserted out of reset, placing GTMINT and GTM-IP in Stop mode.
System clock			
SYS_CLK/SYS_CLK_G	I/O	100 MHz	Provides the clock for the address and data bus for memory-mapped register access through the peripheral bridge and AEIMUX. This clock is unaffected by Halt mode. This clock is stopped when the GTM subsystem is in Stop mode.
Peripheral clocks			
GTMIP_CLK/GTMIP_CLK_G	I/O	80 MHz	Provides the clock for GTM-IP timer operation. This clock is stopped when the GTM subsystem is in Stop mode and Halt mode.
GTMDI_CLK/GTMDI_CLK_G	I/O	80 MHz	Provides the clock for GTMDI. This clock is unaffected by Halt mode. This clock is stopped when the GTM subsystem is in Stop mode.
GTMINT_CLK	I	80 MHz	Provides the clock for GTMINT, the GTM-IP registers and the RAM. This clock is unaffected by Halt mode. This clock is stopped when the GTM subsystem is in Stop mode.

45.3.4 Important guidelines for selecting clocks

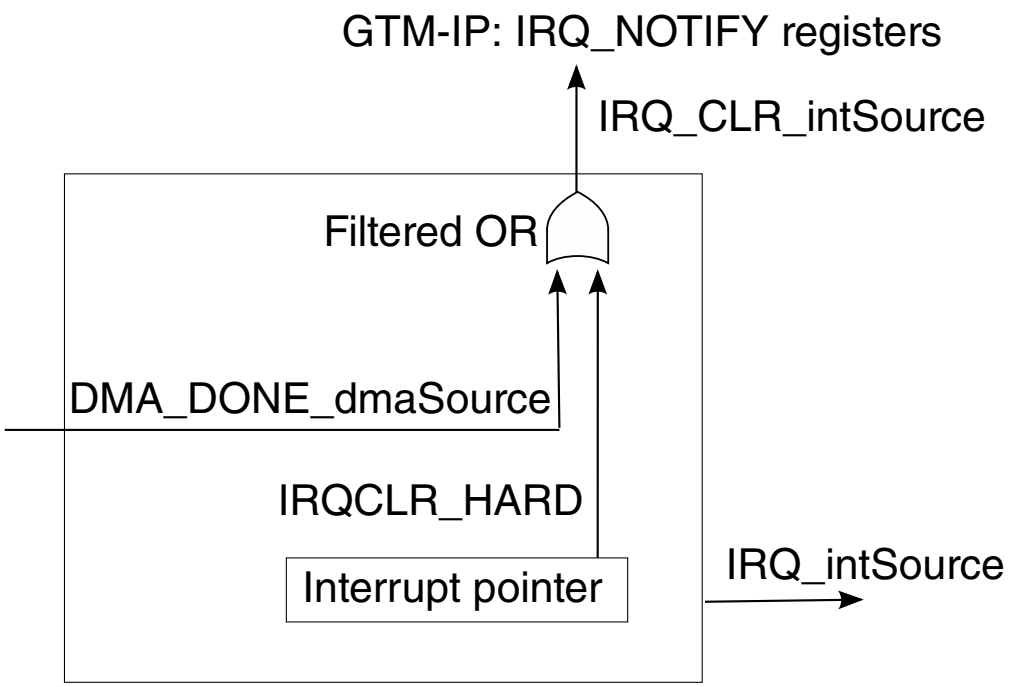
Follow these guidelines for SYS_CLK and the peripheral clocks:

- If your application requires GTM-IP to run in Synchronous mode, ensure that SYS_CLK and the peripheral clocks have the same frequency and phase.
- If your application requires GTM-IP to run in Asynchronous mode, ensure that the frequency of SYS_CLK is greater than or equal to the peripheral clock; the phases of these clocks do not have to be the same.

45.4 Event controller

45.4.1 Event controller block diagram

This diagram shows the event controller:



45.4.2 Event controller components

This table describes the components of the event controller:

Component	Function
Interrupt pointer	Asserts IRQCLR_HARD based on the value of the pointer (GTMINTCLR[INTPTR]) provided by the core.
Filtered OR	Combines the DMA_DONE signals (from the DMA controller) and IRQCLR_HARD and prevents them from introducing unintended state changes (caused by clock domain differences) on the IRQ_CLR signals.

45.4.3 Event controller signals

This table describes the event controller signals:

Signal	I/O	Function
IRQCLR_HARD	I	Initiates the interrupt clear request. Initiated by interrupt-pointer write accesses.
IRQ_CLR_*intSource*[1]	O	Clears the GTM-IP submodule interrupt request.
IRQ_*intSource*[1]	O	Raises an interrupt request to the core's interrupt controller or DMA controller.
DMA_DONE_*dmaSource*[2]	I	Initiates the interrupt clear request. Initiated by the DMA controller when the DMA transfer is completed.

1. *intSource* represents one of the following GTM subsystem interrupt sources: ERR, AEI, ARU, BRC, SPE, CMP, PSM, DPLL, MCS, TIM, TOM, ATOM.
2. *dmaSource* represents one of the following GTM subsystem DMA sources: ERR, AEI, ARU, BRC, SPE, CMP, PSM, DPLL, MCS, TIM, TOM, ATOM.

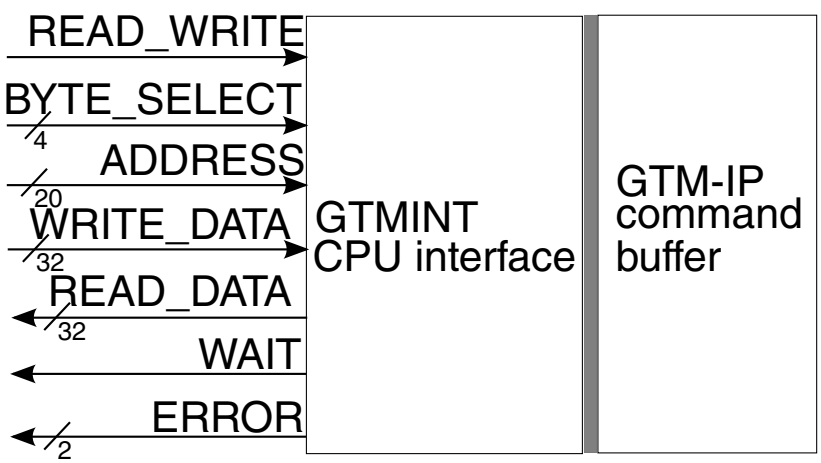
NOTE

The Interrupt Concentrator Module (ICM) bundles interrupt sources inside GTM-IP. This bundling also applies to DMA sources.

45.5 CPU interface

45.5.1 CPU interface block diagram

This diagram shows the CPU interface (the command buffer is not part of the CPU interface):



45.5.2 CPU interface signals

This table describes the CPU interface signals:

Signal	I/O	Function
READ_WRITE	I	Indicates whether the current command from the CPU to GTMI-IP is a data write or data read request.
BYTE_SELECT	I	Selects which byte (or bytes) of data within the 32-bit word is to be read from GTM-IP or GTMINT by the CPU. All bytes are selected when reading a GTM_IP register When the CPU requests a read from a GTMINT register any combination of bytes can be read.
ADDRESS	I	Specifies the 20-bit address of the word that the CPU wants to access.
WRITE_DATA	I	Carries write data from the CPU to GTM-IP or GTMINT.
READ_DATA	O	Carries read data from GTM-IP or GTMINT to the CPU.
WAIT	O	Indicates that the GTM-IP command buffer is full and GTM-IP is fulfilling a CPU read or write command. The peripheral bridge port uses this indication to delay further CPU requests until there is room in the command buffer.
ERROR	O	Indicates the current command has resulted in an error. See your GTM-IP reference manual—for example, *GTM104 Reference Manual*, document GTM104RM—for a description of the potential causes, such as Illegal Byte Addressing, Illegal Address Access, or Unsupported Address.

NOTE

A *request* is a command that may or may not be executed.

A *transfer* is the result of a successfully executed command.

45.5.3 Important guidelines for configuring the CPU interface

This table describes the typical number of wait cycles for accesses through the CPU interface:

Read accesses to	Wait cycles[1]
GTMINT registers	Zero. Commands that access the GTMINT register address range (C0h to FCh) are not added to the command buffer and executed immediately.[2]
GTM-IP registers	Up to 12

Table continues on the next page...

Read accesses to	Wait cycles[1]
MCS RAMs	Up to 12
DPLL RAMs	Up to 13

1. These approximated values are obtained for a core clock frequency equal to 100 MHz and GTM-IP clock frequency equal to 80 MHz. They can change if the ratio of these frequencies is changed.
2. This is also valid for write commands.

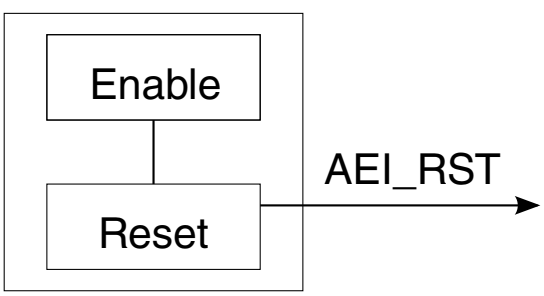
Write operations from chip cores that are executed through GTM-IP's command buffer can be executed differently depending on the configuration of GTM-IP (BRIDGE_MODE[MSK_WR_RSP]).

BRIDGE_MODE[MSK_WR_RSP]	Meaning
1	Does not return error indication. The error is indicated by AEI_IRQ.
	The command buffer is used to receive several write commands until the buffer is full. While the buffer is not full, the slave bus indicates no wait requests. When the buffer is full, a write command generates wait states to the bus master.
0 (default)	Each write operation is executed and generates the error indication and wait cycles until the operation has been executed. The error is also indicated by AEI_IRQ.
	The multiple entries of the command buffer are not used because the bus does not send a new request until the previous one has finished.

45.6 AEI reset

45.6.1 Reset controller block diagram

This diagram shows the reset controller:



45.6.2 Reset controller components

This table describes the components of the reset controller:

Component	Function
Enable	Enables soft reset signaling (GTMMCR[AEISREN]) to the Automotive Electronics Interface (AEI).
Reset	Asserts a soft reset (GTMAEICR[AEIRST]).

45.6.3 Reset controller signals

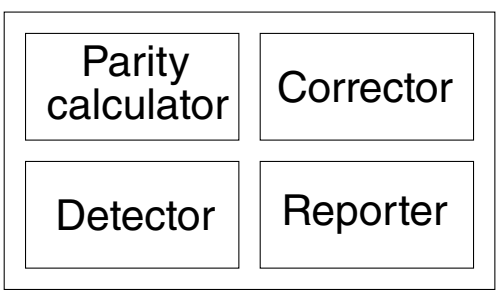
This table describes the reset controller signals:

Signal	I/O	Function
AEI_RST	O	Initiates the Automotive Electronics Interface (AEI) reset sequence.

45.7 ECC controller

45.7.1 ECC controller block diagram

This diagram shows the error-correcting code (ECC) controller:



45.7.2 ECC controller components

This table describes the components of the error-correcting code (ECC) controller:

Component	Used for memory	Function
Parity calculator	Writes	Calculates parity bits and appends them to the original data in the specified memory address. [Covers: Saf1776][Covers: Saf1311] Data and address are considered in the parity-bit calculation. [Covers: Saf1309] This ECC is based on the Hsiao code[1] with 7 parity-bits for each data word.
Detector	Reads	Detects memory errors on reads.

Table continues on the next page...

Component	Used for memory	Function
Corrector	Reads	Uses the ECC data to correct single-bit errors when signaled by the Detector on reads.
Reporter	Reads	Generates and reports the error information when an error is detected.

1. Hsiao, M.Y;.A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; *IBM Journal of Research and Development* [July 1970]

45.7.3 Automatic GTM RAM initialization

Each location in each memory served by the error-correcting code (ECC) controller must be initialized because parity bits need to be stored in each memory address before any read operation. GTM-IP does this automatically for all memories, except for first-in first-out (FIFO) RAM that must be written before being read.

This table presents a summary of GTM-IP memories and the ECCs for single-bit error correction and double-bit error detection.

Memory space	Number of words	Address width (bits)	Data width (bits)	ECC width (bits)	MEM data in/out (data + ECC) (bits)	Matrix Size (number of syndromes)
FIFOx RAM	**1024**	**10**	29	7	**36**	46
DPLL RAM1A	**1286**	**7**	24	7	**31**	38
DPLL RAM1BC	**384**	**9**	24	7	**31**	40
DPLL RAM2	**4096**	**11**	24	7	**31**	42
MCSx RAM0	**1024**	**10**	32	7	**39**	49
MCSx RAM1	**512**	**9**	32	7	**39**	48

45.7.4 ECC syndromes

This table shows the definition of the syndrome field (SYND[6:0]) for each bit position.

NOTE

The error-correcting code (ECC) data-vector width can be different for each memory, so the detector considers only the necessary positions for each one, not all the table positions.

SYND[6:0] / element value	Error result on	Bit number		SYND[6:0] / element value	Error result on	Bit number
40h	code	6		54h	data	23
20h		5		15h		22
10h		4		16h		21
08h		3		34h		20
04h		2		25h		19
02h		1		26h		18
01h		0		64h		17
79h	data[1]	41		2Ch		16
37h		40		1Ah		15
5Bh		39		23h		14
76h		38		2Ah		13
5Dh		37		32h		12
2Fh		36		46h		11
1Fh		35		4Ah		10
70h		34		52h		9
68h		33		62h		8
07h		32		13h		7
49h		31		29h		6
0Dh		30		31h		5
0Eh		29		43h		4
38h		28		45h		3
4Ch		27		19h		2
1Ch		26		51h		1
58h		25		61h		0
0Bh		24		—	—	—
00h	**no error**	—		**any other value**[2]	**noncorrectable error**	—

1. Can be data or address
2. For the FIFOx RAM with 29 data bits and 10 address bits, the valid error positions are from bit 0 to bit 38 only. The syndromes with values for bits 39 to 41 of the table are considered also for noncorrectable errors.

45.7.5 Error report

[Covers: Saf1771] Each RAM read access generates a defined set of information.

Reported information	Description
Error address	The mapped address as defined in the GTM-IP reference manual. This field has meaning only when an error occurs and is flagged by the error signals below.

Table continues on the next page...

Reported information	Description
	It is reported on reads and writes.
Noncorrectable error	An error field indicating that there are detected errors in the read that can't be corrected. The error can occur in the RAM read data bus (parity bits + data) or in the address value that the RAM has received.
Correctable error	An error field indicating that the ECC controller detected and corrected a single-bit error on the RAM read data bus. The parity bits are discarded after the ECC decoder, but this error report includes these bits to obtain the performance of the whole RAM data-storage sector.

The error report remains active for only one RAM clock cycle and should be captured by the external RAM error-monitor module. [Covers: Saf3257] Noncorrectable ECC error indications are provided to GTM-IP, but the reaction to the errors depends on this module itself. For example, if an ECC error occurs while a Multi Channel Sequencer (MCS) channel reads data from a memory page, the channel is disabled and an error bit is asserted. For more information, see your GTM-IP reference manual—for example, *GTM104 Reference Manual*.

45.8 Using GTMINT

45.8.1 Clearing interrupts

45.8.1.1 Deciding whether to use GTMINT or GTM-IP to clear interrupts

This table compares how GTMINT and GTM-IP clear interrupts:

Comparing	GTMINT (See Clearing interrupts via GTMINT.)	GTM-IP (See your GTM-IP reference manual—for example, *GTM104 Reference Manual*, document GTM104RM.)
Interrupt-clearing latency	Low	High[1]
Number of interrupts cleared per request	All interrupts from the same source[2]	Only the requested interrupt[3]
When clearing completes	At the next clock rising edge	Variable, depending on the CPU interface's command buffer depth[4]

1. There is a delay between the command buffer and the actual clearing of the flags inside GTM-IP.
2. Any interrupt from the source that occurs during the interrupt handler, before IRQCLR_HARD is raised, is cleared.

3. Can generate a second interrupt request if the interrupt handler is completed and interrupts are enabled before IRQCLR_SOFT has reached the IRQ_NOTIFY field.
4. It is at the user's discretion whether to wait for the flag to be cleared by polling the *subModule*_IRQ_NOTIFY register or whether to continue with the rest of the program once the clear is initiated.

45.8.1.2 Clearing interrupts via GTMINT

To clear an interrupt source:

1. Write the number for the interrupt source to GTMINTCLR[INTCLR_PTR].

   For example, to clear the IRQ_AEI interrupt, write 2C2h to GTMINTCLR[INTCLR_PTR].

   For a list of interrupts and their corresponding interrupt numbers, see Correspondence between the INTCLR_PTR and the interrupts outputs.

   The event controller asserts the IRQCLR_HARD signal to clear the interrupt.

45.8.1.3 Correspondence between the INTCLR_PTR and the interrupts outputs

INTCLR_PTR[0:9]		Interrupt signal to be cleared
Hexadecimal	Decimal	
000	0	No interrupt is selected
001 to 2C1	1 to 705	Reserved
2C2	706	IRQ_CLR_AEI
2C3 to 2C5	707 to 709	IRQ_CLR_ARU
2C6	710	IRQ_CLR_BRC
2C7	711	IRQ_CLR_CMP
2C8	712	IRQ_CLR_SPE0
2C9	713	IRQ_CLR_SPE1
2CA to 2D1	714 to 721	IRQ_CLR_PSM0
2D2 to 2EC	722 to 748	IRQ_CLR_DPLL
2ED to 2F4	749 to 756	IRQ_CLR_TIM0
2F5 to 2FC	757 to 764	IRQ_CLR_TIM1

45.8.2 Resetting the GTM Subsystem

45.8.2.1 Deciding what type of reset to use

This table compares the different types of resets:

Comparing	Submodule channel (See your GTM-IP reference manual—for example, *GTM104 Reference Manual*, document GTM104RM.)	GTM-IP (See your GTM-IP reference manual—for example, *GTM104 Reference Manual*, document GTM104RM.)	AEI (See Resetting the AEI.)	GTM subsystem (See the chip reference manual.)
What is reset	A single submodule channel	GTM-IP	The peripheral bridge interface	The GTM subsystem
What you must reconfigure	The channel	GTM-IP. GTMINT and GTMDI are unaffected.	The GTM-IP GTM_BRIDGE_MODE register	The entire GTM subsystem
Reset protection?	No	Yes. [Covers: ADD13.014]The GTM-IP reset (GTM_RST[RST]) is write protected by GTM_CTRL[RF_PROT].	Yes. The AEI reset (GTMAEICR[AEIRST]) is write protected by GTMMCR[AEISREN].	No
System dependencies?	No	No	Yes. Use this type of reset only when the buffer is empty or in an error state.	No

45.8.2.2 Resetting the AEI

NOTE

Reset the GTM-IP bridge reset (GTM_BRIDGE_MODE[BRG_RST]) before resetting the AEI.

To reset the Automotive Electronics Interface (AEI):

1. Write 1 to GTMMCR[AEISREN].

   The reset controller enables the AEI reset functionality by un-protecting the GTMAEICR[AEIRST] field.
2. Write 1 to GTMAEICR[AEIRST].

   The reset controller asserts the AEI_RST signal in the next clock cycle and takes one bus clock cycle to complete.

   The GTMINT clears the AEI buffer, resets the configuration registers, aborts slave bus accesses (which means that access commands in the buffer memory are lost).

45.9 Memory map and registers

45.9.1 Memory map

This section contains the description of additional registers on the integration module. Descriptions of GTM-IP registers, or GTMDI registers are found in their respective documentation.

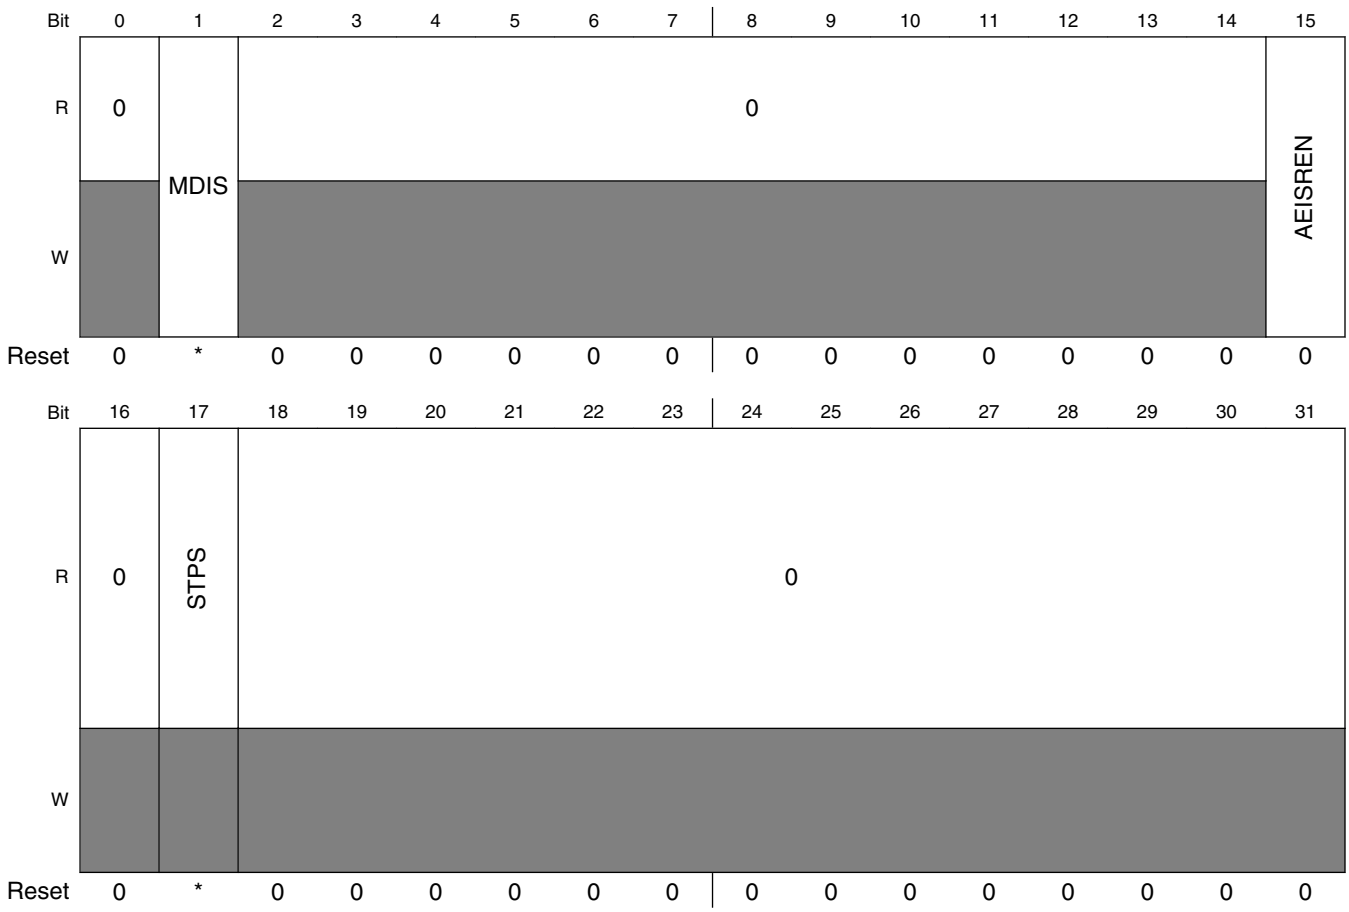
GTMINT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C0	GTM Module Configuration Register (GTMINT_GTMMCR)	32	R/W	See section	45.9.1.1/ 1728
C8	GTM Interrupts Clear Register (GTMINT_GTMINTCLR)	32	W	0000_0000h	45.9.1.2/ 1729
CC	GTM AEI Control Register (GTMINT_GTMAEICR)	32	W	0000_0000h	45.9.1.3/ 1730

45.9.1.1 GTM Module Configuration Register (GTMINT_GTMMCR)

GTMMCR contains the control bits to configure the general operation of GTMINT and GTM-IP.

Address: 0h base + C0h offset = C0h



* Notes:
- STPS field: Reset value is chip dependent.
- MDIS field: Reset value is chip dependent.

GTMINT_GTMMCR field descriptions

Field	Description
0 Reserved	This read-only field is reserved and always has the value 0.
1 MDIS	[Covers: Saf1461] MDIS Module Disable.

Table continues on the next page...

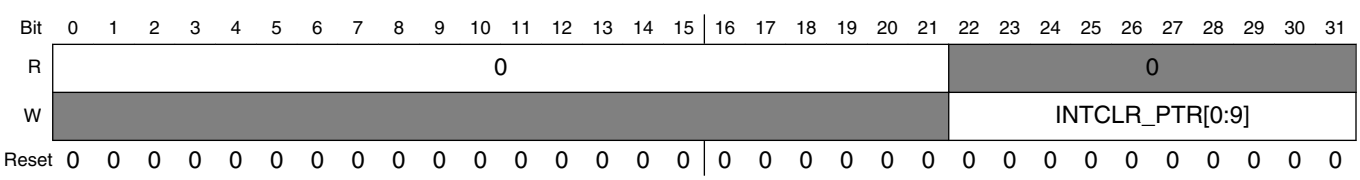
GTMINT_GTMMCR field descriptions (continued)

Field	Description
	MDIS puts GTMINT in stop mode. Communication through the peripheral bus is ignored in this mode except reads/writes to the GTMMCR register and reads from other integration registers, which are allowed. Refer to Entering Normal mode and Entering Stop mode sections for more details. [Covers: Saf1462] 0 Normal mode 1 Module disable requested
2–14 Reserved	This read-only field is reserved and always has the value 0.
15 AEISREN	Saf1276 - Safety-critical AEISREN AEI interface soft-reset control enable. AEISREN enables the soft-reset of the AEI interface that is controlled by AEISRST bit in GTMAEICR register. Refer to Resetting the AEI section for more details. 0 AEI soft-reset control is disabled 1 AEI soft-reset control is enabled
16 Reserved	This read-only field is reserved and always has the value 0.
17 STPS	[Covers: Saf1461] STPS Stop Mode Status. STPS indicates when GTM-IP is in stop mode. Refer to Entering Stop mode section for more details. 0 Normal Mode 1 GTM subsystem is in Stop Mode
18–31 Reserved	This read-only field is reserved and always has the value 0.

45.9.1.2 GTM Interrupts Clear Register (GTMINT_GTMINTCLR)

GTMINTCLR contains the control bits to clear some specific interrupt request.

Address: 0h base + C8h offset = C8h



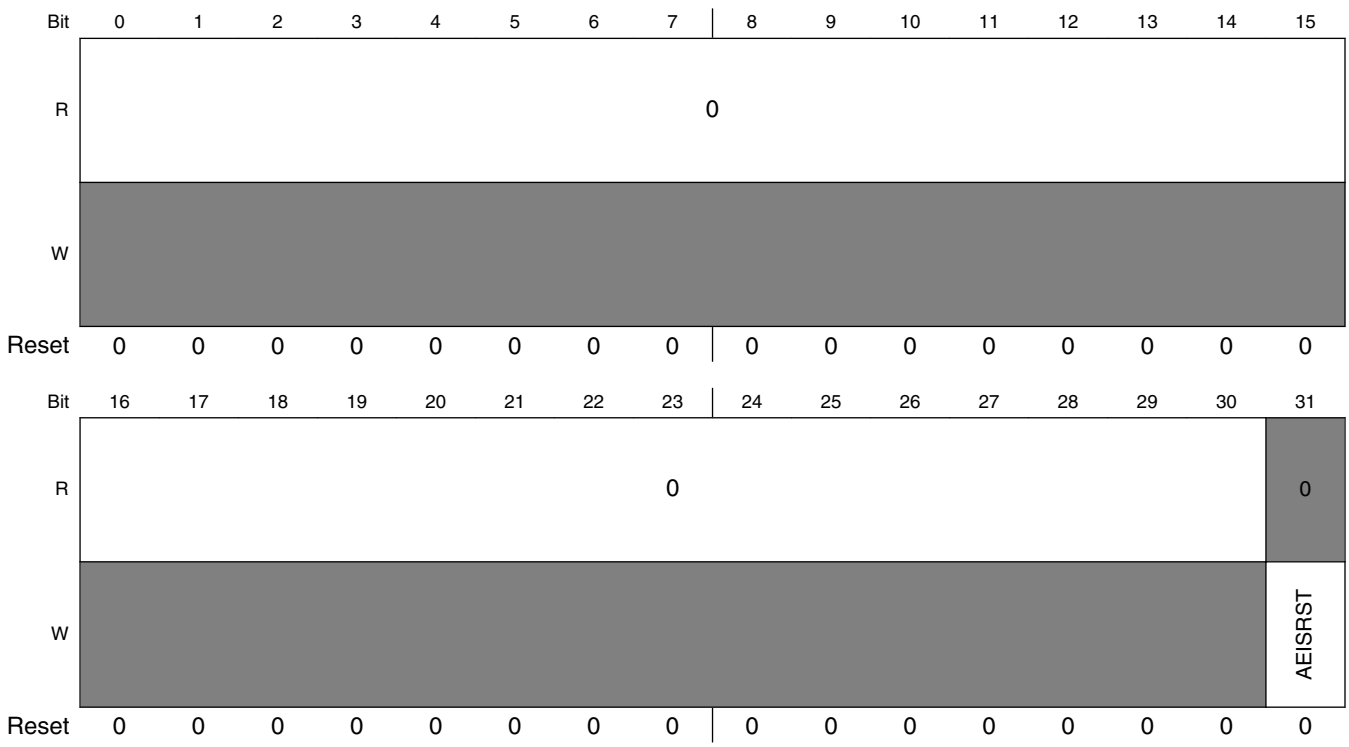
GTMINT_GTMINTCLR field descriptions

Field	Description
0–21 Reserved	This read-only field is reserved and always has the value 0.
22–31 INTCLR_ PTR[0:9]	[Covers: Saf1461] INTCLR_PTR Interrupt Clear Pointer. This field selects which interrupt will be cleared. The correspondence between the number and the interrupt is given in Correspondence between the INTCLR_PTR and the interrupts outputs. Refer to Clearing interrupts via GTMINT for more details.

45.9.1.3 GTM AEI Control Register (GTMINT_GTMAEICR)

GTMAEICR contains the control bits for the AEI interface soft reset.

Address: 0h base + CCh offset = CCh



GTMINT_GTMAEICR field descriptions

Field	Description
0–30 Reserved	This read-only field is reserved and always has the value 0.
31 AEISRST	[Covers: Saf1461] AEISRST

Table continues on the next page...

GTMINT_GTMAEICR field descriptions (continued)

Field	Description
	AEI interface soft-reset control. AEISRST applies a reset signal to GTM-IP AEI interface. The signal is enabled by the AEISREN bit in GTMMCR register. This is a self clear bit and is always read as 0. Refer to Resetting the AEI for more details. 0 No reset 1 Reset applied to GTM-IP AEI interface

Chapter 46
Generic Timer Module (GTM104)

46.1 About this module

GTM104 is a programmable timer that can perform complex timing and I/O management independently of the chip's processor cores.

46.2 For more information

For more information on GTM104, see the *Generic Timer Module 104 (GTM104) Reference Manual*.

Chapter 47
GTM Development Interface (GTMDI)

47.1 About this module

The GTMDI debug module unit is a hardware module that:

- Monitors the software and hardware activities of GTM-IP
- Read the registers without interfering with the logic status, even for FIFOs, by configuring the debug access controls.

47.2 Introduction

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including MCS cores, ARU data trace, Input Channel Filters trace, Output Timer channels, DPLL and SPE submodules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules in order to implement complex debug features. Trace capability is also provided along with a global time-stamp that allows real time trace for several GTM submodule events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and NPC Aurora router on-chip modules. Note that the Nexus standard is only used for the physical interfaces. In order to implement the debug features such as breakpoint and messages required for the GTM debug, the Nexus standard could not be followed.

This figure shows a block diagram of the Generic Timer Module (GTM) Development Interface.

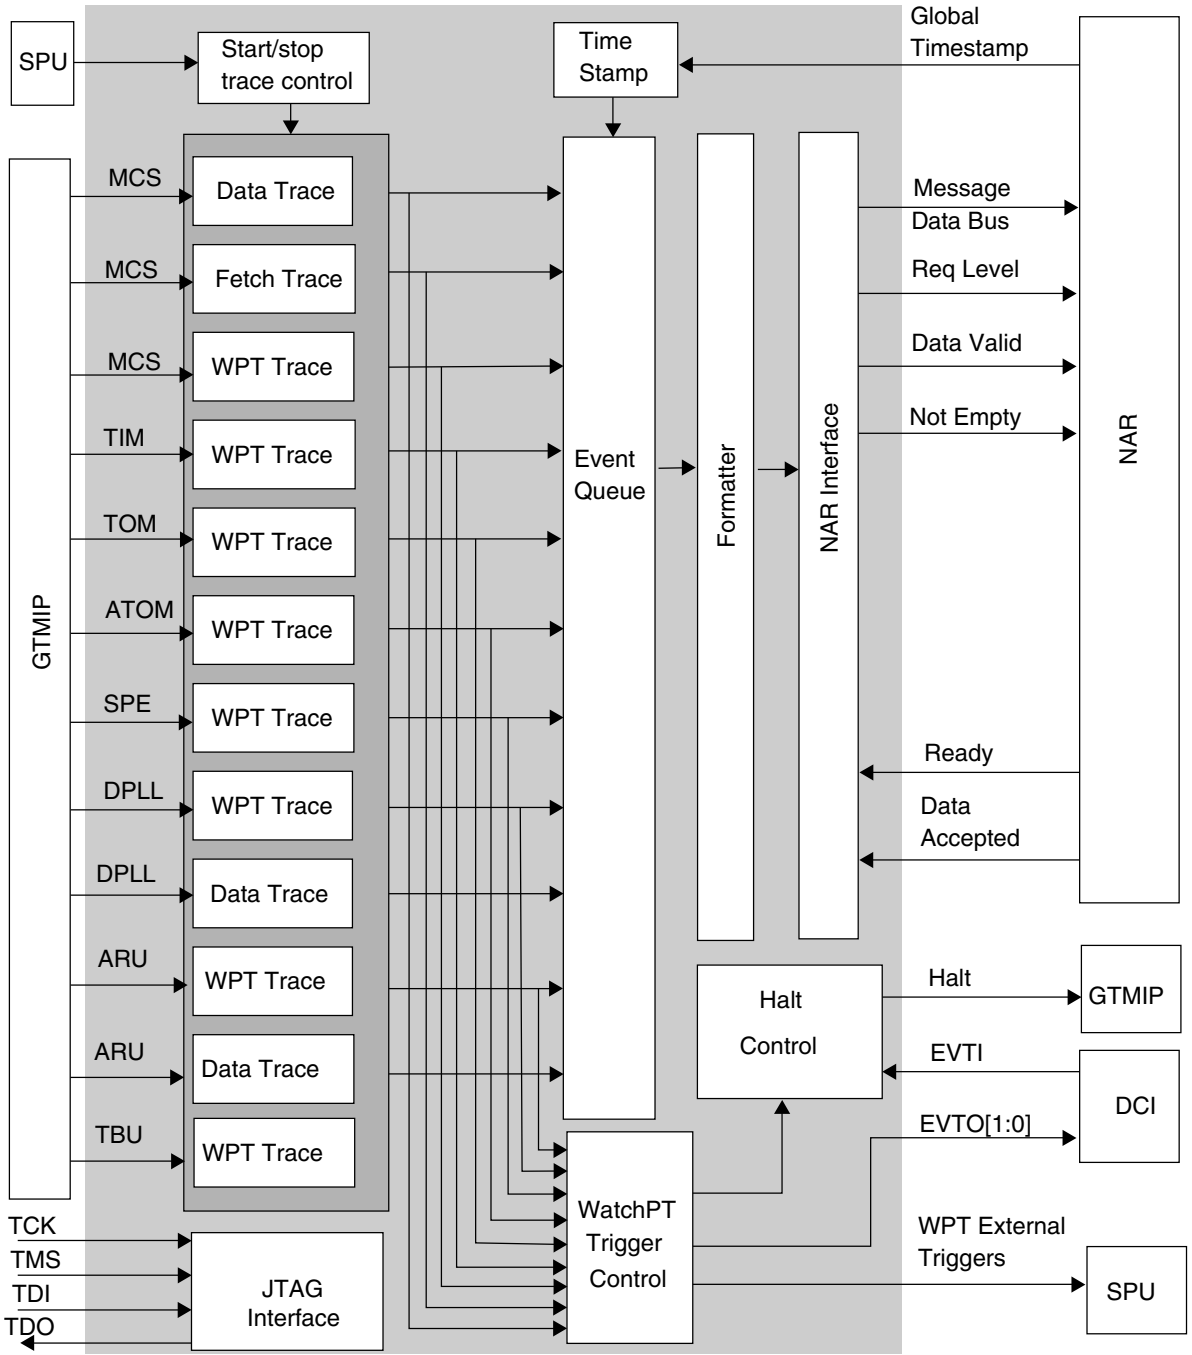


Figure 47-1. GTMDI block diagram

47.3 Overview

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-Channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, input channel filters trace, output timer channels, DPLL and Sensor Pattern Evaluation (SPE) sub-modules. The GTMDI interfaces to the GTM IP

using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and NAR on-chip modules. The Nexus standard is only used for the physical interfaces. Due to specific requirements for the GTM debug, the Nexus standard is not followed.

The following figure describes the interconnection between the GTMDI and GTM modules. The GTMDI selects which signal or bus to monitor since it does not have the capability to monitor all signals in parallel. The multiplexing architecture is described in the following sections.

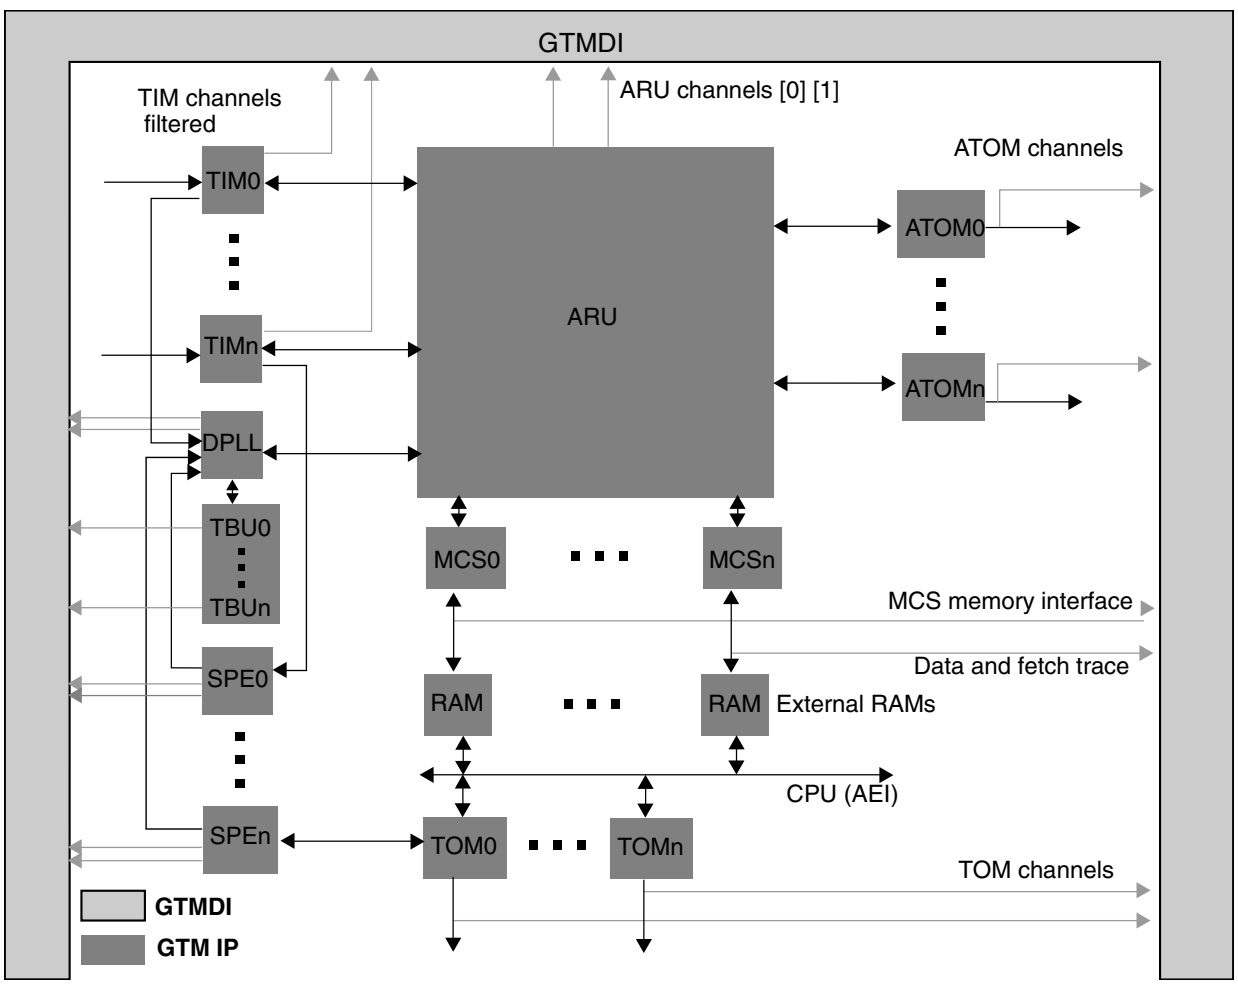

Figure 47-2. GTMDI and GTM interface

Note

Figure 47-2 does not show all of the GTM internal modules. It shows only the modules that interface to the GTMDI debug module.

The number of ATOM, TIM, TOM, MCS and SPE modules in the GTMDI and GTM interface figure is shown in this table.

Table 47-1. GTM Sub-module instances

Module	Number of instances
ATOM	9
TIM	6
TOM	5
MCS	6
SPE	4

The following figure shows the Watchpoint Triggers (WPT) and Watchpoint Messages (WPM). Each GTM sub-module generates two watchpoints which can be routed internally to the GTMDI and generate watchpoint triggers or routed to the message formatter and generate watchpoint messages. The selection between watchpoint triggers and messages is implemented per sub-module. Messages and watchpoint triggers can also be generated at the same time based on the same event within a sub-module, thus a TIM channel transition can generate a watchpoint trigger and a watchpoint message. The watchpoint triggers may be sent to the Sequence Processing Unit (SPU) outside the GTMDI if enabled by appropriate control register bits for each sub-module, such as Timer Input Module (TIM), Timer Output Module (TOM) and ARU-connected Timer Output Module (ATOM). The watchpoint messages, if enabled, are sent to the NAR through the Nexus Client interface.

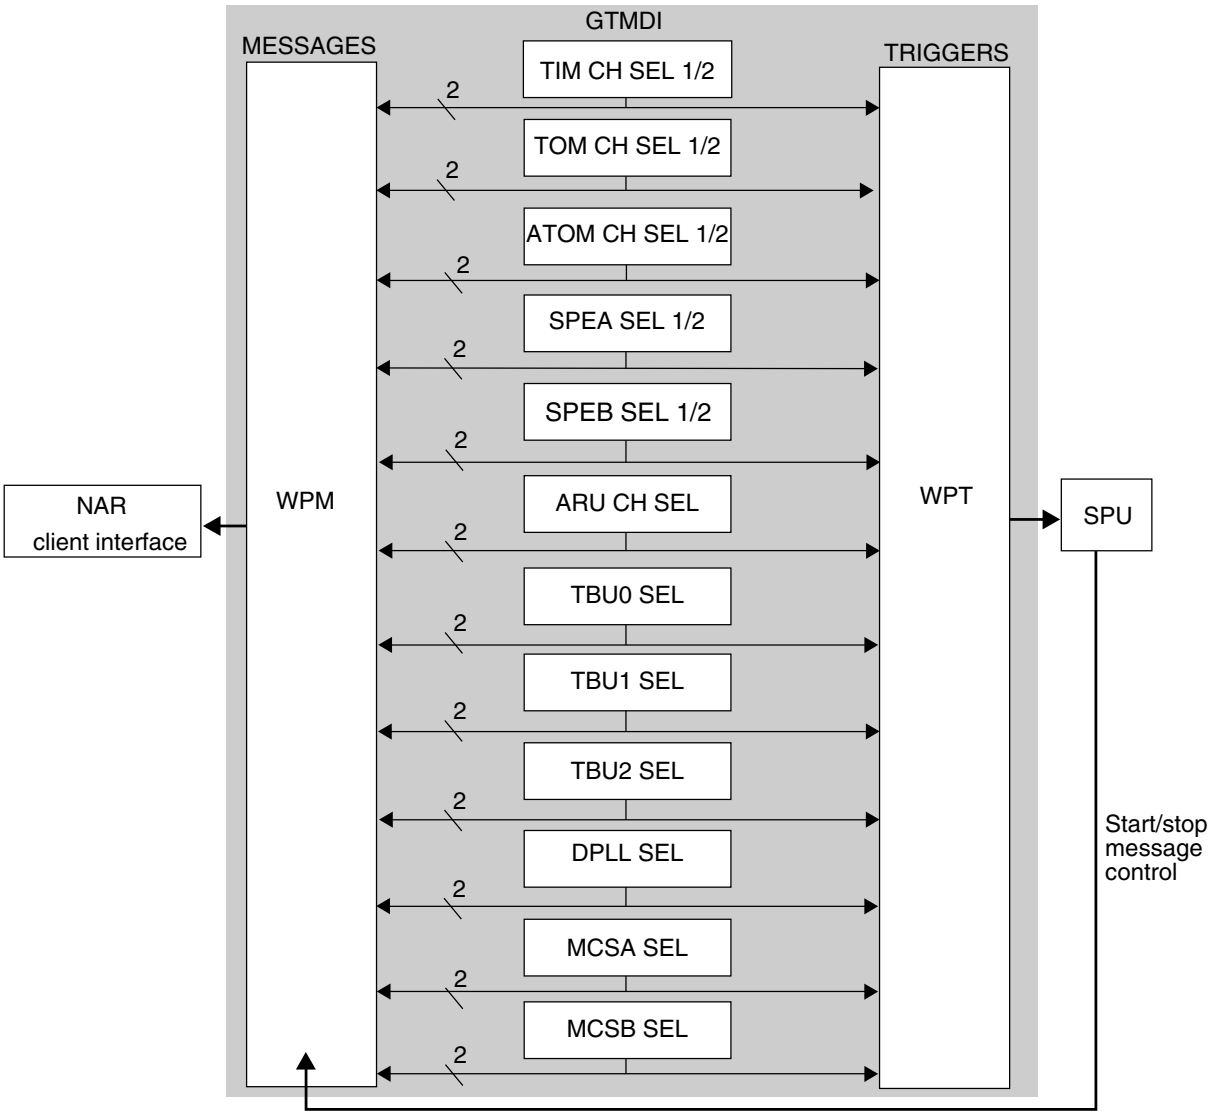

Figure 47-3. Watchpoint triggers and watchpoint messages

The SPU provides external control of the watchpoint messages generated by the GTMDI thus controlling the bandwidth over the Nexus Client interface. This functionality is implemented through Start/Stop control signals from the SPU. These signals are connected to the sub-module register bit that enables the message transmission implementing a dual control over these registers, either by JTAG interface programing or by SPU Start/Stop signals. See Functional description for more details about register control and general architecture.

47.3.1 Features

The GTMDI block implements the following features:

- Full duplex pin interface for medium and high visibility throughput
  - 2 $\overline{\text{EVTO}}$ (Event Out) for GTM real time signal monitoring
  - 1 $\overline{\text{EVTI}}$ (Event In)
  - IEEE 1149.1 (JTAG) Test Access Port (TAP)
    - 4 pins (TDI, TDO, TMS, and TCK)
    - Reset input $\overline{\text{TRST}}$ driven by either the Nexus Port Controller or an external pin
- GTM Development Support
  - Read/Write registers in debug mode from JTAG port
  - Ability to enter debug mode at reset negation or during normal execution

Note

Enter debug out-of-reset is provided through the SoC system level debug control signal. In order to allow this functionality the GDE and SDBE control bits in the GTMDI_DC register should be set.

  - Halt and Watchpoint Configuration
  - MCS Data Trace Messaging (DTM) and Watchpoint Messaging (WPM) allows the development tool to trace reads and writes to selected MCS RAM address ranges
    - Two data trace windows for each MCS core with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the Aurora port bandwidth by constraining the number of trace locations.
    - Fetch trace capability controlled by two programmable Watchpoints.
    - Private messages are used to indicate special MCS core cases not covered by public messages. Two MCS cores can be debugged at the same time.

Note

Enabling two MCS cores at the same time for data trace can exceed the capacity of the NAR Client interface throughput thus information can be lost.

    - DPLL Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace reads and writes to selected DPLL RAM addresses and selected data value.
    - ARU Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace selected ARU channels.
    - Watchpoint Messaging (WPM)
- Trigger Control
    - The GTMDI provides selection of trigger signals that generate debug actions at system level such as Halt GTM itself or cores in the same device.
    - Trace enable signals are provided to control the start/stop of trace messages for each one of the GTM Nexus message sources, such as Timer Input Module (TIM), Timer Output Module (TOM), ARU-connected Timer Output Module (ATOM), etc.
- GTMDI clock operation
    - The module is able to operate in any frequency ratio considering GTMDI and JTAG frequency. The GTMDI operates from the same clock source as the GTM IP module.

47.3.2 Modes of operation

The GTMDI block is placed in reset when the Nexus reset signal is asserted. The JTAG registers controlled by the TCK clock are also put into the reset state if the TAP controller is in the TEST-LOGIC-RESET state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the TEST-LOGIC-RESET state regardless of the initial TAP controller state. Asserting the Nexus reset signal results in asynchronous entry into the reset state not only of the TCK controlled registers but all registers in the GTMDI. The GTMDI is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the TEST-LOGIC-RESET state
- The auxiliary output port pins are negated
- The auxiliary output port enable outputs are negated

- The TDI, TMS, and TCK TAP inputs are ignored (The TMS and TCK signal are ignored only while the Nexus reset signal is asserted.)
- Registers default back to their reset values

Note

The GTMDI is not reset by the system reset signal. It is reset during device Power On reset or by a dedicated Nexus reset thus preserving internal registers state and programming during system reset.

Debug Mode can be controlled by on-chip logic through the system debug signal. The level on this signal defines if the GTM module is in debug mode, meaning that it is in Halt state and accepts write and read accesses to internal registers that do not modify the state of those registers. If asserted, the GTM enters Halt state. If negated, the GTM debug mode is controlled by other sources, internal to the GTMDI. The GTM may enter debug out of reset by asserting the system debug signal while the device is being reset. By detecting this condition, the GTMDI puts the GTM into the Halt state. The GDE and SDBE bits described in GTMDI development control register (GTMDI_DC) must be set during reset allowing the GTM to enter debug state.

47.3.2.1 DATA port

GTMDI messages are sent through the Message Data Bus. The Message Data Bus has a fixed width of 32 bits which defines one BEAT of data. There are three BEATS per NAR clock, thus 96 bits are transmitted in parallel.

47.4 External signal description

The GTMDI pinout provides interface for the transmission of messages and for accessing Nexus registers. The GTMDI pin definition is outlined in the following table.

Table 47-2. GTMDI signal properties

Name	Port	Function	Reset State
$\overline{\text{EVTI}}$	Auxiliary	Event In pin	—
$\overline{\text{EVTO}}$[1:0]	Auxiliary	Event Out pin	[11]
TCK	TAP	Test Clock Input	—
TDI	TAP	Test Data Input	—

Table continues on the next page...

Table 47-2. GTMDI signal properties (continued)

Name	Port	Function	Reset State
TDO	TAP	Test Data Output	0
TMS	TAP	Test Mode Select Input	—
$\overline{\text{TRST}}$	TAP	Test Reset Input	—

Each of the signals listed in this table is described in more detail in the following sections.

47.4.1 Event in ($\overline{\text{EVTI}}$)

Event In ($\overline{\text{EVTI}}$) is used to generate a Halt if enabled by the corresponding control bit. $\overline{\text{EVTI}}$ is an edge-sensitive signal. It is synchronized at the GTMDI input and a falling edge is detected.

47.4.2 Event out $\overline{\text{EVTO}}$[1:0]

Event Out ($\overline{\text{EVTO}}$) are two outputs from GTMDI for development tools with exact timing for a two watchpoints or Halt occurrence. $\overline{\text{EVTO}}$ is asserted for one system clock cycle when Halt or watchpoints are monitored. When internal GTM signals are monitored, such as TIM filtered signals or TOM/ATOM outputs, the $\overline{\text{EVTO}}$ represent the exact signal shape with a certain delay. In this monitoring mode the signal is not inverted through the $\overline{\text{EVTO}}$ output. The real time monitoring mode is intended for oscilloscope type of monitoring thus allowing the user to evaluate the actual shape of the signals. The source selection for the $\overline{\text{EVTO}}$ is centralized in the Development Control register GTMDI_DC.

47.4.3 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the JTAG port.

47.4.4 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

47.4.5 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is actively driven in the SHIFT-IR and SHIFT-DR states of the JTAG state machine. TDO changes on the falling edge of TCK and is sampled on the rising edge of TCK.

47.4.6 Test Mode Select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the JTAG state machine. TMS is sampled on the rising edge of TCK.

47.5 Register definition

This section provides a detailed description of all GTMDI registers accessible to the development tool. Individual bit-level descriptions and reset states of each register are included. The following table shows the GTMDI registers and index values. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 47-3. GTMDI registers

Register	Index	Read/write

47.5.1 Register descriptions

This section consists of GTMDI register descriptions. The registers are shown in Table 47-3 . The MCS cores selected for debugging are named MCSA and MCSB thus two MCS cores can be debugged at the same time. See registers GTMDI_MCSA_DC and GTMDI_MCSB_DC which specify the real number of the MCS associated with MCSA and MCSB.

47.5.1.1 Device identity register (DID)

The DID register contains the unique identification information as shown in this table.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number

R	Part Identification Number				Manufacturer Identity Code											1
W																
RESET	DID_PIN (contd)				DID_MIC											1

This table describes the device identification register functions.

Table 47-4. DID field descriptions

Field	Description
31–28 PRN	Part Revision Number. Contains the revision number of the part. Value is 0x1.
27–22 DC	Design Center. Indicates the design center. Value is 0x2b.
21–12 PIN	Part Identification Number. Contains the part number of the device. Value is 0x3E4.
11–1 MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
0 IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

47.5.1.2 GTMDI development control register (GTMDI_DC)

The GTMDI_DC register controls various trace and debug features of the GTM modules as described in this table.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This table describes the GTMDI_DC register functions.

Table 47-5. GTMDI_DC field descriptions

Field	Description
31 GDE	Global Debug Enable. This control bit disables all debug features of the GTMDI module including ability to put GTM IP in Halt state, modify EVTO output, send messages to the DATA bus and set triggers to the SPU module. Before changing the GTMDI configuration it is recommended to clear GDE bit to prevent spurious behavior of the module outputs. See Figure 47-4 for details about debug enable logic. 0 GTMDI Global debug is disabled 1 GTMDI Global debug is enabled
27–24 EOS0	$\overline{\text{EVTO0}}$ Output Selection. This signal is dedicated to sel 1 which is the selection 1 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output EVTO0 remains at one 0001 Halt Indication, If $\overline{\text{EVTO0}}$ is zero indicates that GTM is halted 0010 TIM, Map EVTO0 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO0 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO0 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO0 from SPEA, controlled by TSS1 described in SPEA watchpoint control 1 register (GTMDI_SPEA_WPC1) 0110 SPEB, Map EVTO0 from SPEB, controlled by TSS1 described in SPEB watchpoint control 1 register (GTMDI_SPEB_WPC1) 0111 ARU CH0, Map EVTO0 from ARU CH0l 1000 DPLL, Map EVTO0 from DPLL according to TSEL1 in DPLL watchpoint control 1 register (GTMDI_DPLL_WPC1) 1001 MCSA, Map EVTO0 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO0 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved
19–16 EOS1	$\overline{\text{EVTO1}}$ Output Selection. This signal is dedicated to sel 2 which is the selection 2 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output EVTO1 remains at one 0001 Halt Indication, If $\overline{\text{EVTO1}}$ is zero indicates that GTM is halted 0010 TIM, Map EVTO1 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO1 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO1 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO1 from SPEA, controlled by TSS2 described in SPEA watchpoint control 1 register (GTMDI_SPEA_WPC1) 0110 SPEB, Map EVTO1 from SPEB, controlled by TSS2 described in SPEB watchpoint control 1 register (GTMDI_SPEB_WPC1)

Table continues on the next page...

Table 47-5. GTMDI_DC field descriptions (continued)

Field	Description
	0111 ARU CH1, Map EVTO1 from ARU CH1 1000 DPLL, Map EVTO1 from DPLL according to TSEL2A/B in DPLL watchpoint control 1 register (GTMDI_DPLL_WPC1) 1001 MCSA, Map EVTO1 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO1 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved
8 CHR	Clear Halt Request. Writing this bit to one clears halt requests., which means GTM resumes normal operation out of halt state. The status bits of the GTMDI_DS register are cleared. This bit is self-cleared thus read always as zero. 0 No action 1 Clear halt requests
6 EIDR	EVTI Debug Request enable. The EIDR bit enables EVTI input to request the GTM to enter Halt state. After the GTM enters Halt state due to a pulse in EVTI signal, the EIDR bit state is not meaningful, thus it may be cleared and the GTM continues in Halt state. See Figure 47-4 for details about debug enable logic. 0 Disable EVTI to control GTM to enter Halt state 1 Enable EVTI to control GTM to enter Halt state
4 DBE	Debug Enable. DBE enables debug mode thus allowing the GTM to enter debug mode which means halt regular operation. The debug events controlled by this register are the ones generated internally to the GTMDI, excluding ipg_debug and EVTI which have their dedicated enable control. See Figure 47-4 for details about debug enable logic. 0 Debug mode disabled 1 Debug mode enabled
3 DBR	Debug Request. Mechanism to allow development tool to request modules to enter debug mode directly. See Figure 47-4 for details about debug enable logic. 0 Does not modify GTM IP debug state 1 Request GTM IP to enter debug mode
2 SDBE	System Debug Enable. The SDBE bit enables the GTM to enter halt state if system level debug enable signal is asserted. This bit allows the debug controller to select specific sub-groups of cores or modules to halt, while others continue to operate. GDE bit must also be set to allow GTM to halt. See Figure 47-4 for details about debug enable logic. 0 GTM does not enter halt state due to system debug enable signal assertion 1 GTM is enabled to enter halt state due to system debug enable signal assertion
0 TSFT	Timestamp Force Transmission. Forces the transmission of the Timestamp value along with the Nexus message data for all messages transmitted by the GTMDI Client module. When Timestamp inclusion is not forced into the client message, its inclusion depends upon the NAR settings. 0 Does not force transmission of Timestamp value 1 Forces transmission of Timestamp along with Nexus message

47.5.1.3 GTMDI development status register (GTMDI_DS)

The GTMDI_DS register, described in the following table, shows the status of various conditions that impact GTM development support. All status bits are dynamic and do not require clearing. Debug Status Event is queued due to a change in the Halt or Stop modes and a Debug Status Message is generated as soon as there is an opportunity in the NAR interface. If any status bit changes before the Status message is sent, this change is reflected in the message. The GTMDI_DS register dynamically tracks the debug condition status even when several of them are simultaneously set.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	HLT	0	0	HS1												
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STP	0	0	HS2												
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table describes the GTMDI_DS register functions.

Note

The HS1 and HS2 bit fields are cleared as soon as the GTM resumes normal operation which is controlled by the CHR bit in the GTMDI_DC register. One exception is HS1[0] that indicates system debug request, which is not cleared by CHR. This bit is cleared when system debug request is negated.

Table 47-6. GTMDI_DS field descriptions

Field	Description	
31 HLT	Halt Indication. The HLT bit indicates if the GTM IP is in Halt state, ready to receive debug accesses.	
	0	GTM is running
	1	GTM is in Halt state
28–16 HS1	Halt Status1. The HS1 field shows which source generated the halt condition. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt sources that occurred immediately when the halt mode is entered.	
	0000000000000	No Trigger generated
	1xxxxxxxxxxx	TIM
	x1xxxxxxxxxx	TOM

Table continues on the next page...

Table 47-6. GTMDI_DS field descriptions (continued)

Field	Description	
	xx1xxxxxxxxx	ATOM
	xxx1xxxxxxxx	SPEA
	xxxx1xxxxxxx	SPEB
	xxxxx1xxxxxx	ARU
	xxxxxx1xxxxx	DPLL
	xxxxxxx1xxxx	MCSA

	xxxxxxxxx1xx	TBU0 Watchpoint 1
	xxxxxxxxxx1x	TBU1 Watchpoint 1
	xxxxxxxxxxx1	TBU2 Watchpoint 1
	xxxxxxxxxxxx1	External through system debug enable signal
15 STP	Stop Status. Indicates if the GTM is in stop mode with no active clocks. Besides the system level stop mode mechanism, the GTM may independently be programmed for STOP mode by setting the Module Disable Control bit. Thus, the STP field indicates if the GTM is in stop mode no matter if due to the system stop mode assertion or due to the MDIS bit in the GTM module control register.	
	0	GTM not stopped
	1	GTM is stopped in low power mode
12–0 HS2	Halt Status2. Similarly to HS1 this field indicates the source for the halt condition selection 2. See Figure 47-5 for reference about source selection 1 and 2. The HS2 field shows which source generated the halt condition 2. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt condition source that occurred when the halt mode is entered.	
	0000000000000	No Trigger generated
	1xxxxxxxxxxx	TIM
	x1xxxxxxxxxx	TOM

	xxxxxxxxxxxx1	$\overline{\text{EVTI}}$

47.5.1.4 TIM watchpoint control register 1 (GTMDI_TIM_WPC1)

The GTMDI_TIM_WPC1 register, shown in the following table, controls the Watchpoint Triggers WPT issued by TIM channels. These triggers are used by the GTM internal modules in order to control GTM Halt mode entering and also at SoC level. See Figure 47-5 which describes the use of this register.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG. The SEN1 and SEN2 control bits from the GTMDI_TIM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Register index: 11

Field	Description
	101 TIM5 110 Reserved 111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
18–16 CHSEL1	TIM channel selection 1. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7
13–12 TSS2	TIM Channel Slope Selection 2. The TSS2 field selects the slope for the TIM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
10–8 SSEL2	TIM sub-module Source Selection 2. Selects which TIM sub-module is the source for watchpoint generation. 000 TIM0 001 TIM1 010 TIM2 011 TIM3 100 TIM4 101 TIM5 110 Reserved 111 Reserved
7 HEN2	Halt Enable 2. The HEN1 Halt Enable 2 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM

Table continues on the next page...

Table 47-7. GTMDI_TIM_WPC1 field descriptions (continued)

Field	Description
	1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC1 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
2–0 CHSEL2	TIM channel selection 2. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7

47.5.1.5 TIM watchpoint control register 2 (GTMDI_TIM_WPC2)

The GTMDI_TIM_WPC2 register, shown in the following table, controls the Watchpoint Triggers WPT issued by TIM channels. These watchpoint triggers are used to control GTM Halt state entering, watchpoint messages and control external logic to the GTMDI. See Figure 47-5 for details of the logic that uses the bits in this register.

Register index: 12

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This table describes the GTMDI_TIM_WPC2 register functions.

Note

The SHARED_WPT and SHARED_WPT_ST signals mentioned in Table 47-8 and in other tables in this document, refer to the GTMDI top level connections. They correspond to Watchpoint trigger outputs of GTMDI and Stop/Start input signals respectively.

Table 47-8. GTMDI_TIM_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same WTSEL1 value, in this case the result watchpoint signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a Watchpoint external trigger is issued. This enable refers to the output selected by the WTSEL1 field. 0 Disable Watchpoint Trigger Generation 1 Enable Watchpoint Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected TIM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same watchpoint trigger, in this case the result signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4]

Table continues on the next page...

Table 47-8. GTMDI_TIM_WPC2 field descriptions (continued)

Field	Description
	101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used to control the watchpoint trace messages for the selected TIM channel. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TIM channel. This enable refers to the output selected by the WTSEL2 field. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.6 TOM watchpoint control register 1 (GTMDI_TOM_WPC1)

The GTMDI_TOM_WPC1 register shown in the following table controls the Watchpoint Triggers issued by TOM channels. These Watchpoint triggers are used to control the GTM requests to enter Halt, issue watchpoint messages and also by logic external to the GTMDI at SoC level.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Register index: 17

Table 47-10. GTMDI_TOM_WPC2 field descriptions (continued)

Field	Description
	10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TOM channel. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs of the GTMDI to control Watchpoint trace messages generated by the TOM selected channel. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.8 ATOM watchpoint control 1 register (GTMDI_ATOM_WPC1)

The GTMDI_ATOM_WPC1 register, shown in the following table, controls the Watchpoint Triggers issued by ATOM channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ATOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the SPEB DIR selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_SPEB_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.14 DPLL watchpoint control 1 register (GTMDI_DPLL_WPC1)

The GTMDI_DPLL_WPC1 register, shown in the following table, controls various trace and debug features of the DPLL modules as described below.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_DPLL_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

This table describes the GTMDI_DPLL_WPC1 register functions.

Table 47-17. GTMDI_DPLL_WPC1 field descriptions

Field	Description
25–24 TSEL1	Watchpoint Selection 1. The TSEL1[1:0] field selects if a watchpoint trigger is issued based on TASI or SASI events. 00 Watchpoint on TASI event 01 Watchpoint on SASI event 10 Reserved 11 Reserved
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on DPLL SASI or TASI to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

Table continues on the next page...

Table 47-17. GTMDI_DPLL_WPC1 field descriptions (continued)

Field	Description
21–20 TSS1	TASI/SASI Slope Selection. The TSS1 field selects the slope for TASI or SASI depending on TSEL1 selection. The selected slope is monitored by watchpoints. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
17 HEN1	The HEN1 Halt Enable 1 bit controls if the DPLL SASI or TASI selected signal is enabled to HALT the GTM module. If this bit is set and an event occurs on the DPLL selected signal, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
13–12 TSEL2B	Watchpoint Selection 2B. The TSEL2B field selects the RAM access type to mach on 00 Watchpoint is issued on any access (read or write) 01 Watchpoint is issued based on write accesses 10 Watchpoint is issued based on read accesses 11 Reserved
9–8 TSEL2A	Watchpoint Selection 2A. The TSEL2A field selects if a watchpoint is issued based on the RAM1a, RAM1bc or RAM2 access. 00 Watchpoint is issued based on RAM1a access 01 Watchpoint is issued based on RAM1b access 10 Watchpoint is issued based on RAM2 access 11 Reserved
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables selected accesses on DPLL RAMs to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
1 HEN2	Halt Enable 2. The HEN Halt Enable bit controls if watchpoint from TSEL2 selection is enabled to HALT the GTM module. If this bit is set and an event occurs on an DPLL selected RAM, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM

47.5.1.15 DPLL watchpoint control 2 register (GTMDI_DPLL_WPC2)

The GTMDI_DPLL_WPC2 register, shown in the following table, controls the Watchpoint Triggers issued by DPLL. These triggers are used for GTM to enter Halt state and by GTMDI external logic at SoC level. This register also controls the Watchpoint Trace messages WPM.

Register index: 42

This table describes the GTMDI_DPLL_WPC2 register functions.

Table 47-18. GTMDI_DPLL_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL SASI or TASI signal. Other modules can select this same WTSEL1 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages related to DPLL SASI or TASI signals. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a watchpoint external trigger is issued by the DPLL TASI or SASI selected event. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enable the DPLL TASI or SASI selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table continues on the next page...

Table 47-18. GTMDI_DPLL_WPC2 field descriptions (continued)

Field	Description
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL RAM access signal. Other modules can select this same WTSEL2 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used by the watchpoint trace messages related to DPLL RAM access events for RAM1A, RAM1B and RAM2. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a watchpoint external trigger is issued by the DPLL RAM selected access. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the DPLL RAM selected access event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.16 DPLL watchpoint control 3 register (GTMDI_DPLL_WPC3)

The GTMDI_DPLL_WPC3 register, shown in the following table, defines the data value observed in the selected DPLL RAM access. A match to this value causes a Watchpoint.

Register index: 43

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This table describes the GTMDI_DPLL_WPC3 register functions.

Table 47-19. GTMDI_DPLL_WPC3 field descriptions

Field	Description
28 DMASK	Data Mask. The DMASK field is a mask for the data comparator. If set, the data read or written to the memory should not be considered for watchpoint generation. 0 RAM_DATA should be compared with data from RAM access 1 RAM_DATA is masked and should not be compared
23–0 RAM_DATA	Data value. The RAM_DATA[23:0] field defines the data value that is compared against the data accessed from the selected DPLL RAM.

47.5.1.17 DPLL watchpoint control 4 register (GTMDI_DPLL_WPC4)

The GTMDI_DPLL_WPC4 register, shown in the following table, defines the RAM address mask for the DPLL selected RAM address comparisson.

Register index: 44

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table describes the GTMDI_DPLL_WPC4 register functions.

Table 47-20. GTMDI_DPLL_WPC4 field descriptions

Field	Description
11–0 RAM_ADDR_MASK	RAM Address mask. The RAM_ADDR_MASK[11:0] field is a mask applied bit by bit to the RAM_ADDR defined in the GTMDI_DPLL_WPC5 register. If mask is 1, the corresponding RAM_ADDR bit is not valid for comparison, thus it always returns a match when compared to the selected RAM address.

47.5.1.18 DPLL watchpoint control 5 register (GTMDI_DPLL_WPC5)

The GTMDI_DPLL_WPC5 register, shown in the following table, defines the address value that is monitored during DPLL selected RAM access. Once this address value matches with the DPLL RAM address a Watchpoint is issued.

Register index: 45

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table describes the GTMDI_DPLL_WPC5 register functions.

Table 47-21. GTMDI_DPLL_WPC5 field descriptions

Field	Description
11–0 RAM_ADDR	RAM Address Compare. The RAM_ADDR[11:0] field defines the address value that is compared against the address for write and read DPLL RAM accesses. Before the comparison is executed the RAM_ADDR_MASK should be considered thus masking corresponding bits. A masked bit is always considered a match. **Note:** DPLL module has three RAM modules with different address widths. The address value in the RAM_ADDR field and the RAM address should be right aligned in order to be compared.

47.5.1.19 DPLL data trace control register (GTMDI_DPLL_DTC)

The GTMDI_DPLL_DTC register, shown in the following table, controls data trace message transmission.

Register index: 46

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	RWC		0	0	RAMSEL		0	DMC	STSEL		0	0	0	SEN
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the DMC control bit thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit from the GTMDI_DPLL_DTC register need to be set in order to allow external Start/Stop signals to control the DMC bit.

This table describes the GTMDI_DPLL_DTC register functions.

Table 47-22. GTMDI_DPLL_DTC field descriptions

Field	Description
13–12 RWC	Read/Write Control. This bit controls DPLL data trace message transmission. 00 Transmits only memory reads 01 Transmits only memory writes 10 Transmits all memory accesses 11 Reserved
9–8 RAMSEL	RAM Module Selection. This field selects a DPLL memory module for data tracing. 00 RAM1a selected for data tracing 01 RAM1b selected for data tracing 10 RAM2 selected for data tracing 11 Reserved
6 DMC	Data Trace Message Control. This bit is written by JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Data Trace Messages disabled

Table continues on the next page...

Table 47-22. GTMDI_DPLL_DTC field descriptions (continued)

Field	Description
	1 Data Trace Messages enabled
5–4 STSEL	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
0 SEN	Start/Stop Enable. The SEN bit field enables the DPLL data trace message generator to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DMC Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.20 ARU watchpoint control 1 register (GTMDI_ARU_WPC1)

The GTMDI_ARU_WPC1 register, shown in the following table, controls the Watchpoint Triggers issued by ARU Debugging Channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ARU_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

This table describes the GTMDI_ARU_WPC1 register functions.

Table 47-23. GTMDI_ARU_WPC1 field descriptions

Field	Description
28 TSS1	ARU Debugging Channel 0 Data Activity Selection 1. The TSS1 bit selects the type of data activity to monitor on ARU Debugging Channel 0. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel 0 1 Compare data with expected value
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the ARU Debugging Channel 0 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 0, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches on the ARU Debugging Channel 0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
12 TSS2	ARU Debugging Channel 1 Data Activity Selection. The TSS2 bit selects the type of data activity to monitor on the ARU Debugging Channel 1. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel Monitor 1 1 Compare data with expected value
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the ARU debugging Channel 1 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 1, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match on the ARU Debugging Channel 1 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

47.5.1.21 ARU watchpoint control 2 register (GTMDI_ARU_WPC2)

The GTMDI_ARU_WPC2 register, shown in the following table, controls the Watchpoint Triggers issued by ARU Debugging Channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Register index: 51

Table 47-28. GTMDI_ARU_DATA1L field descriptions

Field	Description
28–0 DATA1L	Watchpoint DATA1L. This field is compared against the low word of the ARU Debugging Channel 1.

47.5.1.26 ARU data trace control register (GTMDI_ARU_DTC)

The GTMDI_ARU_DTC register, shown in the following table, controls the ARU data trace message transmission. The GTM Module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1. The data trace for these two channels is controlled by DMC1/2 bits in this register. Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the DMC1 and DMC2 control bits thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC1 or DMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits need to be set in order to allow external Start/Stop signals to control the DMC1/2 bits.

Table 47-29. GTMDI_ARU_DTC field descriptions

Field	Description
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used by the ARU Debugging Channel 0 data trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 DMC1	Data Trace Message Control. This bit controls ARU data trace messages transmission for ARU Debugging Channel 0. This bit is written by the JTAG interface but can also be controlled at SoC level by dedicated Start/Stop signals, inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
16 SEN1	Start/Stop Enable 1. The SEN 1 bit field enables the ARU data trace message generator for ARU Debugging Channel 0 to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DMC1 Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table continues on the next page...

Table 47-29. GTMDI_ARU_DTC field descriptions (continued)

Field	Description
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used by the ARU Debugging Channel 1 data trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 DMC2	Data Trace Message Control. This bit controls ARU data trace message transmission for ARU Debugging Channel 1. This bit is written by the JTAG interface but can also be controlled at SoC level by dedicated Start/Stop signals, inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
0 SEN2	The SEN2 bit field enables the ARU data trace message generator for ARU Debugging Channel 1 to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to DMC2 Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

47.5.1.27 MCSA/B development control register (GTMDI_MCSA_DC and GTMDI_MCSB_DC)

The GTMDI_MCSA_DC and GTMDI_MCSB_DC registers, shown in the following table, control various trace and debug features.

Note

Since MCSA and MCSB have a common sets of registers they are described together to avoiding duplication of similar information.

Register index: MCSA-60 / MCSB-77

Field	Description
11–8 MCSA/B_SEL	MCSA/B Selection field. The MCSA/B_SEL[3:0] selection field selects which one of the MCS cores in the GTM module are assigned as MCSA/B. 0000 MCS0 0001 MCS1 0010 MCS2 0011 MCS3 0100 MCS4 0101 MCS5 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

47.5.1.28 MCSA/B watchpoint control register (GTMDI_MCSA_WPC and GTMDI_MCSB_WPC)

The MCSA/B Watchpoint Control Registers, shown in the following table, are used to configure MCSA/B watchpoints. These registers can be configured for halt/watchpoint based on instruction fetch, data read or data write, with address and data masking options.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC control bit thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC bit and Start/Stop signals occur at the same time also modifying the

same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit needs to be asserted in order to allow external Start/Stop signals to control the WMC bit.

The watchpoint channel selection is made through the GTMDI_MCSA_CE and GTMDI_MCSB_CE by the WPCE field.

Register index: MCSA-62 / MCSB-79

This table describes the GTMDI_MCSA_WPC and GTMDI_MCSB_WPC register functions.

Table 47-31. GTMDI_MCSA_WPC and GTMDI_MCSB_WPC field descriptions

Field	Description
25–24 HACH	Halt/Watchpoint on Active Channel. The HACH field selects which type of MCS RAM access generates a watchpoint or halt. Combining this field with HWO gives GTMDI the capability of monitoring channel activity as well as accesses to specific addresses or data. 00 Match on Instruction Fetch 01 Match on Data Read 10 Match on Data Write 11 Match on Data Read or Write
22 WMC	Watchpoint Message Control. The WMC Watchpoint Message Control bit controls the watchpoint message sent through the Message Data bus.. If this bit is asserted it enables MCSA/B Watchpoints to generate a watchpoint message This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
19–16 HME	Halt/Watchpoint Data Mask Enable. The HME field selects which data bytes are used for hardware halt/watchpoint generation when comparing to HWD register. This register field is only meaningful if HWO bit field is [x1], otherwise the data comparison is disabled independent of HME value. 0000 All bytes of data compared xxx1 Least significant byte of data masked out

Table continues on the next page...

Table 47-31. GTMDI_MCSA_WPC and GTMDI_MCSB_WPC field descriptions (continued)

Field	Description
	xx1x Second least significant byte of data masked out x1xx Second most significant byte of data masked out 1xxx Most significant byte of data masked out
15–14 HWO	Halt/Watchpoint Operand. The HWO field selects if address and/or data matching is done. Registers WPA and WPD are used for address and data comparison, respectively. If address is not compared WPA is not use. If data is not compared then WPD is not used. 00 Comparison Disabled for address or data x1 Compare data with HWD field 1x Compare address with HWA field
8 EOC	$\overline{\text{EVTO}}$ Control. The EOC bit controls the indication on the $\overline{\text{EVTO}}$ output. See MCSA/B watchpoint address 1 register (GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1), MCSA/B watchpoint address 2 register (GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2), MCSA/B watchpoint data 1 register (GTMDI_MCSA_WPD1 and GTMDI_MCSB_WPD1) and MCSA/B watchpoint data 2 register (GTMDI_MCSA_WPD2 and GTMDI_MCSB_WPD2) for definition about watchpoint 1 and 2. 0 Indicates Watchpoint 2 occurrence 1 Indicates Watchpoint 1 occurrence
7 HEN	Halt Enable. The HEN Halt Enable bit controls if the MCSA/B Watchpoint is enabled to HALT the GTM IP module. If this bit is set and watchpoint occurs on the MCSA/B a Halt signal is generated to the GTM IP which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
5–4 STSEL	Start/Stop input signal selection. Selects the Start/Stop input that is used to control the watchpoint messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN	Watchpoint Trigger Enable.The TEN field controls if a external trigger is issued by the MCSA/B when a watchpoint occurs. 0 Disables Trigger Generation 1 Enables Trigger Generation
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Watchpoint message to consider the Start/Stop inputs for watchpoint message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC Watchpoint Trace Message Control bit. 0 Disables trace control from Start/Stop inputs 1 Enables trace control from Start/Stop inputs

47.5.1.29 MCSA/B program fetch trace control register (GTMDI_MCSA_PTC and GTMDI_MCSB_PTC)

The GTMDI_MCSA_PTC and GTMDI_MCSB_PTC registers, shown in the following table, allow program fetch traces to be enabled and/or disabled on the occurrence of a watchpoint. If the same watchpoint is programed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags. If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags also toggle.

Table 47-33. GTMDI_MCSA_DTC and GTMDI_MCSB_DTC field descriptions

Field	Description
17 RC0	Range Control 0. Controls the range on data trace window 0. The window 0 is defined by DTAR1 register. See MCSA/B data trace address range 1 register (GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1). 0 Trace addresses outside (exclusive) of data trace window 0 1 Trace address inside (inclusive) of data trace window 0
16 RC1	Range Control 1. Controls the range on data trace window 1. The window 1 is defined by DTAR2 register. See MCSA/B data trace address range 2 register (GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2). 0 Trace addresses outside (exclusive) of data trace window 1 1 Trace address inside (inclusive) of data trace window 1
13–12 RWT0	MCSA/B Read/Write Trace Control 0. RWT0 controls whether data trace messages are generated for MCSA/B RAM read or write accesses.

Table continues on the next page...

Table 47-33. GTMDI_MCSA_DTC and GTMDI_MCSB_DTC field descriptions (continued)

Field	Description	
	00	No MCSA/B data trace messages generated for data trace window 0
	01	Enable MCSA/B data read trace for MCS window 0
	10	Enable MCSA/B data write trace for MCS window 0
	11	Enable MCSA/B data read and write trace for data trace window 0
9–8 RWT1	MCSA/B Read/Write Trace Control 1. RWT1 controls whether data trace messages are generated for MCSA/B accesses inside MCS data trace window, and if so, whether reads, writes, or both generate the data trace messages.	
	00	No MCSA/B data trace messages generated for data trace window 1
	01	Enable MCSA/B data read trace for MCS window 1
	10	Enable MCSA/B data write trace for MCS window 1
	11	Enable MCSA/B data read and write trace for data trace window 1
6 DTC	Data Trace Control. This bit controls the Data Trace message sent through the Message Data bus. If this bit is asserted it enables MCSA/B Data access to generate a data trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI	
	0	Data Messages disabled
	1	Data Messages enabled
5–4 DTS	Data Trace Start. This bit field allows data trace to be enabled at a watchpoint occurrence.	
	00	No watchpoint selected
	01	Data Trace enabled on MCSA/B Watchpoint 1 occurrence
	10	Data Trace enabled on MCSA/B Watchpoint 2 occurrence
	11	Reserved
2–1 DTE	Data Trace End. This bit field allows data trace to be disabled at a watchpoint occurrence.	
	00	No watchpoint selected
	01	Data Trace disabled on MCSA/B Watchpoint 1 occurrence
	10	Data Trace disabled on MCSA/B Watchpoint 2 occurrence
	11	Reserved
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Data message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DTC Data Trace Message Control bit.	
	0	Disable data trace control from Start/Stop inputs
	1	Enable data trace control from Start/Stop inputs

47.5.1.31 MCSA/B watchpoint address 1 register (GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1)

The MCSA/B Watchpoint Address Registers 1, shown in the following table, are used to configure the MCSA/B halt/watchpoint hardware. They are used for data and instruction fetch accesses.

Register index: MCSA-65 / MCSB-82

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table describes the GTMDI_MCSA_CE and GTMDI_MCSB_CE register functions.

Table 47-38. GTMDI_MCSA_CE and GTMDI_MCSB_CE field descriptions

Field	Description
7–0 CFTE	MCSA/B Channel Fetch Trace Enable. The CFTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for fetch traces. If enabled, the corresponding channel Fetches are monitored by Fetch Trace messages. Start and Stop message controls are controlled by the FTC bit in the GTMDI_MCSA/B_PTC registers, MCSA/B program fetch trace control register (GTMDI_MCSA_PTC and GTMDI_MCSB_PTC). 00000000 No channel selected for trace xxxxxxx1 Channel [0] selected xxxxxx1x Channel [1] selected xxxxx1xx Channel [2] selected xxxx1xxx Channel [3] selected xxx1xxxx Channel [4] selected xx1xxxxx Channel [5] selected x1xxxxxx Channel [6] selected 1xxxxxxx Channel [7] selected 11111111 All Channels selected

Table continues on the next page...

Table 47-38. GTMDI_MCSA_CE and GTMDI_MCSB_CE field descriptions (continued)

Field	Description
7–0 CDTE	MCSA/B Channel Data Trace Enable. The CDTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for data trace messages. If enabled, the corresponding channel Data Accesses are monitored by Data Trace messages. Start and Stop message are controlled by the DTC bit in the GTMDI_MCSA/B_DTC registers, MCSA/B data trace control register (GTMDI_MCSA_DTC and GTMDI_MCSB_DTC) and by the Data trace window. 00000000 No channel selected for trace xxxxxxx1 Channel [0] selected xxxxxx1x Channel [1] selected xxxxx1xx Channel [2] selected xxxx1xxx Channel [3] selected xxx1xxxx Channel [4] selected xx1xxxxx Channel [5] selected x1xxxxxx Channel [6] selected 1xxxxxxx Channel [7] selected 11111111 All Channels selected
7–0 WPCE	MCSA/B Channel Enable. The WPCE[7:0] is a one hot bit field which defines the channel or channels to be monitored for watchpoint, data and fetch traces. The messages controlled by this bit must be also enabled and disabled according to occurrence of Watchpoints and Address Ranges. 00000000 No channel selected for trace xxxxxxx1 Channel [0] selected xxxxxx1x Channel [1] selected xxxxx1xx Channel [2] selected xxxx1xxx Channel [3] selected xxx1xxxx Channel [4] selected xx1xxxxx Channel [5] selected x1xxxxxx Channel [6] selected 1xxxxxxx Channel [7] selected 11111111 All Channels selected

47.5.1.36 MCSA/B data trace address range 1 register (GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1)

The GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 registers, shown in the following table, define a data trace address range. The address range is used by the MCSA/B and enables the range for reads and/or writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.

Register index: MCSA–71 / MCSB–88

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	DTEA [13:2]												0	0
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NOTE

The DTSA and DTEA fields represent word addresses relative to the MCS address map, not the CPU address.

This table describes the GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 register functions.

Table 47-39. GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 field descriptions

Field	Description
29–18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSA/B data trace window.
13–2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSA/B data trace window.

47.5.1.37 MCSA/B data trace address range 2 register (GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2)

The GTMDI_MCSA_DTAR2 and GTMDI_MCSA_DTAR2 registers, shown in the following table, define a data trace address range. The address range is used by the MCSA/B and enables the range for reads and/or writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 1.

Register index: MCSA–72 / MCSB–89

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note

DTSA and DTEA fields represent word addresses which are included in the address range.

This table describes the GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR12 register functions.

Table 47-40. GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2 field descriptions

Field	Description
29–18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSA/B data trace window.
13–2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSA/B data trace window.

47.5.1.38 TBU0 watchpoint control 1 register (GTMDI_TBU0_WPC1)

The GTMDI_TBU0_WPC1 register, shown in the following table, controls the Watchpoint issued by TBU0 GTM Time Base Units (TBU). These watchpoints are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TBU0_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Register index: 94

Table 47-41. GTMDI_TBU0_WPC1 field descriptions (continued)

Field	Description
	101 Reserved 110 Reserved 111 Reserved
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the TBU0 valid event, which is a match or increment, is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU0, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match or increment on TBU0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

1. Only bits from 26 to 3 from register GTMDI_TBU0_DATA are used for comparison

47.5.1.39 TBU0 watchpoint control 2 register (GTMDI_TBU0_WPC2)

The GTMDI_TBU0_WPC2 register, shown in the following table, controls the Watchpoint Triggers issued by TBU0. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Register index: 95

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
23–0 TBU1_DATA	TBU1 Watchpoint DATA. The field TBU1_DATA[23:0] is used to compare against the TBU1 data.

47.5.1.44 TBU2 watchpoint control 1 register (GTMDI_TBU2_WPC1)

The GTMDI_TBU2_WPC1 register, shown in the following table, controls the Watchpoint issued by TBU2 GTM Time Base Units. These watchpoints are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note

Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TBU2_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Register index: 108

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This table describes the GTMDI_TBU2_WPC1 register functions.

Table 47-47. GTMDI_TBU2_WPC1 field descriptions

Field	Description
29–28 TSS1	TBU2 Watchpoint 2 Compare Selection. The TSS1[1:0] field controls the type of comparison used for TBU2 watchpoint generation. 00 TBU2 update (do not compare data) 01 Compare TBU2 value with expected data 10 Reserved 11 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the TBU2 event is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU2 a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches or increment on selected TBU2 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
13–12 TSS2	TBU2 Watchpoint 2 Compare Selection 2. The TSS2[1:0] field controls the type of comparison used for TBU2 watchpoint generation. 00 TBU2 update (do not compare data) 01 Compare TBU2 value with expected data 10 Reserved 11 Reserved
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the TBU2 valid event, which is a match or increment, is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU2, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match or increment on TBU2 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

47.5.1.45 TBU2 watchpoint control 2 register (GTMDI_TBU2_WPC2)

The GTMDI_TBU2_WPC2 register, shown in the following table, controls the Watchpoint Triggers issued by TBU2. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Register index: 109

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

This table describes the GTMDI_TBU2_DATA register functions.

Table 47-49. GTMDI_TBU2_DATA field descriptions

Field	Description
23–0 TBU2_DATA	TBU2 Watchpoint DATA. The field TBU2_DATA[23:0] is used to compare against the TBU2 data.

47.5.2 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 47-3 . Unimplemented registers should not be accessed. GTMDI treats unimplemented registers like the JTAG BYPASS instruction.

47.6 Functional description

This section describes in detail the main functionality of the GTMDI module.

47.6.1 GTM-IP Debug / Halt mode description

The GTM-IP debug / halt mode is requested via GTMDI and is used to debug the GTM-IP module. In this mode it is required that the GTM-IP is halted by stopping its clock. Therefore all time bases and counters are frozen.

[Covers: ADD21.010] GTM halt is only activated when no read- or write-access to GTM over AEI are taking place in parallel. Only in this condition the GTM is released to change to debug / halt mode read.

It is important to notice that any peripheral slave bus access is active in this mode. [Covers: ADD21.009] The debugger is able to read all GTM addresses read-/writeable from the peripheral bus when GTM is running or halted. All registers in the register map can be accessed by the peripheral slave bus, even the RAMs because they are in the register map. Of course, the clocks for the RAMs are not stopped in debug mode.

Note

If GTM-IP is in Stop mode by the setting of GTMMCR[MDIS], the debug request is not considered until the MDIS bit is cleared.

47.6.2 Debug enable logic

In Debug mode, the GTM-IP main clock is requested to stop and the bus interface clocks remain running to access all registers and memories.In order to enable the GTM to enter Halt state, which is the module debug state, there are some registers that need to be set. The sources that can put GTM in halt state are events from TIM, TOM, ATOM, MCS and several other internal GTM modules that are selected and controlled by the GTMDI_DC register bits shown in GTMDI development control register (GTMDI_DC). The system debug request external signal is also a source of halts, as well as direct JTAG write to control register. The following figure describes the logic behind the Halt signal generated by GTMDI. See GTMDI development control register (GTMDI_DC) for a description of the register bits mentioned in Figure 47-4.

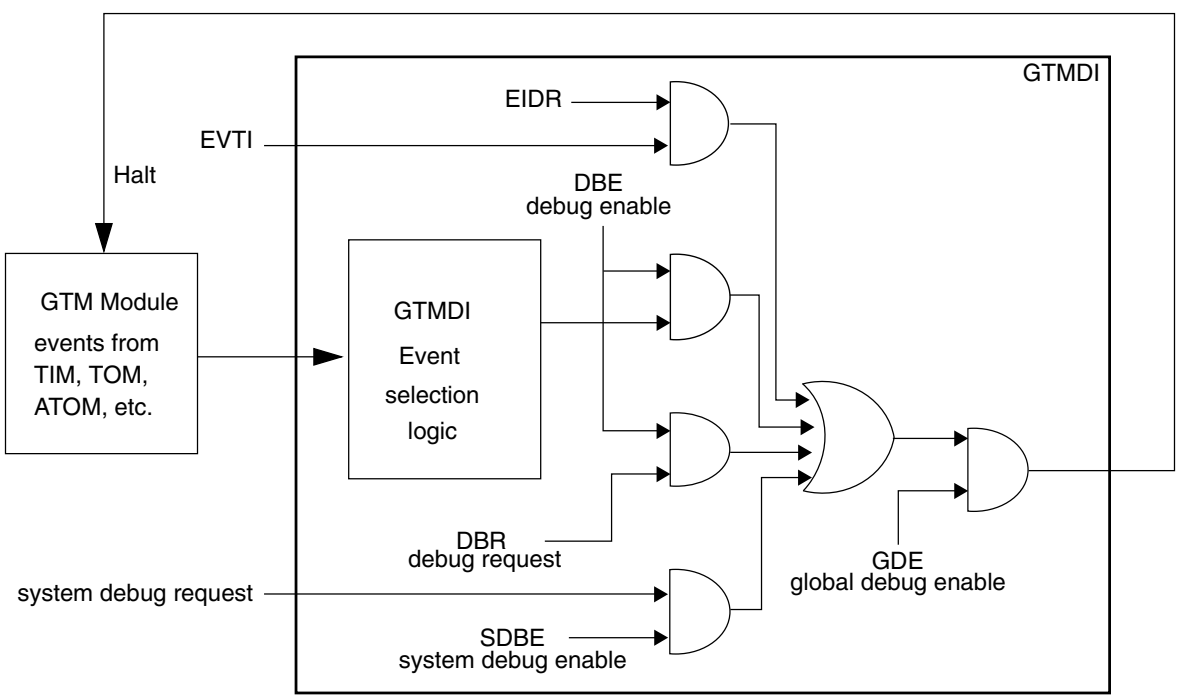

Figure 47-4. GTM Halt signal enable logic

47.6.3 TIM-TOM-ATOM selection and control logic

The TIM sub-modules can be selected to generate signals that control the watchpoint messages, Halt GTM and watchpoint outputs from the GTMDI module. The following figure describes the TIM selection logic for generation of watchpoint messages, GTM halt and external watchpoint triggers. This logic is duplicated thus allowing independent selection of two TIM filtered inputs. Figure 47-5 also shows the register bits that control the selection process. Watchpoint Logic 1 and Watchpoint Logic 2 are two implementations for the same logic.

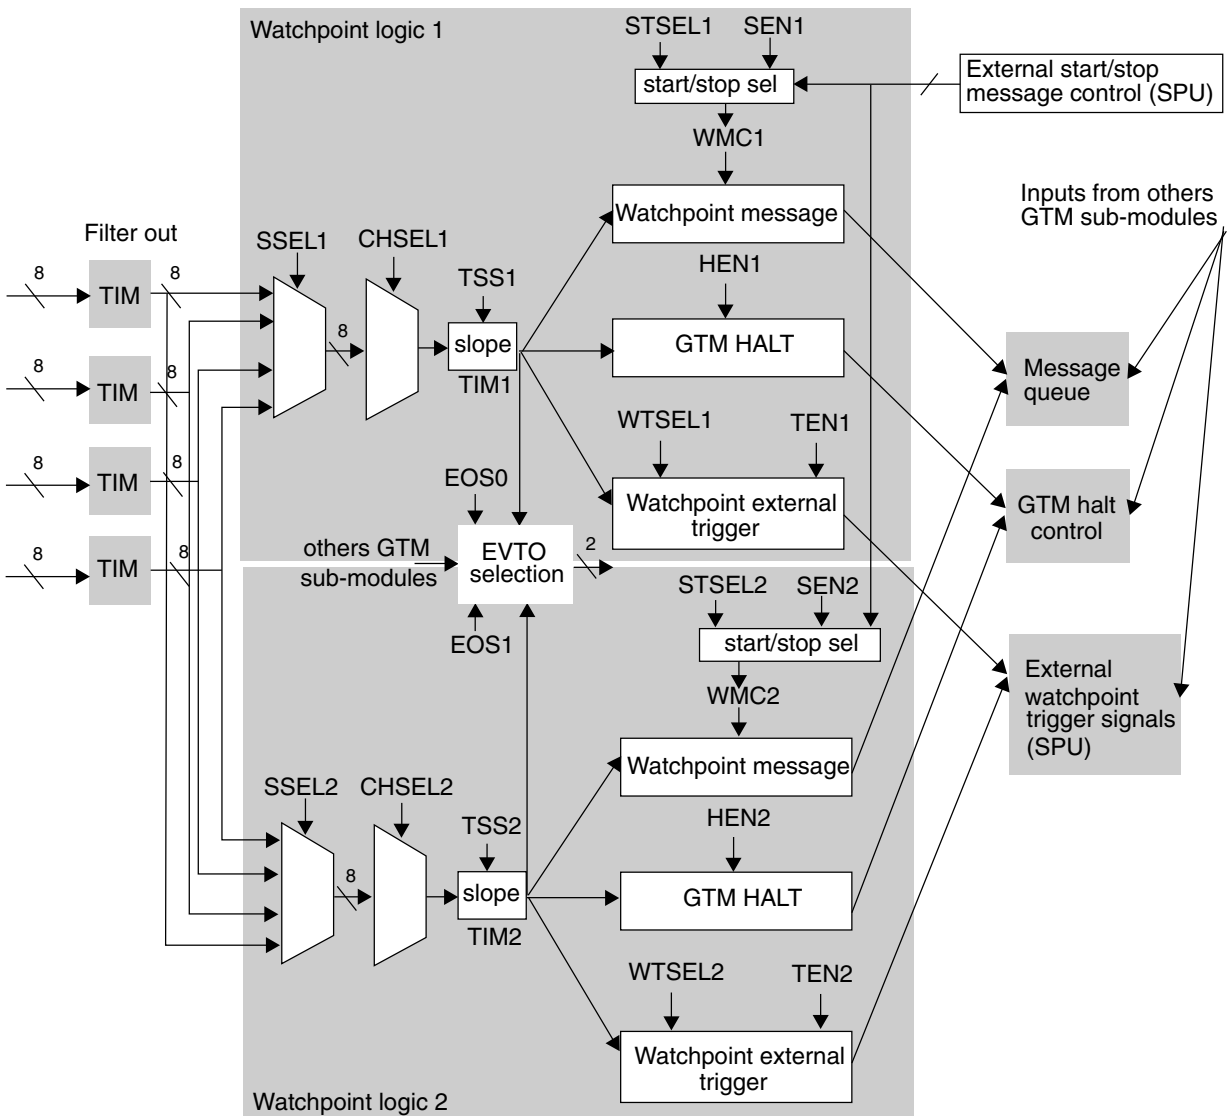

Figure 47-5. TIM selection logic

NOTE

This figure shows four instances of the TIM sub-module which corresponds to the GTM104 IP configuration. Different configurations may have different number of TIM sub-modules,

thus SSEL1/2 signals have to be able to select different number of TIM sub-modules.

The selection logic for TOM and ATOM sub-modules is similar to the TIM logic. The register names are also kept the same for easy correlation of functionality.

47.6.4 GTMDI reset configuration

This section describes the GTMDI reset configuration.

47.6.4.1 Enabling GTMDI class 1 operation

The GTMDI Class 1 features are always enabled after exiting the JTAG TEST-LOGIC-RESET state. But they are disabled while the JTAG is in this state. Thus, allowing low power mode. The registers are always reset while in the JTAG TEST-LOGIC-RESET state.

47.6.4.2 Enabling GTMDI class 3 operation

After exiting JTAG TEST-LOGIC-RESET state, the GTMDI classes 1 and 3 are enabled, otherwise the GTMDI class 3 features are disabled, entering in the Disable-Port Mode, thus no trace output is provided, and auxiliary port output pins are disabled.

47.6.5 Message Data bus—interface with NAR module

This section describes the Message Data bus.

47.6.5.1 Output messages

This table describes the messages that the GTMDI can transmit on the Message Data bus.

Table 47-50. GTMDI Nexus trace message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Debug Status Message	6	6	fixed	TCODE	Value = 0
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7

Table continues on the next page...

Table 47-50. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
	32	32	fixed	STATUS	Value of the Development Status register GTMDI_DS, see Table 47-51
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message	6	6	fixed	TCODE	Value = 8
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	4	4	fixed	ETYPE	Always 0 for GTMDI
	15	15	fixed	ECODE	Error Code, see Table 47-52
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
MCS Data Trace, Data Write with Sync Message	6	6	fixed	TCODE	Value = 56
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location written
	32	32	fixed	DATA	Data value written
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
MCS Data Trace, Data Read with Sync Message	6	6	fixed	TCODE	Value = 57
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location read
	32	32	fixed	DATA	Data value read
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message[1]	6	6	fixed	TCODE	Value = 15
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	15	15	fixed	WPHIT	Number indicating watchpoint source (binary coded), see Table 47-53, Table 47-54 and Table 47-55
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace	6	6	fixed	TCODE	Value = 58
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT[2]	Fetch Sequential Counter. Value 0 indicates there is no relationship between the last fetch trace message and the current message. The counter rolls back to one when a non sequential address is fetched. The counter increments every time a sequential address is fetched. When counter reaches 63 a message is sent and the counter rolls back to one. If an ERROR message is sent the counter rolls back to zero.

Table continues on the next page...

Table 47-50. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
	14	14	fixed	FADDR	First element address of the next fetch sequence
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace End (fetch trace was turned off, no faddr field is sent)	6	6	fixed	TCODE	Value = 59
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT	The message is sent with the current value in the FSCNT counter and the counter rolls back to zero after the message is sent.
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
ARU Data Trace	6	6	fixed	TCODE	Value = 60
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	CHN	ARU Debugging Channel number (0/1)
	58	58	fixed	DATA	Data value read {ARU_DATAH, ARU_DATAL}
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
DPLL Data Trace, Data Read/Write	6	6	fixed	TCODE	Value = 61
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	24	24	fixed	DATA	Data value read/written
	12	12	fixed	ADDR	Full address of the memory location written
	1	1	fixed	RW	Read 1, Write 0
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Watchpoint Hit Message conforms to the IEEE-ISTO 5001-2003 standard, however, other messages conform to the IEEE-ISTO 5001-2011 standard.
2. FSCNT is the sequential instruction fetch counter that indicates the number of sequential instruction fetches executed by the MCS core for a channel. See Fetch trace state machine, Fetch trace state machine for more information.

11:6	Reserved

47.6.5.1.1 Temporal ordering of transmitted messages

All messages are sent out in the sequence their related event actually occurred. The GTM interface with the GTMDI provides the GTM signals to be monitored and captured. At the occurrence of any event that would cause a message, a snapshot of all information needed by the message formatter to generate a message is queued. Doing so, several events from either MCS, TIM, ATOM, ARU, etc., can be queued at the same time.

47.6.5.1.2 Interleaved messages

Two MCS cores, TIM channels and other sources can be enabled for trace. The GTMDI formats and queues all messages in the order they are generated. Since there can be message inversion among sources during the send process, if enabled by the TSFT bit in GTMDI development control register (GTMDI_DC) or by the NAR, the messages are sent along with a timestamp. This timestamp is globally synchronized among all Nexus clients at SoC level.

47.6.6 IEEE 1149.1 (JTAG) input port

The GTMDI block uses the IEEE 1149.1 TAP for accessing registers. This port is shared among all TAP controllers on the SoC. This sharing is controlled by the value in the instruction register and client select control register. The GTMDI implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1 state machine shown in Figure 47-7 . The Nexus controller state machine, shown in the following table, is defined by the IEEE-ISTO 5001-2002 standard.

The instructions implemented by the GTMDI TAP controller are listed in the following table. If any other instruction is received it is treated as a BYPASS.

Table 47-57. Implemented instructions

Instruction name	Private/ public	Opcode	Description
NEXUS-ENABLE	Public	4b0000	Activate Nexus controller state machine to read and write GTMDI registers
BYPASS	Public	4b1111	Implements a single shift register stage providing a minimum serial length between TDI and TDO

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

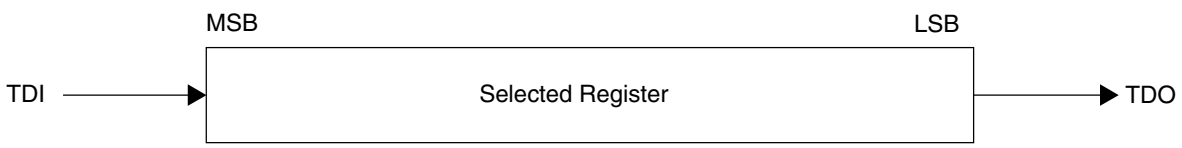

Figure 47-6. Shifting data into register

47.6.6.1 Enabling the GTMDI TAP controller

Assertion of the $\overline{\text{TRST}}$ input resets all TAP controllers on the SoC. The controllers are loaded with the BYPASS instruction upon exit of the TEST-LOGIC-RESET JTAG controller state. Loading the NEXUS-ENABLE instruction grants access to Nexus debug. GTMDI acts as BYPASS by loading any other instruction. The TDO bit is driven with the value of the instruction register while in SHIFT-IR state.

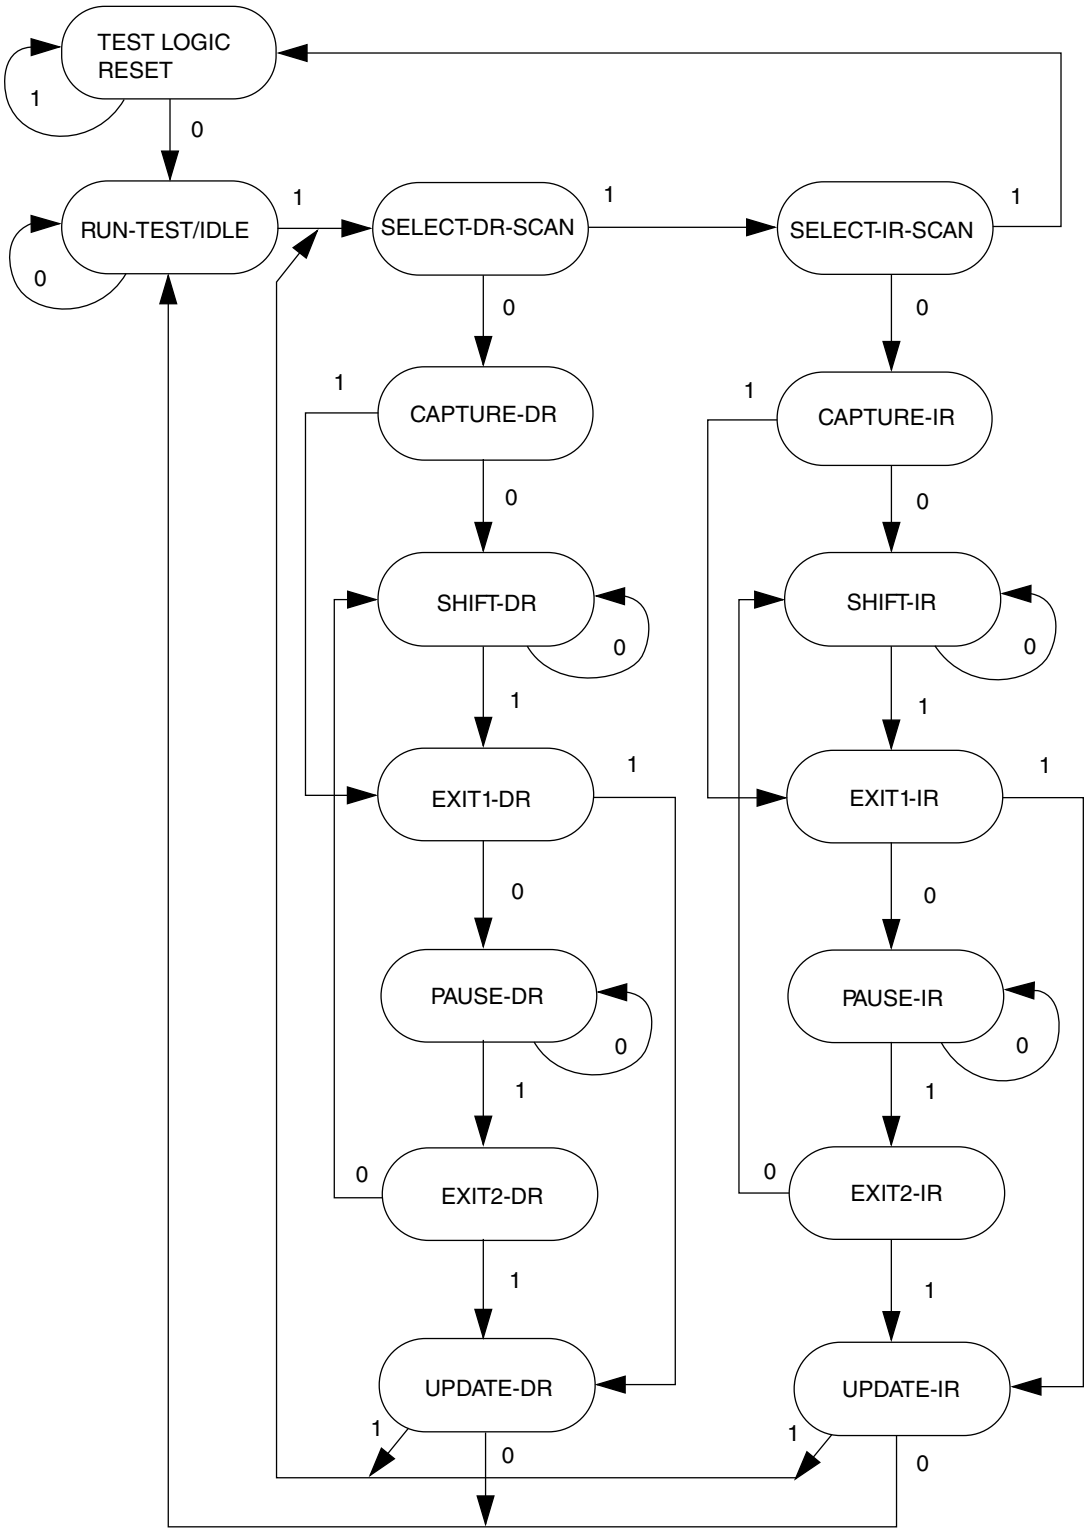

Figure 47-7. IEEE 1149.1 16-State finite state machine

47.6.6.2 Loading NEXUS-ENABLE instruction

Access to the GTMDI registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. The current instruction value is loaded into the IEEE 1149.1 shifter in the CAPTURE-IR state. The instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in the following figure, transitions to the REG_SELECT state. Table 47-58 illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

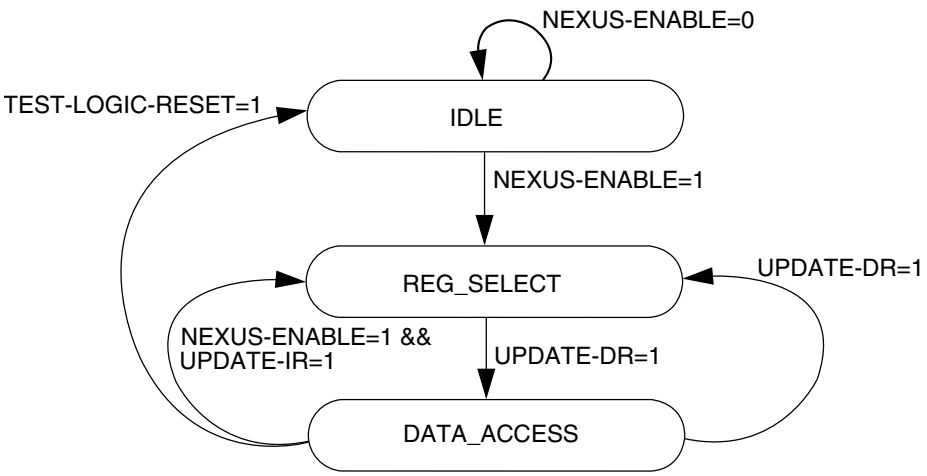

Figure 47-8. Nexus controller state machine

Table 47-58. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction
4 TCKs				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	NEXUS-ENABLE ready to be read

47.6.6.3 Selecting an IEEE 1149.1 register

When the NEXUS-ENABLE instruction is loaded in the GTMDI TAP controller instruction register, the input port allows development tool access to all GTMDI registers. Each register has a 7-bit address index. Some clients have registers with the same index as registers in other clients. Therefore, to access the registers of a particular client, the Client Select Control register must be set for that client.

All register access is performed via the SELECT-DR-SCAN path. The Nexus state machine defaults to the register select state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The current value of the Controller Command Input is captured into the IEEE 1149.1 shifter during the CAPTURE-DR state while the Nexus controller state machine is in the REG_SELECT state.

Table 47-59. IEEE 1149.1 controller command input

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the current register value is loaded into the IEEE 1149.1 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 47-60. Writing to a register

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI

Table continues on the next page...

Table 47-60. Writing to a register (continued)

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register

47.6.7 Nexus Class 1 development support

The GTMDI contains a number of hardware hooks that aid in the development of software for the GTM MCS cores. This features described in this section are compliant with the following Nexus Class 1 features:

- Enter a debug mode at reset negation
- Enter a debug mode during normal execution
- Set halts or watchpoints

Refer to Initialization/application information for how the following functions provide these features.

47.6.8 Debug status

The GTMDI module provides the Debug Status via the NAR SoC level modules.

47.6.8.1 Messaging

The GTMDI block provides debug status messaging using IEEE-ISTO 5001-2002 standard-defined public messages. If the message queue is full and a new message has to be sent, this message is lost and an ERROR message is queued instead, indicating the loss of trace messages. The debug status message format is shown in this figure.

Table 47-61. Debug status message format

6 bits	K bits	32 bits
TCODE (0)	SRC	STATUS

Length = 38 + K bits

47.6.8.2 Error messages

A debug status overrun error event is queued if a debug status event occurs while the Event Queue is full and is not able to store snapshots. The error message is stored to the event queue indicating a message was lost. The error message is sent as soon as the client is enabled for transmission. The error message format is shown in this figure.

Table 47-62. Debug status error message format

6 bits	K bits	4 bits	15 bits
TCODE (8)	SRC	ETYPE (Table 47-50)	ECODE (Table 47-52)

Length = 25 + K bits

Note

The timestamp value in an Error Message does not contain valid information.

47.6.9 Data trace

MCS cores, ARU and DPLL perform loads and stores to RAM memory modules. The GTMDI block gathers information about these accesses and generate trace messages if enabled.

47.6.9.1 MCS data write message

The MCS data write message contains the data write value and the address of the RAM target location. The data write message format is shown in the figure.

Table 47-63. Data write message format

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (56)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

47.6.9.2 MCS data read message

The MCS data read message contains the data read value and the address of the RAM target location. The data read message format is shown in this figure.

Table 47-64. Data read message format

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (57)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

47.6.9.3 MCS data trace operation

Data tracing is performed by snooping a dedicated MCS/Nexus interface for RAM read and write cycles. Data trace functions are enabled by setting the appropriate fields in the following registers:

- MCSx Development Control (GTMDI_MCSx_DC) Register
- MCSx Data Trace Control (GTMDI_MCSx_DTC) Register
- MCSx Data Trace Address Range (GTMDI_MCSx_DTAR) Register

For details on register configuration, refer to Register descriptions. The MCSx data tracing have independent Data Trace Address Range registers which allows more flexibility. An Error condition may occur in case of Queue full event. Data trace flow is depicted in this figure.

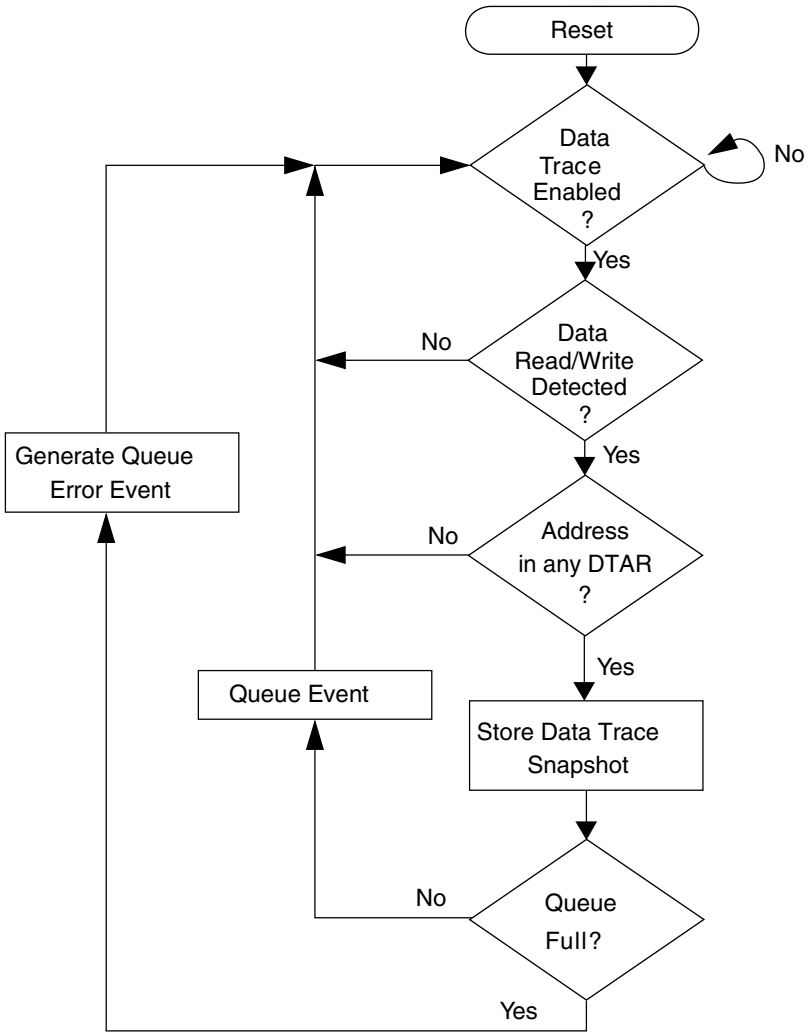

Figure 47-9. GTMDI generic data trace flow diagram

47.6.9.3.1 MCS data trace windowing

Data trace windowing is provided so that the development tool can decrease the auxiliary port usage by limiting the accesses that are traced. Data trace windowing is achieved via the address range defined by the DTSA and the DTEA fields of the DTAR register. RAM accesses are traced if their address fall in any of these ranges and the specific range is enabled in the data trace control register. Data read and/or data write trace may be enabled via the Read/Write Trace Control fields in the data trace control registers.

Data trace ranges are 32-bit aligned. This alignment is done by making the two least significant bits of the DTSA and DTEA fields read only. Since the two least significant bits of DTSA and DTEA are read only and default to different values, DTSA can never be equal to DTEA. This figure shows the relationship between the DTSA and DTEA fields.

Table 47-65. Data trace address range options

Programmed Value	Range Selected
DTSA =< DTEA	[DTSA: DTEA]
DTSA > DTEA	All addresses are out of range[1]

1. Since all addresses are considered to be out of range, a Data Trace Event may be recognized if the DTC register is programmed so that addresses out of range are queued.

Note

Before sending through the NAR interface, the MCS, DPLL or ARU Data Trace message is buffered. Due to bandwidth constraints in the NAR interface and in the data trace buffering, this data trace message can be lost when superseded by another data trace message from the same source. In this case an error message is sent. See Table 47-50 for more details about GTMDI NAR messages.

47.6.9.4 DPLL data trace

DPLL Data Trace is a straight forward implementation in which the trace is enabled using the DMC bit in the DPLL data trace control register (GTMDI_DPLL_DTC). It is possible to select individual DPLL RAM modules such as RAM1a, RAM1b or RAM2 for tracing using the RAMSEL bit in the same register. Only one memory module is selected for tracing at a given time. Start/Stop inputs from the SPU module can be used to control the DPLL Data Trace messages as well as JTAG interface. This is achieved by controlling the DMC bit which can be done from SPU or JTAG interface. See Table 47-22 for more details about the bits that should be used in this process.

47.6.9.5 ARU data trace

The GTM module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1, see the GTM documentation for details on how to program these channels. The data trace for these two channels is controlled by DMC1/2 bits in the GTMDI_ARU_DTC, see ARU data trace control register (GTMDI_ARU_DTC). Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

47.6.10 Fetch trace

Fetch trace tries to record all instruction fetch accesses done by an MCS channel. Fetch trace is handled independently for each MCS channel; therefore what happens to a certain channel does not affect other channels since all channels run independently. Even error conditions are handled independently for each channel.

Fetch trace can be enabled/disabled by two ways:

- By watchpoint hit, if the watchpoint is configured to do so
- Directly by register

When a fetch access hits a watchpoint and the last enables fetch trace (having it disabled before the watchpoint hit), that access is ignored by the fetch trace logic.

47.6.10.1 Enabling MCS program fetch trace

Program fetch trace for the MCS is enabled on a channel by channel basis. This selective enabling allows the debug tool to control the bandwidth for the transmitted messages. The program fetch trace is enabled through a JTAG register, see MCSA/B program fetch trace control register (GTMDI_MCSA_PTC and GTMDI_MCSB_PTC). Since the registers may be changed in the middle of a program execution, program fetch trace may be enabled or disabled during program execution as well.

47.6.10.2 Fetch trace state machine

Fetch trace state machine is composed basically by three states: Start, Running and End. When the fetch trace is enabled, the fetch state machine goes to the Start state. This figure describes the fetch trace machine state diagram.

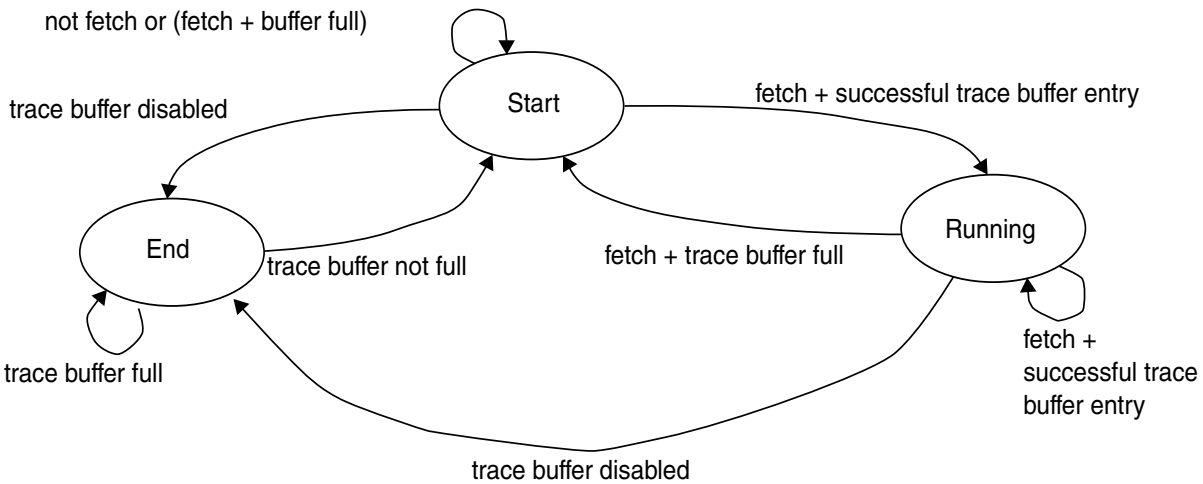

Figure 47-10. Fetch trace state machine state diagram

47.6.10.2.1 Fetch trace start state

In this state, the fetch trace logic waits for a fetch access to occur. When a fetch access occurs, the fetch trace logic tries to insert (into the corresponding MCS trace buffer) a fetch trace message with FSCNT=0 and the FADDR field equal to the fetch access address. It is possible that the corresponding MCS trace message buffer is full when fetch trace logic tries to insert the message. In this case, the fetch trace logic ignores the current fetch access, does not generate any error, and tries again when another fetch access occurs.

After inserting a message into the buffer, the fetch trace state machine goes to the Running state. It is also possible that the fetch trace is disabled before a message is inserted into the MCS trace buffer. In this case state machine goes to the End state.

47.6.10.2.2 Fetch trace running state

When the fetch trace state machine enters the Running state, a counter called CNT, is initialized to 1 and starts counting the number of sequential instruction fetch accesses.

When a fetch access with address ADDR is detected, the fetch trace logic tests if ADDR is equal to the previous fetch address, ADDR_PRV, +1 (ADDR = ADDR_PRV + 1). If so, no message is buffered for transmission and CNT increments by 1 (CNT = CNT + 1). Otherwise, if ADDR is not a sequential address, a fetch trace message is generated with the FSCNT field equals to the CNT counter value (FSCNT = CNT) and FADDR equals to the current address ADDR. The CNT counter is then initialized to 1.

At the moment the previous message is generated, the corresponding MCS fetch trace buffer may or may not be full. If the buffer is not full, the message is inserted into the buffer and the fetch trace state machine continues in the Running state, otherwise a fetch trace error message is generated for the corresponding MCS and the fetch trace state machine goes to the Start state.

NOTE

The MCS is a multi-thread core which executes eight threads, also called channels, in fixed time-slots of one system clock for each thread. Fetch trace is a per channel resource. Thus if more than one channel is selected for trace, each one generates its corresponding fetch trace message. There is one independent fetch state machine and CNT counter for each selected channel.

47.6.10.2.3 Fetch trace end state

In this state, the fetch trace logic ignores all fetch accesses and waits for the corresponding MCS trace buffer to be not full. When this happens, a fetch trace end message is inserted into the buffer with FSCNT equal to CNT (FSCNT = CNT). The CNT value is always reset to 0 when previous state was Start state.

If the buffer is always full, the fetch trace logic does not exit End state until a reset occurs.

Note

A fetch trace end message is sent when a system reset is detected in the GTM module. There are no further indications about the GTM reset condition.

47.6.11 Watchpoint trace

The GTMDI module provides watchpoint messaging via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

47.6.11.1 Messaging

The GTMDI block provides watchpoint messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When a watchpoint occurs, a watchpoint event is sent to the Event Queue. If the watchpoint condition occurs while the Event Queue is full, an error message is generated. The watchpoint message format is shown in this figure.

Table 47-66. Watchpoint hit message format

6 bits	K bits	15 bits
TCODE (15)	SRC	WPHIT

Length = 21+Kbits

The values for the WPHIT packet are described in Table 47-53, Table 47-54 and Table 47-55. Notice that WPHIT is never 0 because the message is only generated when a watchpoint has occurred.

47.7 Initialization/application information

This section describes the initialization and application information.

47.7.1 Accessing GTMDI tool-mapped registers

To initialize the JTAG port for register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Retrieve Device ID if needed
3. Load the Nexus TAP controller with the NEXUS-ENABLE instruction

To write control data to GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select register with a pass through the SELECT-DR-SCAN path in the JTAG state machine
2. Write the register value with a pass through the SELECT-DR-SCAN path. The prior value of this register is shifted out during the write

To read status and control data from GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear write bit to select register with a pass through SELECT-DR-SCAN path
2. Read the register value with a pass through the SELECT-DR-SCAN path. Data shifted in is ignored

See IEEE 1149.1 (JTAG) input port for more detail.

Chapter 48
CAN Subsystem

48.1 Introduction

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules and Time triggered CAN (M_TTCAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection and M_TTCAN trigger memory from CPU write access. The subsystem follows the little endian format.

Note

Please refer to the Device Configuration chapter to see the number of CAN nodes used in the device.

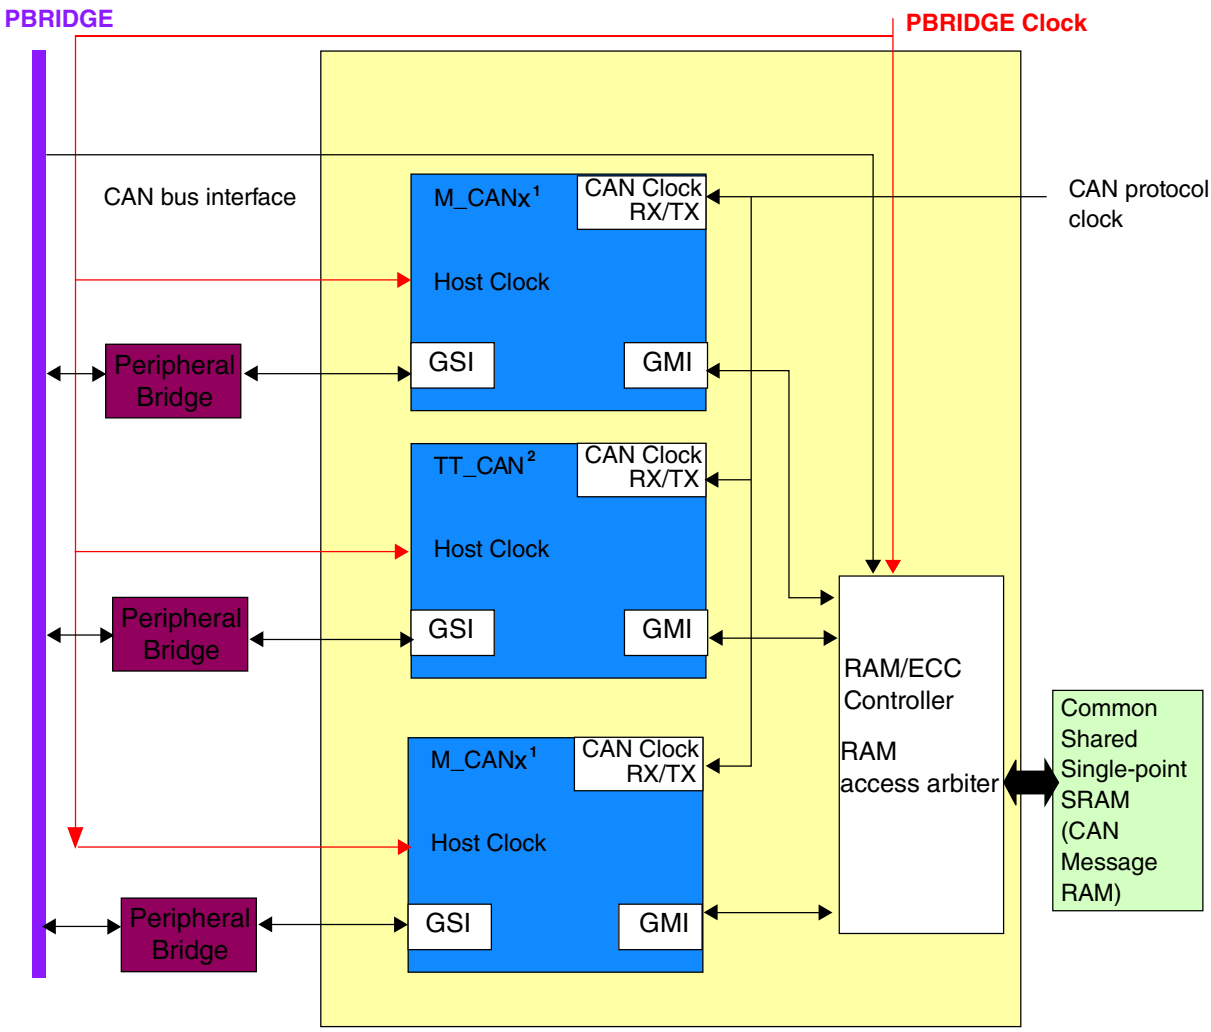
Note

M_TTCAN is implemented in a lower IP revision compared to M_CAN and therefore the supported CAN FD features are different.

Table 48-1. References

IP name	Version
M_CAN IP	Revision 3.0
M_TTCAN IP	Revision 2.0

The general CAN subsystem implementation is shown in Figure 48-1. It interfaces with the host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.



1: Number of MCAN nodes vary per device. x = 1...n. Please refer Device Configuration chapter to see the number of MCAN nodes used in the device.
2: Please refer Device Configuration chapter to see the number of M_TTCAN nodes used in the device.

Figure 48-1. CAN subsystem generic block diagram

48.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI).
- Time triggered CAN core. The registers of the CAN module can be accessed using the Generic Slave Interface (GSI).

- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller

48.3 Modular CAN cores

CAN functionality conforms to CAN specification V2.0B active for each CAN node.The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0. Flexible assignment of Message Objects to nodes. The bit rate can be programmed to values up to 1 Mbit/s for standard CAN FD mode. High bit rates are possible in CAN FD mode. Additional transceiver hardware is required for connection to the physical layer.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN Core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN Core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.

48.3.1 Features

The following are the features of Modular CAN Cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1
- CAN Flexible data-rate (CAN–FD) protocol with maximum 64 data bytes on M_CAN is supported
- Bit rates up to 1 Mbit/s in standard CAN mode

- Bit rates up to 8 Mbit/s in CAN FD mode
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN

48.3.2 Block diagram

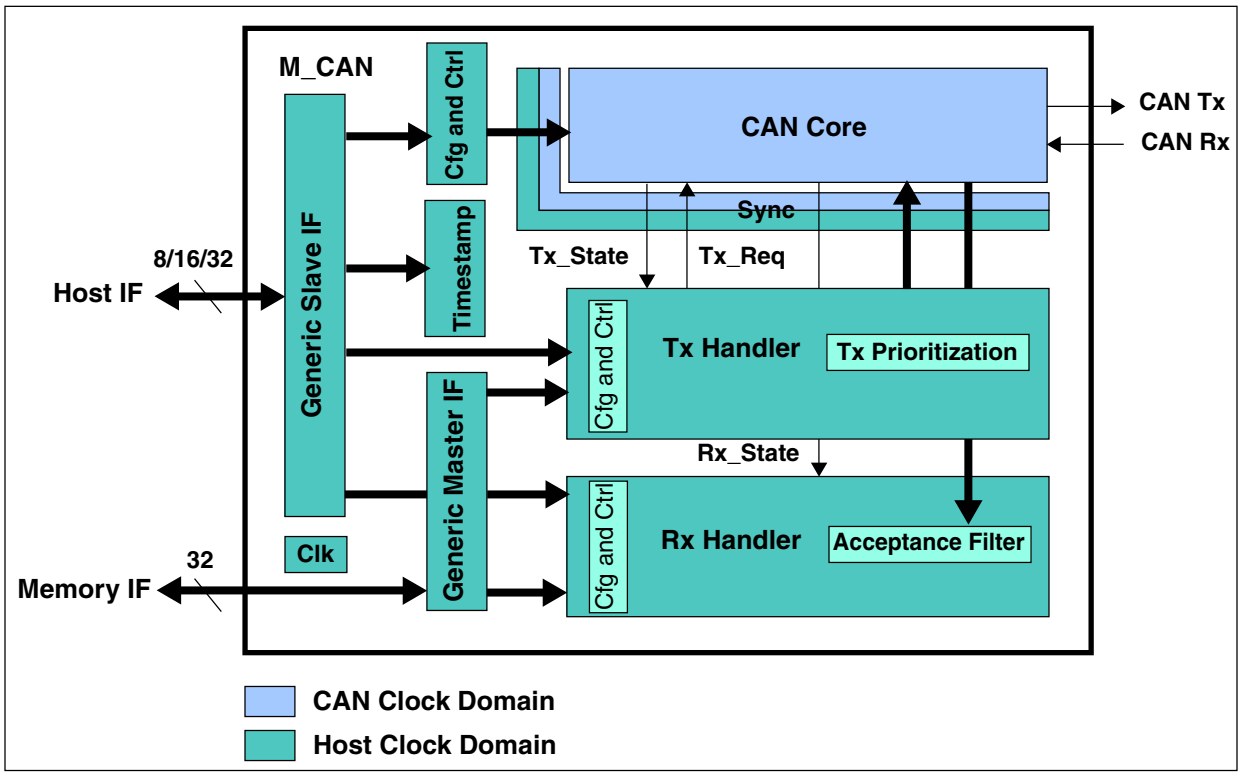


Figure 48-2. MCAN core block diagram

- CAN Core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN Core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

- Rx Handler: Controls the transfer of received messages from the CAN Core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, holding all messages that have passed acceptance filtering. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.
- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bit. Refer Table 48-37.

48.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note

In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

CAUTION

Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

48.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to EINT0 or to EINT 1. By default all interrupts are routed to interrupt line EINT 0. By programming ILE[EINT0] and ILE[EINT1], the interrupt lines can be enabled or disabled separately.

48.3.5 Memory map and register description

After hardware reset, the registers of the M_CAN hold the reset values listed in the memory map. Additionally the Bus_Off state is reset and the MCAN Tx output is set to recessive (HIGH). The value 0x0001 (bit 0 [INIT] of the CCCR = '1') in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets bit 0 [INIT] of the CCCR register = '0'.

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

NOTE

Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR is set to '1'.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

CAUTION

Any write access to reserved or not implemented registers in the 16 KB slot assigned by the peripherals bridge to the M_CAN IP will not generate any bus access error.

M_CAN_ENDN field descriptions

Field	Description
0–31 ETV	Endianness Test Value. The endianness test value is 0x87654321.

48.3.5.3 Fast Bit Timing and Prescaler Register (M_CAN_FBTP)

The CAN bit time may be programed in the range of 4 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 M_CAN clock periods. tq = (FBRP + 1) MCAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. FTSEG2 is Phase_Seg2. Therefore the length of the bit time is (prog rammed values) [FTSEG1 + FTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

NOTE

With a M_CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

The bit rate configured for the CAN FD data phase via FBTP must be higher or equal to the bit rate configured for the arbitration phase via BTP.

To archive high bit rates in CAN FD mode for the data phase up to 8 Mbit/s the number of time quanta bits per CAN bit can be chosen down to 4 time quanta per bit time.

Address: 0h base + Ch offset = Ch

M_CAN_FBTP field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 TDCO	Transceiver Delay Compensation Offset (0x0–0x1F)— Offset value defining the distance between the measured delay from m_can_tx to m_can_rx and the secondary sample point. Valid values are 0 to 31 M_CAN clock periods. **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’.
8 TDC	Transceiver Delay Compensation **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’. 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 FBRP	Fast Baud Rate Prescaler (0x000–0x1F)— The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the value prog rammed here is used. **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 FTSEG1	Fast time segment before sample point (0x1–0xF)— Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used. **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 FTSEG2	Fast time segment before sample point (0x0–0x7)— Valid values are 0 to 7. The actual interpretation by the hardware of this value is such that one more than the programmed value is used. **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’.
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FSJW	Fast (Re) Synchronization Jump Width 0x0-0x3 Valid values are 0 to 3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Table continues on the next page...

M_CAN_FBTP field descriptions (continued)

Field	Description
	NOTE: These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to ‘1’.

48.3.5.4 Test Register (M_CAN_TEST)

Write access to the Test Register has to be enabled by setting CCCR[TEST] to '1'. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back mode and software control of MCAN Tx pin are hardware test modes. Programming of TX other than"00" may disturb the message transfer on the CAN bus.

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

Address: 0h base + 10h offset = 10h

M_CAN_TEST field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

M_CAN_TEST field descriptions (continued)

Field	Description
18–23 TDCV	Transceiver Delay Compensation Value (0x00–0x3F)— Position of the secondary sample point, defined by the sum of the measured delay from m_can_tx to m_can_rx and FBTP.TDCO. Valid values are 0 to 63 M_CAN core clock periods.
24 RX	Receive Pin. Monitors the actual value of pin m_ can_rx **NOTE:** The reset value of this bit is undefined 0 The CAN bus is dominant (m_can_rx = '0') 1 The CAN bus is recessive (m_can_rx = '1')
25–26 TX	Control of Transmit Pin **NOTE:** Protected write (P) bit(s) which means that the write access to this field is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'. 00 Reset value, M_CAN transmit is controlled by the CAN Core, updated at the end of the CAN bit time 01 Sample Point can be monitored at M_CAN transmit pin 10 Dominant ('0') level at M_CAN transmit pin 11 Recessive ('1') at M_CAN transmit pin
27 LBCK	Loop Back mode **NOTE:** Protected write (P) bit(s) which means that the write access to this field is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'. 0 Reset value, Loop Back mode is disabled 1 Loop Back mode is enabled (see Test modes)
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

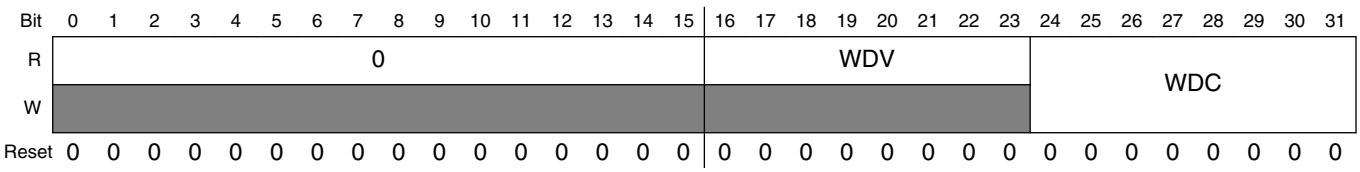
48.3.5.5 RAM Watchdog Register (M_CAN_RWD)

The RAM Watchdog monitors the READY output of the Message RAM . A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR is set. The RAM Watchdog Counter is clocked by the Host clock .

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

Address: 0h base + 14h offset = 14h



M_CAN_RWD field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 WDV	Watchdog Value. Actual Message RAM Watchdog Counter Value
24–31 WDC	Watchdog Configuration. Start value of the Message RAM Watchdog Counter. With the reset value of "00" the counter is disabled. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.

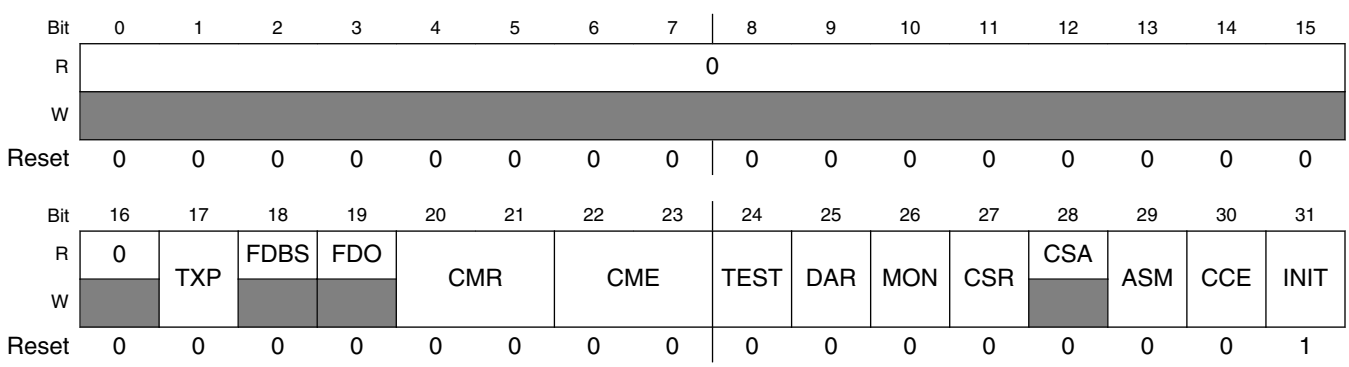
48.3.5.6 CC Control Register (M_CAN_CCCR)

This section explains the CAN Control register. For details about setting and resetting of single bits see Software initialization section.

NOTE

RWPp - Protected write and protected set register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

Address: 0h base + 18h offset = 18h



M_CAN_CCCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

M_CAN_CCCR field descriptions (continued)

Field	Description
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 Long Frame Mode disabled, LACT may not be set 1 Long Frame Mode enabled, LACT may be set
17 TXP	Transmit Pause If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame 0 Transmit pause disabled 1 Transmit pause enabled
18 FDBS	CAN FD Bit Rate Switching 0 This node transmits no frames with bit rate switching 1 This node transmits all frames (excluding remote frames) with bit rate switching
19 FDO	Fast Frame Mode Active 0 This node transmits all frames in CAN format according to ISO11898-1 1 This node transmits all frames (excluding remote frames) in CAN FD format
20–21 CMR	CAN Mode Request A change of the CAN operation mode is requested by writing to this bit field. After change to the requested operation mode the bit field is reset to '00' and the status flags FDBS and FDO are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CMR is retained until it is overwritten by the next mode change request. In case CME = '01'/'10'/'11' a change to CAN operation according to ISO 11898-1 is always possible. Default is CAN operation according to ISO11898-1. 00 unchanged 01 Request CAN FD operation 10 Request CAN FD operation with bit rate switching 11 Request CAN operation according ISO11898-1
22–23 CME	CAN Mode Enable **NOTE:** These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR are set to '1'. **NOTE:** When CME = '00', received frames are strictly interpreted according to ISO11898-1, which leads to the transmission of an error frame when receiving a CAN FD frame. In case CME = '01', transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CME = '10'/'11', transmission and reception of long and fast CAN FD frames is enabled 00 CAN operation according to ISO11898-1 enabled 01 CAN FD operation enabled 10 CAN FD operation with bit rate switching enabled 11 CAN FD operation with bit rate switching enabled
24 TEST	Test Enable Mode **NOTE:** This is protected set (p) bit. 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled

Table continues on the next page...

M_CAN_CCCR field descriptions (continued)

Field	Description
25 DAR	DAR: Disable Automatic Retransmission **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode. Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. **NOTE:** This is protected set (p) bit. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping host clock and core clock
29 ASM	ASM Restricted Operation Mode. Bit ASM is only set by the Host when both CCE and INIT are set to ‘1’. The bit is reset by the Host at any time. **NOTE:** This is protected set (p) bit. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization **NOTE:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value. 0 Normal Operation 1 Initialization is started

48.3.5.7 Bit Timing and Prescaler Register (M_CAN_BTP)

The CAN bit time may be programed in the range of [4....81] time quanta. The CAN time quantum may be programmed in the range of [1....1024] MCAN clock periods.

tq = (BRP + 1) MCAN clock period.

TSEG1 is the sum of Prop_Seg and Phase_Seg1. TSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

NOTE

With a CAN clock of 8 MHz, the reset value of 0x0000_0A33 configures the M_CAN for a bit rate of 500 kBit/s.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 BRP	Baud Rate Prescaler (0x000-0x3FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value prog rammed here is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TSEG1	(0x01-0x3F) Valid values are 1 to 63. The actual interpretation by the hardware of this value is such that one more than the prog rammed value is used.

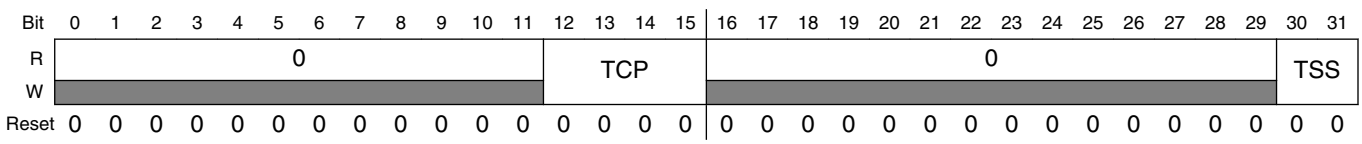
Table continues on the next page...

M_CAN_BTP field descriptions (continued)

Field	Description
	NOTE: Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
24–27 TSEG2	(0x0-0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the prog rammed value is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
28–31 SJW	(0x0-0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value prog rammed here is used **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.

48.3.5.8 Timestamp Counter Configuration Register (M_CAN_TSCC)

Address: 0h base + 20h offset = 20h

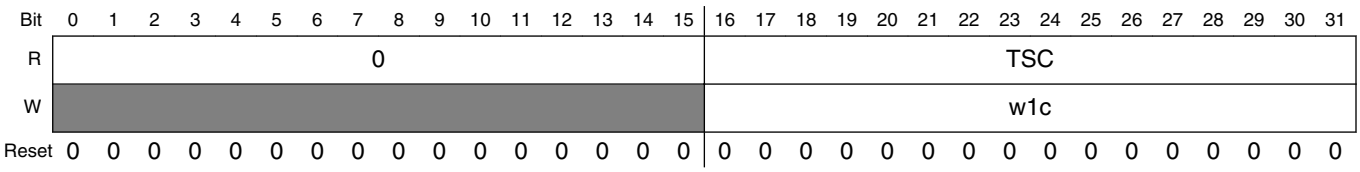


M_CAN_TSCC field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 TCP	Timestamp Counter Prescaler 0x0-0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1...16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase.
16–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 TSS	Timestamp Select **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to **TCP** 10 Reserved 11 Same as "00"

48.3.5.9 Timestamp Counter Value Register (M_CAN_TSCV)

Address: 0h base + 24h offset = 24h



M_CAN_TSCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TSC	Timestamp Counter The internal Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC.TSS = '01', the Timestamp Counter is incremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC.TCP. A wrap around sets interrupt flag IR.TSW. Write access resets the counter to zero. A write access has no impact. **NOTE:** A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

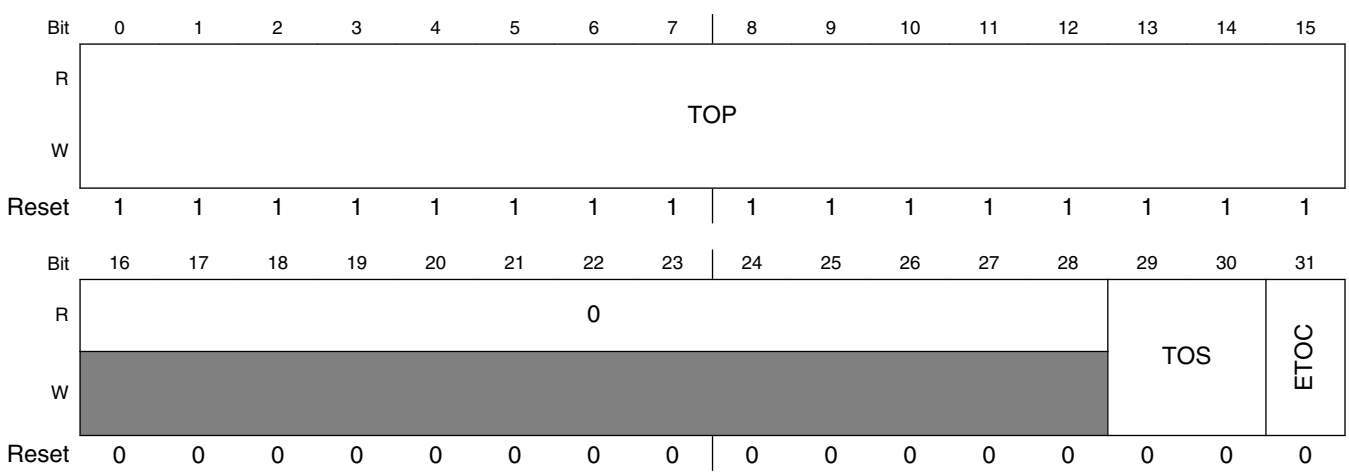
48.3.5.10 Timeout Counter Configuration Register (M_CAN_TOCC)

For a description of the Timeout Counter see Timeout counter .

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

Address: 0h base + 28h offset = 28h



M_CAN_TOCC field descriptions

Field	Description
0–15 TOP	Timeout Period. Start value of the Timeout Counter (down-counter). Configures the Timeout Period. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
16–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 TOS	Timeout Select When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 01 Timeout controlled by Tx Event FIFO 10 Timeout controlled by Rx FIFO 0 11 Timeout controlled by Rx FIFO 1 00 00 Continuous operation
31 ETOC	Enable Timeout Counter **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. **NOTE:** For use of timeout function with CAN FD see section, "Timeout Counter". 0 Timeout Counter disabled 1 Timeout Counter enabled

48.3.5.11 Timeout Counter Value Register (M_CAN_TOCV)

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																TOC															
W																	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

M_CAN_TOCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TOC	The Timeout Counter is decremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC.TCP. When decremented to zero, interrupt flag IR.TOO is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via TOCC.TOS.

48.3.5.12 Error Counter Register (M_CAN_ECR)

NOTE

When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								CEL							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RP	REC							TEC							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_ECR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 CEL	CAN Error Logging. The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17–23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127
24–31 TEC	Transmit Error Counter. Actual state of the Transmit Error Counter, values between 0 and 255.

48.3.5.13 Protocol Status Register (M_CAN_PSR)

NOTE

When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error .

NOTE

The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT.] If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 x 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

Address: 0h base + 44h offset = 44h

M_CAN_PSR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

M_CAN_PSR field descriptions (continued)

Field	Description
18 REDL	Received CAN FD Message with EDL flag **NOTE:** This field is reset by a read operation. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with EDL flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. **NOTE:** This field is reset by a read operation. 0 Last received CAN FD message did not ha ve its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with REDL, independent of acceptance filtering. **NOTE:** This field is reset by a read operation. 0 Last received CAN FD message did not ha ve its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21–23 FLEC	Fast Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. **NOTE:** This field is set by a read operation.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state
27–28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter
29–31 LEC	Last Error Code

Table continues on the next page...

M_CAN_PSR field descriptions (continued)

Field	Description
	The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010: Form Error: A fixed format part of a received frame has the wrong format. 011: AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111: NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register. **NOTE:** This field is set by a read operation.

48.3.5.14 Interrupt Register (M_CAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Address: 0h base + 50h offset = 50h

M_CAN_IR field descriptions

Field	Description
0 STE	Stuff Error 0 No Stuff Error detected 1 More than 5 equal bits in a sequence occurred
1 FOE	Format Error 0 No Format Error detected 1 A fixed format part of a received frame has the wrong format
2 ACKE	Acknowledge Error 0 No Acknowledge Error detected 1 A transmitted message was not acknowledged by another node
3 BE	Bit Error

Table continues on the next page...

M_CAN_IR field descriptions (continued)

Field	Description
	0 No Bit Error detected 1 Device wanted to send a rec / dom level, but monitored bus level was dom / rec
4 CRCE	CRC Error 0 No CRC Error detected 1 Received CRC did not match the calculated CRC
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status 0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred
10 BEU	Bit Error Uncorrected. Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic)
11 BEC	Bit Error Corrected. Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (e.g. ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 MRAF	Message RAM Access Failure

Table continues on the next page...

M_CAN_IR field descriptions (continued)

Field	Description
	The flag is set, when the Rx Handler • has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message. • was not able to write a message to the Message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx Handler is not able to read a message from the Message RAM in time. In this case message transmission is aborted. To leave Restricted Operation Mode, the Host CPU has to reset CCCR.ASM. 0 No Message RAM access failure occurred 1 Message RAM access failure occurred
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark
19 TEFN	Tx Event FIDO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element
20 TFE	Tx FIFO Empty 0 Tx FIFO non-empty 1 Tx FIFO empty
21 TCF	Transmission Cancellation Finished 0 No transmission cancellation finished 1 Transmission cancellation finished
22 TC	Transmission Completed 0 No transmission completed 1 Transmission completed
23 HPM	High Priority Message 0 No high priority message received 1 High priority message received
24 RF1L	Rx FIFO 1 Message Lost

Table continues on the next page...

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_HPMS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 FLST	Filter List Indicates the filter list of the matching filter element. 0 Standard Filter List 1 Extended Filter List
17–23 FIDX	Filter Index Index of matching filter element. Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
24–25 MSI	Message Storage Indicator 00 No FIFO selected 01 FIFO overrun 10 Message stored in FIFO 0 11 Message stored in FIFO 1
26–31 BIDX	Buffer Index Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = '1'.

48.3.5.23 New Data 1 Register (M_CAN_NDAT1)

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ND1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_CAN_NDAT1 field descriptions

Field	Description
0–31 ND1	New Data[0:31] The register holds the New Data flags of Rx Buffers 0 to 31. The flags are set when the respective Rx Buffer has been updated from a received frame. The flags remain set until the Host clears them. A flag is cleared by writing a ’1’ to the corresponding bit position. Writing a ’0’ has no effect. A hard reset will clear the register.

48.3.5.24 New Data 2 Register (M_CAN_NDAT2)

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

48.3.5.33 Tx Buffer Configuration Register (M_CAN_TXBC)

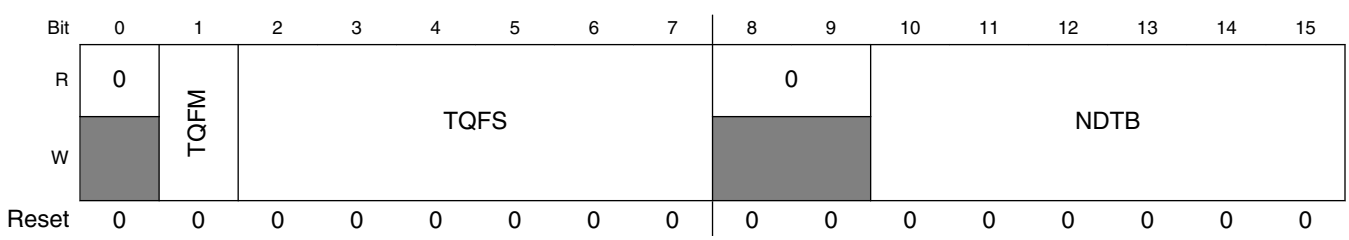
NOTE

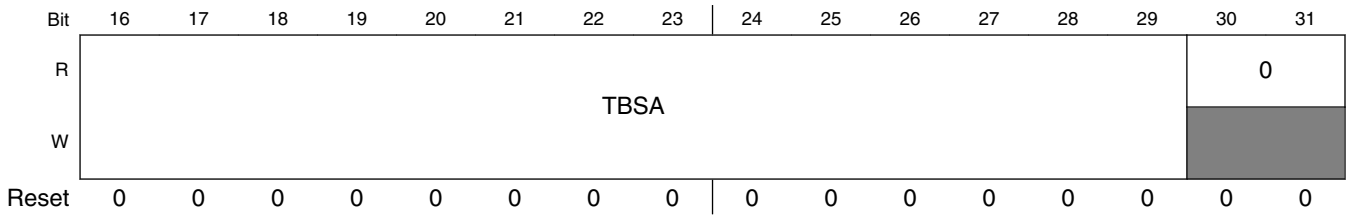
Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to '1'.

Address: 0h base + C0h offset = C0h





M_CAN_TXBC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TQFM	Tx FIFO/Queue Mode **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 0 Tx FIFO operation 1 Tx Queue operation
2–7 TQFS	Tx FIFO/Queue Size **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'. 0 No Tx FIFO/Queue 1-32 Number of Tx Buffers used for Tx FIFO/Queue >32 Values greater than 32 are interpreted as 32
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 NDTB	Number of Dedicated Transmit Buffers 0 No Dedicated Tx Buffers 1-32 Number of Dedicated Tx Buffers >32 Values greater than 32 are interpreted as 32 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
16–29 TBSA	Tx Buffers Start Address Start address of Tx Buffers section in Message RAM (32-bit word address, see Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.3.5.34 Tx FIFO/Queue Status Register (M_CAN_TXFQS)

NOTE

In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers. Example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

Address: 0h base + C4h offset = C4h

M_CAN_TXBRP field descriptions

Field	Description
0–31 TRP	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (see Tx handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signalled via TXBCF • after successful transmission together with the corresponding TXBTO bit • when the transmission has not yet been started at the point of cancellation • when the transmission has been aborted due to lost arbitration • when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

48.3.5.37 Tx Buffer Add Request register (M_CAN_TXBAR)

NOTE

If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_CAN_TXBCF field descriptions

Field	Description
0–31 CF	Cancellation Finished Each Tx Buffer has its own Cancellation Finished bit. The bits are set when the corresponding TXBRP bit is cleared after a cancellation was requested via TXBCR. In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are reset when a new transmission is requested by writing a '1' to the corresponding bit of register TXBAR. 0 No transmit buffer cancellation 1 Transmit buffer cancellation finished

48.3.5.41 Tx Buffer Transmission Interrupt Enable register (M_CAN_TXBTIE)

Address: 0h base + E0h offset = E0h

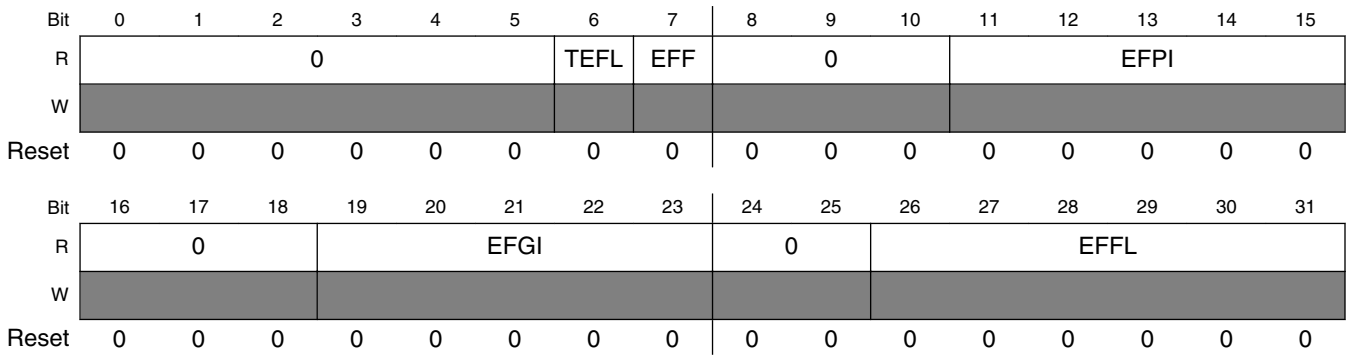
M_CAN_TXEFC field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 EFWM	Event FIFO Watermark. 0 Watermark interrupt disabled 1-32 Level for Tx Event FIFO watermark interrupt (IR[TEFW]) >32 Watermark interrupt disabled **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 EFS	Event FIFO Size. 0 Tx Event FIFO disabled 1-32 Number of Tx Event FIFO elements >32 Values greater than 32 are interpreted as 32 The Tx Event FIFO elements are indexed from 0 to EFS - 1 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
16–29 EFSA	Event FIFO Start Address. Start address of Tx Event FIFO in Message RAM (32-bit word address, Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to '1'.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.3.5.44 Tx Event FIFO Status register (M_CAN_TXEFS)

Address: 0h base + F4h offset = F4h



M_CAN_TXEFS field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 TEFL	Tx Event FIFO Element Lost. This bit is a copy of interrupt flag IR[TEFL]. When IR[TEFL] is reset, this bit is also reset. 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero.
7 EFF	Event FIFO Full. 0 Tx Event FIFO not full 1 Tx Event FIFO full
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 EFPI	Event FIFO Put Index. Tx Event FIFO write index pointer, range 0 to 31.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 EFGI	Event FIFO Get Index. Tx Event FIFO read index pointer, range 0 to 31.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 EFFL	Event FIFO Fill Level. Number of elements stored in Tx Event FIFO, range 0 to 32.

48.3.5.45 Tx Event FIFO Acknowledge register (M_CAN_TXEFA)

Address: 0h base + F8h offset = F8h

Bit	0–26	27–31
R	0	EFAI
W		
Reset	0	0

M_CAN_TXEFA field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 EFAI	Event FIFO Acknowledge Index. After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

48.3.6 Message RAM

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 4352 words in the Message RAM. It is not necessary to configure each of the sections listed in the following figure, nor is there any restriction with respect to the sequence of the sections.

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

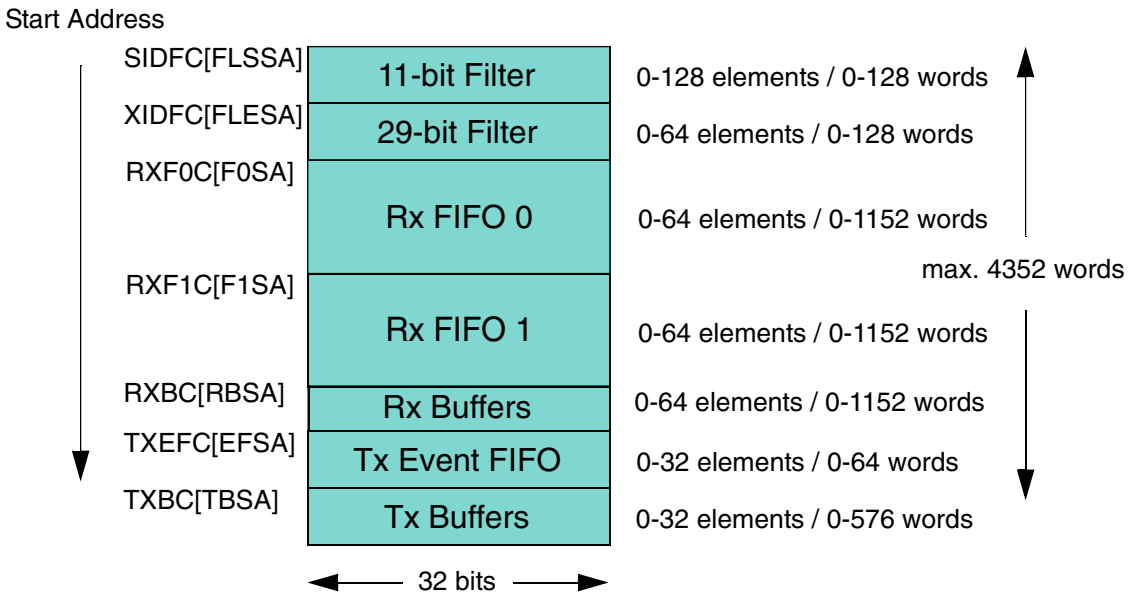


Figure 45. Message RAM Configuration

Figure 48-3. Message RAM Configuration

NOTE

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC[F0DS], RXESC[F1DS], RXESC[RBDS], and TXESC[TBDS].

The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

48.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

Table 48-2. Rx FIFO Element

Rn Bits 16:23	DBm-2[7:0]: Data Byte m-2
Rn Bits 24:31	DBm-3[7:0]: Data Byte m-3

NOTE

Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words (Rn = 3 ..17) are used for storage of a CAN message's data field.

48.3.6.2 Tx buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC[TFQS] and TXBC[NDTB]. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

Table 48-4. Tx Buffer Element

Tn Bits 24:31	DBm-3[7:0]: Data Byte m-3

NOTE

Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage of a CAN message's data field.

48.3.6.3 Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

Table 48-6. Tx Event FIFO Element

	0	7	8	15	16	23	24	31

E1 Bits 16:31TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

48.3.6.4 Standard message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC.FLSSA plus the index of the filter element (0…127).

Table 48-8. Standard Message ID Filter Element

	0		7	8	15	16	23	24	31
S0	SFT[1:0]	SFEC[2:0]		SFID1[10:0]		res	SFID2[10:0]		

Table 48-9. Standard Message ID Filter Element Field Description

Bits 0:1 SFT[1:0]	Standard Filter Type First ID of standard ID filter element. 00 Range filter from SF1ID to SF2ID (SF2ID > SF1ID) 01 Dual ID filter for SF1ID or SF2ID 10 Classic filter: SF1ID = filter, SF2ID = mask 11 Reserved
Bit 2:4 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = “100”, “101”, or “110” a match sets interrupt flag IE[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches

Table continues on the next page...

Table 48-9. Standard Message ID Filter Element Field Description (continued)

		100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of SFT[1:0] ignored
Bits 5:15 SFID1[10:0]		Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a tandard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: SFEC = '001'...'110' Second ID of standard ID filter element SFEC = '111' Filter for Rx Buffers or for debug messages
	SFID2[10:9]	Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C
	SFID2[8:6]	Is used to control the M_CAN filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN host clock period in case the filter matches.
	SFID2[5:0]	Defines the offset to the Rx Buffer Start Address RXBC[RBSA] for storage of a matching message.

48.3.6.5 Extended message ID filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0…63).

Table 48-10. Extended Message ID Filter Element

Table 48-11. Extended Message ID Filter Element Field Description

F0 Bits 0:2 EFEC[2:0]		Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = “100”, “101”, or “110” a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 Bits 3:31 **EFID1[28:0]**		Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffer or debug messages this field defines the ID of a extended debug message to be stored. The received identifiers must match exactly, no masking mechanism is used.
F1 Bits 0:1 EFT[1:0]		Extended Filter Type 00 — Range filter from EF1ID to EF2ID (EF2ID ≥ EF1ID) 01 — Dual ID filter for EF1ID or EF2ID 10 — Classic filter: EF1ID = filter, EF2ID = mask 11 — Range filter from EF1ID to EF2ID (EF2ID ≥ EF1ID), XIDAM mask not applied
F1 Bits 3:31	EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = “001”...”110” Second ID of extended ID filter element

Table continues on the next page...

Table 48-11. Extended Message ID Filter Element Field Description (continued)

		2) EFEC = “111” Filter for Rx Buffers or for debug messages
	EFID2[10:9]	Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00= Store message into an Rx Buffer 01= Debug Message A 10= Debug Message B 11= Debug Message C
	EFID2[8:6]	It is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN clock period in case the filter matches
	EFID2[5:0]	Defines the offset to the Rx Buffer Start Address RXBC[RBSA] for storage of a matching message.

48.3.7 M_CAN functional description

48.3.7.1 Operating modes

48.3.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = '1'. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS–High Priority Message Status
- RXF0S–Rx FIFO 0 Status
- RXF1S–Rx FIFO 1 Status
- TXFQS–Tx FIFO/Queue Status
- TXBRP–Tx Buffer Request Pending
- TXBTO–Tx Buffer Transmission Occurred
- TXBCF–Tx Buffer Cancellation Finished
- TXEFS–Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = '1'.

The following registers are only writable while CCCR[CCE] = '0'

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = '1' and CCCR[CCE] = '1'. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = '1' and CCCR[CCE] = '1'.

Following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
          while (read_data != 0x003){
            write(MCAN0,0xF,driver.regs.can0_cccr.addr,0x003);
    read_data = read(MCAN0,0xF,driver.regs.can0_cccr.addr);
          };

-- Configuring the time stamp and timeout registers
          write(MCAN0,0xF,driver.regs.can0_tscc.addr,0x000);
          write(MCAN0,0xF,driver.regs.can0_tocc.addr,0x000);

-- Configuring the interrupt registers
          write(MCAN0,0xF,driver.regs.can0_ie.addr,0xFFFFFFFF);
          write(MCAN0,0xF,driver.regs.can0_ils.addr,0x00000002);
          write(MCAN0,0xF,driver.regs.can0_ile.addr,0x00000003);

          write(MCAN0,0xF,driver.regs.can0_gfc.addr,0x000);
          write(MCAN0,0xF,driver.regs.can0_xidam.addr,0x00FFFFFF);

--Writing the start addresses of all the MCAN Buffers
          generate and drive MCAN0 can0_rxf0c keeping {
                                                        .f0sa == 0x100;
```

```
                                                        .f0s  == 0x03;
                                                        .f0wm == 0x01;
                                                        };
          generate and drive MCAN0 can0_rxf1c keeping {
                                                        .f1sa == 0x200;
                                                        .f1s  == 0x03;
                                                        .f1wm == 0x01;

```

48.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

48.3.7.3 CAN FD Operations

There are two stages in the CAN FD protocol, first the Long Frame Mode where the data field of a CAN frame may be longer that 8 bytes. The second stage is the Fast Frame Mode where control field, data field, and CRC field of a CAN Frame are transmitted with a higher bit rate than the beginning and the end of the frame. Fast Frame Mode can only be used in combination with Long Frame Mode.

The CAN operation mode is chosen by programming CCCR.CME. In case CCCR.CME = “01” transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CCCR.CME = “10”/“11” transmission and reception of long and fast CAN FD frames is enabled. CCCR.CME can only be changed while CCCR.INIT and CCCR.CCE are both set.

When initialization is left (CCCR.INIT set to ‘0’), both Long Frame Mode and Fast Frame Mode are inactive, they have to be requested by writing to CCCR.CMR.

A mode change requested by writing to CCCR.CMR will be executed next time the CAN protocol controller FSM reaches idle phase between CAN frames. Upon this event CCCR.CMR is reset to “00” and the status flags CCCR.FDBS and CCCR.FDO are set

accordingly. In case the requested CAN operation mode is not enabled, the value written to CCCR.CMR is retained until it is overwritten by the next mode change request. Default is CAN operation according to ISO11898-1.

It is not necessary to change the CAN operation mode after system startup. A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting according to ISO11898-1 until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in silent mode until programming has completed. Then all nodes switch back to CAN communication according ISO11898-1.

When CCCR.CME is not ‘00’, received CAN FD frames are interpreted according to the CAN FD Protocol Specification. The reserved bit in CAN frames with 11-bit identifiers and the first reserved bit in CAN frames with 29-bit identifiers will be decoded as EDL bit. EDL = recessive signifies a CAN FD frame, EDL = dominant signifies a standard CAN frame. In a CAN FD frame, the two bits following EDL, r0 and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by r0 = dominant and BRS = recessive. The coding of r0 = recessive is reserved for future expansion of the protocol.

Reception of CAN frames according to ISO 11898-1 is possible in all CAN operation modes.

The status bits CCCR.FDO and CCCR.FDBS indicate the format of transmitted frames. When CCCR.FDO is set, frames will be transmitted in CAN FD format with EDL = recessive. When both CCCR.FDO and CCCR.FDBS are set, frames will be transmitted in CAN FD format with bit rate switching and both bits EDL and BRS = recessive.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table.

Table 48-12. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing & Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the Fast Bit Timing & Prescaler Register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency. Example: with a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

48.3.7.3.1 Transceiver Delay Compensation

The length of the bus line has no impact. When transmitting via M_CAN_Tx pin the protocol controller receives the transmitted data from its local CAN transceiver via M_CAN_Rx pin. The received data is delayed by the CAN transceiver's loop delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transceivers loop delay.

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. The following figure below describes how the transceiver loop delay is measured.

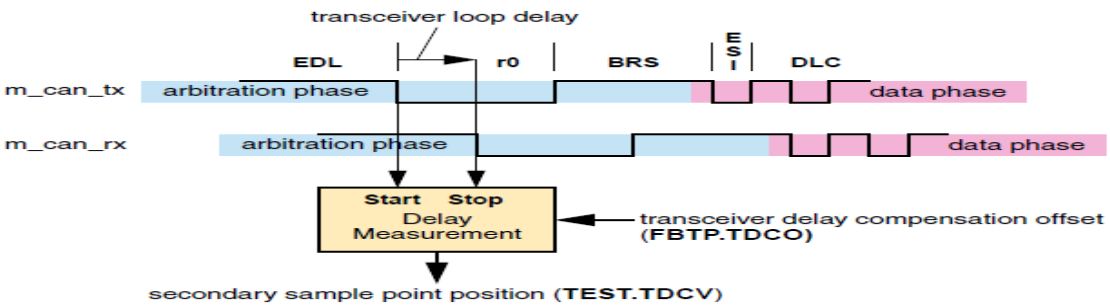

Figure 48-4. Transceiver delay measurement

Within each CAN FD frame, the transmitter measures the delay between the data transmitted at pin M_CAN_Tx and the data received at M_CAN_Rx pin, starting with the falling edge of bit EDL. The delay is measured in M_CAN core clock periods.

A secondary sample point is calculated by adding a configurable transceiver delay compensation offset (FBTP.TDCO) to the measured transceiver delay. The transceiver delay compensation offset is used to adjust the secondary sample point inside the bit time (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of time quanta tq.

To check for bit errors during the data phase, the delayed transmit data is compared against the received data at the secondary sample point. If a bit error is detected at the secondary sample point, the transmitter will react to this bit error at the next following sample point. During arbitration phase the delay compensation is always disabled.

For the transceiver delay compensation the following boundary conditions have to be considered:

- The sum of the measured delay from M_CAN_Tx to M_CAN_Rx and the configured transceiver delay compensation offset FBTP.TDCO has to be less than 3 bit times in the data phase.
- The sum of the measured delay from M_CAN_Tx to M_CAN_Rx and the configured transceiver delay compensation offset FBTP.TDCO has to be less or equal 63 M_CAN core clock periods. In case this sum exceeds 63 M_CAN core clock periods, the maximum value of 63 M_CAN core clock periods is used for transceiver delay compensation.

The actual delay compensation value is monitored by reading TEST.TDCV

48.3.7.3.2 Configuration and status

Compensation for the transceiver loop delay by the M_CAN is enabled via FBTP[TDC]. The transceiver delay compensation offset is configured via FBTP[TDCO]. The actual delay compensation value applied by the M_CAN's protocol engine can be read from TEST[TDCV].

48.3.7.4 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. The Host can set the M_CAN into Restricted Operation mode by setting bit CCCR[ASM]. The bit can only be set by the Host when both CCCR[CCE] and CCCR[INIT] are set to '1'. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR[ASM].

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

48.3.7.5 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

The following figure shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

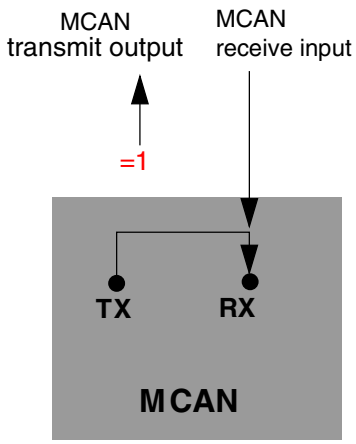

Figure 48-5. Pin Control in Bus Monitoring Mode

48.3.7.6 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

48.3.7.6.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
- Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = "10" (transmission in spite of cancellation).

48.3.7.7 Power down (Sleep mode)

The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

48.3.7.8 Test modes

To enable write access to register TEST (see Test Register (M_CAN_TEST)), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin m_can_tx by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at MCAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].

Note

Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

48.3.7.8.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if the y pass acceptance filtering) into Rx FIFOs. The following figure shows the connection of MCAN Tx and Rx signals in External Loop Back mode. This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the MCAN Tx pin.

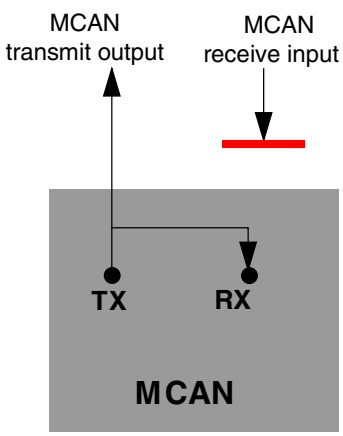

Figure 48-6. External Loop Back mode

48.3.7.8.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a "Hot Selftest", meaning the M_CAN can be tested without affecting a running CAN system connected to the MCAN Tx and Rx pins. In this mode MCAN Tx pin is disconnected from the M_CAN and MCAN Tx pin is held recessive. The following figure shows the connection of MCAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

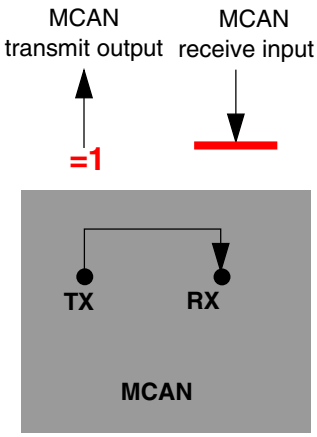

Figure 48-7. Internal loop back mode

48.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of a Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

48.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = '0'. It is stopped when CCCR[INIT] = '1', e.g. when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note

The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

48.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to one of the two Rx FIFOs, as well as the Rx FIFOs Put and Get Indices.

48.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)
  - Filter for one or two dedicated IDs
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[FLEC].

Rx FIFO

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[FLEC]. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in "Rx FIFO Overwrite Mode" section have to be considered.

Note

When an accepted message is written to one of the two Rx FIFOs, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

48.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID. There are two possibilities when range filtering is used together with extended frames:

- EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering

48.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

48.3.10.1.3 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

48.3.10.1.4 Standard message ID filtering

Table 48-8 shows the flow for standard message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in Standard message ID Filter element.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

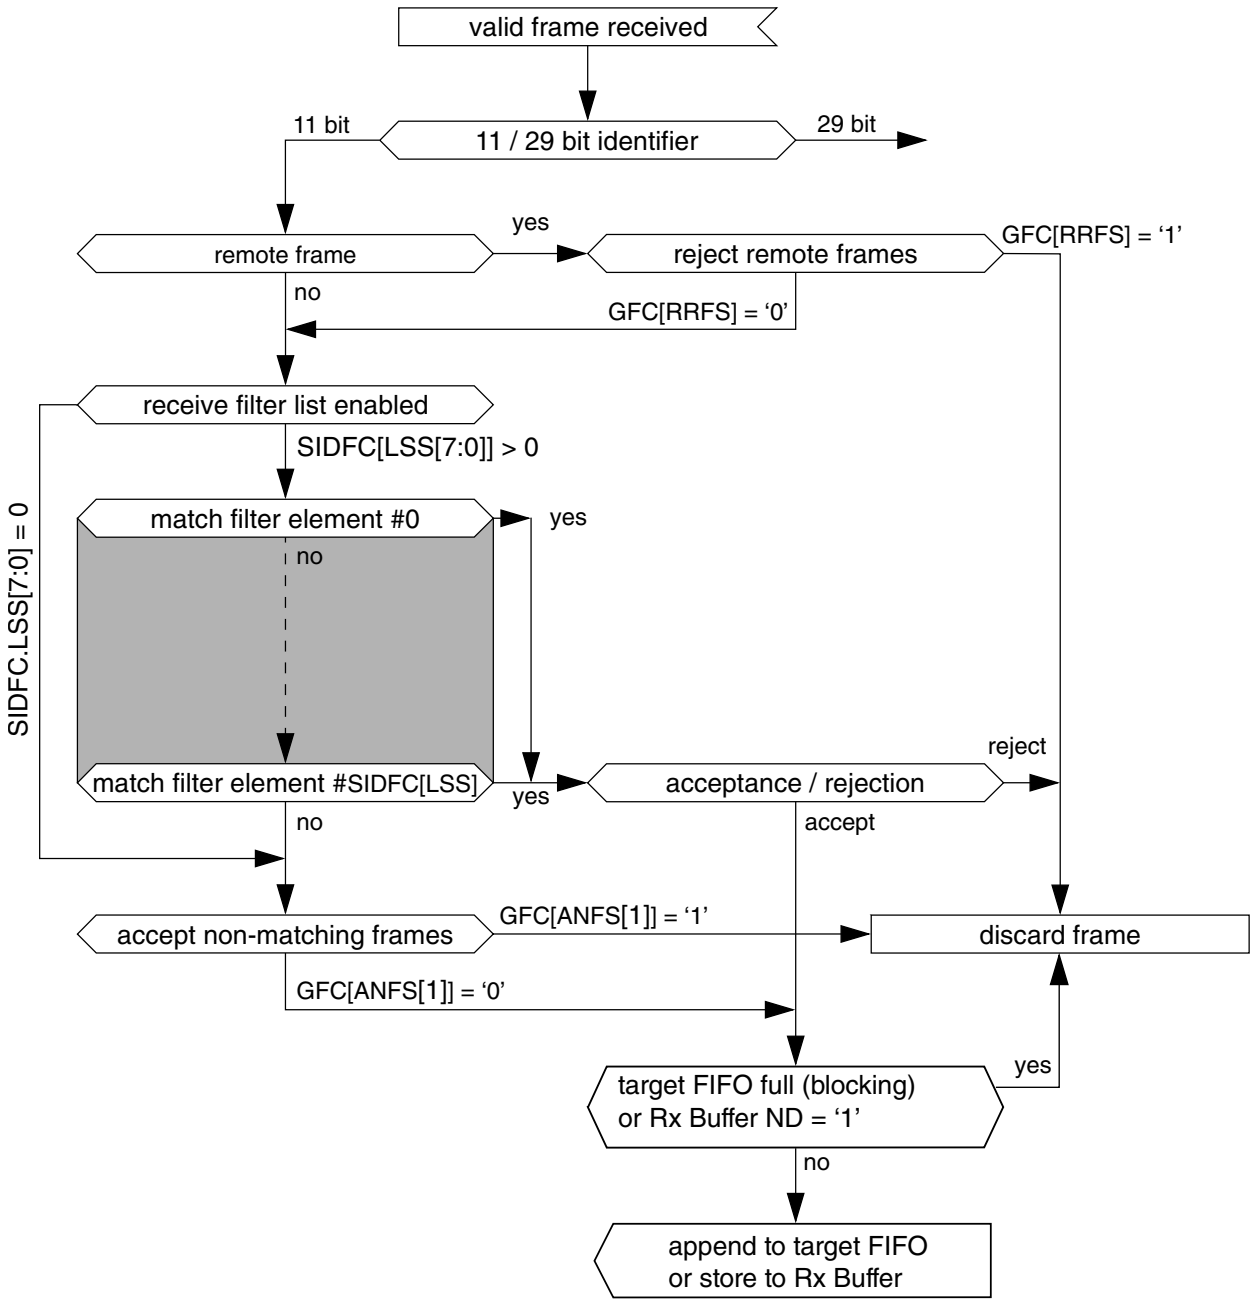

Figure 48-8. Standard Message ID Filter Path

48.3.10.1.5 Extended message ID filtering

The figure below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in the Extended ID Filter Configuration Register (M_CAN_XIDFC).

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

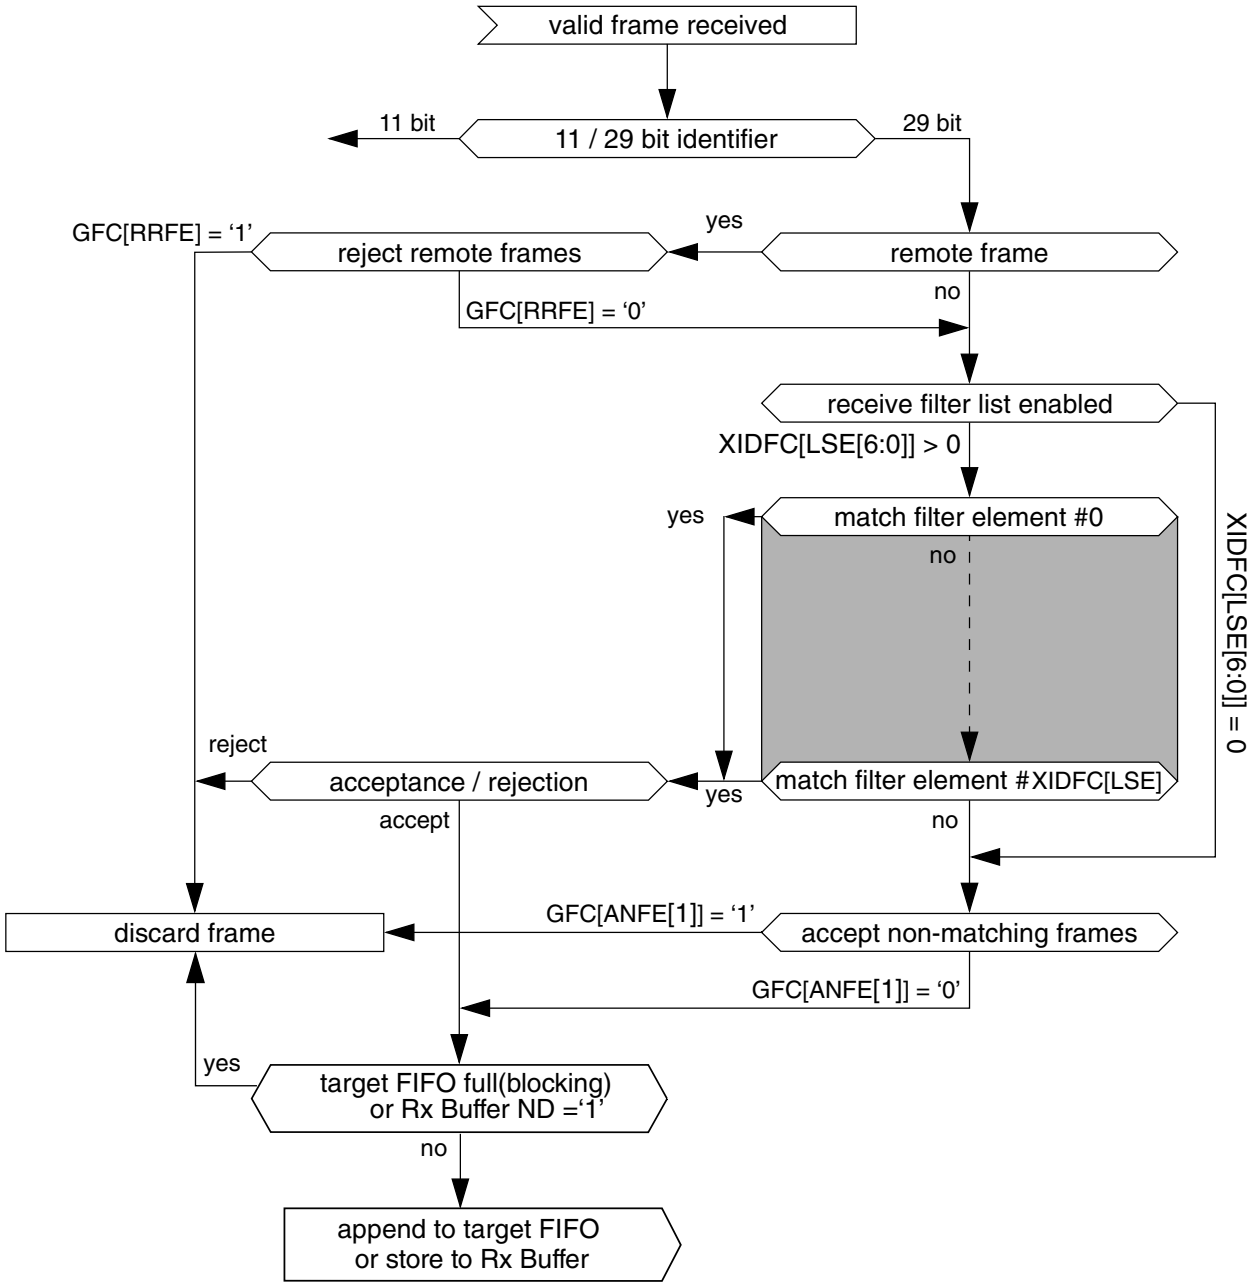

Figure 48-9. Extended Message ID Filter Path

48.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C. Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see Acceptance filtering. The Rx FIFO element is described in Rx Buffer and FIFO element.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS[FnF]. In addition interrupt flag IR[RFnF] is set.

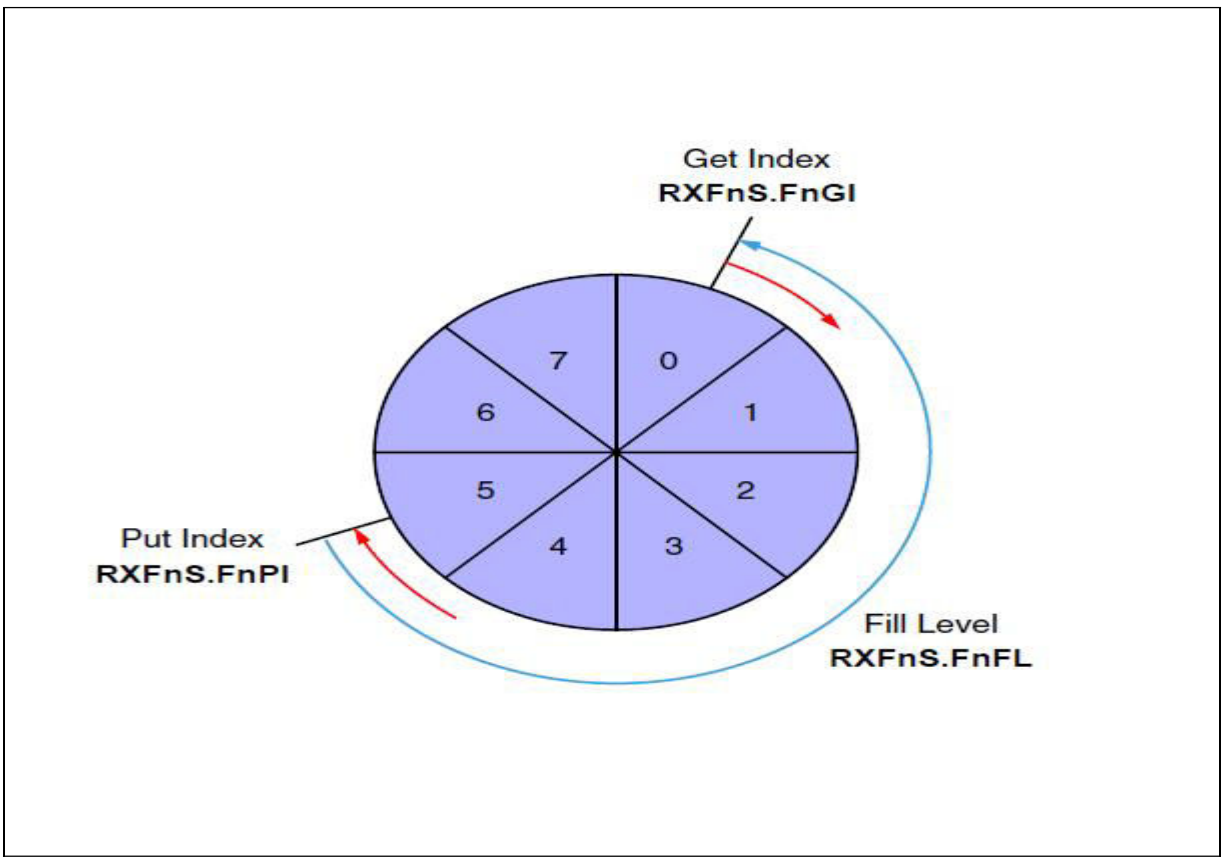

Figure 48-10. Rx FIFO Status

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS[FnGI] x FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

Table 48-13. Rx Buffer / FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

48.3.10.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by RXFnC[FnOM] = ‘0’. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS[FnPI] = RXFnS[FnGI]), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by RXFnS[FnF] = ‘1’. In addition interrupt flag IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by RXFnS[RFnL] = ‘1’. In addition interrupt flag IR[RFnL] is set.

48.3.10.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by RXFnC[FnOM]= ‘1’.

When an Rx FIFO full condition (RXFnS[FnPI] = RXFnS[FnGI]) is signalled by RXFnS[FnF] = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. Figure 9 shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

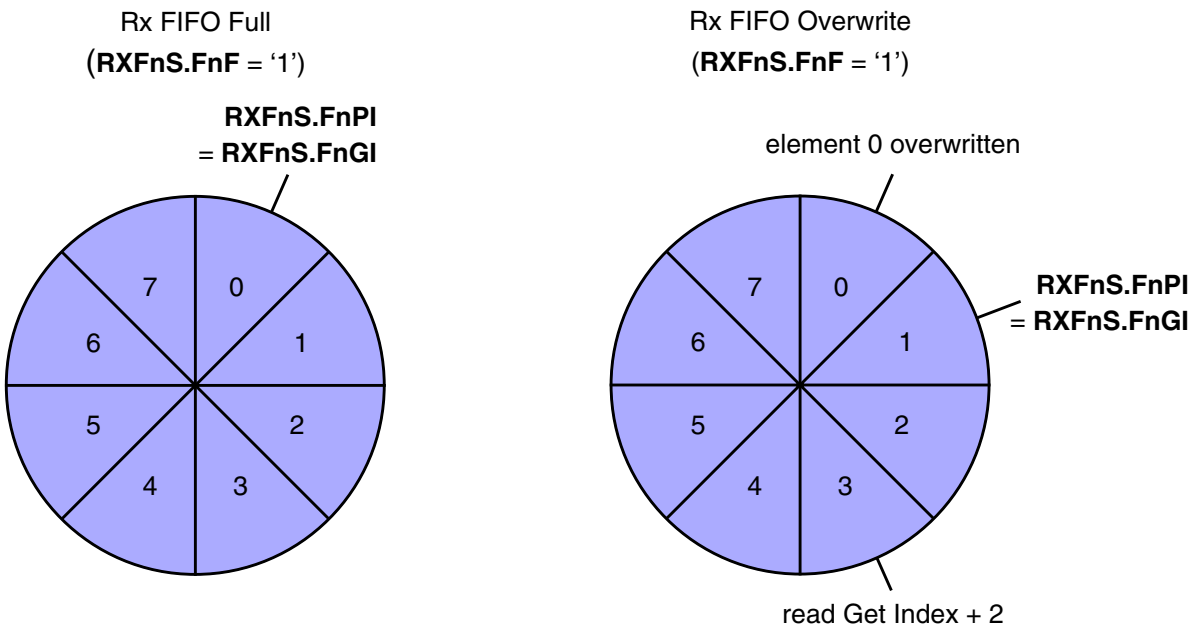

Figure 48-11. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA[FnA]. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS[FnF] = '0').

48.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = "111" and SFID2 / EFID2[10:9] = "00" has to be configured.

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 48-14. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a ‘1’ to the respective bit position.

While an Rx Buffer’s New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration

48.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

48.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element.

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = “111” have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output m_can_dma_req is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while m_can_dma_req is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets m_can_dma_ack. This resets m_can_dma_req. Now the M_CAN is prepared to receive the next set of debug messages.

NOTE

To use full ‘Debug on CAN Support’ feature on a M_CAN instance, a DMA channel is required. Refer to device DMA map, to see which M_CAN instances has been assigned with DMA channel.

48.3.12.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to “111”. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR[DRX] are set. The reception of debug messages can be monitored via RXF1S[DMS].

Table 48-15. Example Filter Configuration for Debug Messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

48.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S[DMS].

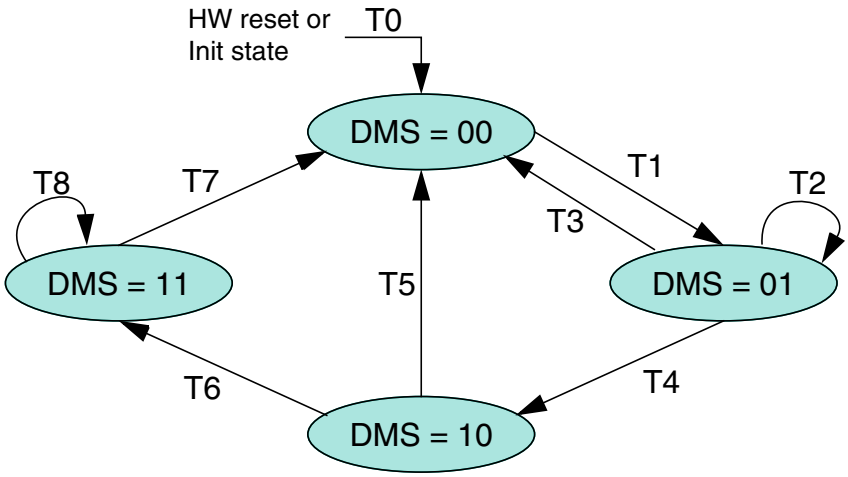

Figure 48-12. Debug Message Handling State Machine

T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C

T1: reception of debug message A

T2: reception of debug message A

T3: reception of debug message C

T4: reception of debug message B

T5: reception of debug messages A, B

T6: reception of debug message C

T7: DMA transfer completed

T8: reception of debug message A,B,C (message rejected)

48.3.13 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message handling state machine enters idle state (DMS = "00") and waits for reception of the next debug messages.

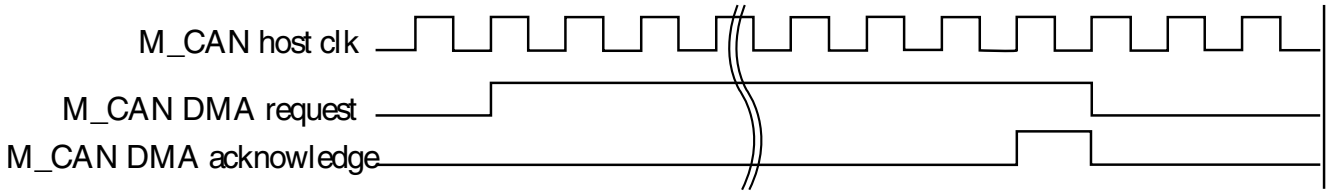

Figure 48-13. Timing of DMA interface signals

48.3.14 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in Tx buffer element.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

48.3.14.1 Transmit Pause

The Rx FIFO overwrite mode is configured by RXFnC[FnOM]= ‘1’.

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU’s CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If e.g. CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR[TXP]. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR[TXP] = ‘0’).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

48.3.14.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) to the Tx Buffer Start Address TXBC[TBSA].

Table 48-16. Tx Buffer / FIFO / Queue Element Size

TXESC.TBDS[2:0]	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

48.3.14.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = '1') is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0…31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

48.3.14.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding four times the Tx FIFO/Queue Put Index TXFQS[TFQPI] (0…31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

48.3.14.5 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

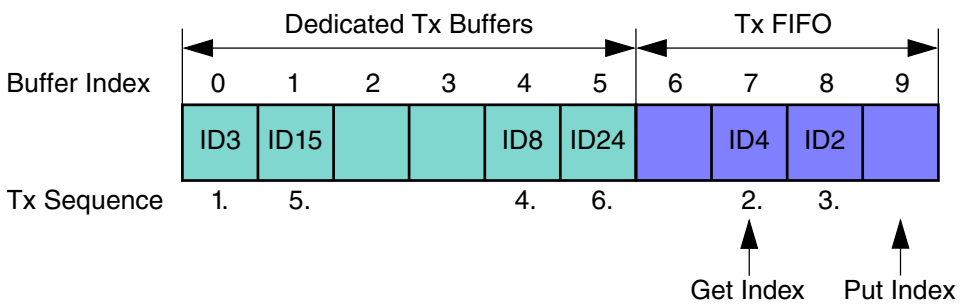

Figure 48-14. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.14.6 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

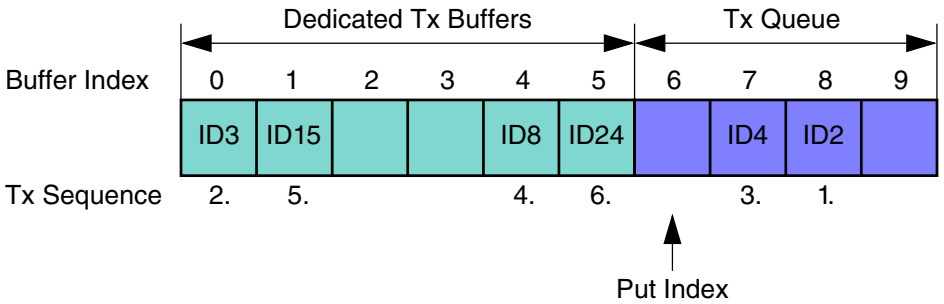

Figure 48-15. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

48.3.14.7 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note

In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

48.3.14.8 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in Tx event FIFO element. When a Tx Event FIFO full condition is signalled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

48.3.15 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see Rx FIFO 0 Acknowledge Register (M_CAN_RXF0A), Rx FIFO 1 Acknowledge Register (M_CAN_RXF1A) and Tx Event FIFO Acknowledge register (M_CAN_TXEFA)) . Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the

two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

48.4 Time Triggered Modular CAN (M_TTCAN) core

The M_TTCAN performs communication according to ISO 11898-1 (identical to Bosch CAN protocol specification 2.0 part A,B) and according to ISO 11898-4 (time-triggered communication on CAN). The M_TTCAN provides all features of time-triggered communication specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation.

In addition the M_TTCAN supports communication according to CAN FD protocol specification 1.0 with data fields of up to eight bytes length. The CAN FD option can be used together with event-triggered and time-triggered CAN communication.

The message storage is intended to be a single-ported or dual-ported Message RAM outside of the module. It is connected to the M_TTCAN via the Generic Master Interface. Depending on the chosen ASIC integration, multiple M_TTCAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information. It implements all functions concerning the time schedule and the global system time.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_TTCAN can be connected to a wide range of Host CPUs via its 8/16/32-bit Generic Slave Interface. The M_TTCAN’s clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.

48.4.1 Features

The following are the features of M_TTCAN.

- M_TTCAN protocol level 1 and level 2 completely in hardware
- AUTOSAR optimized
- SAE J1939 optimized
- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1, -4
- CAN FD with maximum 8 data bytes supported
- Event synchronized time-triggered communication supported
- CAN Error Logging
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 Transmit Buffers
- Configurable Transmit FIFO / Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_TTCAN share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug on CAN support

48.4.2 Block Diagram

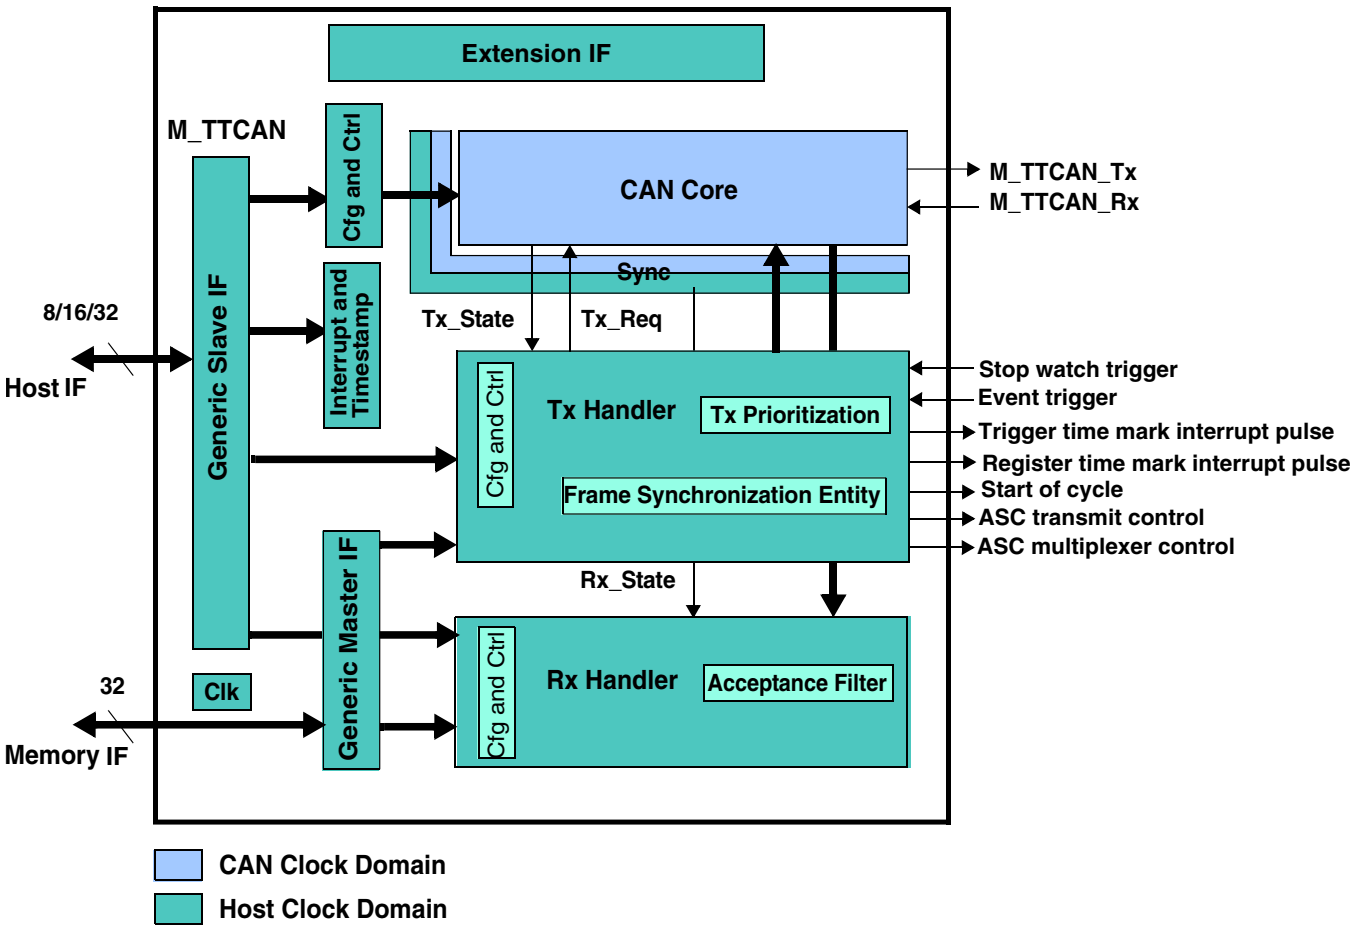

Figure 48-16. M_TTCAN Core block diagram

- CAN Core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Cfg and Ctrl: CAN Core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported. The Tx Handler

also implements the Frame Synchronization Entity FSE which controls time-triggered communication according to ISO11898-4. It synchronizes itself to the reference messages on the CAN bus, controls cycle time and global time, and handles transmissions according to the predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the Message RAM. Stop Watch Trigger, Event Trigger, and Time Mark Interrupt are synchronization interfaces.

- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Generic Slave Interface: Connects the M_TTCAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_TTCAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bit. Refer Table 48-38.
- Extension Interface: All flags from the Interrupt Register IR and TT Interrupt Register TTIR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M_TTCAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

48.4.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN Core, a separate clock without any modulation has to be provided as M_TTCAN clock. The CAN Core should be programmed to have at least 8 clocks per bit time, this is e.g. 1 Mbaud at M_TTCAN clock ≤ 8 MHz. Even in case of a very high Host clock frequency, the clock frequency of the CAN Core needs not to be higher than 8 MHz.

Within the M_TTCAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note

In order to achieve a stable function of the M_TTCAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

CAUTION

It is strongly recommended to stop this module when the device is in the STOP mode or in case, if the CAN message reception is mandatory, please check if the PLL is unlocked before transmitting any message, or use the external oscillator instead of the IRC during the STOP mode.

48.4.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to M_TTCAN INT 0 or to M_TTCAN INT 1. By default all interrupts are routed to interrupt line M_TTCAN INT 0. By programming EINT0 and EINT1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

48.4.5 Memory map and register description

After hardware reset, the registers of the M_TTCAN hold the reset values listed in the memory map. Additionally the Bus_Off state is reset and the CAN transmit output is set to recessive (HIGH). The value 0x0001 (CCCR[INIT] = '1') in the CC Control Register enables software initialization. The M_TTCAN does not influence the CAN bus until the CPU resets CCCR[INIT] to '0'.

The M_TTCAN module allocates an address space of 512 bytes. All registers are organized as 32-bit registers. The M_TTCAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

NOTE

Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only with CCCR[CCE]= '1' and CCCR[INIT]= '1'. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

R	ETV	
W		
Reset	1 0 0 0 0 1 1 1 0 1 1 0 0 1 0 1	0 1 0 0 0 0 1 1 0 0 1 0 0 0 0 1

M_TTCAN_ENDN field descriptions

Field	Description
0–31 ETV	Endianness Test Value The endianness test value is 0x87654321.

48.4.5.3 Fast Bit Timing and Prescaler Register (M_TTCAN_FBTP)

The CAN bit time may be programed in the range of 4 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to 1024 M_TTCAN clock periods.

tq = (FBRP + 1) M_TTCAN clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. FTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [FTSEG1 + FTSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

NOTE

With a M_TTCAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_TTCAN for a fast bit rate of 500 kbit/s.

Address: 0h base + Ch offset = Ch

M_TTCAN_FBTP field descriptions

Field	Description
0–3 TDCO	Transceiver Delay Compensation Offset

Table continues on the next page...

M_TTCAN_FBTP field descriptions (continued)

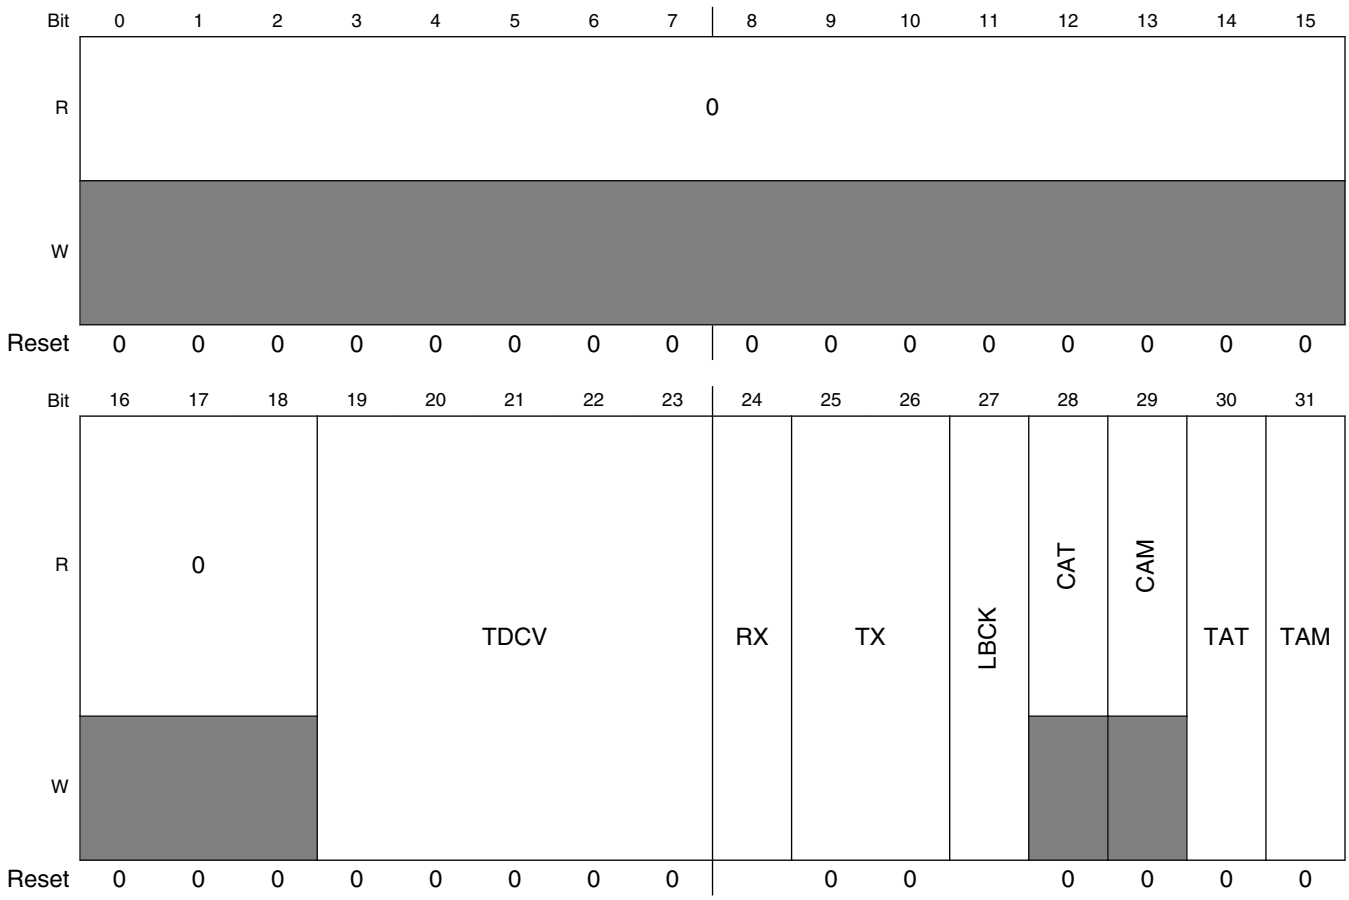
Field	Description
	(0x0-0xF) - Offset value defining the distance between the measured delay from M_TTCAN transmit to M_TTCAN receive and the secondary sample point. Valid values are 0 to 15 M_TTCAN clock periods.
4 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FBRP	Fast Baud Rate Prescaler (0x000-0x3FF)- The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 FTSEG1	Fast time segment before sample point (0x1-0xF) Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 FTSEG2	Fast time segment before sample point (0x0-0x7) Valid values are 0 to 7. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 FSJW	Fast (Re) Synchronization Jump Width 0x0-0x3 Valid values are 0 to 3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

48.4.5.4 Test Register (M_TTCAN_TEST)

Write access to the Test Register has to be enabled by setting bit CCCR[TEST] to '1'. All Test Register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back mode and software control of Tx pin are hardware test modes. Programming of TX to values other than "00" may disturb the message transfer on the CAN bus.

Address: 0h base + 10h offset = 10h



M_TTCAN_TEST field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 TDCV	Transceiver Delay Compensation Value (0x00-0x1F)- Position of the secondary sample point, defined by the sum of the measured delay from M_TTCAN transmit and to receive and FBTP.TDCO. Valid values are 0 to 31 M_TTCAN core clock periods.
24 RX	Receive Pin Monitors the actual value of transmit pin 0 The CAN bus is dominant 1 The CAN bus is recessive
25–26 TX	Control of Transmit Pin **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 Reset value TX is controlled by the CAN Core, updated at the end of the CAN bit time 01 Sample Point can be monitored at pin

Table continues on the next page...

M_TTCAN_TEST field descriptions (continued)

Field	Description
	10 Dominant ('0') level at pin 11 Recessive ('1') at pin
27 LBCK	Loop Back mode **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Reset value, Loop Back mode is disabled 1 Loop Back mode is enabled (see Test modes)
28 CAT	Check ASC Transmit Control Monitors level at M_TTCAN ASC transmit control. 0 Output M_TTCAN ASC transmit control pin = ‘0’ 1 Output M_TTCAN ASC transmit control pin = ‘1’
29 CAM	Check ASC Multiplexer Control Monitors level at M_TTCAN ASC multiplexer control. 0 Output M_TTCAN ASC multiplexer control pin = ‘0’ 1 Output M_TTCAN ASC multiplexer control pin = ‘1’
30 TAT	Test ASC Transmit Control Controls output ASC Transmit Control pin in test mode, ORed with the signal from the FSE. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Level at M_TTCAN ASC transmit control pin controlled by FSE 1 Level at M_TTCAN ASC transmit control pin = ‘1’
31 TAM	Test ASC Multiplexer Control Controls output M_TTCAN ASC multiplexer control in test mode, ORed with the signal from the FSE. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Level at M_TTCAN ASC multiplexer control pin controlled by FSE 1 Level at M_TTCAN ASC multiplexer control pin = ‘1’

48.4.5.5 RAM Watchdog Register (M_TTCAN_RWD)

The RAM Watchdog monitors the READY output of the Message RAM . A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the RWD[WDC] bits. The counter is reloaded with RWD[WDC] bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag IR[WDI] bit is set. The RAM Watchdog Counter is clocked by the Host clock .

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_TTCAN_RWD field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 WDV	Watchdog Value. Actual Message RAM Watchdog Counter Value.
24–31 WDC	Watchdog Configuration. Start value of the Message RAM Watchdog Counter. With the reset value of "00" the counter is disabled. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.6 CC Control Register (M_TTCAN_CCCR)

NOTE

Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

M_TTCAN_CCCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 FDBS	Long Frame Mode Active CAN FD Bit Rate Switching 0 This node transmits no frames with bit rate switching 1 This node transmits all frames (excl. remote frames) with bit rate switching
19 FDO	Fast Frame Mode Active CAN FD Operation 0 This node transmits all frames in CAN format according to ISO11898-1 1 This node transmits all frames (excl. remote frames) in CAN FD format
20–21 CMR	CAN Mode Request A change of the CAN operation mode is requested by writing to this bit field. After change to the requested operation mode the bit field is reset to ‘00’ and the status flags FDBS and FDO are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CMR is retained until it is overwritten by the next mode change request. Default is CAN operation according to ISO11898-1. 00 unchanged 01 Request CAN FD operation

Table continues on the next page...

M_TTCAN_CCCR field descriptions (continued)

Field	Description
	10 Request CAN FD operation with bit rate switching 11 Request CAN operation according ISO11898-1
22–23 CME	CAN Mode Enable 00 CAN operation according to ISO11898-1 enabled 01 Long Frame Mode enabled 10 Long + Fast Frame Mode enabled 11 CAN FD operation with bit rate switching enabled **NOTE:** When CME = ‘00’, received frames are strictly interpreted according to ISO11898-1, which leads to the transmission of an error frame when receiving a CAN FD frame. In case CME = ‘01’, transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CME = ‘10’/‘11’, transmission and reception of long and fast CAN FD frames is enabled.
24 TEST	Test Enable Mode **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle. .
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_TTCAN may be set in power down by stopping host clock and core clock
29 ASM	ASM Restricted Operation Mode The Restricted Operation Mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame. In the optional Restricted Operation Mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication.

Table continues on the next page...

M_TTCAN_CCCR field descriptions (continued)

Field	Description
	The error counters are not incremented. Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR[INIT] = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started

48.4.5.7 Bit Timing and Prescaler Register (M_TTCAN_BTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programed in the range of [4....81] time This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programed in the range of 4 to 81 time quanta. The CAN time quantum may be programmed in the range of 1 to 1024 M_TTCAN core clock periods.

tq = (BRP + 1) M_TTCAN core clock period.

TSEG1 is the sum of Prop_Seg and Phase_Seg1. TSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

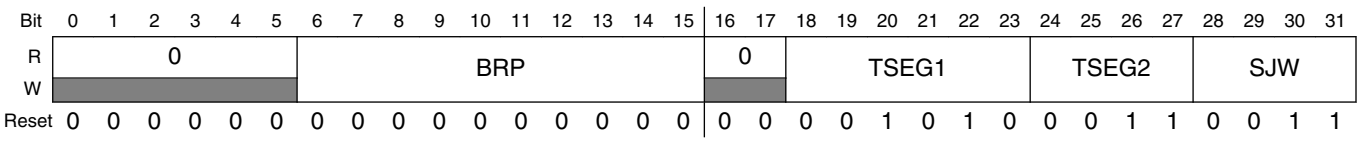
NOTE

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

NOTE

With a M_TTCAN clock of 8 MHz,the reset value of 0x000_00A33 configures the M_TTCAN for a bit rate of 500 kbit/s.

Address: 0h base + 1Ch offset = 1Ch

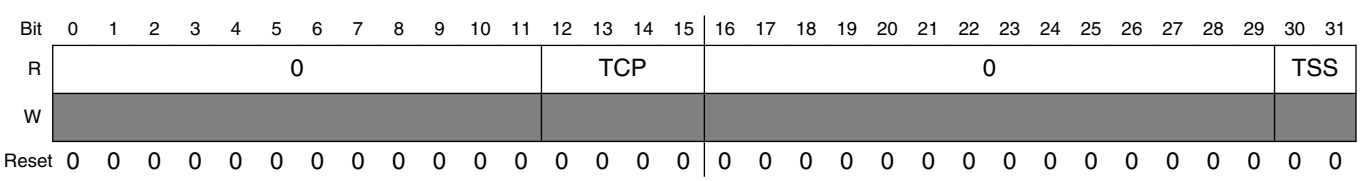


M_TTCAN_BTP field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 BRP	Baud Rate Prescaler (0x000-0x3FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TSEG1	The time segment before the sample point (0x0–0x3F) Valid values are 0 to 63. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
24–27 TSEG2	Time segment after sample point (0x0-0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
28–31 SJW	(Re) Synchronization Jump Width (0x0-0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value prog rammed here is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.8 Timestamp Counter Configuration Register (M_TTCAN_TSCC)

Address: 0h base + 20h offset = 20h



M_TTCAN_TSCC field descriptions

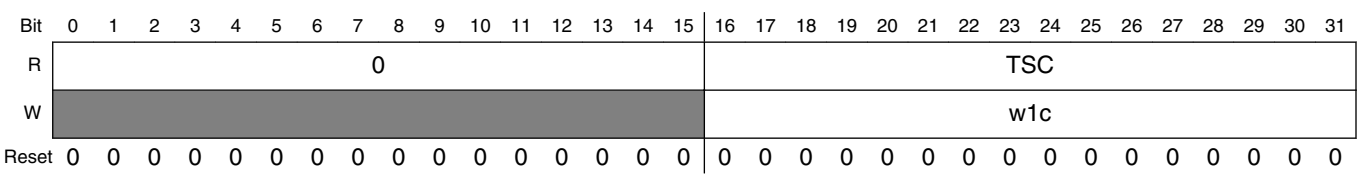
Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 TCP	Timestamp Counter Prescaler 0x0-0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1...16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". **NOTE:** In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase.
16–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 TSS	Timestamp Select **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to TCP 10 Reserved 11 Same as "00"

48.4.5.9 Timestamp Counter Value Register (M_TTCAN_TSCV)

NOTE

A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

Address: 0h base + 24h offset = 24h



M_TTCAN_TSCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TSC	Timestamp Counter.The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = ‘01’, the Timestamp Counter is incremented in multiples of CAN bit times [1…16] depending on the configuration of TSCC[TCP]. A wrap around sets interrupt flag IR[TSW]. Write access resets the counter to zero. A write access has no impact.

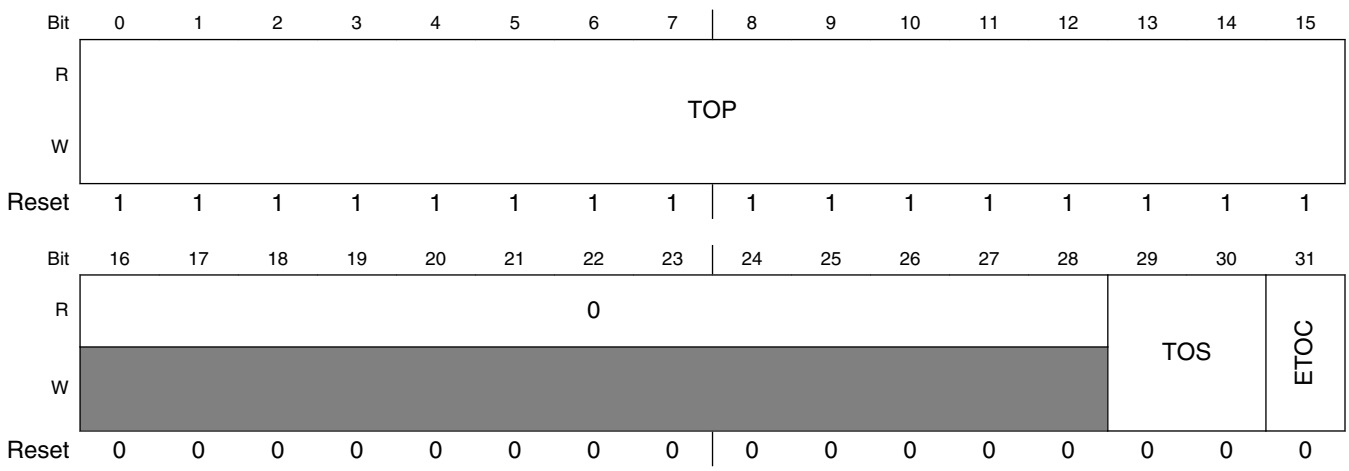
M_TTCAN_TSCV field descriptions (continued)

Field	Description

48.4.5.10 Timeout Counter Configuration Register (M_TTCAN_TOCC)

For a description of the Timeout Counter see Test modes .

Address: 0h base + 28h offset = 28h



M_TTCAN_TOCC field descriptions

Field	Description
0–15 TOP	Timeout Period Start value of the Timeout Counter (down-counter). Configures the Timeout Period. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 TOS	Timeout Select. When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 Continuous operation 01 Timeout controlled by Tx Event FIFO 10 Timeout controlled by Rx FIFO 0 11 Timeout controlled by Rx FIFO 1
31 ETOC	Enable Timeout Counter

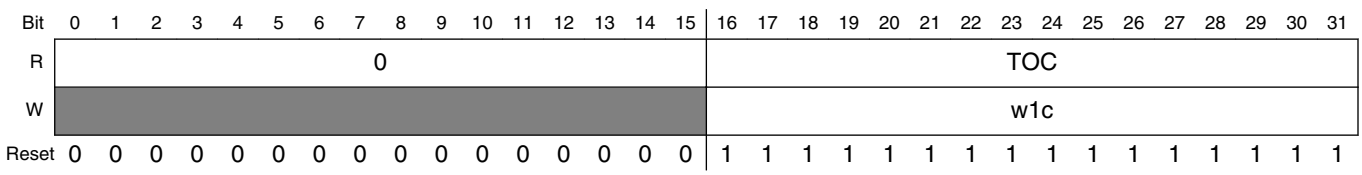
Table continues on the next page...

M_TTCAN_TOCC field descriptions (continued)

Field	Description
	NOTE: Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". **NOTE:** For use of timeout function with CAN FD, see section "Timeout counter". 0 Timeout Counter disabled 1 Timeout Counter enabled

48.4.5.11 Timeout Counter Value Register (M_TTCAN_TOCV)

Address: 0h base + 2Ch offset = 2Ch

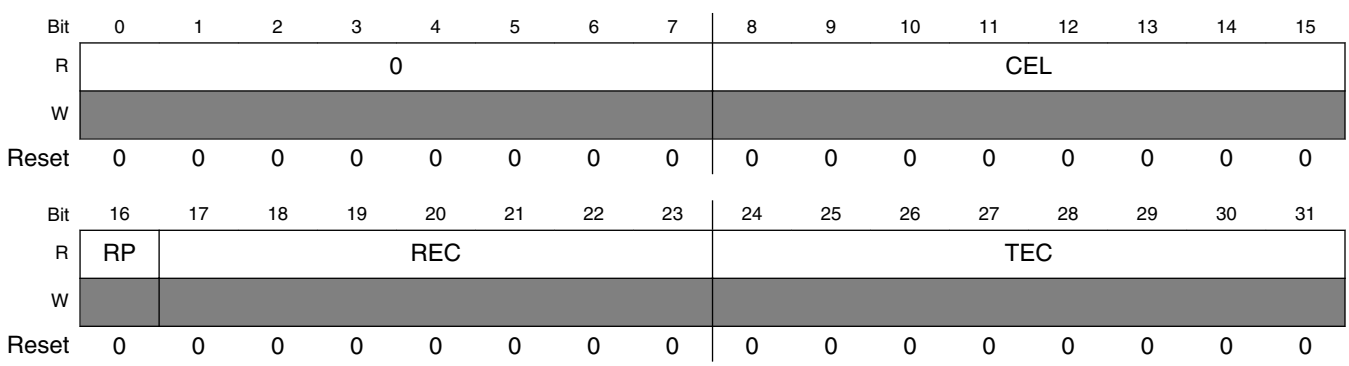


M_TTCAN_TOCV field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TOC	Timeout Counter. The Timeout Counter is decremented in multiples of CAN bit times [1:16] depending on the configuration of TSCC[TCP]. When decremented to zero, interrupt flag IR[TOO] is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via TOCC[TOS].

48.4.5.12 Error Counter Register (M_TTCAN_ECR)

Address: 0h base + 40h offset = 40h



M_TTCAN_ECR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 CEL	CAN Error Logging. The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[ELO]. **NOTE:** This bit resets on read.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the *errorpassive* level of 128 1 The Receive Error Counter has reached the *errorpassive* level of 128
17–23 REC	Receive Error Counter. Actual state of the Receive Error Counter, values between 0 and 127
24–31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255 **NOTE:** When CCCR[ASM] is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented. This enables monitoring of collisions between CAN frames and ASC frames.

48.4.5.13 Protocol Status Register (M_TTCAN_PSR)

NOTE

Access type is RS: This register is set on read.

NOTE

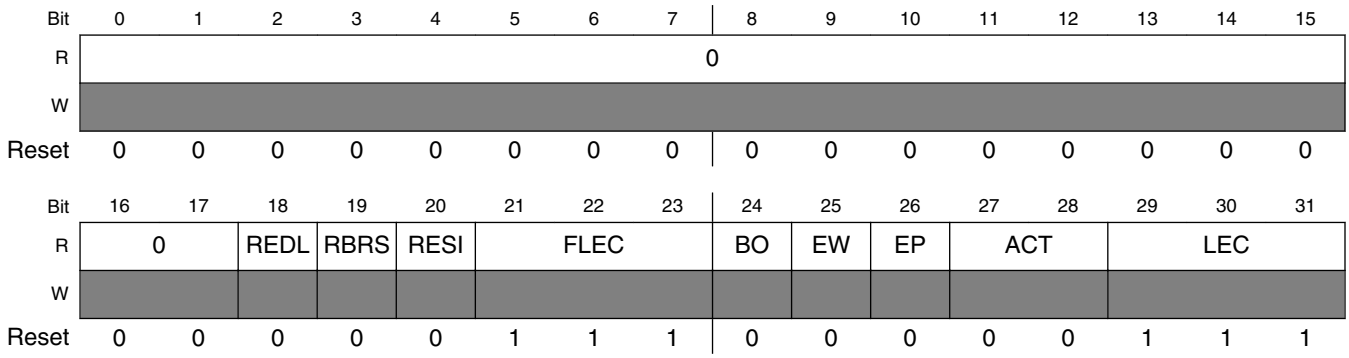
When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

NOTE

The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 x 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive

bits has been monitored, a Bit0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

Address: 0h base + 44h offset = 44h



M_TTCAN_PSR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 REDL	Received a CAN FD Message This bit is set independent of acceptance filtering. 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with EDL flag set has been received **NOTE:** This bit sets on reset.
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not ha ve its BRS flag set. 1 Last received CAN FD message had its BRS flag set. **NOTE:** This bit sets on reset.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not ha ve its ESI flag set. 1 Last received CAN FD message had its ESI flag set **NOTE:** This bit sets on reset.
21–23 FLEC	Fast Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. **NOTE:** This bit resets on read.

Table continues on the next page...

M_TTCAN_PSR field descriptions (continued)

Field	Description
24 BO	Bus_Off Status 0 The M_TTCAN is not Bus_Off 1 The M_TTCAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_TTCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_TTCAN is in the Error_Passive state
27–28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing - node is synchronizing on CAN communication 01 Idle - node is neither receiver nor transmitter 10 Receiver - node is operating as receiver 11 Transmitter - node is operating as transmitter
29–31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_TTCAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a *recessive* level (bit of logical value '1'), but the monitored bus value was *dominant* . 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a *dominant* level (data or identifier bit logical value '0'), but the monitored bus value was *recessive* . During *Bus_Off* recovery this status is set each time a sequence of 11 *recessive* bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register. **NOTE:** This bit resets on read.

48.4.5.14 Interrupt Register (M_TTCAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

M_TTCAN_IR field descriptions

Field	Description
0 STE	Stuff Error 0 No Stuff Error detected 1 More than 5 equal bits in a sequence occurred
1 FOE	Format Error 0 No Format Error detected 1 A fixed format part of a received frame has the wrong format
2 ACKE	Acknowledge Error 0 No Acknowledge Error detected 1 A transmitted message was not acknowledged by another node
3 BE	Bit Error 0 No Bit Error detected 1 Device wanted to send a *rec* / *dom* level, but monitored bus level was *dom* / rec
4 CRCE	CRC Error

Table continues on the next page...

M_TTCAN_IR field descriptions (continued)

Field	Description
	0 No CRC Error detected 1 Received CRC did not match the calculated CRC
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status 0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (e.g. ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buff er
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 UMD	Unprocessed Message Discarded. When a new message is received while the acceptance filtering process for the previously received message has not yet completed, this message is discarded. 0 No unprocessed message discarded 1 Unprocessed message discarded

48.4.5.16 Interrupt Line Select Register (M_TTCAN_ILS)

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1].

Address: 0h base + 58h offset = 58h

M_TTCAN_XIDFC field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LSE	List Size Extended 0 No extended Message ID filter 1-64 Number of extended Message ID filter elements >64 Values greater than 64 are interpreted as 64 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–29 FLESA	Filter List Extended Start Address. Start address of extended Message ID filter list (32-bit word address, see Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.21 Extended ID and Mask Register (M_TTCAN_XIDAM)

Address: 0h base + 90h offset = 90h

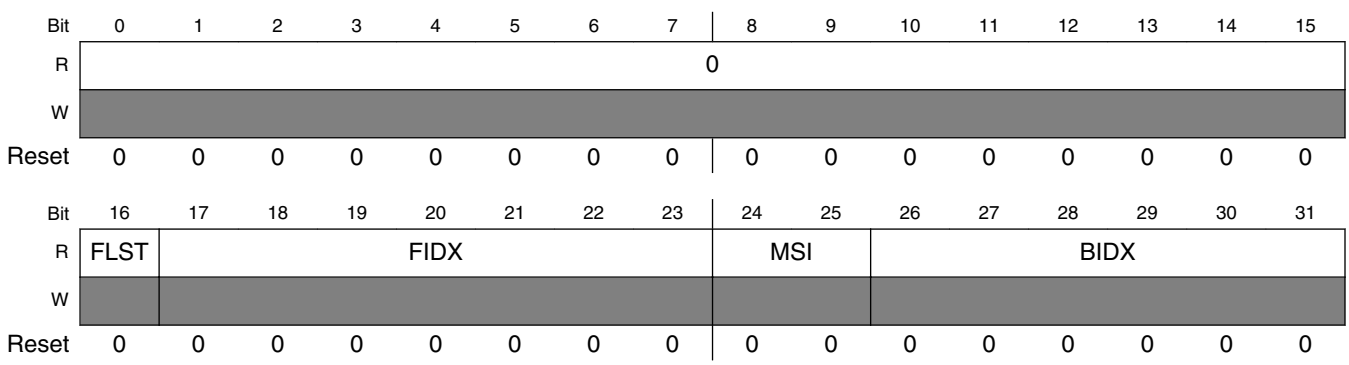
M_TTCAN_XIDAM field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–31 EIDM	Extended ID Mask. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.22 High Priority Message Status Register (M_TTCAN_HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Address: 0h base + 94h offset = 94h



M_TTCAN_HPMS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

M_TTCAN_HPMS field descriptions (continued)

Field	Description
16 FLST	Filter List. Indicates the filter list of the matching filter element. 0 Standard Filter List 1 Extended Filter List
17–23 FIDX	Filter Index. Index of matching filter element. Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
24–25 MSI	Message Storage Indicator 00 No FIFO selected 01 FIFO overrun 10 Message stored in FIFO 0 11 Message stored in FIFO 1
26–31 BIDX	Buffer Index. Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = '1'.

48.4.5.23 New Data 1 Register (M_TTCAN_NDAT1)

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_TTCAN_RXF0S field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 RF0L	Rx FIFO 0 Message Lost. This bit is a copy of interrupt flag IR[RF0L]. When IR[RF0L] is reset, this bit is also reset. 0 No Rx FIFO 0 message lost 1 Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
7 F0F	Rx FIFO 0 Full 0 Rx FIFO 0 not full 1 Rx FIFO 0 full
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 F0PI	Rx FIFO 0 Put Index. Rx FIFO 0 write index pointer, range 0 to 63.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 F0GI	Rx FIFO 0 Get Index. Rx FIFO 0 read index pointer, range 0 to 63.

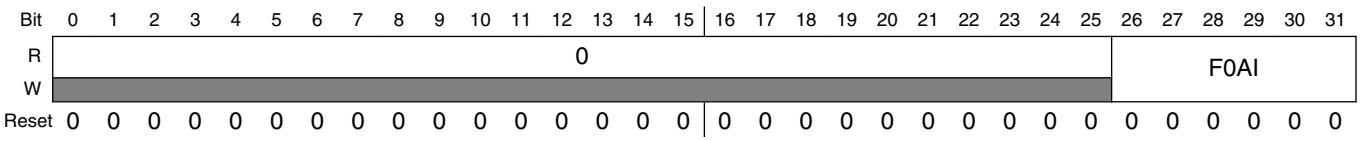
Table continues on the next page...

M_TTCAN_RXF0S field descriptions (continued)

Field	Description
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 F0FL	Rx FIFO 0 Fill Level. Number of elements stored in Rx FIFO 0, range 0 to 64.

48.4.5.27 Rx FIFO 0 Acknowledge Register (M_TTCAN_RXF0A)

Address: 0h base + A8h offset = A8h

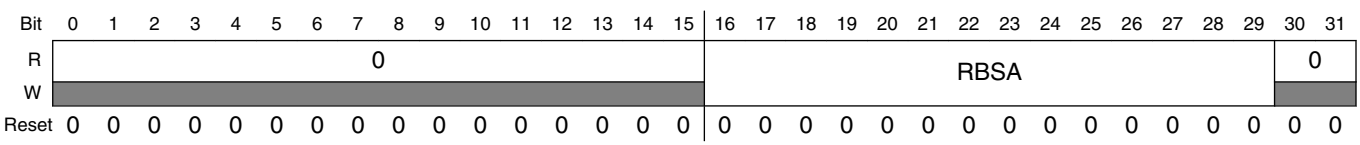


M_TTCAN_RXF0A field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 F0AI	Rx FIFO 0 Acknowledge Index. After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This will set the Rx FIFO 0 Get Index RXF0S[F0GI] to F0AI + 1 and update the FIFO 0 Fill Level RXF0S[F0FL].

48.4.5.28 Rx Buffer Configuration Register (M_TTCAN_RXBC)

Address: 0h base + ACh offset = ACh

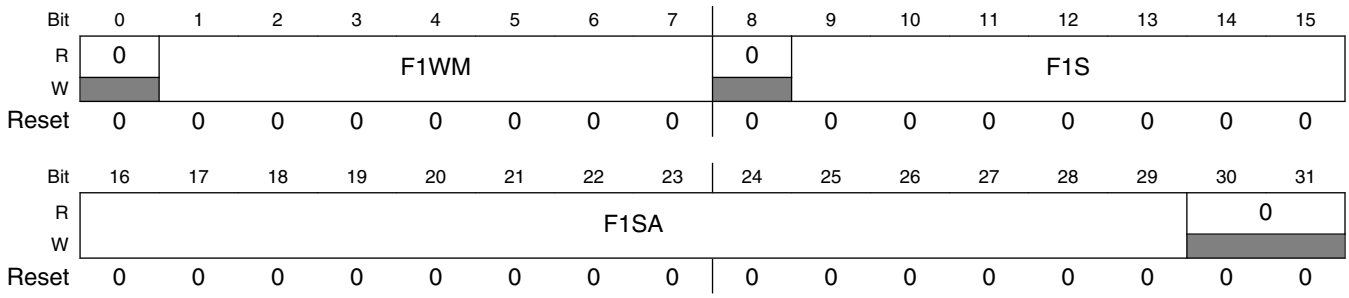


M_TTCAN_RXBC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–29 RBSA	Rx Buffer Start Address Configures the start address of the Rx Buffers section in the Message RAM (32-bit word address). Also used to reference debug messages A,B,C. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.29 Rx FIFO 1 Configuration Register (M_TTCAN_RXF1C)

Address: 0h base + B0h offset = B0h



M_TTCAN_RXF1C field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 F1WM	Rx FIFO 1 Watermark 0 Watermark interrupt disabled 1-64 Level for Rx FIFO 1 watermark interrupt (IR[RF1W]) >64 Watermark interrupt disabled **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 F1S	Rx FIFO 1 Size 0 No Rx FIFO 1 1-64 Number of Rx FIFO 1 elements >64 Values greater than 64 are interpreted as 64 The Rx FIFO 1 elements are indexed from 0 to F1S - 1 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–29 F1SA	Rx FIFO 1 Start Address. Start address of Rx FIFO 1 in Message RAM (32-bit word address, see Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.30 Rx FIFO 1 Status Register (M_TTCAN_RXF1S)

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

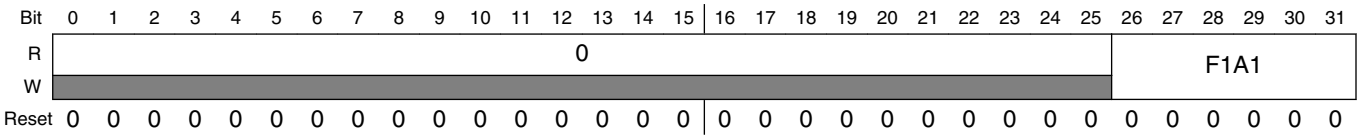
R	0		F1GI						0	F1FL						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_TTCAN_RXF1S field descriptions

Field	Description
0–1 DMS	Debug Message Status 00 Idle state, wait for reception of debug messages, DMA request is cleared 01 Debug message A received 10 Debug messages A, B received 11 Debug messages A, B, C received, DMA request is set
2–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 RF1L	Rx FIFO 1 Message Lost. This bit is a copy of interrupt flag IR[RF1L]. When IR[RF1L] is reset, this bit is also reset. 0 No Rx FIFO 1 message lost 1 Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
7 F1F	Rx FIFO 1 Full 0 Rx FIFO 1 not full 1 Rx FIFO 1 full
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 F1PI	Rx FIFO 1 Put Index. Rx FIFO 1 write index pointer, range 0 to 63.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 F1GI	Rx FIFO 1 Get Index. Rx FIFO 1 read index pointer, range 0 to 63.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 F1FL	Rx FIFO 1 Fill Level. Number of elements stored in Rx FIFO 1, range 0 to 64.

48.4.5.31 Rx FIFO 1 Acknowledge register (M_TTCAN_RXF1A)

Address: 0h base + B8h offset = B8h



M_TTCAN_RXF1A field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 F1A1	Rx FIFO 1 Acknowledge Index. After the Host has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This will set the Rx FIFO 1 Get Index RXF1S[F1GI] to F1AI + 1 and update the FIFO 1 Fill Level RXF1S[F1FL].

48.4.5.32 Tx Buffer Configuration register (M_TTCAN_TXBC)

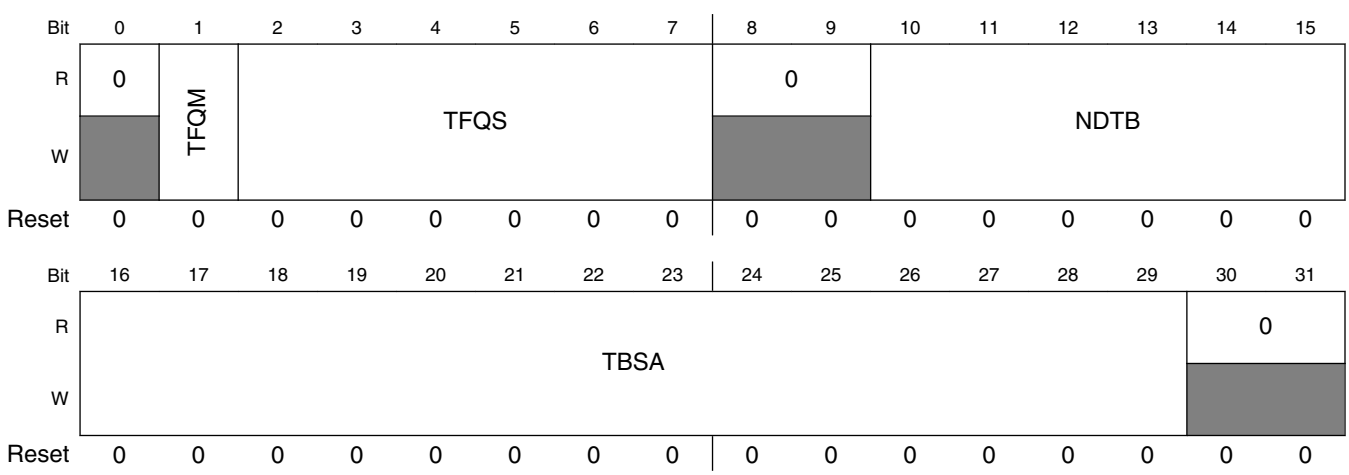
NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

NOTE

Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.

Address: 0h base + C0h offset = C0h



M_TTCAN_TXBC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 TFQM	Tx FIFO/Queue Mode. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Tx FIFO operation 1 Tx Queue operation
2–7 TFQS	Transmit FIFO/Queue Size. 0 No Tx FIFO/Queue 1-32 Number of Tx Buffers used for Tx FIFO/Queue >32 Values greater than 32 are interpreted as 32 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 NDTB	Number of Dedicated Transmit Buffers. 0 No Dedicated Tx Buffers 1-32 Number of Dedicated Tx Buffers >32 Values greater than 32 are interpreted as 32 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–29 TBSA	Tx Buffers Start Address. Start address of Tx Buffers section in Message RAM (32-bit word address, Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.33 Tx FIFO/Queue Status register (M_TTCAN_TXFQS)

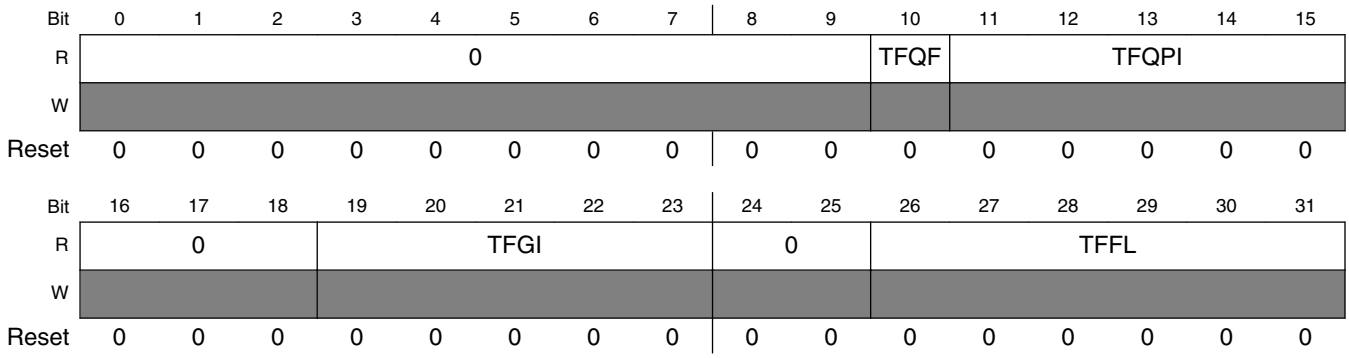
The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

NOTE

In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put Index indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

For example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

Address: 0h base + C4h offset = C4h



M_TTCAN_TXFQS field descriptions

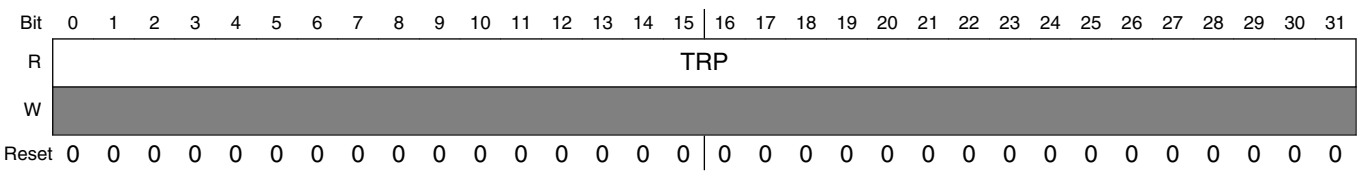
Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 TFQF	Tx FIFO/Queue Full. 0 Tx FIFO/Queue not full 1 Tx FIFO/Queue full
11–15 TFQPI	Tx FIFO/Queue Put Index. Tx FIFO/Queue write index pointer, range 0 to 31.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 TFGI	Tx FIFO Get Index. Tx FIFO read index pointer, range 0 to 31. For internal use only. Read as zero when Tx Queue operation is configured (TXBC.TFQM = â€˜1â€™).
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFFL	Tx FIFO Free Level. Number of consecutive free Tx FIFO elements , range 0 to 32. Read as zero when Tx Queue operation is configured (TXBC[TFQM] = '1')

48.4.5.34 Tx Buffer Request Pending register (M_TTCAN_TXBRP)

NOTE

TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

Address: 0h base + CCh offset = CCh



M_TTCAN_TXBRP field descriptions

Field	Description
0–31 TRP	Transmission Request Pending. Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (see Debug on CAN Support) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF • After successful transmission together with the corresponding TXBTO bit • When the transmission has not yet been started at the point of cancellation • When the transmission has been aborted due to lost arbitration • When an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

48.4.5.35 Tx Buffer Add Request register (M_TTCAN_TXBAR)

NOTE

If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

Address: 0h base + D0h offset = D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

M_TTCAN_TXBCF field descriptions

Field	Description
0–31 CF	Cancellation Finished. Each Tx Buffer has its own Cancellation Finished bit. The bits are set when the corresponding TXBRP bit is cleared after a cancellation was requested via TXBCR. In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are reset when a new transmission is requested by writing a '1' to the corresponding bit of register TXBAR. 0 No transmit buffer cancellation 1 Transmit buffer cancellation finished

48.4.5.39 Tx Buffer Transmission Interrupt Enable register (M_TTCAN_TXBTIE)

Address: 0h base + E0h offset = E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TIE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

M_TTCAN_TXBTIE field descriptions

Field	Description
0–31 TIE	Transmission Interrupt Enable Each Tx Buffer has its own Transmission Interrupt Enable bit. 0 Transmission interrupt disabled 1 Transmission interrupt enable

48.4.5.40 Tx Buffer Cancellation Finished Interrupt Enable register (M_TTCAN_TXBCIE)

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

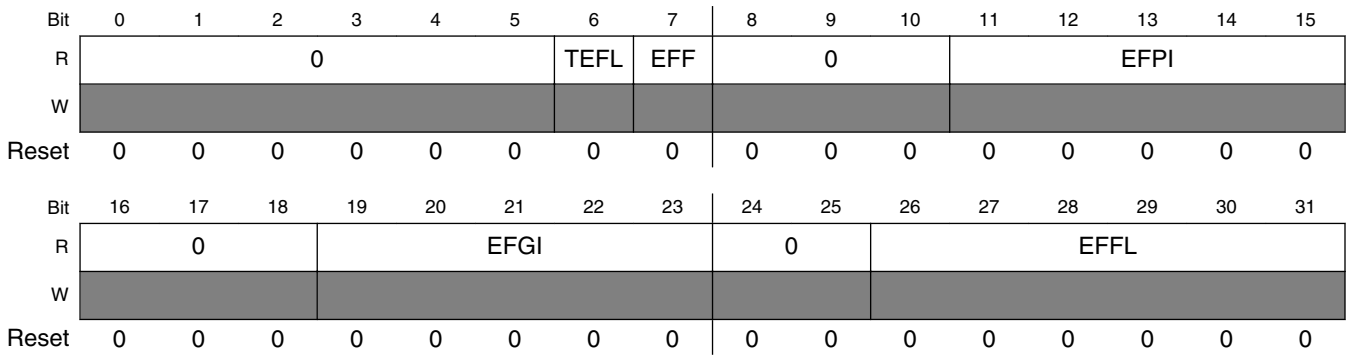
M_TTCAN_TXEFC field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 EFWM	Event FIFO Watermark 0 Watermark interrupt disabled 1-32 Level for Tx Event FIFO watermark interrupt (IR[TEFW]) >32 Watermark interrupt disabled **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 EFS	Event FIFO Size. 0 Tx Event FIFO disabled 1-32 Number of Tx Event FIFO elements >32 Values greater than 32 are interpreted as 32 The Tx Event FIFO elements are indexed from 0 to EFS-1 **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–29 EFSA	Event FIFO Start Address Start address of Tx Event FIFO in Message RAM (32-bit word address, Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.42 Tx Event FIFO Status register (M_TTCAN_TXEFS)

Address: 0h base + F4h offset = F4h



M_TTCAN_TXEFS field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 TEFL	Tx Event FIFO Element Lost. This bit is a copy of interrupt flag IR[TEFL]. When IR[TEFL] is reset, this bit is also reset. 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero.
7 EFF	Event FIFO Full. 0 Tx Event FIFO not full 1 Tx Event FIFO full
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 EFPI	Event FIFO Put Index. Tx Event FIFO write index pointer, range 0 to 31.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 EFGI	Event FIFO Get Index. Tx Event FIFO read index pointer, range 0 to 31.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 EFFL	Event FIFO Fill Level. Number of elements stored in Tx Event FIFO, range 0 to 32.

48.4.5.43 Tx Event FIFO Acknowledge register (M_TTCAN_TXEFA)

Address: 0h base + F8h offset = F8h

Bit	0–26	27–31
R	0	EFAI
W		
Reset	0	0

M_TTCAN_TXEFA field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 EFAI	Event FIFO Acknowledge Index. After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL].

48.4.5.44 TT Trigger Memory Configuration register (M_TTCAN_TTTMC)

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

Address: 0h base + 100h offset = 100h

Bit	0–8	9–15	16–29	30–31
R	0	TME	TMSA	0
W				
Reset	0	0	0	0

M_TTCAN_TTTMC field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 TME	Trigger Memory Elements. 0 No Trigger Memory 1-64 Number of Trigger Memory elements >64 Values greater than 64 are interpreted as 64

Table continues on the next page...

M_TTCAN_TTTMC field descriptions (continued)

Field	Description
	NOTE: Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–29 TMSA	Trigger Memory Start Address. Start address of Trigger Memory in Message RAM (32-bit word address, Message RAM). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

48.4.5.45 TT Reference Message Configuration register (M_TTCAN_TTRMC)

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
28 GEN	Gap Enable. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Strictly time-triggered operation 1 External event-synchronized time-triggered operation
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 OM	Operation Mode. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 Event-driven CAN communication, default 01 M_TTCAN level 1 10 M_TTCAN level 2 11 M_TTCAN level 0

48.4.5.47 TT Matrix Limits register (M_TTCAN_TTMLM)

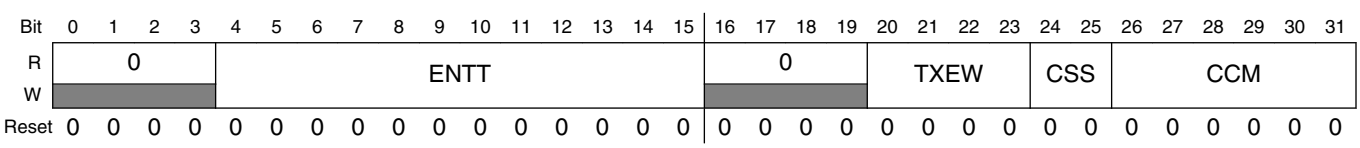
NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

NOTE

ISO 11898-4, Section 5.2.1 requires, that only the listed cycle count values are configured. Other values are possible but may lead to inconsistent matrix cycles.

Address: 0h base + 10Ch offset = 10Ch



M_TTCAN_TTMLM field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 ENTT	Expected Number of Tx Triggers 0x000-FFF Expected number of Tx Triggers in one Matrix Cycle

Table continues on the next page...

M_TTCAN_TTMLM field descriptions (continued)

Field	Description
	NOTE: Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 TXEW	Tx Enable Window. 0x0-F Length of Tx enable window, 1-16 NTU cycles **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
24–25 CSS	Cycle Start Synchronization Enables sync pulse output at M_TTCAN start of cycle pin. 00 No sync pulse 01 Sync pulse at start of basic cycle 10 Sync pulse at start of matrix cycle 11 Reserved **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
26–31 CCM	Cycle Count Max. 0x00 1 Basic Cycle per Matrix Cycle 0x01 2 Basic Cycles per Matrix Cycle 0x03 4 Basic Cycles per Matrix Cycle 0x07 8 Basic Cycles per Matrix Cycle 0x0F 16 Basic Cycles per Matrix Cycle 0x1F 32 Basic Cycles per Matrix Cycle 0x3F 64 Basic Cycles per Matrix Cycle others Reserved **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.48 TUR Configuration register (M_TTCAN_TURCF)

NOTE

Protected write (P) register which means that the write access to this register is possible only when the CCCR[CCE] and CCCR[INIT] register fields are set to "1".

The length of the NTU is given by: NTU = CAN Clock Period x NC/DC

NC is an 18-bit value. Its high part, NCH[17:16] is hard wired to 0b01. Therefore the range of NC is 0x10000:0x1FFFF. The value configured by NCL is the initial value for TURNA[NAV[15:0]]. DC is set to 0x1000 by hardware reset and it may not be written to 0x0000.

Level 1: NC >= 4 x DC and NTU = CAN bit time

Level 0, 2: NC >=8 x DC

The actual value of TUR may be changed by the clock drift compensation function of M_TTCAN Level 0 and Level 2 in order to adjust the node's local view of the NTU to the time master's view of the NTU. DC will not be changed by the automatic drift compensation, TURNA[NAV] may be adjusted around NC in the range of the Synchronization Deviation Limit given by TTOCF[LDSDL]. NC and DC should be programmed to the largest suitable values in order to allow the best computational accuracy for the drift compensation process.

NOTE

If NC < 7 x DC in M_TTCAN Level 1, then it is required that subsequent Time Marks in the Trigger Memory must differ by at least two NTU.

Address: 0h base + 110h offset = 110h

M_TTCAN_TURCF field descriptions

Field	Description
0 ELT	Enable Local Time. Please note that the local time is started by setting ELT. It remains active until ELT is reset or until the next hardware reset. TURCF[DC] is locked when TURCF[ELT] = '1'. If ELT is written to '0', the readable value will stay at '1' until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register remains locked. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Local time is stopped, default 1 Local time is enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 DC	Denominator Configuration.

Table continues on the next page...

M_TTCAN_TURCF field descriptions (continued)

Field	Description
	0x0000 Illegal value 0x0001-3FFF Denominator Configuration **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
16–31 NCL	Numerator Configuration Low. Write access to the TUR Numerator Configuration Low is only possible during configuration with TURCF[ELT] = '0' or if TTOCF[EECS] (external clock synchronization enabled) is set. When a new value for NCL is written outside TT Configuration Mode, the new value takes effect when TTOST.WECS is cleared to '0'. NCL is locked TTOST[WECS] is '1'. 0x0000-FFFF Numerator Configuration Low **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.49 TT Operation Control register (M_TTCAN_TTOCN)

NOTE

Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

Address: 0h base + 114h offset = 114h

M_TTCAN_TTOCN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 LCKC	TT Operation Control Register Locked. Set by a write access to register TTOCN. Reset when the updated configuration has been synchronized into the CAN clock domain. 0 Write access to TTOCN enabled 1 Write access to TTOCN locked

Table continues on the next page...

M_TTCAN_TTOCN field descriptions (continued)

Field	Description
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ESCN	External Synchronization Control. If enabled the M_TTCAN synchronizes its cycle time phase to an external event signaled by a rising edge at Event Trigger pin (Synchronization to external time schedule). **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 External synchronization disabled 1 External synchronization enabled
19 NIG	Next is Gap. This bit can only be set when the M_TTCAN is the actual Time Master and when it is configured for external event-synchronized time-triggered operation (TTOCF[GEN] = '1') **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 No action, reset by reception of any Reference message 1 Transmit next Reference Message with Next_is_Gap = '1'
20 TMG	Time Mark Gap. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Reset by each Reference message 1 Next Reference message started when Register Time Mark interrupt TTIR[RTMI] is activated
21 FGP	Finish Gap. Set by the CPU, reset by each reference message **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 No reference message requested 1 Application requested start of reference message
22 GCS	Gap Control Select **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Gap control independent from Event trigger 1 Gap control by input Event trigger pin
23 TTIE	Trigger Time Mark Interrupt Pulse Enable External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the M_TTCAN is in synchronization state In_Schedule or In_Gap. 0 Trigger Time Mark Interrupt output m_ttcan_tmp disabled 1 Trigger Time Mark Interrupt output m_ttcan_tmp enabled
24–25 TMC	Register Time Mark Compare. **NOTE:** When changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = "00", then reconfigure TTTMK, and finally set TMC to the intended time reference.

Table continues on the next page...

M_TTCAN_TTOCN field descriptions (continued)

Field	Description
	NOTE: Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 No Register Time Mark Interrupt generated 01 Register Time Mark Interrupt if Time Mark = cycle time 10 Register Time Mark Interrupt if Time Mark = local time 11 Register Time Mark Interrupt if Time Mark = global time
26 RTIE	Register Time Mark Interrupt Pulse Enable. Register time mark interrupts are configured by register TTTMK. A register time mark interrupt pulse with the length of one m_ttcan_clk period is generated when time referenced by TTOCN[TMC] (cycle, local, or global) equals TTTMK[TM], independent of the synchronization state. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Register Time Mark Interrupt output disabled 1 Register Time Mark Interrupt output enabled
27–28 SWS	Stop Watch Source. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 00 Stop Watch disabled 01 Actual value of cycle time is copied to TTCPT[SWV] 10 Actual value of local time is copied to TTCPT[SWV] 11 Actual value of global time is copied to TTCPT[SWV]
29 SWP	Stop Watch Polarity. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1". 0 Rising edge trigger 1 Falling edge trigger
30 ECS	External Clock Synchronization. Writing a '1' to ECS sets TTOST[WECS] if the node is the actual Time Master. ECS is reset after one Host clock period. The external clock synchronization takes effect at the start of the next basic cycle. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".
31 SGT	Set Global time. Writing a '1' to SGT sets TTOST[WGDT] if the node is the actual Time Master. SGT is reset after one Host clock period. The global time preset takes effect when the node transmits the next Reference message with the Master_Ref_Mark modified by the preset value written to TTGTP. **NOTE:** Protected write (P) bit(s) which means that write access by the bit(s) is possible only when the bit 1 [CCE] CCCR[INIT] register fields are set to "1".

48.4.5.50 TT Global Time Preset register (M_TTCAN_TTGTP)

If TTOST.WGDT is set, the next Reference message will be transmitted with the Master_Ref_Mark modified by the preset value and with Disc_Bit = '1', presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a Reference message with Disc_Bit = '1' becomes valid or if the node is not the current Time Master. TP is locked while TTOST[WGTD] = '1' after setting TTOCN[SGT] until the Reference message with Disc_Bit = '1' becomes valid or until the node is no longer the current Time Master.

Address: 0h base + 118h offset = 118h

M_TTCAN_TTGTP field descriptions

Field	Description
0–15 CTP	Cycle Time Target Phase. CTP is write-protected while TTOCN[ESCN] or TTOST[SPL] are set (see Synchronization to external time schedule). 0x0000-FFFF Defines target value of cycle time when a rising edge of event trigger is expected
16–31 TP	Time Preset. TP is write-protected while TTOST[WGTD] is set. 0x0000-7FFF Next Master Reference Mark = Master Reference Mark + TP 0x8000 reserved 0x8001-FFFF Next Master Reference Mark = Master Reference Mark - (0x10000 - TP)

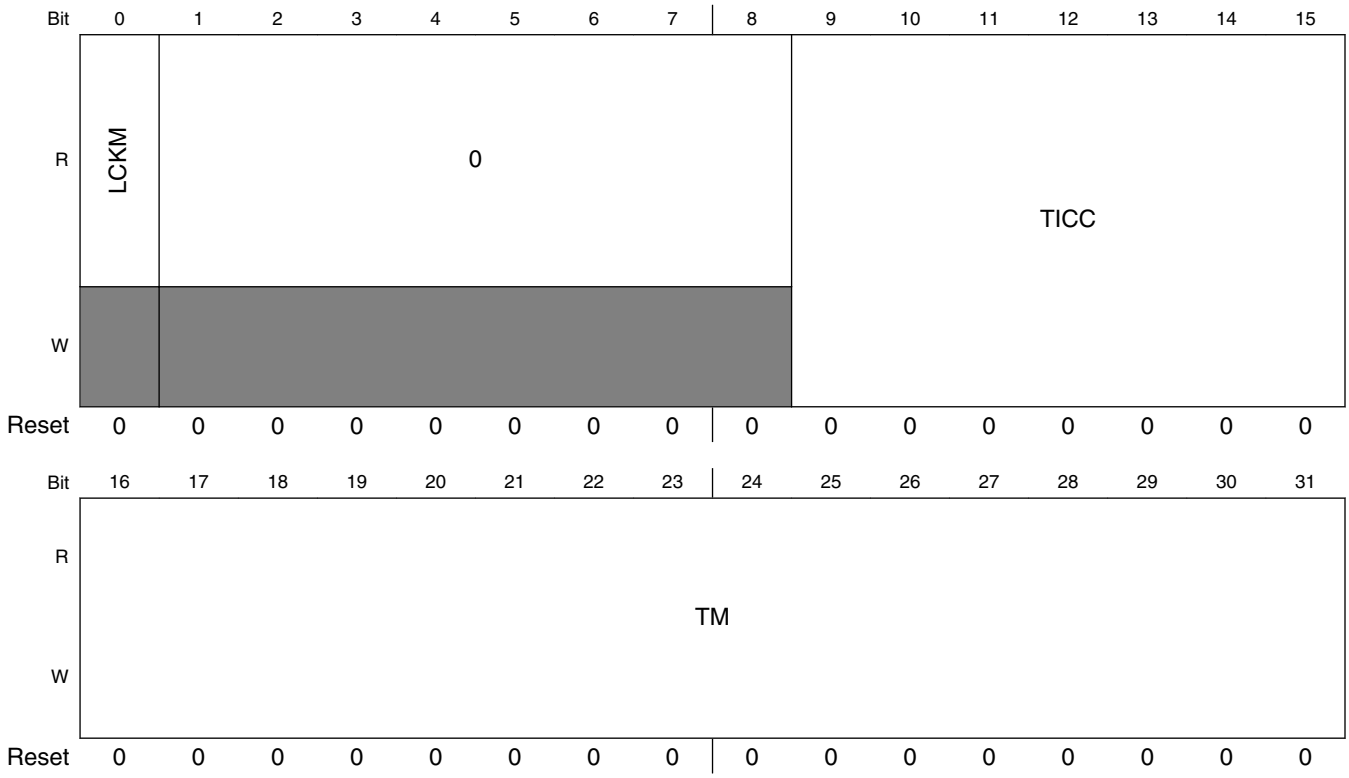
48.4.5.51 TT Time Mark register (M_TTCAN_TTTMK)

A time mark interrupt (TTIR[TMI] = '1') is generated when the time base indicated by TTOCN[TMC] (cycle time, local time, or global time) has the same value as TM.

NOTE

When using byte access to register TTTMK it is recommended to first disable the time mark compare function (TTOCN[TMC] = "00") to avoid compares on inconsistent register values.

Address: 0h base + 11Ch offset = 11Ch



M_TTCAN_TTTMK field descriptions

Field	Description
0 LCKM	TT Time Mark Register Locked. Always set by a write access to registers TTOCN. Set by write access to register TTTMK when TTOCN[TMC] "00". Reset when the registers have been synchronized into the CAN clock domain. 0 Write access to TTTMK enabled 1 Write access to TTTMK locked
1–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 TICC	Time Mark Cycle Code. Cycle count for which the time mark is valid. 0b000000x valid for all cycles 0b000001c valid every second cycle at cycle count mod2 = c 0b00001cc valid every fourth cycle at cycle count mod4 = cc 0b0001ccc valid every eighth cycle at cycle count mod8 = ccc 0b001cccc valid every sixteenth cycle at cycle count mod16 = cccc 0b01ccccc valid every thirty-second cycle at cycle count mod32 = ccccc 0b1cccccc valid every sixty-fourth cycle at cycle count mod64 = cccccc
16–31 TM	Time Mark. 0x0000-FFFF Time Mark

48.4.5.52 TT Interrupt Register (M_TTCAN_TTIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register.

Address: 0h base + 120h offset = 120h

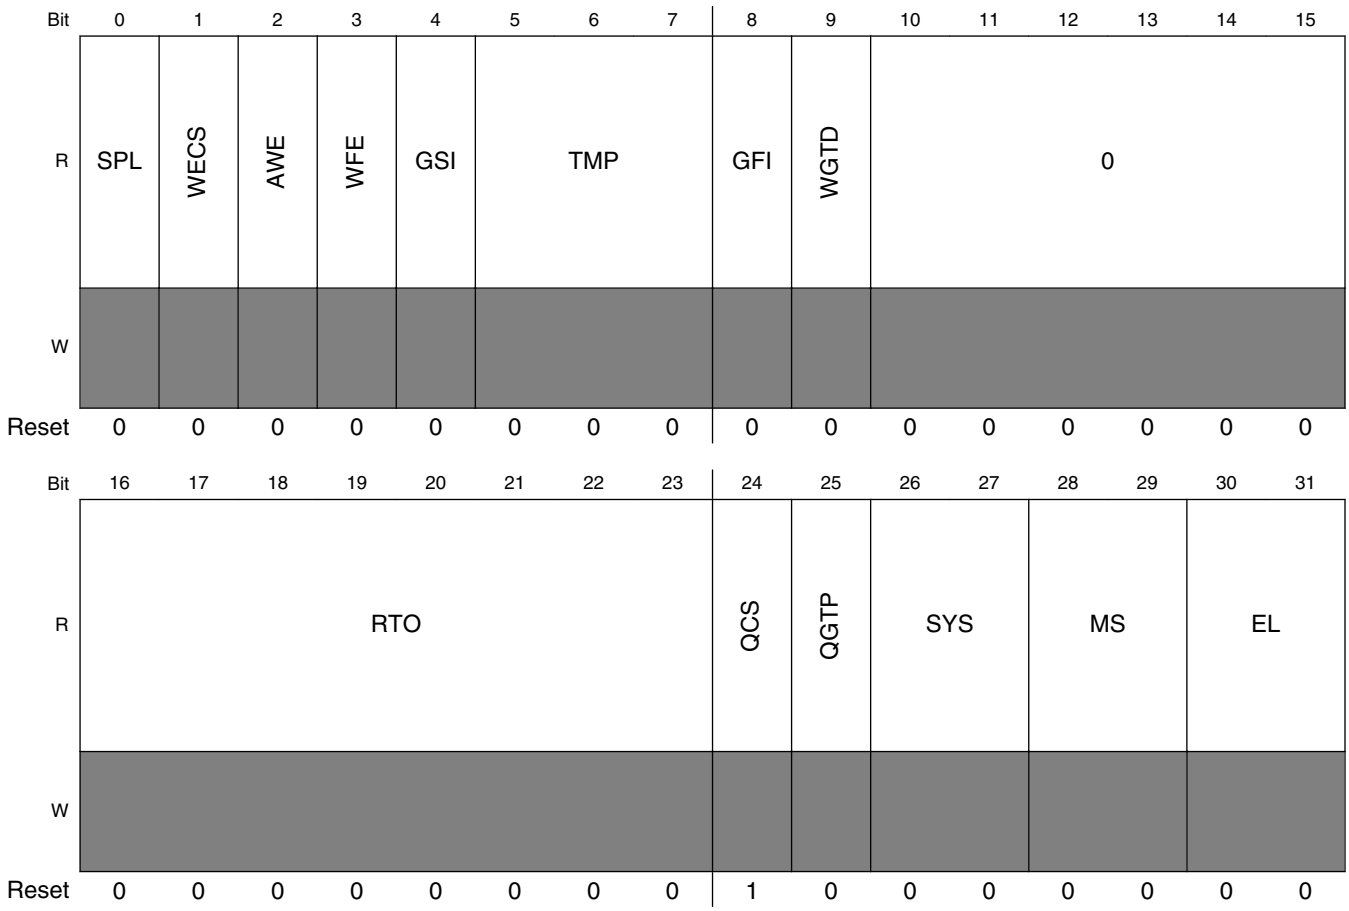
48.4.5.55 TT Operation Status register (M_TTCAN_TTOST)

Address: 0h base + 12Ch offset = 12Ch



M_TTCAN_TTOST field descriptions

Field	Description
0 SPL	Schedule Phase Lock. The bit is valid only when external synchronization is enabled (TTOCN[ESCN] = '1'). In this case it signals that the difference between cycle time configured by TTGTP[CTP] and the cycle time at the rising edge at event trigger pin is less or equal 9 NTU (see Synchronization to external time schedule). 0 Phase outside range 1 Phase inside range
1 WECS	Wait for External Clock Synchronization. 0 No external clock synchronization pending 1 Node waits for external clock synchronization to take effect. The bit is reset at the start of the next basic cycle.
2 AWE	Application Watchdog Event. The application watchdog is served by reading TTOST. When the watchdog is not served in time, bit AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode.

Table continues on the next page...

M_TTCAN_TTOST field descriptions (continued)

Field	Description
	0 Application Watchdog served in time 1 Failed to serve Application Watchdog in time
3 WFE	Wait for Event. 0 No Gap announced, reset by a Reference Message with Next_is_Gap = '0' 1 Reference Message with Next_is_Gap = '1' received
4 GSI	Gap Started Indicator. 0 No Gap in schedule, reset by each reference message and for all time slaves 1 Gap time after Basic Cycle has started
5–7 TMP	Time Master Priority. 0x0-7 Priority of actual Time Master
8 GFI	Gap Finished Indicator. Set when the CPU writes TTOCN[FGP], or by a Time Mark Interrupt if TMG = '1', or via input pin (event trigger) if TTOCN[GCS] = '1'. Not set by Ref_Trigger_Gap or when Gap is finished by another node sending a reference message. 0 Reset at the end of each reference message 1 Gap finished by M_TTCAN
9 WGTD	Wait for Global Time Discontinuity. 0 No global time preset pending 1 Node waits for the global time preset to take effect. The bit is reset when the node has transmitted a Reference message with Disc_Bit = '1' or after it received a Reference message.
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 RTO	Reference Trigger Offset. The Reference Trigger Offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F). There is no notification when the lower limit of-127 is reached. In case the M_TTCAN becomes Time Master (MS[1:0] = "11"), the reset of RTO is delayed due to synchronization between Host and CAN clock domain. For time slaves the value configured by TTOCF[IRTO] is read. 0x00-FF Actual Reference Trigger offset value
24 QCS	Quality of Clock Speed. Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '1'. 0 Local clock speed not synchronized to Time Master clock speed 1 Synchronization Deviation SDL <= SDL
25 QGTP	Quality of Global Time Phase. Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '0'. 0 Global time not valid 1 Global time in phase with Time Master
26–27 SYS	Synchronization State. 00 Out of Synchronization 01 Synchronizing to M_TTCAN communication 10 Schedule suspended by Gap (In_Gap) 11 Synchronized to schedule (In_Schedule)
28–29 MS	Master State. 00 Master_Off, no master properties relevant

Table continues on the next page...

48.4.5.56 TUR Numerator Actual register (M_TTCAN_TURNA)

There is no drift compensation in M_TTCAN Level 1 (NAV = NC). In M_TTCAN Level 0 and Level 2, the drift between the node's local clock and the time master's local clock is calculated. The drift is compensated when the Synchronization Deviation (difference between NC and the calculated NAV) is not more than $2^{(\text{TTOCF[LDSDL]} + 5)}$. With TTOCF[LDSDL] <=7, this results in a maximum range for NAV of

(NC - 0x1000) <= NAV <= (NC + 0x1000).

Address: 0h base + 130h offset = 130h

M_TTCAN_TTCSM field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CSM	Cycle Sync Mark. The Cycle Sync Mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid. 0x0000-FFFF Captured cycle time

48.4.6 Message RAM

For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M_TTCAN module.

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_TTCAN module can be configured to allocate up to 1344 words in the Message RAM. It is not necessary to configure each of the sections listed in the following figure, nor is there any restriction with respect to the sequence of the sections.

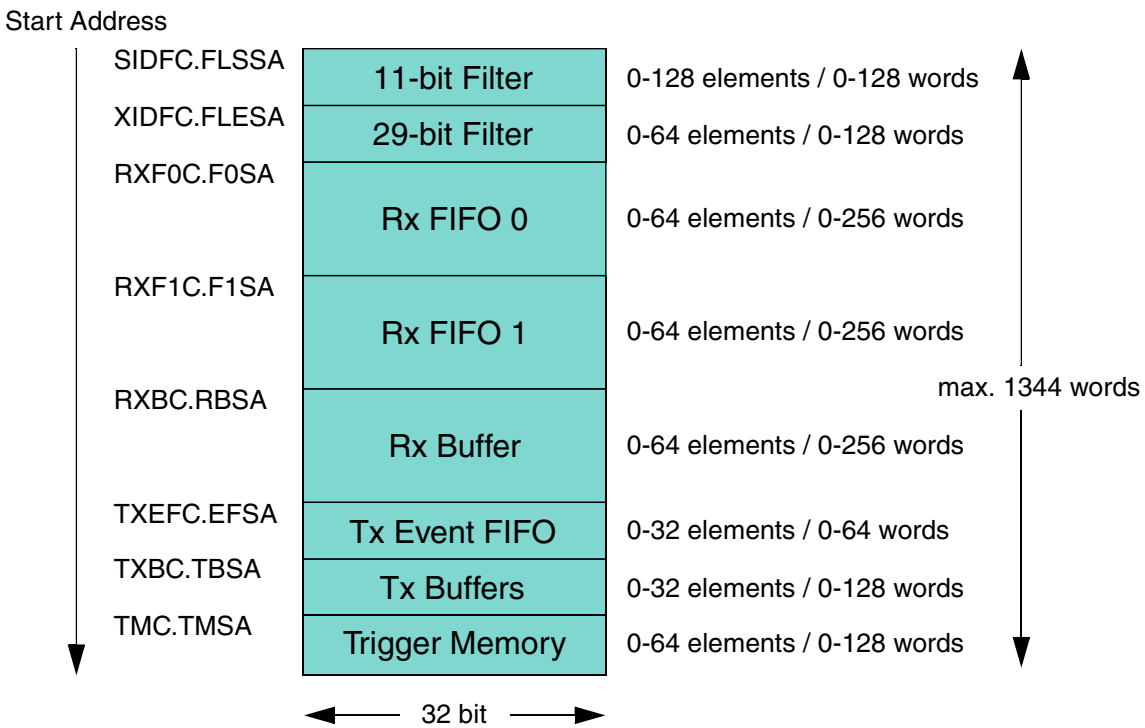

Figure 48-17. Message RAM Configuration

When the M_TTCAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configured start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

NOTE

The M_TTCAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

48.4.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure.

Table 48-17. Rx FIFO Element

0	7	8	15	16	23	24	31

48.4.6.2 Tx buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS and TXBC.NDTB.

Table 48-19. Tx Buffer Element

	0			7	8			15	16			23	24			31

48.4.6.3 Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

Table 48-21. Tx Event FIFO Element

0	7	8	15	16	23	24	31

Table 48-22. Tx Event FIFO Element (continued)

E0 Bit 2 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 Bits 3:31 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 Bits 0:7 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status
E1 Bits 8:9ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 Bit 10 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 Bit 11 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching
E1 Bits 12:15 DLC[3:0]	Data Length Code 0-8 Frame with 0-8 data bytes transmitted 9-15 Frame with 8 data bytes transmitted
E1 Bits 16:31 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

48.4.6.4 Standard message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC.FLSSA plus the index of the filter element (0…127).

Table 48-23. Standard Message ID Filter Element

	0		7	8	15	16	23	24	31
S0	SFT[1:0]	SFEC[2:0]		SFID1[10:0]		res	SFID2[10:0]		

Table 48-24. Standard Message ID Filter Element Field Description

Bits 0:1 SFT[1:0]		Standard Filter Type First ID of standard ID filter element. 00 Range filter from SF1ID to SF2ID (SF2ID > SF1ID) 01 Dual ID filter for SF1ID or SF2ID 10 Classic filter: SF1ID = filter, SF2ID = mask 11 Reserved
Bit 2:4 SFEC[2:0]		Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = “100”, “101”, or “110” a match sets interrupt flag IE[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of SFT[1:0] ignored
Bits 5:15 SFID1[10:0]		Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a tandard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 21:31	SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: SFEC = ‘001’...‘110’ Second ID of standard ID filter element SFEC = ‘111’ Filter for Rx Buffers or for debug messages
	SFID2[10:9]	Decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B

Table continues on the next page...

Table 48-24. Standard Message ID Filter Element Field Description (continued)

		11 Debug Message C
	SFID2[8:6]	Is used to control the M_TTCAN filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_TTCAN host clock period in case the filter matches.
	SFID2[5:0]	Defines the offset to the Rx Buffer Start Address RXBC[RBSA] for storage of a matching message.

Note

In case a reserved value is configured, the filter element is considered disabled.

48.4.6.5 Extended message ID filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0…63).

Table 48-25. Extended Message ID Filter Element

	0		7	8	15	16	23	24	31

Table 48-28. Trigger Memory Element Field Description

T0 Bit 0:15 TM[15:0]	Time Mark Cycle time for which the trigger becomes active.
T0 Bit 17:23 CC[6:0]	Cycle Code Cycle count for which the trigger is valid. Ignored for trigger types Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, End_of_List. 0b000000x valid for all cycles 0b000001c valid every 2nd cycle at cycle count mod2 = c 0b00001cc valid every 4th cycle at cycle count mod4 = cc 0b0001ccc valid every 8th cycle at cycle count mod8 = ccc 0b001cccc valid every 16th cycle at cycle count mod16 = cccc 0b01ccccc valid every 32nd cycle at cycle count mod32 = ccccc 0b1cccccc valid every 64th cycle at cycle count mod64 = cccccc
T0 Bit 24:25 ASC[1:0]	Asynchronous Serial Communication 00 No ASC operation 01 Reserved, do not use 10 Node is ASC receiver 11 Node is ASC transmitter
T0 Bit 26 TMIN	Extended Filter ID 2 Second ID of extended ID filter element.
T0 Bit 27 TMEX	Time Mark Event External 0 No action

Table continues on the next page...

Table 48-28. Trigger Memory Element Field Description (continued)

	1 Pulse at output m_ttcan_tmp with the length of one m_ttcan_cclk period is generated when the time mark of the trigger memory element becomes active and TTOCN.TTMIE = '1'
T0 Bit 28:31 TYP[3:0]	Trigger Type 0000 Tx_Ref_Trigger - valid when not in Gap 0001 Tx_Ref_Trigger_Gap - valid when in Gap 0010 Tx_Trigger_Single - starts a single transmission in an exclusive time window 0011 Tx_Trigger_Continuous - starts continuous transmission in an exclusive time window 0100 Tx_Trigger_Arbitration - starts a transmission in an arbitrating time window 0101 Tx_Trigger_Merged - starts a merged arbitration window 0110 Watch_Trigger - valid when not in Gap 0111 Watch_Trigger_Gap - valid when in Gap 1000 Rx_Trigger - check for reception 1001 Time_Base_Trigger - only control TMIN, TMEX, and ASC 1010…1111=End_of_List - illegal type, causes config error **Note:** For ASC operation (ASC = "10", "11") only trigger types Rx_Trigger and Time_Base_Trigger should be used.
T1 Bit 8 FTYPE	Filter Type 0 11-bit standard message ID 1 29-bit extended message ID
T1 Bit 9:15 MNR[6:0]	Message Number Transmission: Trigger is valid for configured Tx Buffer number. Valid values are 0 to 31. Reception: Trigger is valid for standard / extended message ID filter element number. Valid values are 0 to 63 resp. 0 to 127
T1 Bits 29:31 MSC[2:0]	Message Status Count Counts scheduling errors for periodic messages in exclusive time windows. It has no function for arbitrating messages and in event-driven CAN communication (ISO11898-1). 0-7= Actual status Note: The trigger memory elements have to be written when the M_TTCAN is in INIT state.Write access to the trigger memory elements outside INIT state is not allowed.There is an exception for TMIN and TMEX when they are defined as part of a trigger memory element of TYPE Tx_Ref_Trigger. In this case they become active at the time mark modified by the actual Reference Trigger Offset (TTOST[RTO]).

48.4.7 M_TTCAN functional description

48.4.7.1 Operating modes

48.4.7.2 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (=Bus_Idle) before it can take part in bus activities and start the message transfer

Access to the M_TTCAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write). CCCR[CCE] can only be set/ reset while CCCR[INIT] = '1'. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set:

- HPMS - High Priority Message Status
- RXF0S - Rx FIFO 0 Status
- RXF1S - Rx FIFO 1 Status
- TXFQS - Tx FIFO/Queue Status
- TXBRP - Tx Buffer Request Pending
- TXBTO - Tx Buffer Transmission Occurred
- TXBCF - Tx Buffer Cancellation Finished
- TXEFS - Tx Event FIFO Status
- TTOST - TT Operation Status
- TTLGT - TT Local and Global Time, only Global Time TTLGT[GT] is reset
- TTCTC - TT Cycle Time and Count
- TTCSM - TT Cycle Sync Mark

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = ‘1’.

The following registers are only writeable while CCCR[CCE] = ‘0’

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

CCCR[TEST] and CCCR[MON] can only be set by the Host while CCCR[INIT] = ‘1’ and CCCR[CCE] =‘1’. Both bits may be reset at any time. CCCR[DAR] can only be set/ reset while CCCR[INIT] = ‘1’ and CCCR[CCE] = ‘1’.

48.4.7.3 Normal operation

The M_TTCAN's default operating mode after hardware reset is event-driven CAN communication without time triggers (TTOCF[OM] = "00"). It is required that both CCCR[INIT]and CCCR[CCE] are set before the TT Operation Mode can be changed.

Once the M_TTCAN is initialized and CCCR[INIT] is reset to zero, the M_TTCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

48.4.7.4 CAN FD Operations

There are two stages in the CAN FD protocol, first the Long Frame Mode where the data field of a CAN frame may be longer that 8 bytes. The second stage is the Fast Frame Mode where control field, data field, and CRC field of a CAN Frame are transmitted with a higher bit rate than the beginning and the end of the frame. Fast Frame Mode can only be used in combination with Long Frame Mode.

The CAN operation mode is chosen by programming CCCR.CME. In case CCCR.CME = “01” transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CCCR.CME = “10”/“11” transmission and reception of long and fast CAN FD frames is enabled. CCCR.CME can only be changed while CCCR.INIT and CCCR.CCE are both set.

When initialization is left (CCCR.INIT set to ‘0’), both Long Frame Mode and Fast Frame Mode are inactive, they have to be requested by writing to CCCR.CMR.

A mode change requested by writing to CCCR.CMR will be executed next time the CAN protocol controller FSM reaches idle phase between CAN frames. Upon this event CCCR.CMR is reset to “00” and the status flags CCCR.FDBS and CCCR.FDO are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CCCR.CMR is retained until it is overwritten by the next mode change request. Default is normal CAN operation. A change of the CAN operation mode should not be requested while there are pending transmission requests.

When CCCR.CME ≠ “00”, received frames are interpreted according to the CAN FD Protocol Specification. The reserved bit in CAN frames with 11-bit identifiers and the first reserved bit in CAN frames with 29-bit identifiers will be decoded as EDL bit. EDL = recessive signifies a CAN FD long frame, EDL = dominant signifies a standard CAN frame. In a CAN FD long frame, the two bits following EDL, r0 and BRS, decide whether this CAN FD long frame is also a CAN FD fast frame. A CAN FD fast frame is signified by r0 = dominant and BRS = recessive. The coding of r0 = recessive is reserved for future expansion of the protocol.

The status bits CCCR.FDO and CCCR.FDBS indicate the format of transmitted frames. When CCCR.FDO is set, frames will be transmitted in CAN FD long format with EDL = recessive. When both CCCR.FDO and CCCR.FDBS are set, frames will be transmitted in CAN FD Fast format with both EDL and BRS = recessive.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table.

Table 48-29. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD fast frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing and Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the Fast Bit Timing and Prescaler. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter’s error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is

transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter's error state. The data length code of CAN FD remote frames is transmitted as zero.

In case a M_TTCAN Tx Buffer is configured for CAN FD transmission with DLC > 8, the first 8 bytes are transmitted as configured in the Tx Buffer while the remaining part of the data field is padded with 0xCC. When the M_TTCAN receives a CAN FD frame with DLC > 8, the first 8 bytes of that frame are stored into the matching Rx Buffer or Rx FIFO. The remaining bytes are discarded.

48.4.7.4.1 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via M_TTCAN_Tx pin, the protocol controller receives the transmitted data from its local CAN transceiver via M_TTCAN_Rx pin. The received data is delayed by the CAN transceiver's loop delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transceiver loop delay, the delay compensation is introduced. Without transceiver delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transceivers loop delay.

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.The following figure describes how the transceiver loop delay is measured

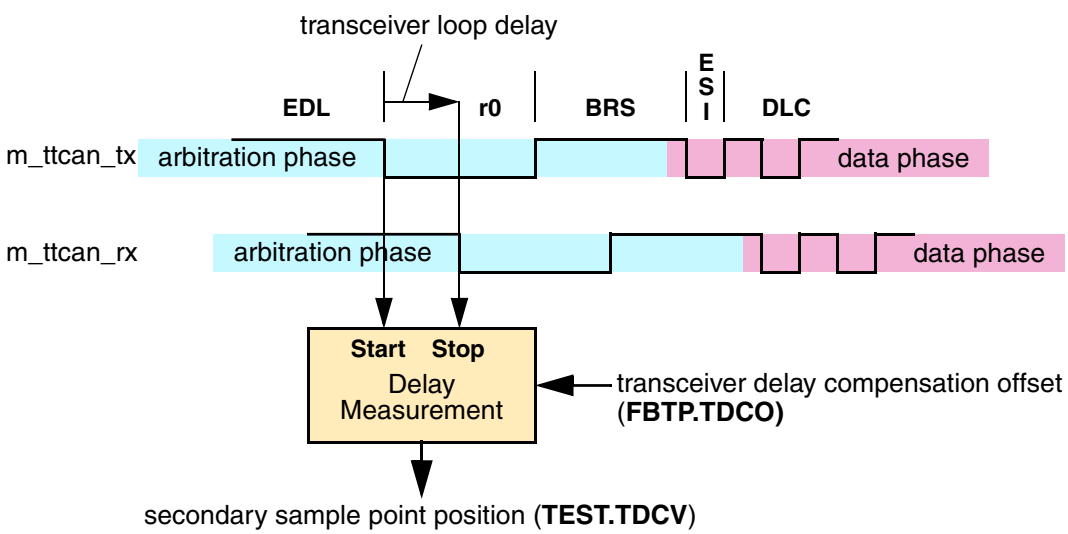

Figure 48-18. Transceiver delay measurement

Within each CAN FD frame, the transmitter measures the delay between the data transmitted at M_TTCAN_Tx pin and the data received at M_TTCAN_Rx pin , starting with the falling edge of bit EDL. The delay is measured in CAN clock frequency periods.

A secondary sample point is calculated by adding a configurable transceiver delay compensation offset FBTP[TDCO] to the measured transceiver delay. The transceiver delay compensation offset is used to adjust the secondary sample point inside the bit time (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of time quanta tq.

To check for bit errors during the data phase, the delayed transmit data is compared against the received data at the secondary sample point. If a bit error is detected at the secondary sample point, the transmitter will react to this bit error at the next following sample point. During arbitration phase the delay compensation is always disabled.

The maximum delay which can be compensated by the M_TTCAN's delay compensation during the data phase is three bit times.

48.4.7.4.2 Configuration and status

Compensation for the transceiver loop delay by the M_TTCAN is enabled via FBTP[TDC]. The transceiver delay compensation offset is configured via FBTP[TDCO]. The actual delay compensation value applied by the M_CAN's protocol engine can be read from TEST[TDCV].

48.4.7.5 Bus Monitoring mode

The M_TTCAN is set in Bus Monitoring Mode by programming CCCR.MON to one or when error level S3 (TTOST[EL] = "1") is entered. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_TTCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the M_TTCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_TTCAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. The following figure shows the connection of signals M_TTCAN transmit output and M_TTCAN transmit output to the M_TTCAN in Bus Monitoring Mode.

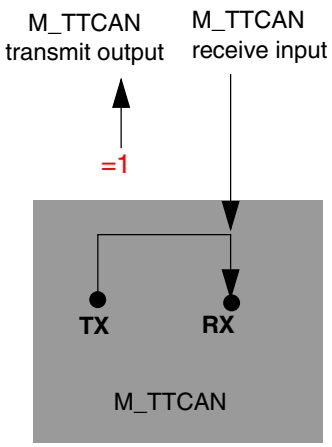

Figure 48-19. Pin Control in Bus Monitoring Mode

48.4.7.6 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_TTCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

48.4.7.7 Frame transmission in DAR mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
- Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = "10" (transmission in spite of cancellation).

48.4.7.8 Power down (Sleep mode)

The M_TTCAN can be set into power down mode controlled by clock stop request input signal or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one.

When all pending transmission requests have completed, the M_TTCAN waits until bus idle state is detected. Then the M_TTCAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_TTCAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs M_TTCAN host clock and M_TTCAN clock may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting clock stop request signal respectively CC Control Register flag CCCR.CSR. The M_TTCAN will acknowledge this by resetting output clock stop acknowledge signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

48.4.7.9 Test modes

To enable write access to register TEST (see Test Register (M_TTCAN_TEST), bit CCCR.TEST has to be set to one. This allows the configuration of the test modes and test functions. Four output functions are available for the M_TTCAN transmit pin by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_TTCAN's bit timing and it can drive constant dominant or recessive values. The actual value at M_TTCAN receive pin can be read from TEST.RX. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST.TX until the new configuration is visible at output pin. This applies also when reading input pinvia TEST.RX.

Note

Test modes should be used for production tests or self test only. The software control for M_TTCAN transmit pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

48.4.7.9.1 Watchdog mode

The application watchdog is served by reading register TTOST. When the application watchdog is not served in time, bit TTOST.AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode.

The TT Application Watchdog can be disabled by programming the Application Watchdog Limit TTOCF[AWL] to 0x00. The TT Application Watchdog should not be disabled in a M_TTCAN application program.

48.4.7.9.2 External Loop Back mode

The M_TTCAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_TTCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) an Rx Buffer or an Rx FIFO. Figure 48-20 shows the connection of transmit and receive signals to the M_TTCAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_TTCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/ remote frame) in Loop Back mode. In this mode the M_TTCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the input pin is disregarded by the M_TTCAN. The transmitted messages can be monitored at the transmit pin.

48.4.7.9.3 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST.LBCK and CCCR.MON to one. This mode can be used for a "Hot Selftest", meaning the M_TTCAN can be tested without affecting a running CAN system connected to the M_TTCAN Tx and Rx pins .

In this mode pin Rx pin is disconnected from the M_TTCAN and Tx pin is held recessive. The following figure shows the connection of M_TTCAN TX and _TTCAN Rx to the M_TTCAN in case of Internal Loop Back Mode.

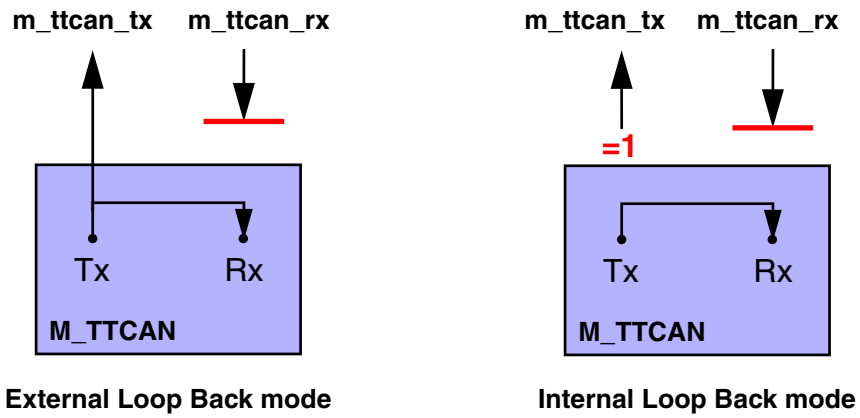

Figure 48-20. Pin Control in Loop Back modes

48.4.7.10 Timestamp generation

For timestamp generation the M_TTCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable via TSCV[TCV]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/ Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

48.4.7.11 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_TTCAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC].

The Timeout Counter can only be started while CCCR[INIT] = '0'. It is stopped when CCCR[INIT] = '1', e.g. when the M_TTCAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOsFIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note

The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

48.4.7.12 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO’s Put and Get Indices.

48.4.7.12.1 Acceptance filtering

The M_TTCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from - to)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering

- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Note

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

48.4.7.12.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering.

48.4.7.12.1.2 Filter for dedicated IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID=SF2ID resp. EF1ID=EF2ID.

48.4.7.12.1.3 Classic bit mask filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID /EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

48.4.7.12.1.4 Standard message ID filtering

The figure below shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in Standard message ID Filter element.

Controlled by the Global Filter Configuration (GFC) and the Standard ID Filter Configuration (SIDFC) Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements

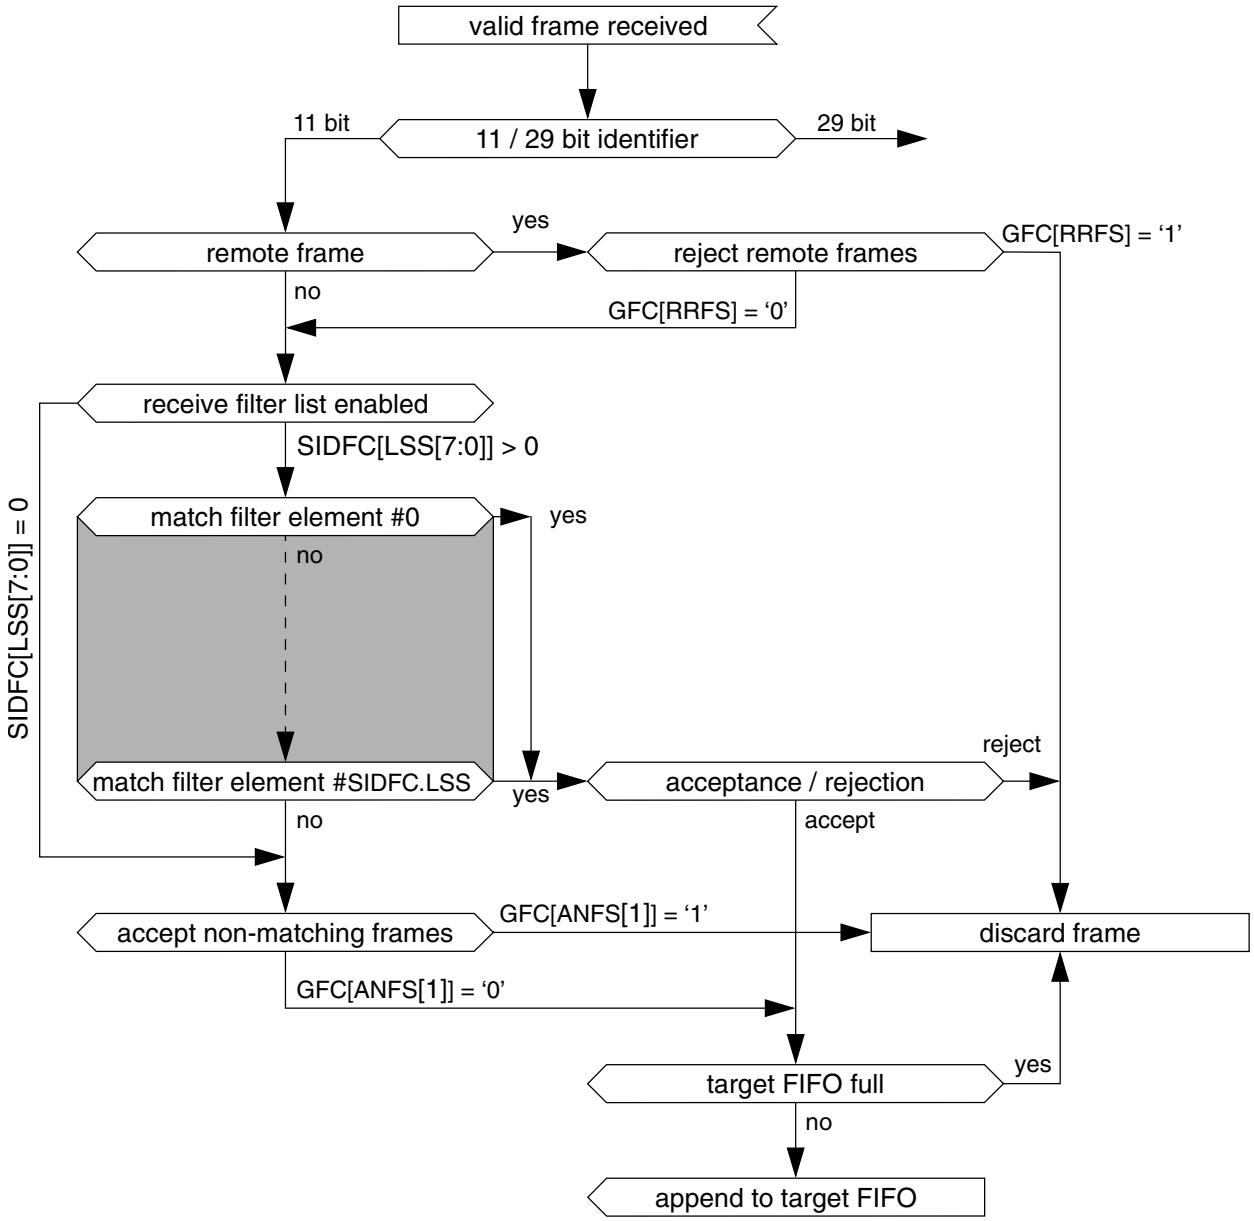

Figure 48-21. Standard Message ID Filter Path

48.4.7.12.1.5 Extended message ID filtering

The figure below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in Extended message ID filter element.

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

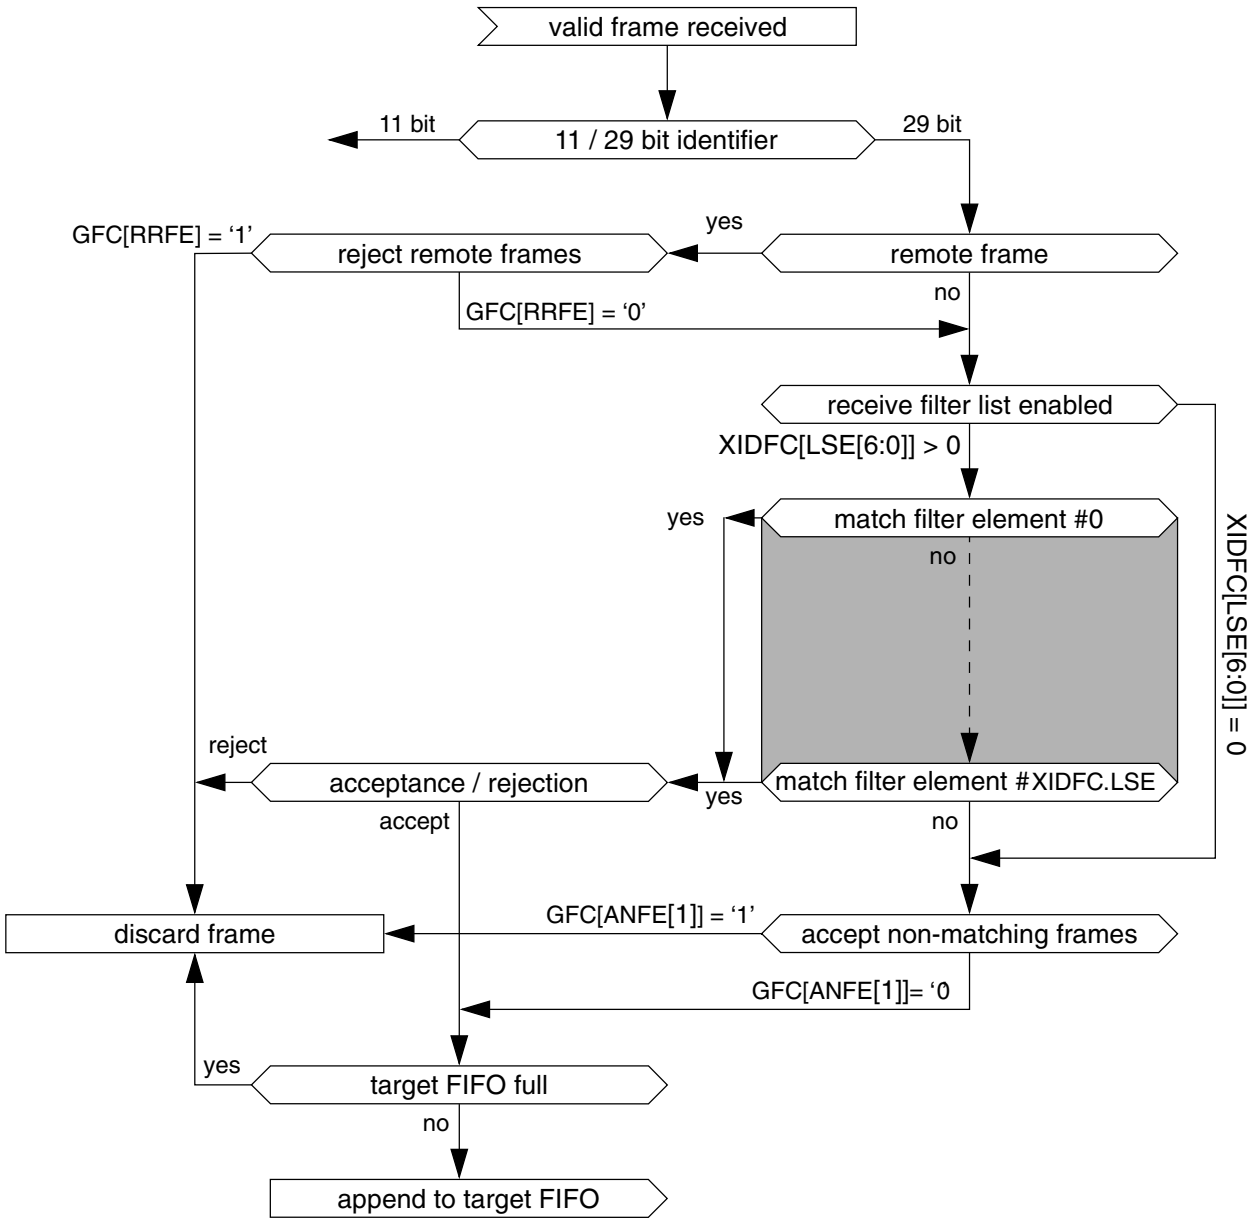

Figure 48-22. Extended Message ID Filter Path

48.4.7.13 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C. Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see Acceptance filtering. The Rx FIFO element is described in Rx

FIFOs. When an Rx FIFO full condition is signalled by IR[RFnF]], no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag IR[RFnL] is set.

To avoid an Rx FIFO over ow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set.

When reading from an Rx FIFO, four times the Rx FIFO Get Index RXFnS[FnGI] has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

48.4.7.14 Dedicated Rx Buffers

The M_TTCAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = “111” and SFID2 / EFID2[10:9] = “00” has to be configured.

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 48-30. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a ‘1’ to the respective bit position.

While an Rx Buffer’s New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration

48.4.7.14.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

48.4.7.15 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element.

Advantage: Fixed start address for the DMA transfers (relative to RXBC[RBSA]), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = “111” have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the M_TTCAN DMA request output is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while M_TTCAN DMA request output is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets M_TTCAN DMA acknowledge. This resets M_TTCAN DMA request output. Now the M_CAN is prepared to receive the next set of debug messages.

NOTE

To use full ‘Debug on CAN Support’ feature on a M_TTCAN instance, a DMA channel is required. Refer to device DMA map, to see which M_TTCAN instances has been assigned with DMA channel.

48.4.7.15.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to “111”. In this case fields

SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR[DRX] are set. The reception of debug messages can be monitored via RXF1S[DMS].

Table 48-31. Example Filter Configuration for Debug Messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

48.4.7.15.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S[DMS].

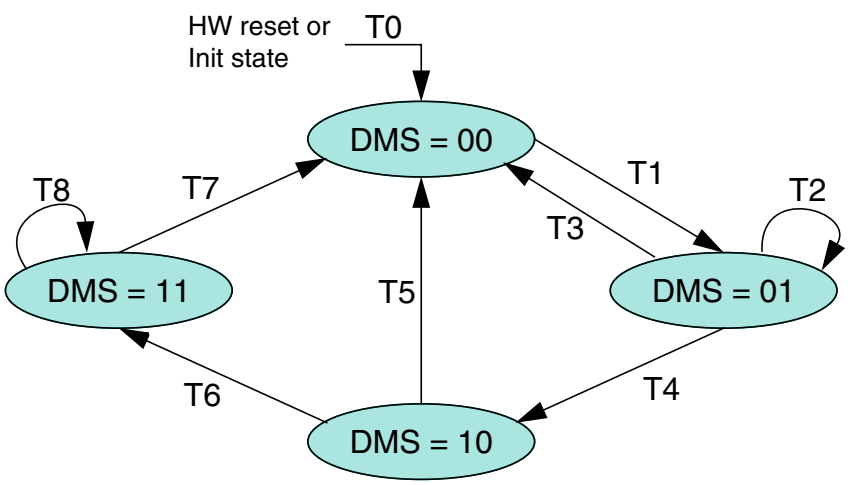

Figure 48-23. Debug Message Handling State Machine

T0: reset M_CAN DMA request output, enable reception of debug messages A, B, and C

T1: reception of debug message A

T2: reception of debug message A

T3: reception of debug message C

T4: reception of debug message B

T5: reception of debug messages A, B

T6: reception of debug message C

T7: DMA transfer completed

T8: reception of debug message A,B,C (message rejected)

48.4.7.16 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_TTCAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_TTCAN while TTM_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_TTCAN DMA ACK signal. This resets M_TTCAN DMA request signal. The debug message handling state machine enters idle state (DMS = "00") and waits for reception of the next debug messages.

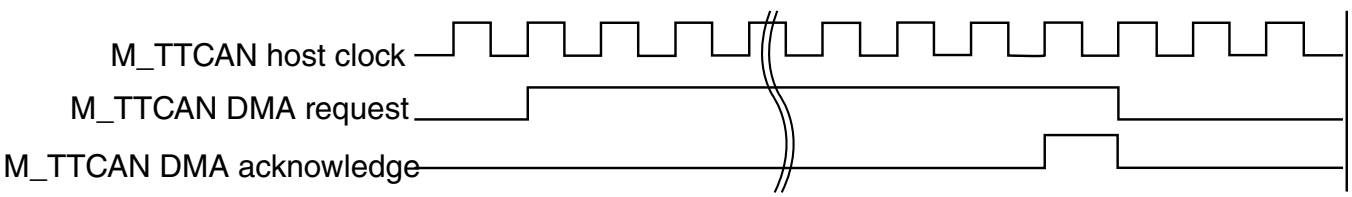

Figure 48-24. Timing of DMA interface signals

NOTE

If the DMA unit activates input signal M_TTCAN DMA ACK before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

48.4.7.17 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in Tx buffer element. The Tx Handler

starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

48.4.7.17.1 Dedicated Tx buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding four times the transmit buffer index (0…31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.17.2 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_TTCAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements. New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF]= '1') is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented. When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index. When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of

free Tx Buffers as indicated by the Tx FIFO Free Level. When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged. A Tx FIFO element allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0…31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.17.3 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index

TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF]= '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding four times the Tx Queue Put Index TXFQS[TFQPI] (0…31) to the Tx Buffer Start Address TXBC[TBSA].

48.4.7.17.4 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case, TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

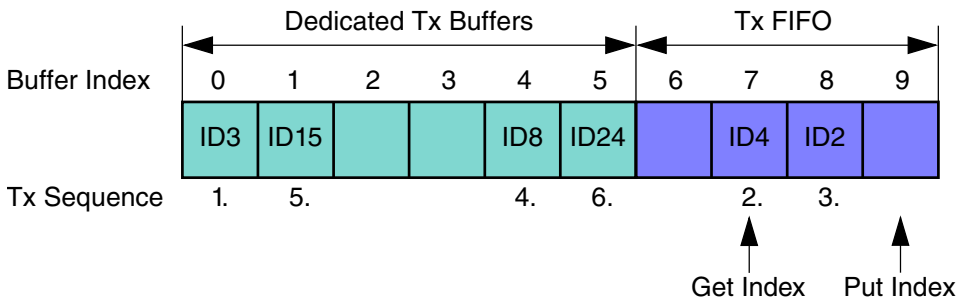

Figure 48-25. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

48.4.7.17.5 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only dedicated Tx Buffers are used.

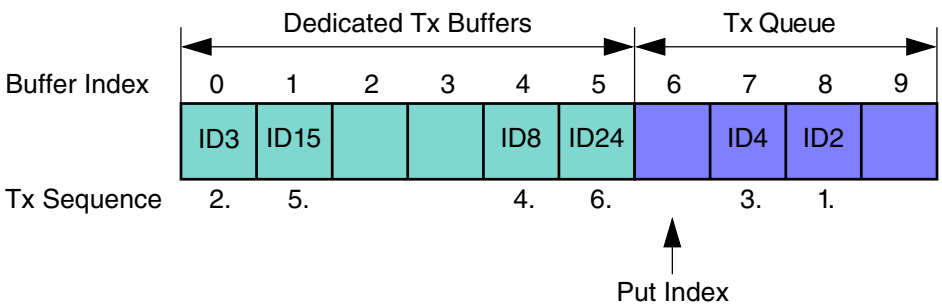

Figure 48-26. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

48.4.7.17.6 Transmit cancellation

The M_TTCAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation. Successful cancellation is signalled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note

In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is star ed even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

48.4.7.17.7 Tx Event handling

To support Tx event handling the M_TTCAN has implemented a Tx Event FIFO. After the M_TTCAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element. The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in Tx event FIFO element. When a Tx Event FIFO full condition is signalled by IR[TEFF], no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

To avoid a Tx Event FIFO over ow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR[TEFW] is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

48.4.8 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see Rx FIFO 0 Acknowledge Register (M_TTCAN_RXF0A), Rx FIFO 1 Acknowledge register (M_TTCAN_RXF1A) and Tx Event FIFO Acknowledge register (M_CAN_TXEFA), and) Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index. When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_TTCAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

48.4.9 M_TTCAN operations

48.4.9.1 Reference message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the Time Master (sender of the reference message). For Level 1 the data length must be at least one; for Level 0, 2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to eight potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference

message is configured via register TTRMC. The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted **Master_Ref_Mark** is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (**Next_is_Gap bit**) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters. The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

48.4.9.2 Level 1

Level 1 operation is configured via TTOCF[OM] = "01" and TTOCF[GEN]. External clock synchronization is not available in Level 1. The information related to the reference message is stored in the first data byte as shown below. Cycle_Count is optional.

Table 48-32. First byte of Level 1 reference message

Bits	***0***	***1***	***2***	3	***4***	***5***	6	7
First Byte	Next_is_Gap	res	Cycle_Count[5:0]					

48.4.9.3 Level 2

Level 2 operation is configured via TTOCF[OM] = "10" and TTOCF[GEN].The information related to the reference message is stored in the first four data bytes as shown below. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Table 48-33. First four bytes of Level 2 reference message

Bits	0	***1***	2	3	***4***	***5***	6	7
First Byte	Next_is_Gap	res	Cycle_Count[5:0]					
Second Byte	NTU_Res[6:4]			NTU_Res[3:0]				Disc_Bit
Third Byte	Master_Ref_Mark[7:0]							

Table continues on the next page...

Table 48-33. First four bytes of Level 2 reference message (continued)

Fourth Byte	Master_Ref_Mark[15:8]

48.4.9.4 Level 0

Level 0 operation is configured via TTOCF[OM] = "11". External event-synchronized time-triggered operation is not available in Level 0. The information related to the reference message is stored in the first four data bytes as shown in the table below. In Level 0 Next_is_Gap is always zero. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Table 48-34. First four bytes of Level 0 reference message

Bits	***0***	1	2	***3***	4	***5***	***6***	7
First Byte	Next_is_Gap	res	Cycle_Count[5:0]					
Second Byte	NTU_Res[6:4]			NTU_Res[3:0]				Disc_Bit
Third Byte	Master_Ref_Mark[7:0]							
Fourth Byte	Master_Ref_Mark[15:8]							

48.4.10 M_TTCAN configuration

48.4.10.1 M_TTCAN timing

The Network Time Unit NTU is the unit in which all times are measured. The NTU is a constant of the whole network and is defined a priority by the network system designer. In M_TTCAN Level 1 the NTU is the nominal CAN bit time. In M_TTCAN Level 0 and Level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable. In M_TTCAN Level 0 and Level 2 the length of the NTU is defined by the

Time Unit Ratio TUR. The TUR is in principle a non-integer number and given by the formula TUR = TURNA[NAV]/TURCF[DC]. The length of the NTU is given by the formula NTU = CAN Clock Period. TUR. The TUR Numerator Configuration NC is an 18-bit number, TURCF[NCL[15:0]] can be programmed in the range 0x0000-0xFFFF. TURCF[NCH[17:16]] is hard wired to 0b01. When the number 0xnnnn is written to TURCF[NCL[15:0]], TURNA[NAV] starts with the value 0x10000 + 0x0nnnn = 0x1nnnn. The TUR Denominator Configuration TURCF[DC] is a 14-bit number. TURCF[DC] may be programmed in the range 0x0001 - 0x3FFF, 0x0000 is an illegal value.

In Level 1, NC must be ≤ 4 × TURCF[DC]. In Level 0, 2 NC must be ≤ 8 × TURCF[DC] to allow the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets TURCF[DC] to 0x1000 and TURCF[NCL] to 0x10000, resulting in an NTU consisting of 16 CAN clock periods. Local time and application watchdog are not started before either the CCCR[INIT] is reset, or TURCF[ELT is set. TURCF[ELT] may not be set before the NTU is configured. Setting TURCF[ELT] to e1f also locks the write access to register TURCF.

At startup TURNA[NAV] is updated from NC (= TURCF[NCL] + 0x10000) when TURCF[ELT] is set. In M_TTCAN Level 1 there is no drift compensation. TURNA.NAV does not change during operation, it always equals NC.

In M_TTCAN Level 0 and Level 2 there are two possibilities for TURNA[NAV] to change. When operating as time slave or backup time master, and when TTOCF[ECC] is set, TURNA[NAV] is updated automatically to the value calculated from the monitored global time speed, as long as the M_TTCAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization it returns to NC. When operating as the actual time master, and when TTOCF[EECS] is set, the Host may update TURCF[NCL]. When the Host sets TTOCN[ECS], TURNA[NAV] will be updated from the new value of NC at the next reference message. The status flag TTOST[WECS] as is set when TTOCN[ECS] is set and is cleared when TURNA[NAV] is updated. TURCF[NCL] is write locked while TTOST[WECS] is set.

In M_TTCAN Level 0 and Level 2 the clock calibration process adapts TURNA[NAV] in the range of the Synchronization Deviation Limit SDL of NC+/- $2^{(TTOCF[LDSDL]+5)}$. TURCF[NCL] should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of TURNA[NAV].

The synchronization deviation SD is the difference between NC and TURNA[NAV] (SD = |NC - TURNA[NAV]|). It is limited by the Synchronization Deviation Limit SDL, which is configured by its dual logarithm TTOCF[LDSDL] (SDL = $2^{(TTOCF[LDSDL]+5)}$) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new Basic Cycle. When the calculated TURNA[NAV] deviates by

more than SDL from NC, or if the Disc_Bit in the Reference Message is set, the drift compensation is suspended and TTIR[GTE] is set and TTOSC[QCS] is reset, or in case of the Disc_Bit = '1', TTIR[GTD] is set.

Table 48-35. TUR configuration examples

TUR	*8*	*10*	*24*	*50*	*510*	*125000*	*32.5*	*100/12*	*529/17*
NC	0x1FFF8	0x1FFFE	0x1FFF8	0x1FFEA	0x1FFFE	0x1E848	0x1FFE0	0x19000	0x10880
TURCF.DC	0x3FFF	0x3333	0x1555	0x0A3D	0x0101	0x0001	0x0FC0	0x3000	0x0880

TTOCN[ECS] schedules NC for activation by the next reference message. TTOCN[SGT] schedules TTGTP[TP] for activation by the next reference message. Setting of TTOCN[ECS] and TTOCN[SGT] requires TTOCF[EECS] to be set (external clock synchronization enabled) while the M_TTCAN is actual time master. The M_TTCAN module provides an application watchdog to verity the function of the application program. The Host has to serve this watchdog regularly, else all CAN bus activity is stopped. The Application Watchdog Limit TTOCF[AWL] specifies the number of NTUs between two times the watchdog has to be served. The maximum number of NTUs is 256. The Application Watchdog is served by reading register TTOST. TTOST[AWE] indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag TTIR[AW] is set. For software development, the application watchdog may be disabled by programming TTOCF[AWL] to 0x00 (see also Watchdog mode).

48.4.10.2 Timing of interface signals

The timing events which cause a pulse at output M_TTCAN trigger time mark interrupt pulse and M_TTCAN register time mark interrupt pulse are generated in the CAN clock domain. There is a clock domain crossing delay to be considered before the same event is visible in the Host clock domain (TTIR[TTMI] resp. TTIR[RTMI] set). The signals can be connected e.g. to the timing input(s) of another M_TTCAN node , in order to automatically synchronize two M_TTCAN networks. Output M_TTCAN start of cycle gets active whenever a reference message is completed (either transmitted or received). The output is controlled in the Host clock domain.

48.4.11 M_TTCAN gap control

All functions related to Gap control apply only when the M_TTCAN is operated in external event synchronized time-triggered mode (**TTOCF[GEN]** = '1'). In this operation mode the M_TTCAN message schedule may be interrupted by inserting Gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a Gap, all transmissions are stopped and the CAN bus remains idle. A Gap is finished when the next reference message starts a new basic cycle. A Gap starts at the end of a basic cycle that itself was started by a reference message with bit **Next_is_Gap** = '1' e.g. Gaps are initiated by the current time master.

The current time master has two options to initiate a Gap. A Gap can be initiated under software control when the application program writes **TTOCN[NIG**] = '1'. The **Next_is_Gap** bit will be transmitted as '1' with the next reference message. A Gap can also be initiated under hardware control when the application program enables the event trigger input pin

by writing **TTOCN[GCS]** = '1'. When a reference message is started and **TTOCN[GCS]** is set, a HIGH level at event trigger pin will set **Next_is_Gap** = '1'.

As soon as that reference message is completed, the **TTOST[WFE]** bit will announce the Gap to the time master as well as to the time slaves. The current basic cycle will continue until its last time window. The time after the last time window is the Gap time.

For the actual time master and the potential time masters, **TTOST[GSI]** will be set when the last basic cycle has finished and the Gap time starts. In nodes that are time slaves, bit **TTOST[GSI]** will remain at '0'.

When a potential time master is in synchronization state In_Gap (**TTOST[SYS]** = "10"), it has four options to intentionally finish a Gap:

Under software control by writing **TTOCN[FGP]** = '1'.

Under hardware control (**TTOCN[GCS]** = '1') an edge from HIGH to LOW at the event-trigger input pin sets **TTOCN[FGP]** and restarts the schedule.

The third option is a time-triggered restart. When **TTOCN[TMG]** = '1', the next register time mark interrupt (**TTIR[RTMI]** = '1') will set **TTOCN[FGP]** and start the reference message.Finally any potential time master will finish a Gap when it reaches its Tx_Ref_Trigger_Gap, assuming that the event to synchronize on did not occur in time.

Neither of these options can cause a basic cycle to be interrupted with a reference message. Setting of **TTOCN[FGP]** after the Gap time has started will start the transmission of a reference message immediately and will thereby synchronize the

message schedule. When **TTOCN[FGP]** is set before the Gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger – there will be no Gap time in the message schedule.

In strictly time-triggered operation, bit **Next_is_Gap** = '1' in the reference message will be ignored, as well as the event-trigger input pinand the bits **TTOCN[NIG]**, **TTOCN[FGP]**, and **TTOCN[TMG]**.

48.4.12 Stop watch

The stop watch function enables capturing of M_TTCAN internal time values (local time, cycle time, or global time) triggered by an external event. To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via **TTOCN[SWS]**. When **TTOCN[SWS]** is ≠ '00' and TT Interrupt Register flag **TTIR[SWE]** is '0', the actual value of the time selected by **TTTOCN[SWS]** will be copied into **TTCPT[SWV]** on the next rising/falling edge (as configured via **TTOCN[SWP]**) on stop watch trigger pin . This will set interrupt flag **TTIR[SWE]**. After the application program has read **TTCPT[SWV]**, it may enable the next stop watch event by resetting **TTIR[SWE]** to '0'.

48.4.13 Local time, cycle time, global time, and external clock synchronization

There are two possible levels in time-triggered CAN: Level 1 and Level 2. Level 1 only provides time-triggered operation using cycle time. Level 2 additionally provides increased synchronization quality, global time and external clock synchronization. In both levels, all timing features are based on a local time base - the local time. The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented 8 times each NTU. If the length of the NTU is shorter than 8 CAN clock periods (as may be configured in Level 1, or as a result of clock calibration in Level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only 4 times each NTU.

Figure 48-27 describes the synchronization of the cycle time and global time, performed in the same manner by all M_TTCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message is frame synchronization event. This frame synchronization event occurs at the sample point of each Start of Frame (SoF) bit and causes the local time to be stored as Sync_Mark. Sync_Marks and Ref_Marks are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the Cycle Sync Mark (Cycle Sync Mark = Sync_Mark - Ref_Mark) stored in register **TTCSM**. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (Cycle Time = Local Time - Ref_Mark).

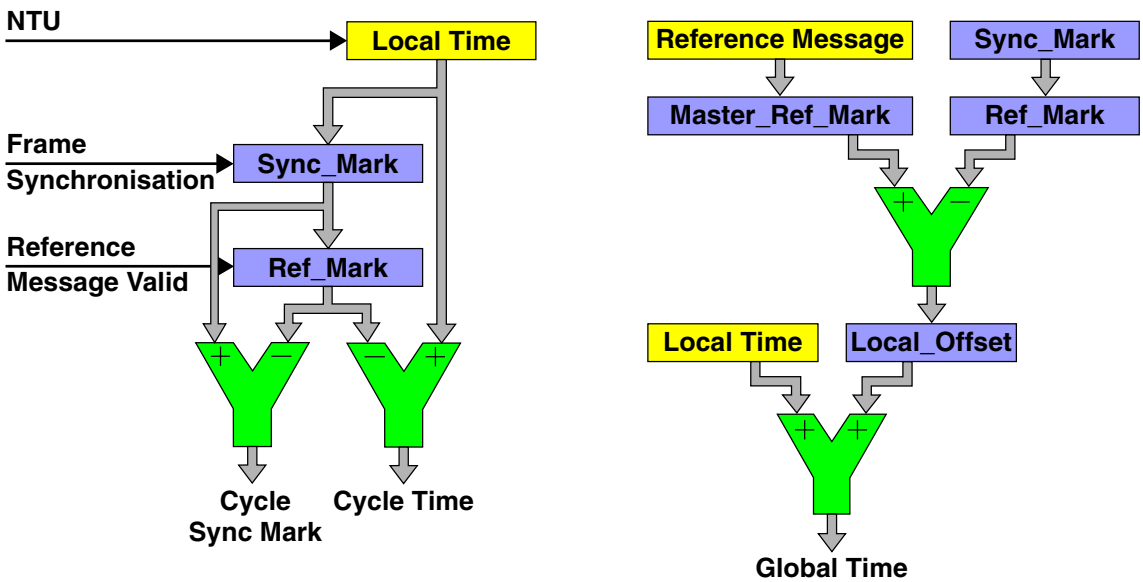

Figure 48-27. Cycle Time and Global Time Synchronization

The cycle time that can be read from **TTCTC[CT]** is the difference of the node's local time and Ref_Mark, both synchronized into the Host clock domain and truncated to 16 bit. The global time exists for M_TTCAN Level 0 and Level 2 only, in Level 1 it is invalid. The node's view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master will use its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3,4). The global time that can be read from **TTLGT[GT]** is the sum of the node's local time and its local offset, both synchronized into the Host clock domain and truncated to 16 bit. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark (see in figure above). The node's view of the global time is local time + local offset. In a potential time master that has never received another time master's reference message, Local_Offset will be zero. When a node becomes the current time master after first having received other reference messages, Local_Offset will be frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signalled

by **Disc_Bit** in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register **TTLGT** is smoothed by a low-pass filtering to have a continuous monotonic value.

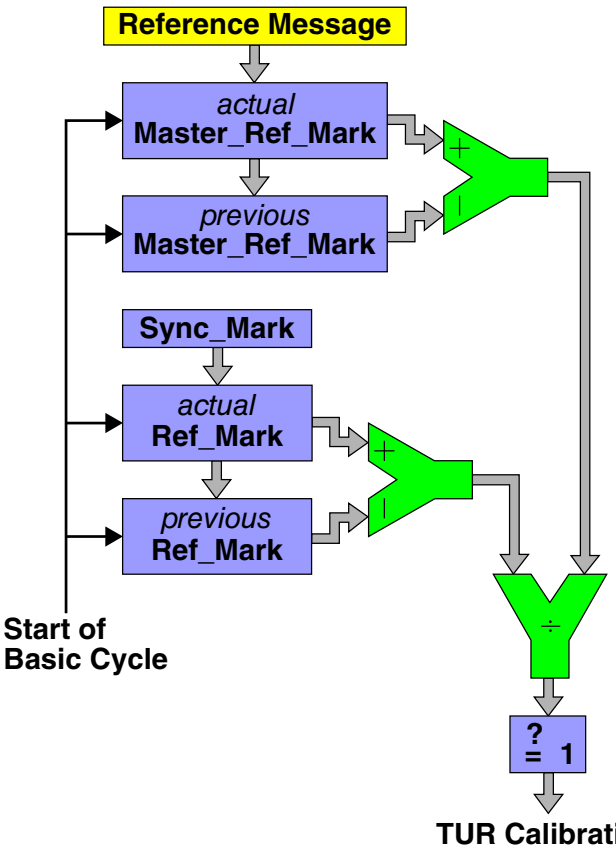

Figure 48-28. M_TTCAN Level 0 and Level 2 Drift Compensation

Figure 48-28 describes how in M_TTCAN Level 0,2 each time receiving node compensates the drift between its own local clock and the time master's clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the **Disc_Bit** in the reference message is not set, a new value for **TURNA[NAV]** is calculated. If the Synchronization Deviation SD = |**NC - TURNA[NAV]**| ≤ SDL (Synchronization Deviation Limit), the new value for **TURNA[NAV]** takes effect. Else the automatic drift compensation is suspended.

In M_TTCAN Level 0 and Level 2, **TTOST[QCS]** indicates whether the automatic drift compensation is active or suspended. In M_TTCAN Level 1, **TTOST[QCS]** is always '1'.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit **TTOCF[EECS]**.

The stop watch function (see Stop watch) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated Numerator Configuration Low to **TURCF[NCL]** (**TURCF[DC]** cannot be updated during operation). The new value takes effect by writing **TTOCN[ECS]** to '1'.

The global time phase is adjusted by first writing the phase offset into the TT Global Time Preset register **TTGTP**. The new value takes effect by writing **TTOCN[SGT]** to '1'. The first reference message transmitted after the global time phase adjustment will have the **Disc_Bit** set to '1'.

TTOST[QGTP] shows whether the node's global time is in phase with the time master's global time. **TTOST[QGTP]** is permanently '0' in M_TTCAN Level 1 and when the Synchronization Deviation Limit is exceeded in M_TTCAN Level 0,2 (**TTOST[QCS]** = '0'). It is temporarily '0' while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a **Disc_Bit** = '1' or when **TTOST[QCS]**='0'.

48.4.14 M_TTCAN error level

The ISO 11898-4 specifies four levels of error severity:

- S0 - No Error
- S1 - Warning- Only notification of application, reaction application-specific.
- S2 Error- Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (i.e. no data or remote frames may be started). Potential time masters still transmit reference messages with the Reference Trigger Offset **TTOST[RTO]** set to the maximum value of 127.
- S3 - Severe Error

  Notification of application. All CAN bus operations are stopped, i.e. transmission of dominant bits is not allowed, and **CCCR[MON]** is set. The S3 error condition remains active until the application updates the configuration (set **CCCR[CCE]**).

  If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by **TTIR[ELC]**. The error level is monitored by **TTOST[EL]**.

The M_TTCAN signals the following error conditions as required by ISO 11898-4:

- Config_Error (S3)

Sets Error Level **TTOST[EL]** to "11" when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.

- Watch_Trigger_Reached (S3)

  Sets Error Level **TTOST[EL]** to "11" when a watch trigger was reached because the reference message is missing.

- Application_Watchdog (S3)

  Sets Error Level **TTOST[EL]** to "11" when the application failed to serve the application watchdog.The application watchdog is configured via **TTOCF[AWL]**. It is served by reading register TTOST.When the watchdog is not served in time, bit **TTOST[AWE]** and interrupt flag **TTIR[AW]** are set, all M_TTCAN communication is stopped, and the M_TTCAN is set into bus monitoring mode (**CCCR[MON]**set to '1').

- CAN_Bus_Off (S3)

  Entering **CAN_Bus_Off** state sets error level **TTOST[EL]** to "11". **CAN_Bus_Off** state is signalled by **PSR[BO]** = '1' and **CCCR[INIT]** = '1'.

- Scheduling_Error_2 (S2)

  Sets Error Level **TTOST[EL]** to "10" if the MSC of one Tx_Trigger has reached 7. In addition interrupt flag **TTIR[SE2]** is set. The Error Level **TTOST[EL]** is reset to "00" at the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.

- Tx_Overflow (S2)

  Sets Error Level **TTOST[EL]** to "10" when the Tx count is equal or higher than the expected number of Tx_T riggers **TTMLM[ENTT]** and a Tx_Trigger event occurs. In addition interrupt flag **TTIR[TXO]** is set. The Error Level **TTOST[EL]** is reset to "00" when the Tx count is no more than **TTMLM[ENTT]** at the start of a new matrix cycle.

- Scheduling_Error_1 (S1)

  Sets Error Level **TTOST[EL]** to "01" if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than 2, or if one of the MSCs of an exclusive Rx_Trigger has reached 7. In addition interrupt flag **TTIR[SE1]** is set. If within one matrix cycle none of these conditions is valid, the Error Level **TTOST[EL]** is reset to "00".

- Tx_Underflow (S1)
- Sets Error Level **TTOST[EL]** to "01" when the Tx count is less than the expected number of Tx_Triggers **TTMLM[ENTT]** at the start of a new matrix cycle. In addition interrupt flag **TTIR[TXU]** is set. The Error Level **TTOST[EL]** is reset to "00" when the Tx count is at least **TTMLM[ENTT]** at the start of a new matrix cycle.

48.4.15 M_TTCAN message handling

48.4.15.1 Reference message

For potential time masters the identifier of the reference message is configured via **TTRMC[RID]**. No dedicated Tx Buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte (M_TTCAN Level 1) resp. the first four data bytes (M_TTCANM_TTCAN Level 0 and Level 2) will be provided by the FSE. In case the Reference Message Payload Select **TTRMC[RMPS]** is set, the rest of the reference message's payload (Level 1: bytes 2-8, Level 0,2: bytes 5-6) is taken from Tx Buffer 0. In this case the data length **DLC** code from message buffer 0 is used.

Table 48-36. Number of Data Bytes transmitted with a Reference Messages

TTRMC.RMPS	TXBRP.TRP0	Level 0	Level 1	Level 2
0	0	4	1	4
0	1	4	1	4
1	0	4	1	4
1	1	4+MBO	1+MBO	4+MBO

To send additional payload with the reference message in Level 1 a **DLC** > 1 has to be configured, for Level 0, 2 a **DLC** > 4 is required. In addition the transmission request pending bit **TXBRP[TRP0]** of message buffer 0 must be set (see the table above). In case bit **TXBRP[TRP0]** is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the Reference Identifier **TTRMC[RID]** is used.

48.4.15.2 Message reception

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (see Rx handling).

The Message Status Count MSC is part of the corresponding trigger memory element and has to be initialized to zero during configuration. It is updated while the M_TTCAN is in synchronization states In_Gap or In_Schedule. The update happens at the message's Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

48.4.15.3 Message transmission

For time-triggered message transmission the M_TTCAN supplies 32 dedicated Tx buffers (see Dedicated Tx buffers). A Tx FIFO or Tx queue is not available when the M_TTCAN is configured for time-triggered operation (**TTOCF[OM]** = "01" or "10"). Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle. The application program has to update the data regularly and on time, synchronized to the cycle time. The Host CPU is responsible that no partially updated messages are transmitted. To assure this the Host has to proceed in the following way:

Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration

- Check whether the previous transmission has completed by reading **TXBTO**
- Update the Tx buffer's configuration and/or payload
- Issue an Add Request to set the Tx Buffer Request Pending bit

Tx_Trigger_Continous

- Issue a Cancellation Request to reset the Tx Buffer Request Pending bit
- Check whether the cancellation has finished by reading **TXBCF**
- Update Tx buffer's configuration and/or payload
- Issue an Add Request to set the Tx Buffer Request Pending bit

The message's **MSC** stored with the corresponding Tx_Trigger provides information on the success of the transmission. The **MSC** is incremented by one when the transmission could not be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and could not be completed successfully. The **MSC** is decremented by one when the message was transmitted successfully or when the message could have been started within its transmit enable window but was not started because transmission was disabled (M_TTCAN in Error Level S2 or Host has disabled this particular message). The Tx buffers may be managed dynamically, i.e. several messages with different identifiers may share the same Tx buffer element. In this case the Host has to assure that no transmission request is pending for the Tx buffer element to be reconfigured by checking **TXBRP**. If a Tx buffer with pending transmission request should be updated, the Host first has to issue a cancellation request and check whether the cancellation has completed by reading **TXBCF** before it starts updating.

The Tx Handler will transfer a message from the Message RAM to its intermediate output buffer at the trigger element which becomes active immediately before the Tx_Trigger element which defines the beginning of the transmit window. During and after the transfer time the transmit message may not be updated and its TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be example of a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger has to be large enough to guarantee that the Tx Handler can read four words from the Message RAM even at high RAM access load from other modules.

48.4.15.3.1 Transmission in exclusive time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continuous. There is no arbitration on the bus with messages from other nodes. The **MSC** is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx Buffer Request Pending bit is reset. After successful transmission started by a Tx_Trigger_Continuous the respective Tx Buffer Request Pending remains set. When the transmission was not successful due to disturbances, it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

48.4.15.3.2 Transmission in arbitrating time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The **MSC** is not updated. When the transmission was not successful (lost arbitration or disturbance), it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

48.4.15.3.3 Transmission in merged arbitrating time windows

The purpose of a merged arbitrating time window is, to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a single node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission will not be started if the corresponding Transmission Request Pending flag was reset by a successful Tx cancellation. In single transmit windows, the Tx Handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmissions will be attempted in the sequence defined by the trigger list. If the time mark of a fourth message is reached before the first is transmitted (or cancelled by the Host), the four the request will be ignored. The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window will be started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if their is compelling bus traffic. This has to be considered for the configuration of the trigger list. Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx Buffer needs to be updated.

48.4.16 M_TTCAN interrupt and error handling

The TT Interrupt Register **TTIR** consists off our segments. Each interrupt can be enabled separately by the corresponding bit in the TT Interrupt Enable register **TTIE**. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. The first segment consists of flags **CER**, **AW**, **WT**, and **IWT**.

Each flag indicates a fatal error condition where the CAN communication is stopped. With the exception of **IWT**, these error conditions require a re-configuration of the M_TTCAN module before the communication can be restarted.

The second segment consists of flags **ELC**, **SE1**, **SE2**, **TXO**, **TXU**, and **GTE**. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, e.g. by disturbances on the CAN bus, they will be handled by the M_TTCAN protocol's failure handling and do not require intervention by the application program.

The third segment consists of flags **GTD**, **GTW**, **SWE**, **TTMI**, and **RTMI**. The first two flags are controlled by global time events (Level 0,2 only) that require a reaction by the application program. With a Stop Watch Event triggered by a rising edge on pininternal time values are captured. The Trigger Time Mark Interrupt notifies the application that a specific Time_Base_Trigger is reached. The Register Time Mark Interrupt signals that the time referenced by **TTOCN[TMC]** (Cycle, Local, or Global) equals time mark **TTTMK[TM]**. It can also be used to finish a Gap. The fourth segment consists of flags **SOG**, **CSM**, **SMC**, and **SBC**. These flags provide a means to synchronize the application program to the communication schedule.

48.4.17 Level 0

M_TTCAN Level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in M_TTCAN Level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1. Level 0 operation is configured via **TTOCF[OM]** = "11". In this mode the M_TTCAN operates in event driven CAN communication, there is no fixed schedule, the configuration of **TTOCF[GEN]** is ignored. External event-synchronized operation is not available in Level 0. A synchronized time base is maintained by transmission of reference messages. In Level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (**TTIR[TTMI]**) is set when the cycle time has reached **TTOCF[IRTO]** × 0x200, it reminds the Host to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (**TTIR[WT]**) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks. Register time mark interrupts (**TTIR[RTMI]**) are also possible. The reference message is configured as for Level 2 operation. Received reference messages are recognized by the identifier configured in register TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the Host sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:

- **TTRMC**
- **TTOCF** except **EVTP**, **AWL**, **GEN**
- **TTMLM** except **ENTT**, **TXEW**
- **TURCF**

Level 0 operation is controlled via:

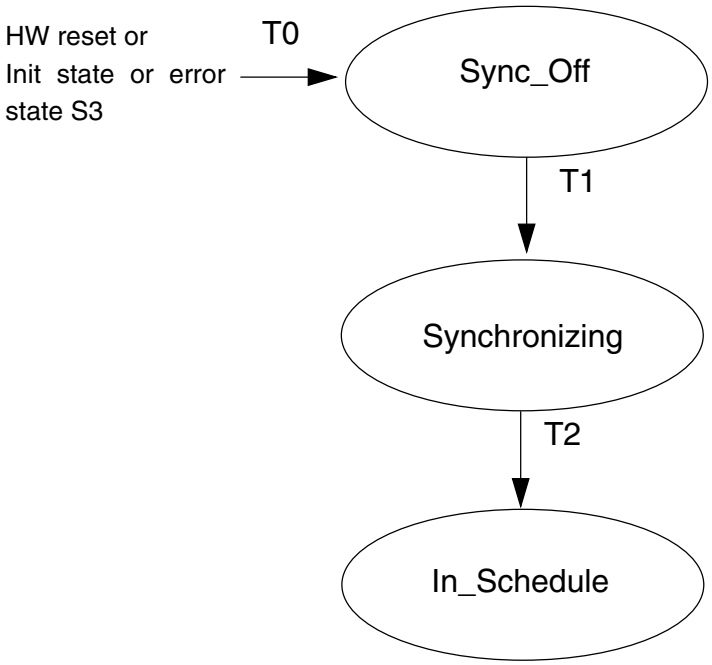
- **TTOCN** except **NIG**, **TMG**, **FGP**, **GCS**, **TTMIE**
- **TTGTP**
- **TTTMK**
- **TTIR** excluding bits **CER**, **AW**, **IWTSE2**, **SE1**, **TXO**, **TXU**, **SOG** (no function)
- **TTIR** the following bits have changed function
  - **TTMI** not defined by trigger memory - activated at cycle time **TTOCF[IRTO]** . 0x200
  - **WT** not defined by trigger memory - activated at cycle time 0xFF00

Level 0 operation is signalled via:

- TTOST excluding bits **AWE**, **WFE**, **GSI**, **GFI**, **RTO** (no function)

48.4.17.1 Synchronizing

The following figure describes the states and state transitions in M_TTCAN Level 0 operation. Level 0 has no In_Gap state.



T0: transition condition always taking prevalence

T1: Init state left, cycle time is zero

T2: at least two successive reference messages observed (last reference message did not contain a set Disc_Bit or Next_is_Gap bit)

Figure 48-29. Level 0 schedule synchronization state machine

48.4.17.2 Handling of error levels

During Level 0 operation only the following error conditions may occur:

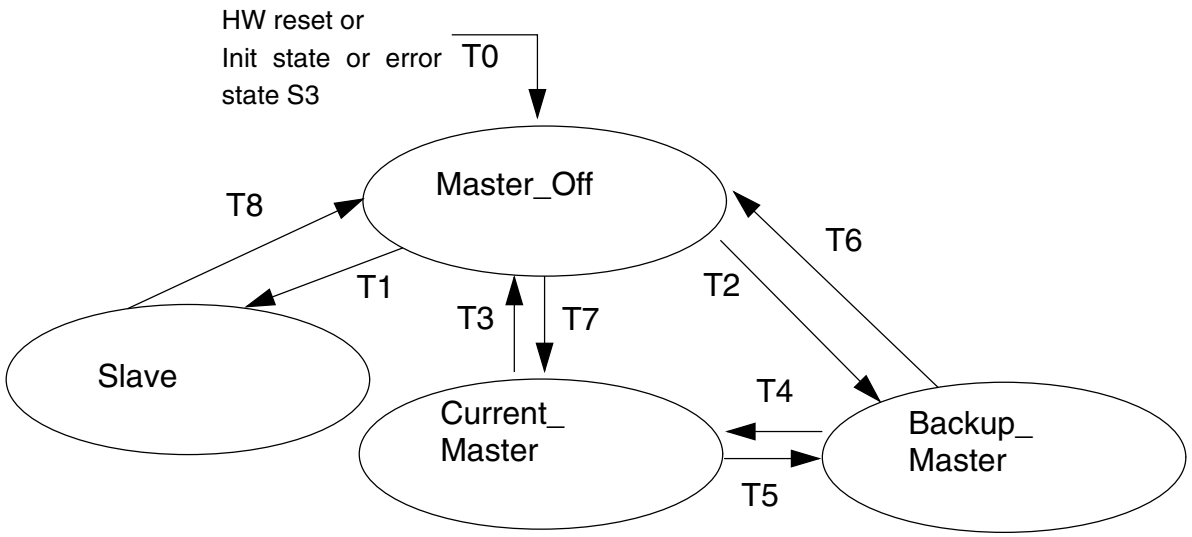
- Watch_Trigger_Reached (S3), reached cycle time 0xFF00
- CAN_Bus_Off (S3)

Since no S1 and S2 error are possible, the error level can only switch between S0 (No Error) and S3 (Severe Error). In M_TTCAN Level 0 an S3 error is handled differently. When error level S3 is reached, both **TTOST[SYS**] and **TTOST[MS]** are reset, and interrupt flags **TTIR[GTE]** and **TTIR[GTD]** are set.

When error level S3 (**TTOST[EL]** = "11") is entered, bus monitoring mode is, contrary to M_TTCAN Level 1 and Level 2, not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.

48.4.17.3 Master slave relation

The following figure describes the master slave relation in M_TTCAN Level 0. In case of an S3 error the M_TTCAN returns to state Master_Off.



T0: transition condition always taking prevalence

T1: reference message observed when not potential time master

T2: reference message observed with master priority ≠ own master priority, error state ≠ S3

T3: reference message observed with master priority =own master priority, error state ≠ S3

T4: reference message observed with own master priority

T5: reference message observed with master priority higher than own master priority

T6: error state S3

Figure 48-30. Level 0 master to slave relation

48.4.18 Synchronization to external time schedule

This feature can be used to synchronize the phase of the M_TTCAN's schedule to an external schedule (e.g. that of a second M_TTCAN network or FlexRay network). It is applicable only when the M_TTCAN is current time master (**TTOST[MS]** = "11"). External synchronization is controlled by event trigger input pin. If bit **TTOCN[ESCN]** is set, a rising edge at event trigger pin the M_TTCAN compares its actual cycle time with the target phase value configured by **TTGTP[CTP]**. Before setting **TTOCN[ESCN]** the Host has to adapt the phases of the two time schedules e.g. by using the M_TTCAN gap control (see M_TTCAN gap control). When the Host sets **TTOCN[ESCN]**, **TTOST[SPL]** is set.

If the difference between the cycle time and the target phase value **TTGTP[CTP]** at the rising edge at event trigger pin is greater than 9 NTU, the phase lock bit **TTOST[SPL]** is reset, and interrupt flag **TTIR[CSM]** is set. **TTOST[SPL]** is also reset (and **TTIR[CSM]** is set), when another node becomes time master. If both **TTOST[SPL]** and **TTOCN[ESCN]** are set, and if the difference between the cycle time and the target phase value **TTGTP[CTP]** at the rising edge at event trigger pin is less or equal 9 NTU, the phase lock bit **TTOST[SPL]** remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

Note

The rising edge detection at event trigger pin is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with TTGTP[CTP]. All further edges until the beginning of the next basic cycle are ignored.

48.5 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note

From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

48.5.1 Features

- Active low asynchronous reset
- 1–CPU + 5–CAN arbiter.

- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth.
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles.
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth.
- Time slot is defined as one peripheral clock cycle.

48.5.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
  - CPU obtains every 2nd slot
  - CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
  - CPU obtains no time slots
  - CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
  - CPU obtains every 2nd time slot
  - Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):

- CPU obtains no time slots
- Active CAN 1/2 obtains every 2nd time slot

48.6 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are summarized in the following sections.

48.6.1 Shared memory

The following table/s shows maximum possible configuration per Filter, FIFO and Buffer but not all of these items can be configured to maximum size at the same time due to the smaller implemented physical memory as listed in Table 48-39.

Table 48-37. M_CAN message memory size requirement1.

Memory element	Number of elements	32-bit word per element	Total 32-bit words
11-bit Filter	128	1	128
29-bit Filter	64	2	128
Rx FIFO 0	64	18	1152
Rx FIFO 1	64	18	1152
Rx Buffer	64	18	1152
Tx Event FIFO	32	2	64
Tx Buffers	32	18	576
		M_CAN message memory size (word)	4352

1. M_CAN Rev 3.x supports CAN FD mode up to 64 data bytes

Table 48-38. M_TTCAN message memory size requirement1

Memory element	Number of elements	32-bit word per element	Total 32-bit words
11-bit Filter	128	1	128
29-bit Filter	64	2	128
Rx FIFO 0	64	4	256
Rx FIFO 1	64	4	256
Tx Event FIFO	32	2	64
Tx Buffers	32	4	128
Triggers	64	2	128
		M_TTCAN message memory size (word)	1344

1. M_TTCAN Rev 2.x supports CAN FD mode up to 8 data bytes.

Please refer Table 48-39 for the exact physical memory space used in the device.

48.6.2 ECC controller

The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access. The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2-bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors display the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

48.6.2.1 Features

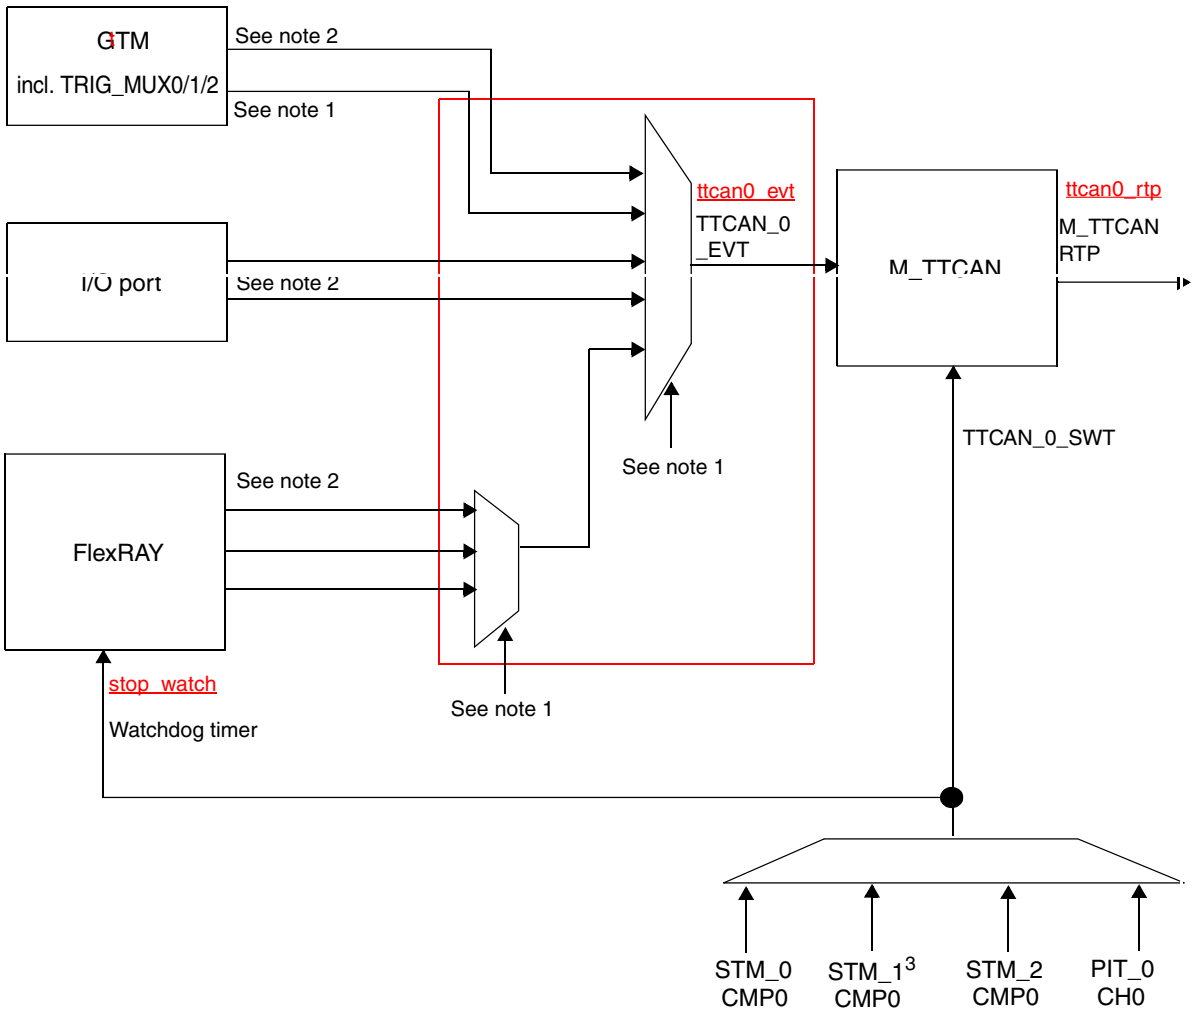
The ECC module supports the following:

- ecc_error = 00 ' No error is detected in the read data from memory
- ecc_error = 01 ' This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.

- ecc_error = 10 ' This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- ecc_error = 11 ' This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

48.7 Time Triggered CAN matrix and basic cycles management

The following figure shows hardware control for M_TTCAN cycles management.



Note 1: Multiplexers and control logic is implemented in the SIUL block. See SIUL Multiplexed Signal Configuration Register (SIUL2: MSCR 753, MSCR 754).
Note 2: For the signal details from various blocks see section SIUL Module-port MSCR assignments and SSS values (SIUL2: MSCR 753, MSCR 754).
Note 3: See device configuration chapter for the availability of the STM instances.

Figure 48-31. Hardware control for M_TTCAN cycles management

48.8 CAN nodes 1 and 2 I/Os sharing

Each CAN node will have its Tx/Rx signals connected to separated GPIO pairs from each others. It is required for MCAN_1 and MCAN_2 to share one common GPIO pair. This feature is described below.

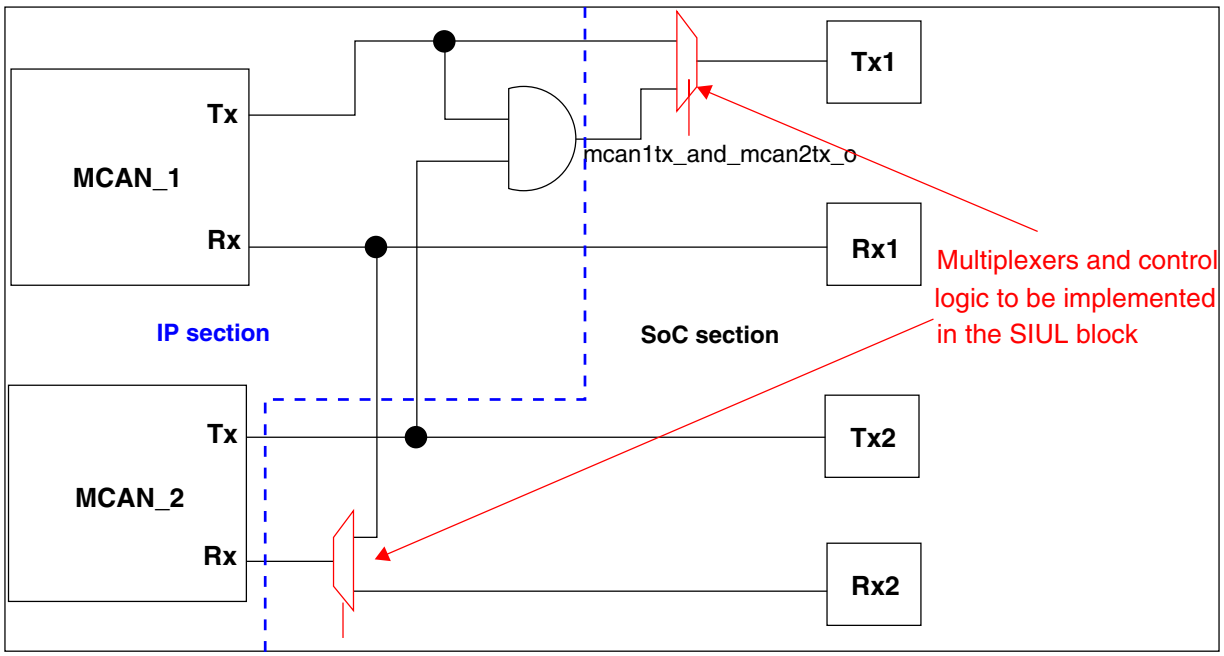


Figure 48-32. MCAN_1 and MCAN_2 connections to GP I/Os

48.9 External signal description

The CAN subsystem has following external pins.

- MCAN_x_RX: M_CAN x receive input
- MCAN_x_TX: M_CAN x transmit output
- M_TTCAN_x_RX: M_TTCAN x receive input
- M_TTCAN_x_TX: M_TTCAN x transmit output

48.10 Memory map and register description

48.10.1 Shared memory map

Table 48-39 shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 48-39. Shared memory map vs CAN transmit, receive and filters elements

Start Address Offset (Byte)	End Address Offset (Byte)	CAN block/sub block		Comment
0x0000	0x4FFF	M_CAN1 M_CAN2 M_CAN3 M_CAN4 M_TTCAN0	Standard Filters Extended Filters Rx FIFO0 Rx FIFO1 Rx Buffer Tx Event FIFO Tx Buffers M_TTCAN triggers	This available physical memory space could be configured for Filters/ FIFO/Buffer according to Table 48-37. This memory space can be flexible, assigned to any of the implemented M_CAN modules.

Note

There is no write access protection from a CAN module to the message memory space. The write access protection is only for CPU access to the message memory.

Note

The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters, Tx/Rx buffers, triggers used, it is mandatory for the user to configure the start address registers, specified in Table 48-40, in order to fit the memory mapping specified in Table 48-39.

Note

The CPU uses the peripheral interface to access the memory locations. It must be noted that there will not be any transfer error reported to the CPU in case of access to reserved memory locations.

Table 48-40. Detailed mapping in CAN subblocks

CAN sub block	Element name	Comment
Standard Filters	Standard Message ID filter 0 --- Standard Message ID filter 127	address configured in SIDFC [FLSSA]
Extended Filters	Extended Message ID filter 0	address configured in XIDFC [FLESA]

Table continues on the next page...

Table 48-40. Detailed mapping in CAN subblocks (continued)

CAN sub block	Element name	Comment
	--- Extended Message ID filter 63	
Rx FIFO0	Rx FIFO0 element 0 --- Rx FIFO0 element 63	address configured in RXF0C[F0SA]
Rx FIFO1	Rx FIFO1 element 0 --- Rx FIFO1 element 63	address configured in RXF1C[F1SA]
Rx Buffer	Rx Buffer element 0 --- Rx Buffer element 63	address configured in RXBC[RBSA
Tx Event FIFO	Tx event FIFO element 0 --- Tx event FIFO element 31	address configured in TXEFC[EFSA]
Tx Buffers	Tx Buffer element 0 --- Tx Buffer element 31	address configured in TXBC[TBSA]
M_TTCAN triggers (on M_TTCAN0 only)	Trigger element 0 --- Trigger element 63	address configured in TMC[TMSA]

Chapter 49
Deserial Serial Peripheral Interface (DSPI)

49.1 Introduction

The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note

For the chip-specific implementation details of the instances of this module, see the Device Configuration chapter.

49.1.1 Block diagram

The following figure provides the block diagram of this module.

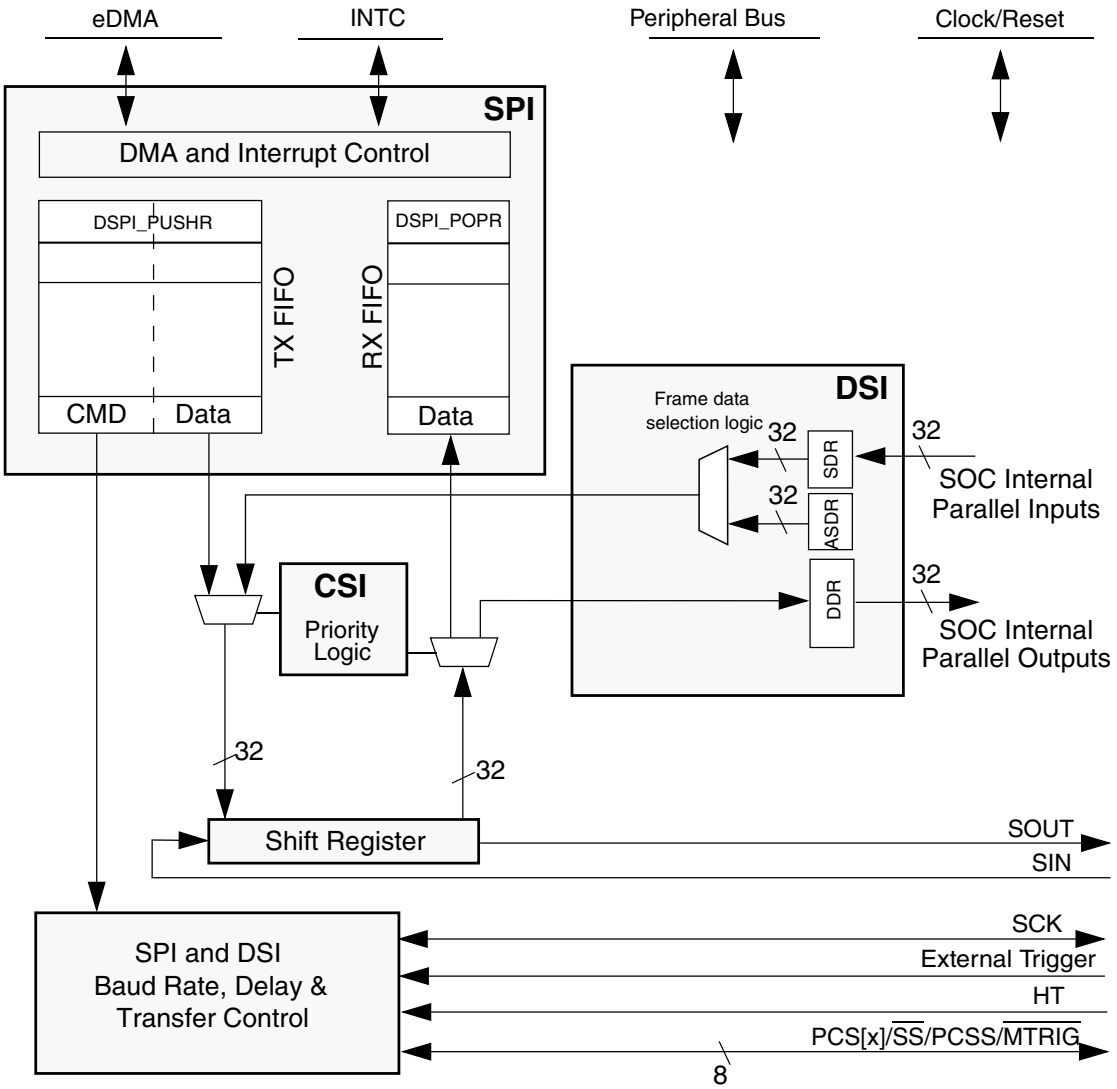

Figure 49-1. DSPI block diagram

49.1.2 Features

The DSPI supports the following features:

- Full-duplex, four-wire synchronous transfers.
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection.
- Buffered transmit operation with 4-entry TX FIFO buffer.
- Buffered receive operation with 4-entry RX FIFO buffer.
- Asynchronous clocking scheme for Register and Protocol interfaces.

- Individual TX and RX FIFOs disabling for low-latency updates to SPI queues.
- Visibility inside TX and RX FIFOs for debugging.
- Programmable transfer attributes on a per-frame basis:
  - 8 transfer attribute registers along with 8 extended transfer attribute registers
  - serial clock with programmable polarity and phase
  - various programmable delays
  - programmable serial frame size of . SPI frames longer than 32 bits are supported using the continuous selection format
  - continuously held chip select capability
  - parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer.
- Deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer.
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - CMD FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End Of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - CMD FIFO is not full (CMDFFF)
  - Transfer of current frame Complete (TCF)
  - Transfers due from current Command frame Complete (CMDTCF)
  - Transfer of current SPI frame Complete (SPITCF)
  - attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - frame received while Receive FIFO is full (RFOF)

    - SPI Parity Error (SPEF)
    - data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line.
- Modified SPI transfer formats for communication with slower peripheral devices.
- Power-saving architectural features: support for stop mode.

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
    - DSPI memory-mapped register
    - parallel input signals
    - programmable selection of source data on bit basis.
- Deserialized data provided as:
    - parallel Output signals
    - bits in a memory-mapped register
- Interrupt conditions:
    - deserialized data matches pre-programmed pattern (DDIF)
    - transfer of current DSI frame complete (DSITCF)
    - DSI parity error (DPEF)
- DMA request support for following conditions:
    - deserialized data matches pre-programmed pattern (DDIF)
- Transfer initiation conditions:
    - continuous
    - edge sensitive hardware trigger
    - change in data
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics.
- Continuous serial communications clock.

DSPI supports a combination of SPI and DSI modes of operation (Combined Serial Interface (CSI)) for the downstream Micro Second Channel in either Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration (configurable by software). Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is performed at frame boundaries.
- Frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame.
- Separate interrupts for frame completion from SPI and DSI.

49.1.3 DSPI configurations

The DSPI module can operate in three configurations: SPI, DSI, and CSI. See the relevant section in the ‘Communication interfaces’ section of the ‘Device Configuration’ chapter.

49.1.3.1 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, DSPI and external queues in system RAM.

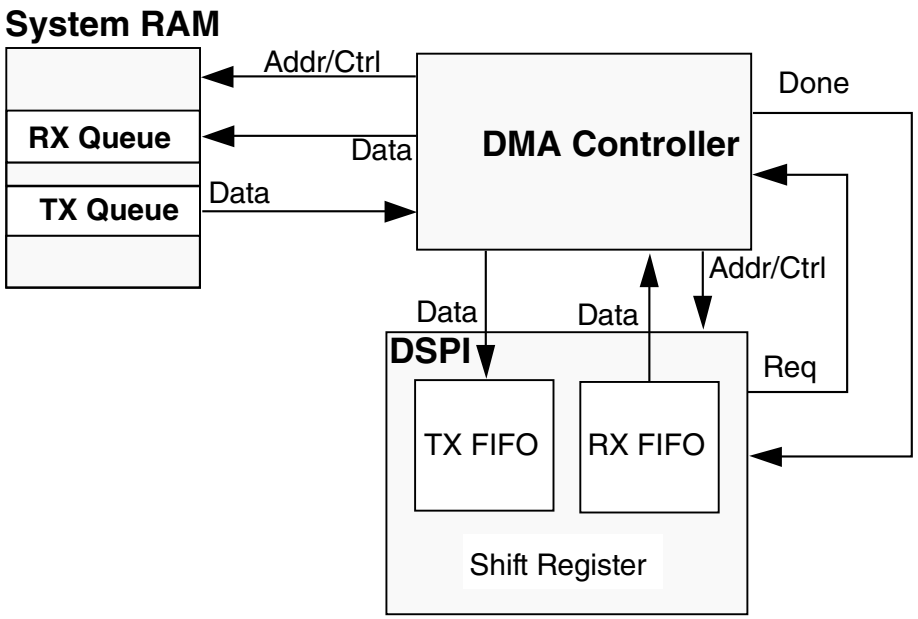

Figure 49-2. DSPI with queues and DMA

49.1.3.2 DSI configuration

In the Deserial Serial Interface (DSI) configuration, DSPI serializes up to 32 parallel input signals or register bits. . The DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

Timed Serial Bus (TSB) mode provides the MicroSecond Channel (MSC) downstream support, serializing from 4 to 32 parallel input signals or register bits. See Timed Serial Bus (TSB).

49.1.3.3 CSI configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.

- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in Interleaved TSB (ITSB) Mode.

49.1.4 Modes of operation

The DSPI modes of operation that can be divided into two categories:

- Module-specific modes
  - Master mode
  - Slave mode
  - Module Disable mode
- MCU-specific modes
  - External Stop mode
  - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

49.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

49.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI/DSI bus masters In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

49.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

49.1.4.4 External Stop mode

External Stop mode is used for MCU power management; the DSPI supports the Peripheral Bus Stop mode mechanism.

Upon a request to enter External Stop mode:

- In Master mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary, it signals that the protocol clock to the DSPI module may be shut off.
- In Slave mode, a request to enter External Stop mode must be run after the last clock cycle or Low-power mode is not entered.

49.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

49.2 DSPI signal description

This section provides the DSPI signals description.

The following table lists the signals that may connect off chip depending on device implementation.

Table 49-1. DSPI signal description

Signal	Description	I/O
PCS0/ SS	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[3:1]	Master mode: Peripheral Chip Select 1–3	O

Table continues on the next page...

Table 49-1. DSPI signal description (continued)

Signal	Description	I/O
	Slave mode: Unused	
PCS4	Master mode: Peripheral Chip Select 4	O
PCS5/ PCSS[1]	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[7:6]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O
HT	Hardware Trigger	I

1. This pin is not available for DSPI_2

49.2.1 PCS0/$\overline{SS}$ — Peripheral Chip Select/Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low SS signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

49.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

49.2.3 PCS4 — Peripheral Chip Select 4

In master mode, PCS4 is a Peripheral Chip Select output signal.

49.2.4 PCS5/$\overline{\text{PCSS}}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

49.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

49.2.6 SIN — Serial Input

SIN is a serial data input signal.

49.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

49.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

49.2.9 HT — Hardware Trigger

In master mode while in DSI or CSI Configurations, the HT signal initiates a data transfer when the DSICR0[TRRE] bit is set and a rising or falling edge is detected on HT. Which edge to trigger on is determined by the DSICR0[TPOL] bit.

49.3 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPIx_POPR also results in a transfer error.

DSPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	DSPI Module Configuration Register (DSPI_MCR)	32	R/W	0000_4001h	49.3.1/2087

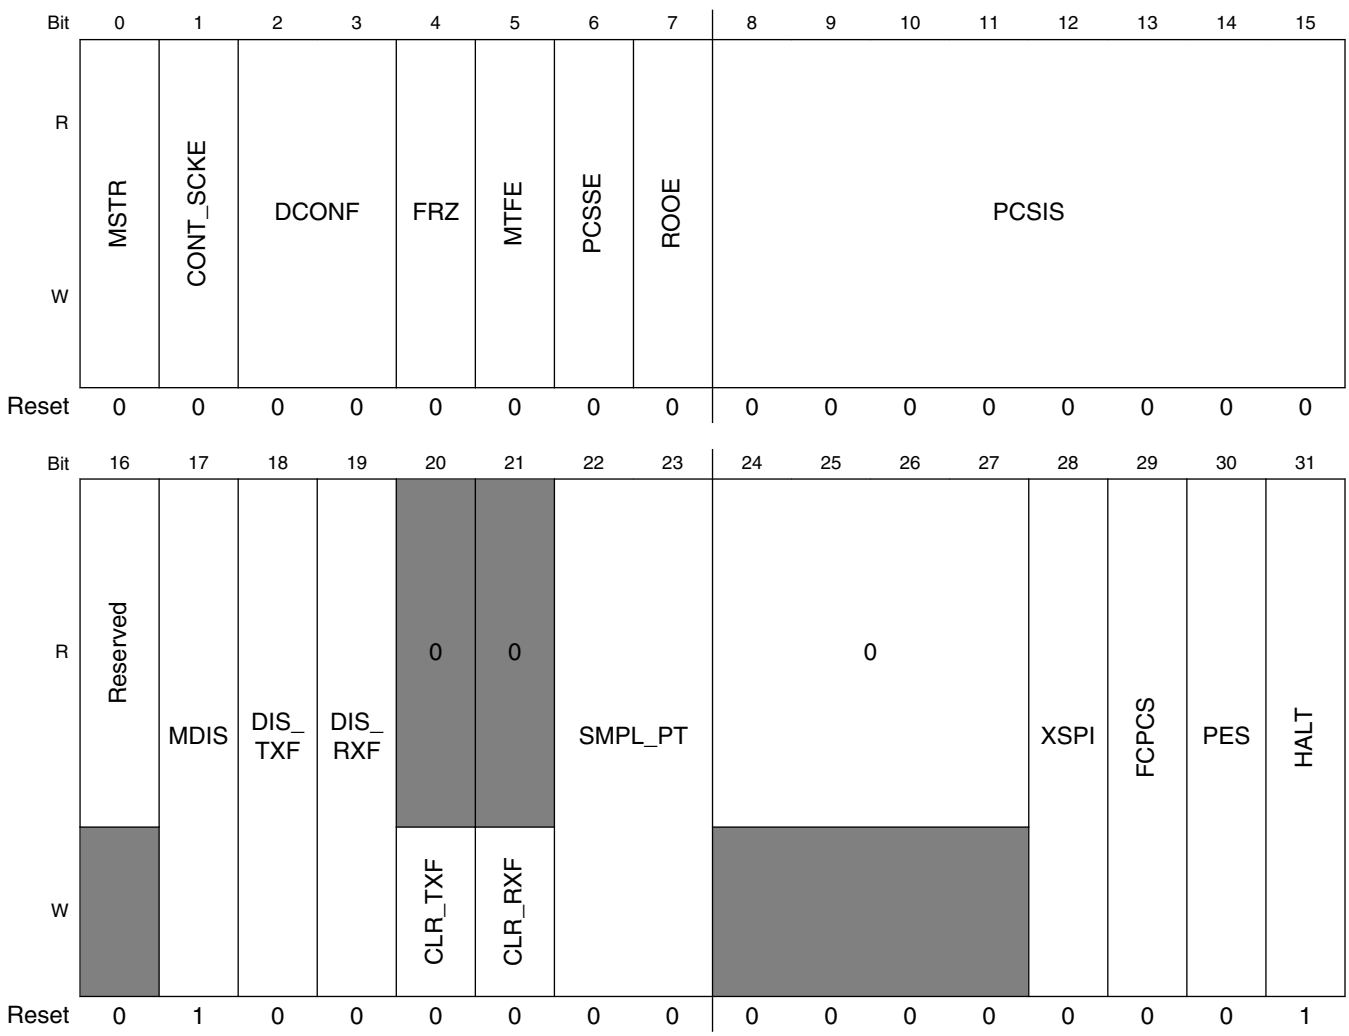
49.3.1 DSPI Module Configuration Register (DSPI_MCR)

The DSPI_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Address: 0h base + 0h offset = 0h



DSPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	DSPI Configuration Selects the DSPI configuration. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. MTFE should not be set in ITSB Mode as Microsecond Channel upstream operation is not supported. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS[5]/PCSS is used as the Peripheral Chip Select[5] signal (PCS[5]). 1 PCS[5]/PCSS is used as an active-low PCS Strobe signal (PCSS).
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer generating the overflow is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–15 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

Field	Description
16 Reserved	This field is reserved. This read-only bit field is reserved and always has the value zero.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI, putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is 1. MDIS should be set to ’0’ in Slave Mode as a slave doesn’t control master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes TX FIFO and CMD FIFO. Writing a '1' to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.
21 CLR_RXF	Clear RX FIFO Flushes RX FIFO. Writing a '1' to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DSPI_MCR field descriptions (continued)

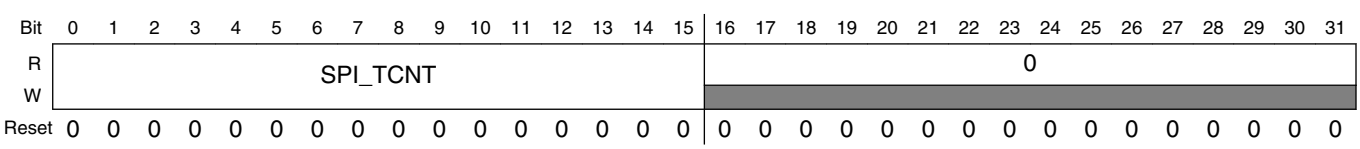
Field	Description
28 XSPI	Extended SPI Mode Enables use of CTARE (Command and Transfer Attribute Register Extended) Registers, which allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled, allowing the user to send multiple Data Frames in a single Command Frame. When MCR[DIS_TXF] is asserted, Extended SPI Mode cannot be used to transmit SPI frames over 16 bits in size. 0 Normal SPI Mode. Up to 16-bit Frames. Command Cycling is not available. 1 Extended SPI Mode. Up to 32-bit SPI Frames. Command Cycling Enabled
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of "After SCK (t_{ASC})" and "PCS to SCK (t_{CSC})" delays when operating in Continuous PCS mode. The individual delay masks are selected via PUSHR[PE_MASC] and PUSHR{PP_MCSC]. The firmware should select appropriate masks when providing continuous frames via the PUSHR. This masking is not available if Continuous SCK mode is enabled. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers.

49.3.2 DSPI Transfer Count Register (DSPI_TCR)

DSPIx_TCR has an SPI transfer counter to assist in queue management.

Do not write the TCR when the DSPI is in the Running state.

Address: 0h base + 8h offset = 8h



DSPI_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. A value written to SPI_TCNT presets the counter to that value. The Transfer Counter wraps around; incrementing past 65535 resets the counter to zero.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.3 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*)

CTARs are used to define different transfer attributes:

- In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays.
- In slave mode, a subset of the bitfields in CTAR0 and CTAR1 set the slave transfer attributes.

Do not write to the CTARs while the DSPI is in the Running state.

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Table 49-2. DSPI SCK duty cycle

DBR	CPHA	PBR	SCK duty cycle

DSPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate. (Master mode only) Doubles the baud rate of the Serial Communications Clock (SCK). It halves the Baud Rate division ratio, supporting faster frequencies and odd division ratios for the Serial Communications Clock (SCK). When DBR is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in Table 49-2. See the BR field description for details on how to compute the baud rate. Refer to Table 49-2 for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid value for the number of bits to be transmitted for any mode is 4.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	There is a constraint on the minimum allowable Frame size, which depends on the Register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. Min. Frame Size = ((4 x fp) + (3 x fr)) / (n x fr) fp = Protocol Clock Frequency fr = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by (PBR x BR) / (1 + DBR) The minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'f_p' can be equal to, less than or greater than 'f_r' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register.
5 CPOL	Clock Polarity. (Master and Slave mode) Selects the inactive state of the Serial Communications Clock (SCK). Devices must have identical clock polarities for successful communication between serial devices. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, this bit is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First. Specifies whether the LSB or MSB of the frame is transferred first. In TSB mode, this bit should comply with the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8–9 PCSSCK	PCS to SCK Delay Prescaler. Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for calculating the PCS to SCK Delay. Refer to PCS to SCK delay (t_{CSC}) for more details. In TSB mode, PCSSCK has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10–11 PASC	After SCK Delay Prescaler. Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for calculating the After SCK Delay. Refer to After SCK delay (t_{ASC}) for more details. In TSB mode, PASC has no effect. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler. (Master mode only) Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In TSB mode, the PDT field defines two MSB bits of the Delay after Transfer. See the DT field description for calculating the Delay after Transfer. Refer to Delay after transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
14–15 PBR	Baud Rate Prescaler. (Master mode only) Selects the prescaler value for the baud rate. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for calculating the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16–19 CSSCK	PCS to SCK Delay Scaler. (Master mode only) Selects the scaler value for the PCS to SCK delay. PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period calculated by: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$ Table 49-3 lists the delay scaler values. Refer to PCS to SCK delay (t_{CSC}) for more details. In TSB mode, the field has no effect.
20–23 ASC	After SCK Delay Scaler. (Master mode only) Selects the scaler value for the After SCK Delay.

Table continues on the next page...

DSPI_CTAR*n* field descriptions (continued)

Field	Description
	The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period calculated by: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer to After SCK delay (t_{ASC}) for more details.
24–27 DT	Delay After Transfer Scaler (Master mode only) Selects the Delay after Transfer Scaler. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period. The Delay after Transfer is a multiple of the protocol clock period calculated by: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer to PCS to SCK delay (t_{CSC}) for more details.
28–31 BR	Baud Rate Scaler. (Master mode only) Selects the scaler value for the baud rate. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is calculated by: SCK baud rate = $(f_P/PBR) \times [(1+DBR)/BR]$ Table 49-4 lists the baud rate scaler values.

49.3.4 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR_SLAVE*n*)

When the DSPI is configured as:

- SPI master – the CTAS field in the command portion of the TX FIFO entry selects which CTAR is used.
- SPI bus slave – the CTAR0 register is used.
- DSI master – the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0) selects which CTAR is used.
- DSI bus slave – the CTAR1 register is used.

In CSI Configuration, the transfer attributes are based on whether the current frame is:

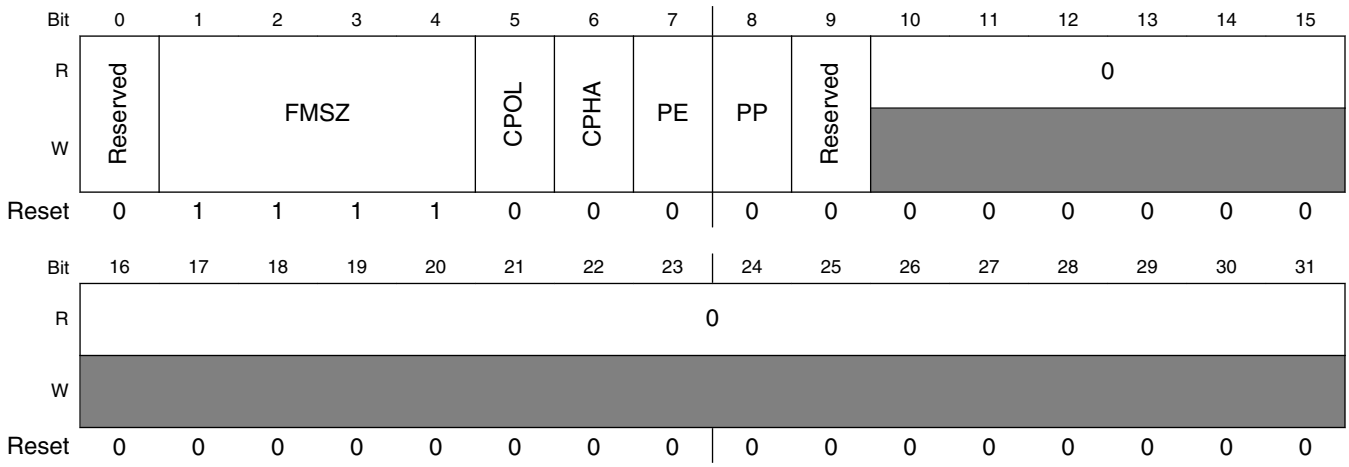
- SPI data – follow the protocol described for SPI Configuration,
- DSI data – follow the protocol described for DSI Configuration.

CSI Configuration is valid only in master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks via PDT and DT fields.

Address: 0h base + Ch offset + (4d × i), where i=0d to 1d



DSPI_CTAR_SLAVE*n* field descriptions

Field	Description
0 Reserved	This field is reserved. Always write the reset value to this field.
1–4 FMSZ	Frame Size - The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode. (Master and Slave mode) Selects which edge of SCK causes data to change and which edge causes data to be captured. Devices must have identical clock phase settings for successful communication between serial devices. In Continuous SCK or TSB modes, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame.

Table continues on the next page...

DSPI_CTAR_SLAVE*n* field descriptions (continued)

Field	Description
	0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 Reserved	This field is reserved.
10–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.5 DSPI Status Register (DSPI_SR)

The status register contains DSPI status bits and interrupt/DMA request event flag bits.

Software can clear most of the flag bits in the SR by writing a ‘1’ to them (w1c). Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DSPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag. Indicates that all bits in a frame have been shifted out. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status. Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2 SPITCF	SPI Frame Transfer Complete Flag. Similar to TCF but only asserted on SPI frame transmission completion in CSI Mode This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag. Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
4 TFUF	Transmit FIFO Underflow Flag. Indicates an underflow condition in the TX FIFO. Transmit underflow is detected only for DSPI blocks in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. Similar to TCF but only asserted on DSI frame transmission completion in CSI Mode.

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
	This includes ITSB and 'TSB in CSI' modes, but not SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag. This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. See Command First In First Out (CMD FIFO) buffering mechanism.. This bit is valid only when DSPI_MCR[XSPI] is enabled. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag. Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9 DPEF	DSI Parity Error Flag. Indicates that a DSI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.
10 SPEF	SPI Parity Error Flag. Indicates that a SPI frame with parity error has been received. 0 No parity error. 1 Parity error has occurred.
11 DDIF	DSI Data Received with Active Bits. Indicates that a DSI frame has been received with bits selected by DIMR with active polarity, defined by the DPIR. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.

Table continues on the next page...

DSPI_SR field descriptions (continued)

Field	Description
12 RFOF	Receive FIFO Overflow Flag. Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Transmit FIFO Invalid Write Flag. Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag. Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag. Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a ‘1’ to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16–19 TXCTR	TX FIFO Counter. Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer. Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter. Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer. Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

49.3.6 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER)

The DSPI_RSER controls DMA and interrupt requests.

Do not write to the RSER while the DSPI is in the Running state.

Address: 0h base + 30h offset = 30h

DSPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable. Enables TCF flag in the SR to generate an interrupt request. 0 Disabled. 1 Enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable. Enables the CMDFFF flag in the Status register to generate a request. DSPIx_RSER[CMDFFF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. Enables SPITCF flag in the Status register to generate an interrupt request. 0 Disabled. 1 Enabled.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the status register to generate an interrupt request.

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	0 Disabled. 1 Enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. Enables DSITCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the status register to generate a request. DSPIx_RSER[TFFF_DIRS] toggles between either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. DSPIx_SR[TFFF] flag and DSPIx_RSER[TFFF_RE] must be set. 0 Interrupt requests. 1 DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the status register to generate an interrupt requests. 0 Disabled. 1 Enabled.
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the status register to generate an interrupt request.

Table continues on the next page...

DSPI_RSER field descriptions (continued)

Field	Description
	0 Disabled. 1 Enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the status register to generate an interrupt request. 0 Disabled. 1 Enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the status register to generate a request. DSPIxRSER[RFDF_DIRS] toggles either an interrupt or a DMA request. 0 Disabled. 1 Enabled.
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPIx_SR[RFDF] flag and DSPIx_RSER[RFDF_RE] must be set. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO FIll DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPIx_SR[CMDFFF] flag and DSPIx_RSER[CMDFFF_RE] must be set. 0 Interrupt request. 1 DMA request.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. DSPIx_SR[DDIF] flag and DSPIx_RSER[DDIF_RE] must be set. 0 Interrupt request. 1 DMA request.
18–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

49.3.7 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO.

Data written to this register is transferred to:

- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.
- The CMD FIFO for writes to the Command field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command Field of PUSHR is reserved.

When Extended SPI Mode is not enabled (MCR[XSPI] = 0):

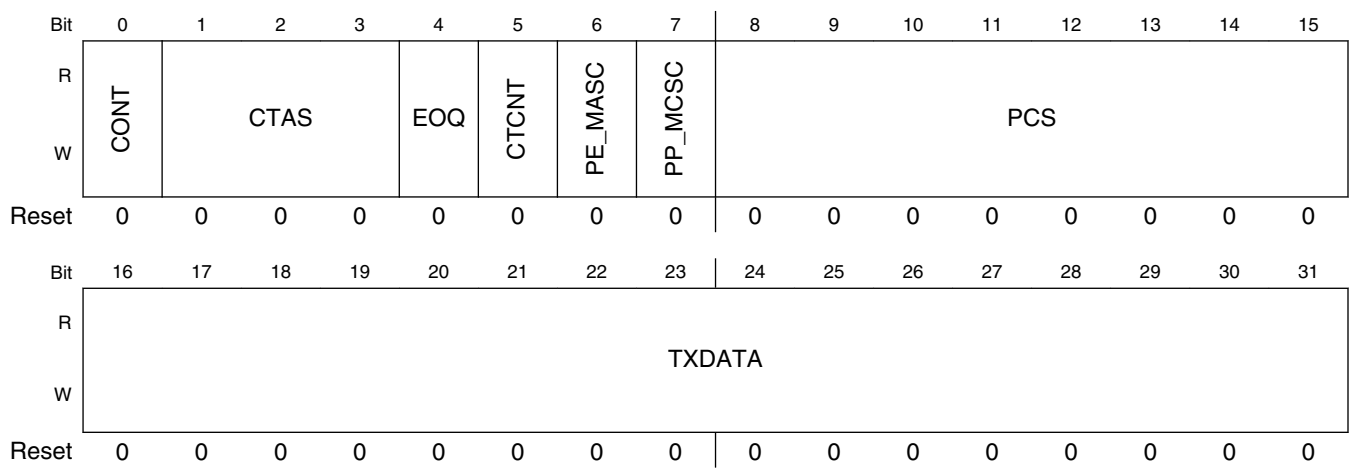
- TX FIFO and CMD FIFO must be filled simultaneously.
- Writes must be given to both Data and Command fields of PUSHR for every PUSHR operation.
- TX FIFO and CMD FIFO can be considered a single 32-bit FIFO.

When Extended SPI Mode is enabled (MCR[XSPI] = 1):

- TX FIFO and CMD FIFO can be written independently.
- A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register do not update the FIFO. Reads during Module disable mode return the last PUSHR write performed when Module was enabled.

Address: 0h base + 34h offset = 34h



DSPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable. (SPI master mode) Continuous Selection Format enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame as EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select. Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
	In SPI slave mode, CTAR0 is used. See the Device Configuration chapter to determine how many CTARs this device has. Do not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. DSPIx_SR[EOQF] is set at the end of the transfer, . 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter. Clears the SPI_TCNT field in the Transfer Count register. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame causes this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE: This bit enables parity bit transmission and parity reception check for the SPI frame. MASC: The current frame has the "after SCK" delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE: No parity bit included/checked. MASC: t_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE: Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC: t_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP: controls the polarity of the parity bit transmitted and checked. MCSC: The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP: Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame.

Table continues on the next page...

DSPI_PUSHR field descriptions (continued)

Field	Description
	MCSC: t_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP: Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC: t_{CSC} delay is masked in the next frame.
8–15 PCS	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command

49.3.8 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO.

Data written to this register is transferred to:

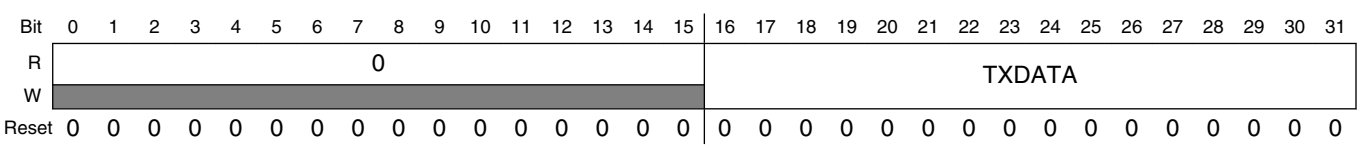
- The TX FIFO for 8- or 16-bit writes to the Data field of PUSHR.

In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO.

In slave mode, CMD FIFO is unused and the 16-bit Command field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Address: 0h base + 34h offset = 34h



DSPI_PUSHR_SLAVE field descriptions

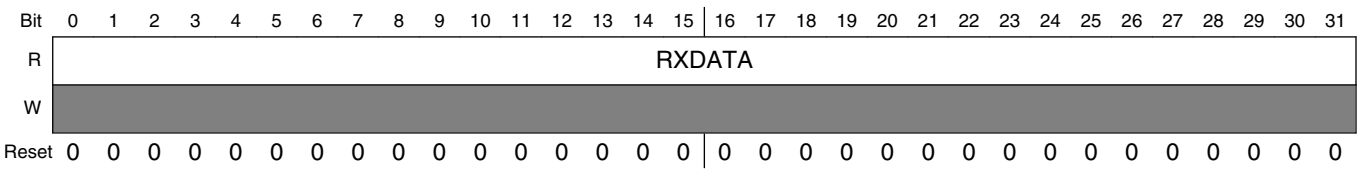
Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred.

49.3.9 DSPI POP FIFO Register (DSPI_POPR)

POPR is used to read the RX FIFO.

8- or 16-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register generates a Transfer Error.

Address: 0h base + 38h offset = 38h



DSPI_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

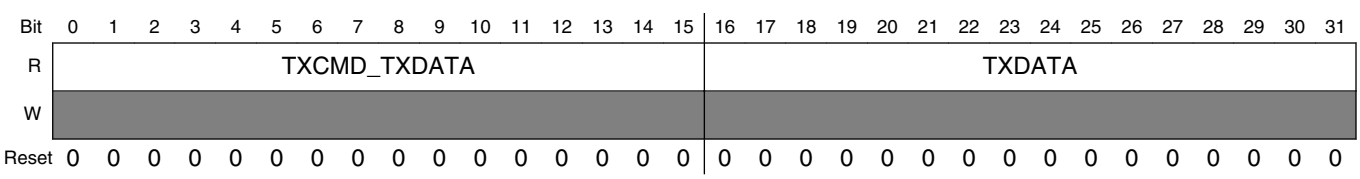
49.3.10 DSPI Transmit FIFO Registers (DSPI_TXFR*n*)

TXFRn provide visibility into the TX FIFO for debugging purposes.

Each read-only register is an entry in the TX FIFO. Reading the TXFRn registers does not alter the state of the TX FIFO.

Reading DSPIx_TXFRn registers is invalid for a DSPI Master when used in Extended SPI (XSPI) mode.

Address: 0h base + 3Ch offset + (4d × i), where i=0d to 3d



DSPI_TXFR*n* field descriptions

Field	Description
0–15 TXCMD_ TXDATA	Transmit Command or Transmit Data In master mode, the TXCMD field sets the transfer attributes for the SPI data. In slave mode, the TXDATA contains 16 MSB bits of the SPI data to be shifted out.
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

49.3.11 DSPI Receive FIFO Registers (DSPI_RXFR*n*)

RXFRn provide visibility into the RX FIFO for debugging purposes.

Each read-only register is an entry in the RX FIFO. Reading the RXFRn registers does not alter the state of the RX FIFO.

MCR[MDIS] must be 0 when RXFR is read.

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 3d

DSPI_DSICR0 field descriptions

Field	Description
0 Reserved	This field is reserved.
1 FMSZ4	MSB of the frame size in master mode when DSI is used in 32-bit mode. If the bit is set, 16 is added to the frame size, as defined by the CTARn[FMSZ] field. The CTARx register is selected by the DSICTAS field.
2–7 Reserved	This field is reserved.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved.
10 ITSB	Interleaved TSB mode. Enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are sent when either the previous transmission was an SPI frame or the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. ITSB mode requires DSICR0[TSBC] set and should be written only when MCR[HALT] is asserted. If ITSB bit is set without setting DSICR0[TSBC], DSPI operates in Normal Mode depending on MCR[DCONF] bit. See Interleaved TSB (ITSB) Mode for more details. 0 Disabled. 1 Enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows up to 64-bit data to be used. It also allows t_{DT} to be programmable. 0 Disabled. 1 Enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either: a) data from host software written to the DSPI DSI Alternate Serialization Data Register (ASDR1/0), or b) parallel input pin states latched into the DSPI DSI Serialization Data Register (SDR1/0). 0 SDR source. 1 ASDR source.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
14 Reserved	This field is reserved.
15 CID	Change In Data Transfer Enable

Table continues on the next page...

DSPI_DSICR0 field descriptions (continued)

Field	Description
	When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out. Do not enable CID when DCONT is enabled. 0 Disabled. 1 Enabled.
16 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. When the TSBC bit is set, DCONT has no effect. Do not enable DCONT when CID is enabled. 0 PCS signals return to inactive. 1 PCS signals remain asserted.
17–19 DSICTAS	DSI Clock and Transfer Attributes Select (DSI Master mode only) Selects the CTAR which provides transfer attributes for DSI frames. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop Stops DSI frame transmissions if DDIF flag is set in the status register. 0 Disabled. 1 Enabled.
21 PES	Parity Error Stop Stops DSI operation if a parity error occurred in the received DSI frame. 0 Disabled. 1 Enabled.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24–31 DPCSx	DSI Peripheral Chip Select 0-7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

49.3.13 DSPI DSI Serialization Data Register 0 (DSPI_SDR0)

Read-only SDR0 contains the states of the 32 LSB parallel input signals.

The states of these signals are latched into the SDR0 on the rising edge of every protocol clock.

When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_SDR0 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals.

49.3.14 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized.

When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames.

Writes to the ASDR0 take effect on the next frame boundary.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_DSICR1 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 TSBCNT	Timed Serial Bus Operation Count TSBCNT defines the length of the data frame When TSBC is set. The length value can vary from 3 to 31 (00011b to 11111b). The length value specifies the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 DSE1	Data Select Enable 1 When DSICR0[TBSC] bit is set, the DSE1 bit enables insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. The TSBCNT field value must be greater than the FMSZ field value plus one for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When DSICR0[TSBC] bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the Data frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16–23 TRGPRD	Internal Trigger Period for the ITSB mode. When DSICR0[TRG] bit is cleared and ITSB Mode is enabled, this field determines the trigger period for the internal trigger in number of baud rate clock cycles. The trigger period should be calculated as:

Table continues on the next page...

DSPI_DSICR1 field descriptions (continued)

Field	Description
	Trigger Period = 32 bits (DSI frame maximum size) + 2 selection bits (maximum) + t_{PF} (passive frame time) Refer CTAR[FMSZ] field for minimum frame size allowed. See Interleaved TSB (ITSB) Mode for more details. 0 - 4 These values are invalid since minimum Command frame size is 5. (i.e. 1 selection bit + minimum frame size which is 4) 5 - 255 Number of baud rate clock cycles to be used as the trigger period. The trigger period implemented is equal to TRGPRD + 1.
24–31 DPCS1_x	DSI Peripheral Chip Select 0-7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

49.3.18 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0.

Each bit in the SSR0 register selects a corresponding bit to be serialized.

When DSICR0[TXSS] is set, the SSR0 register value has no effect.

Address: 0h base + D4h offset = D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DSPI_DIMR0 field descriptions

Field	Description
0–31 MASK	Mask 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame produces a DDI interrupt if the data bit matches the configured polarity.

49.3.20 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0)

DPIR0 defines which data bit value in the 32 LSB of received DSI frame generates the DDI interrupt.

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DP

DSPI_DPIR0 field descriptions

Field	Description
0–31 DP	Data Polarity 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

49.3.21 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*)

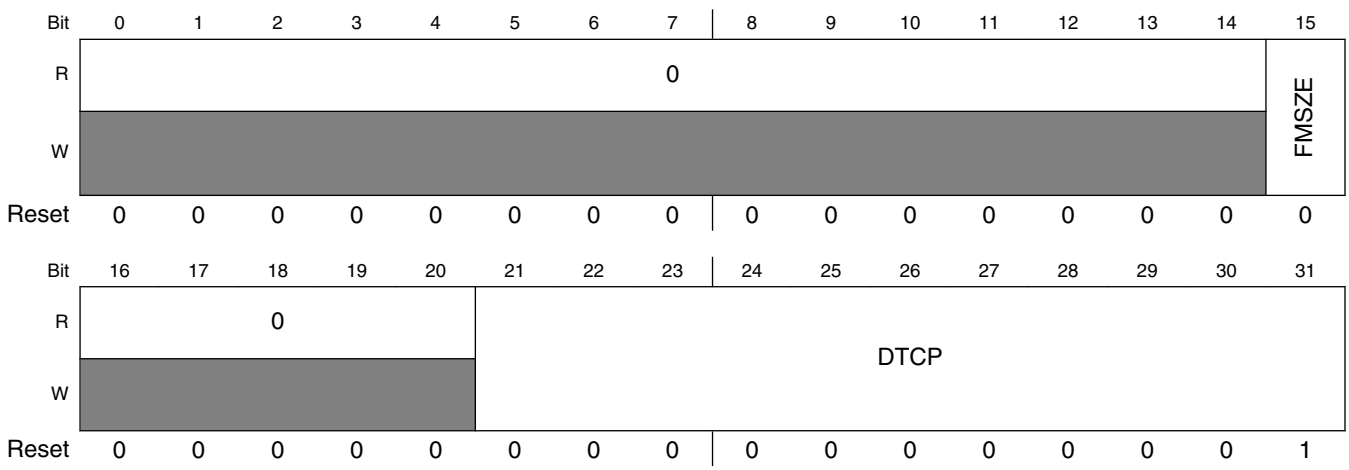
CTARE registers are used to define the extended transfer attributes for an SPI frame.

These registers are valid only when DSPIx_MCR[XSPI] is set.

When the DSPI is configured as:

- an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.
- an SPI bus slave, the CTARE0 register is used.

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 7d



DSPI_CTARE*n* field descriptions

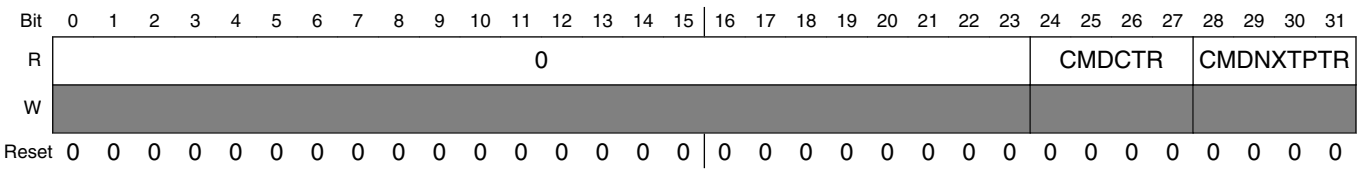
Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 FMSZE	Frame Size Extended This field concatenated with DSPIx_CTAR[FMSZ] defines the frame size of the SPI frames to be transmitted. Frame size is the concatenation of {DSPIx_CTAR[FMSZ], DSPIx_CTARE[FMSZE]} + 1. 0 Default Mode. Up to 16-bit SPI frames can be transferred. 1 Up to 32-bit SPI frames can be transferred. Each frame transfer is a result of 2 TX FIFO Pops.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 DTCP	Data Transfer Count Preload This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame that selected this DSPIx_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

49.3.22 DSPI Status Register Extended (DSPI_SREX)

The DSPIx_SREX contains status fields that reflect the DSPI status and indicate the occurrence of events.

This register is not writable.

Address: 0h base + 13Ch offset = 13Ch



DSPI_SREX field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28–31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

49.4 Register classification for safety

The registers of this module are classified as per safety requirements as follows:

Safety Critical: There are no safety critical registers in this module.

Safety Relevant: The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU. The registers containing these fields must be protected by periodic CRC or equivalent check implemented at chip level. The following register bits/fields are classified in this category:

- DSPI Module Configuration Register (DSPIx_MCR)
- DSPI Transfer Count Register (DSPIx_TCR)

- DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPIx_CTARn)
- DSPI Clock and Transfer Attributes Extended Register (In Master Mode) (DSPIx_CTAREn)
- DSPI DMA/Interrupt Request Select and Enable Register (DSPIx_RSER)
- DSPI PUSH FIFO Register In Master Mode (DSPIx_PUSHR) [0:15]
- DSPI DSI Configuration Register 0 (DSPIx_DSICR0)
- DSPI DSI Configuration Register 1 (DSPIx_DSICR1)

Safety Latent: The register bits/fields in this category should be protected by LBIST at chip level. The following register bits/fields are classified in this category:

- DSPI Status Register (DSPIx_SR) [0:15] (for stuck at 0)
- DSPI Status Register Extended (DSPIx_SREX) [0:8] (for stuck at 0)
- DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPIx_DIMR0)
- DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPIx_DIMR1)
- DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPIx_DPIR0)
- DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPIx_DPIR1)

Non-Safety: All other registers and bits fall in this category.

49.5 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations:

- SPI Configuration in which the DSPI operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes and deserializes Parallel Input/ Output signals or bits from memory-mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI Configuration. See DSPI Module Configuration Register (DSPI_MCR) for the DSPI configuration values.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows CTAR selection on a frame by frame basis by setting a field in the SPI command. Extended SPI Mode (DSPIx_MCR[XSPI]) further allows the usage of CTAREn (CTARn Extended) registers to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates which CTAR is used for the data transfer.

See DSPI Clock and Transfer Attributes Registers for information on the fields of the CTARs.

See DSPI Clock and Transfer Attributes Registers Extended for information on the fields of the CTARE registers.

Typical master to slave connections are shown in the following figure.

When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave: the data that was in the master shift register is now in the shift register of the slave, and vice versa.

At the end of a transfer, the TCF bit in the Status Register is set to indicate a completed transfer.

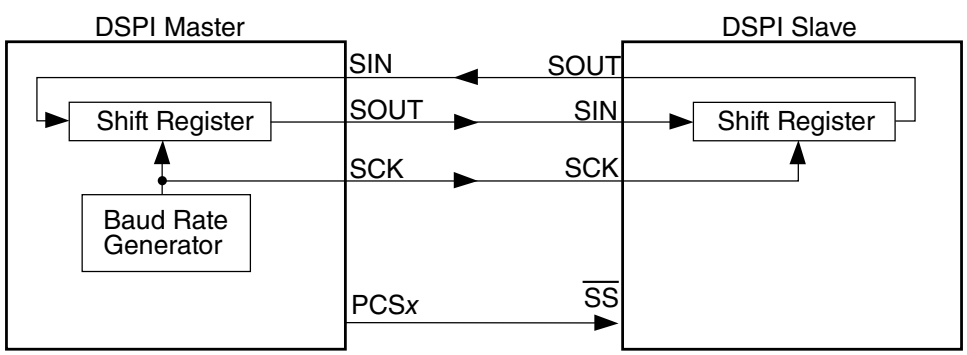


Figure 49-3. SPI serial protocol overview

Generally, more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in Transfer formats.

The transfer rate and delay settings are described in DSPI baud rate and clock delay generation.

49.5.1 Start and Stop of DSPI transfers

The DSPI has two operating states that are independent of DSPI configuration:

- STOPPED is the default DSPI state: no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results.
- RUNNING is the state when serial transfers take place.

DSPIx_SR[TXRXS] indicates what state the DSPI in (‘1’ = RUNNING state).

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

49.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The SPI frames can be 32 bits long.

The DSPI is in SPI Configuration when the DCONF field in the MCR is 0b00.

The host CPU or a DMA controller transfers the SPI data from memory external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer.

Received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI.

The FIFO buffers operation is described in Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) buffering mechanism and Receive First In First Out (RX FIFO) Buffering Mechanism. The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI Configuration supports two block-specific modes:

- Master mode: the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry.
- Slave mode: the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

49.5.2.1 Master mode

In SPI Master mode, the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals.

The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields.

The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin.

In SPI Master mode, each SPI frame to be transmitted has a command associated with it for transfer attribute control on a frame-by-frame basis.

In Extended SPI Master mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. Extended SPI Mode allows for larger frame sizes of up to 32 bits.

49.5.2.2 Slave mode

In SPI slave mode, the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers.

Certain transfer attributes such as clock polarity, clock phase and frame size must be set in CTAR0 and CTARE0 for successful communication with an SPI master. The data is shifted out with MSB first; shifting out of LSB is not supported in this mode.

49.5.2.3 FIFO Disable operation

The FIFO Disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO.

The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled.

The Transmit and Receive side of the FIFOs are disabled separately:

- MCR[DIS_TXF] disables TX FIFO and CMD FIFO.
  - TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in the status register and the extended status register behave as if there is a one-entry FIFO.
  - The contents of the TXFR registers and TXNXTPTR and CMDNXTPTR are undefined.
- MCR[DIS_RXF] bit disables the RX FIFO.
  - The RFDF, RFOF and RXCTR fields in the status register behave as if there is a one-entry FIFO.
  - The contents of the RXFR registers and POPNXTPTR are undefined.

The FIFO Disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

49.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission.

The TX FIFO holds 4 words, each consisting of SPI data that is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR).

The number of entries in the TX FIFO is device-specific.

TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. This field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFRn Registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

49.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set.

When TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete, the TFFF bit is cleared. Writing a ‘1’ to the TFFF bit also clears it. The DSPI ignores attempts to push data to a full TX FIFO; the state of the TX FIFO does not change and no error condition is indicated.

The TFFF can generate a DMA request or an interrupt request. See Transmit FIFO Fill interrupt or DMA request for details.

49.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled and the frame size of SPI Data to be transmitted is more than 16 bits, then two Data entries are popped from TX FIFO simultaneously and transferred to the shift register. The first of the two popped entries forms the 16 LSB bits of the SPI frame. Such an operation also causes TX FIFO Counter to decrement by two.

At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a ‘1’ to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave’s DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave’s SR is set. See Transmit FIFO Underflow interrupt request for details.

49.5.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific.

SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is disabled:

- The TX FIFO and CMD FIFO must be filled together as every CMDFIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled:

- The TX FIFO and CMD FIFO can be filled independently as every CMDFIFO entry can have multiple TXFIFO entries attached to it.
- The CTARE[DTCP] field decides the number of SPI Data Frames of size {FMSZE, FMSZ} to be transmitted using the current Command Entry. FMSZ and FMSZE fields are given in the CTAR/CTARE registers respectively, pointed by the CTAS field in the Command frame.
- The amount of time a command entry is in use is known as a Command Cycle. The Busy flag DSPIx_SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO entry is used during the next command cycle. This field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

The TXFRn Registers are invalid in Extended SPI Mode as TX FIFO and CMD FIFO are used separately.

49.5.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin.

The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific.

SPI data is added to the RX FIFO on completion of a transfer when the received data in the shift register is transferred into the RX FIFO.

SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the status register points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

49.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register.

While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the status register is set to indicating an overflow condition. Consequently:

- If the DSPIx_MCR[ROOE] bit is set, the incoming data is shifted in to the shift register.
- If the DSPIx_MCR[ROOE] bit is cleared, the incoming data is ignored.

49.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one.

Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data read from the empty RX FIFO is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the status register is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete, or by writing a '1' to it.

49.5.3 Deserial Serial Interface (DSI) configuration

The DSI Configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in Transfer formats. The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI_DDR. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR1/0).

The DSI frames can be from 4 to 32 bits.

49.5.3.1 DSI master mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions (described in DSI transfer initiation control) that can initiate a transfer:

- Continuous.
- Change in data.
- Trigger signal.
- Trigger signal combined with a change in data.

Transfer attributes are set during initialization. DSICR0[DSICTAS] field determines which of the DSPI_CTARs will control the transfer attributes.

49.5.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers.

Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1.

The data is shifted out with MSB first.

49.5.3.3 DSI serialization

In the DSI Configuration, up to 32 bits can be serialized using two different sources. The TXSS bit in the DSPI_DSICR0 selects between the DSPI DSI Serialization Data Register (DSPI_SDR0) and the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0) as the source of the serialized data. The DSPI_SDR0 holds the latest 32 parallel input signal values which is sampled at every rising edge of the Bus clock. The DSPI_ASDR0 register is written by host software and used as an alternate source of serialized data.

The DSPI has to sample the inputs (from SDR0 or ASDR0) before it transmits a DSI frame. Due to the asynchronous clocking structure within DSPI, the sampled data (from SDR0 or ASDR0) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.

To prevent Clock Domain Crossing issues, inputs from SDR0 or ASDR0 should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR0 inputs. The initial write performed on ASDR0 register will cause the 32-bit ASDR0 input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR0 write will again trigger this process. If there was a write performed on ASDR0 while the lock was asserted, this will be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted. In case,multiple writes were performed on ASDR0 when lock was asserted, only the latest value will be considered for synchronization once the lock gets de-asserted.

The entire process explained above is also true for the SDR0 input, the only difference being that SDR0 inputs are delayed internally by a single Bus clock (register interface clock) to detect a change in the parallel input pins.

Once the synchronization process for a particular De-serial input begins, it takes up to 5 Bus clock (register interface clock) periods and 5 Protocol clock periods before the synchronization process for the next De-serial input can begin. Hence the writes performed on ASDR0 and SDR0 are constrained with this timing.

Note

The Parallel Input pin state, to be transmitted, should be selected by TXSS or DSPI_SSR0 register and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR0 register provides additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR0 and DSPI_ASDR0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. Control field may come from DSPI_ASDR0 register, set by the device's CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Register (DSPI_COMPR0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. The following figure shows the DSI Serialization logic.

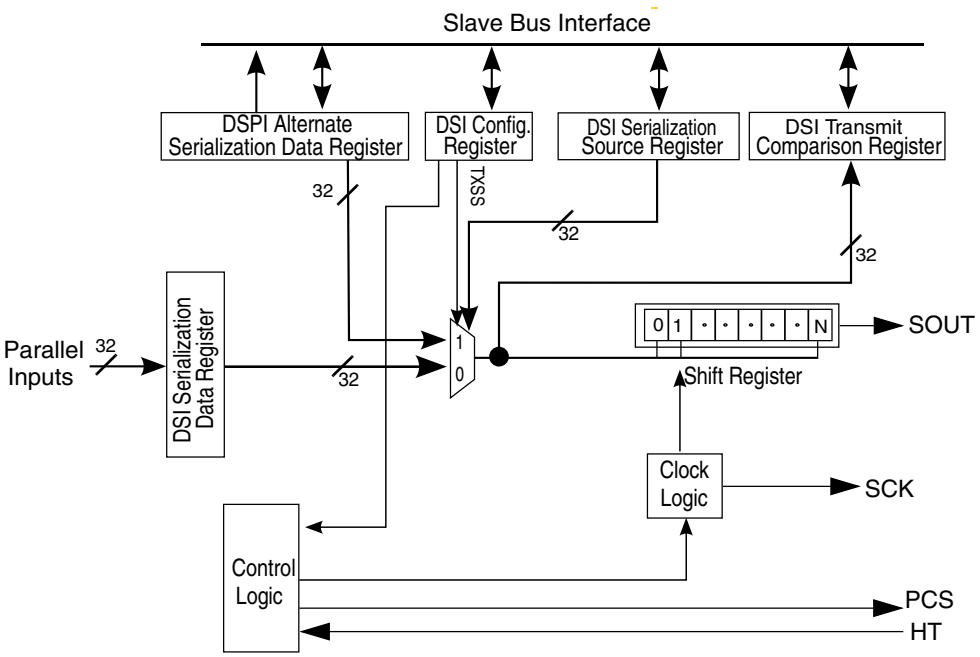

Figure 49-4. DSI serialization diagram

49.5.3.4 DSI deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR0-1). This register presents the deserialized data as Parallel Output signal values. The DSPI_DDR0-1is memory-mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR0-1), bit-wise ANDed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR0-1) and the results ORed to produce DDIF flag in the

DSPI_SR. Which in turn can cause DDIF interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] and/or stop DSI frame transmissions if DSICR0[DMS] bit is set. Figure 49-5 shows the DSI Deserialization logic.

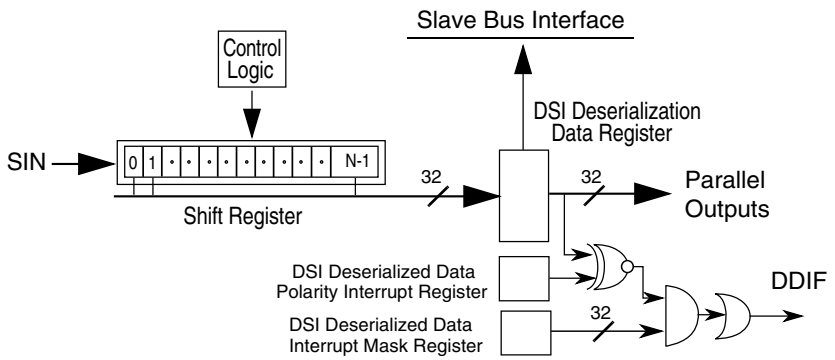

Figure 49-5. DSI deserialization diagram

49.5.3.5 DSI transfer initiation control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the CID bits in the DSPI_DSICR0 register. The following table lists the four transfer initiation conditions.

DSPI_DSICR0 bits	Transfer initiation control
CID	
0	Continuous
1	Change in Data
0	Triggered
1	Triggered or Change in Data

49.5.3.5.1 Continuous control

For continuous control, a new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

49.5.3.5.2 Change in data control

For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_COMPR0. When the data selected for the transfer from the DSPI_SDR0 and DSPI_ASDR0 registers is different from the data in the DSPI_COMPR1/0 a new DSI frame is transmitted.

49.5.3.5.3 Triggered control

For Triggered Control, initiation of a transfer is controlled by the Hardware Trigger signal (HT). DSICR0[TPOL] bit selects the active edge of HT. For HT to have any affect, DSICR0[TRRE] bit must be set.

49.5.3.5.4 Change in data or triggered control

For change in data or triggered control, initiation of a transfer is controlled by the detection of a change in data to be serialized or by the HT signal.

It is not advisable to configure a DSPI Slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1; since the following statement then holds true:

Once slave select is asserted, there is a very small window (of up to three module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occurs, the next frame to be transmitted would be loaded into the shift register. Since it is not feasible that such a write is initiated and completed within this short span of time, the data transmitted by DSPI slave would lag by one data frame.

49.5.4 Combined Serial Interface (CSI) configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis.

CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. Figure 49-6 shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

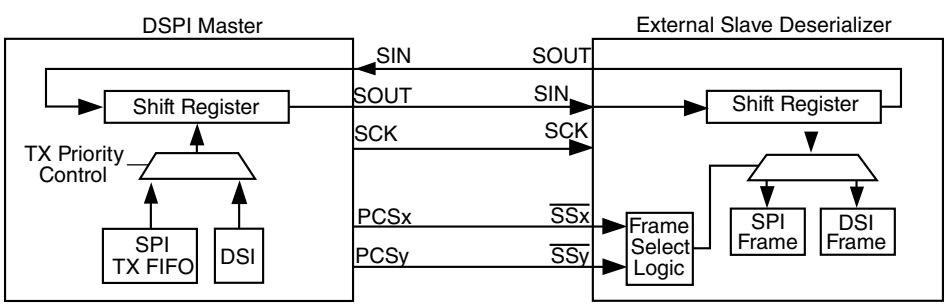

Figure 49-6. Example of System using DSPI in CSI Configuration

In CSI Configuration, the DSPI transfers DSI data based on DSI transfer initiation control. When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTARs associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy.

The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

49.5.4.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR selected by the DSICR0[DSICTAS] field.

The parallel inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR0) on the rising edge of every protocol clock and serialized based on the transfer initiation control settings in the DSPI_DSICR0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty), they have priority over DSI data and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

49.5.4.2 CSI deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred, the returned frames are deserialized and latched into the DSPI_DDR0. When SPI frames are transferred, the returned frames are deserialized and written to the RX FIFO.

49.5.5 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

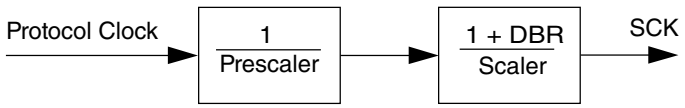

Figure 49-7. Communications clock prescalers and scalers

49.5.5.1 Baud rate generator

The baud Rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 49-5. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note

The clock frequencies mentioned in the table above are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

49.5.5.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See the following table for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTARx registers select the PCS to SCK delay by the formula in the CSSCK field description. Table 49-6 shows an example of how to compute the PCS to SCK delay.

Table 49-6. PCS to SCK delay computation example

f_P	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

Note

The clock frequency mentioned in the table above is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

49.5.5.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. See the following table for an illustration of the After SCK delay. The PASC and ASC fields in the CTARx registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 49-7. After SCK delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

Note

The clock frequency mentioned in the table above is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

49.5.5.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See the following table for an illustration of the delay after transfer. the PDT and DT fields in the CTARx registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the delay after transfer.

Table 49-8. Delay after transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

Note

The clock frequency mentioned in the table above is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode, the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on Timed Serial Bus (TSB).

49.5.5.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs, thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4]and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. Figure 49-8 shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

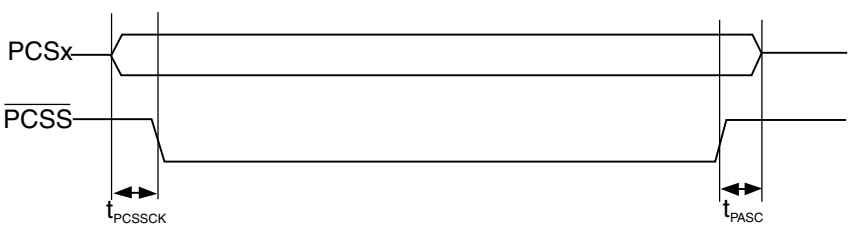

Figure 49-8. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_P} \times \text{PCSSCK}$$

Equation 22. Equation for t_{PCSSCK}

At the end of the transfer the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{PASC} = \frac{1}{f_P} \times PASC$$

Equation 23. Equation for t_{PASC}

Table 49-9 shows an example of how to compute the t_{PCSSCK} delay.

Table 49-9. Peripheral Chip Select Strobe Assert Computation Example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

Table 49-10 shows an example of how to compute the t_{PASC} delay.

Table 49-10. Peripheral Chip Select Strobe Negate Computation Example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK or TSB mode are enabled.

Note

The clock frequency mentioned in the preceding Table 49-9 and Table 49-10 is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

49.5.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL—Selects the idle state polarity of the SCK.
- CPHA—Selects if the data on SOUT is valid before or on the first SCK edge.

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

In DSI slave mode, only CTAR1 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0.
- Classic SPI with CPHA = 1.
- Modified Transfer format with CPHA = 0.
- Modified Transfer format with CPHA = 1.

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI Configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. See Continuous Selection Format for details.

49.5.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in the following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

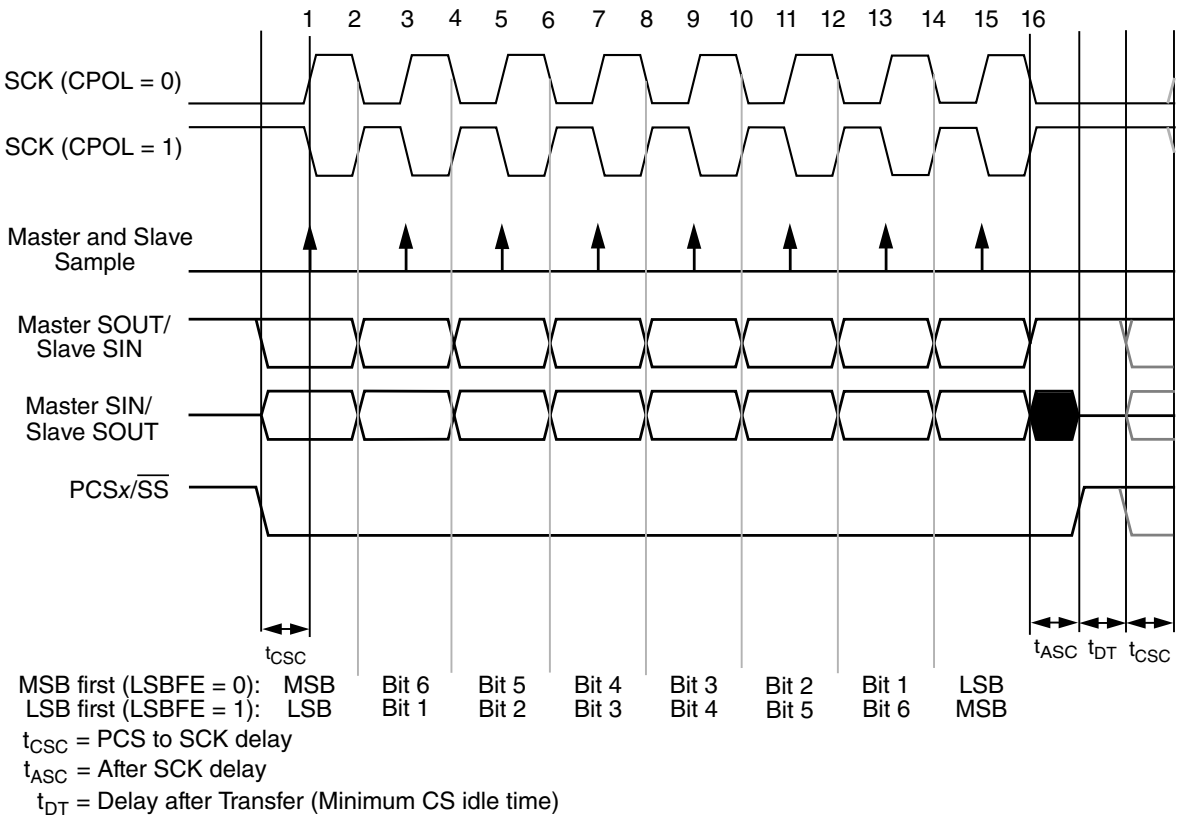

Figure 49-9. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin.

After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals.

At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals.

For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

49.5.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges

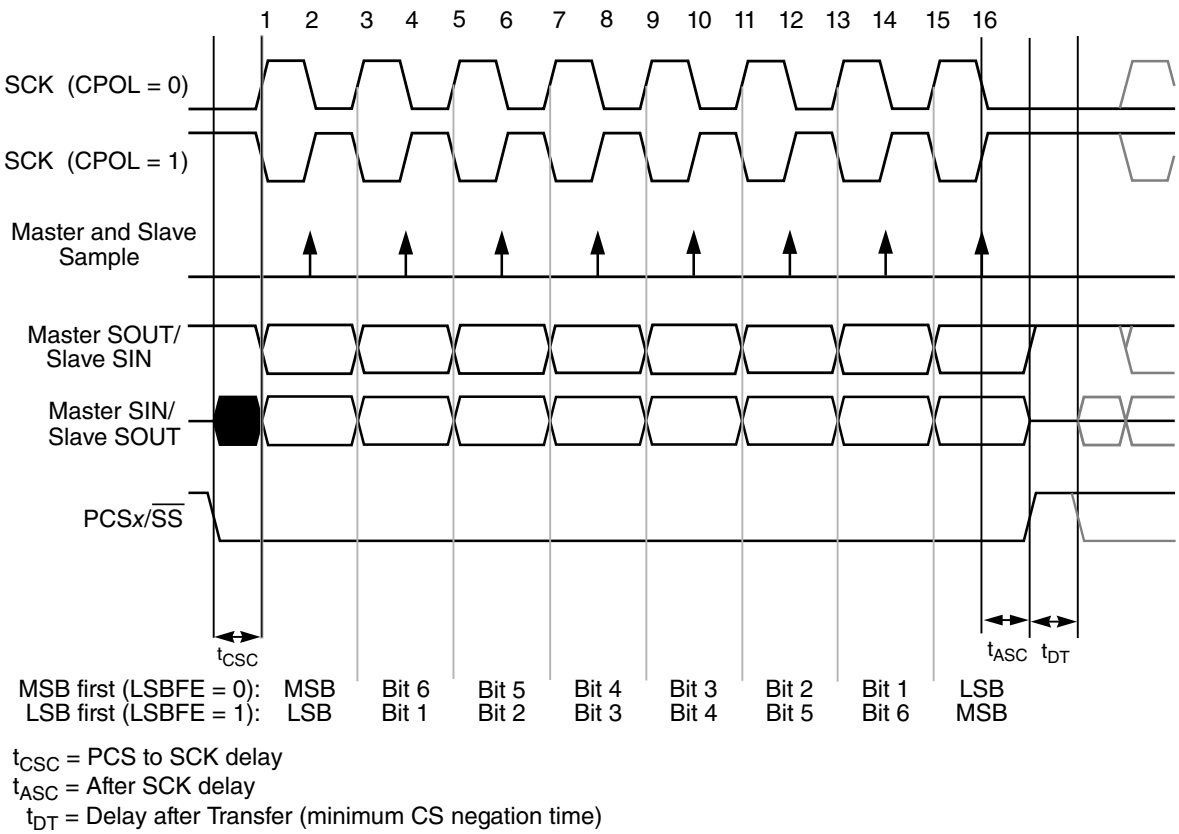

Figure 49-10. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave.

After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins.

For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges.

After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

49.5.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_s}l – data hold time on slave data input
- t_p – protocol clock period

Figure 49-11 shows the modified transfer format for CPHA = 0 and f_p/f_{sck} = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note

In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

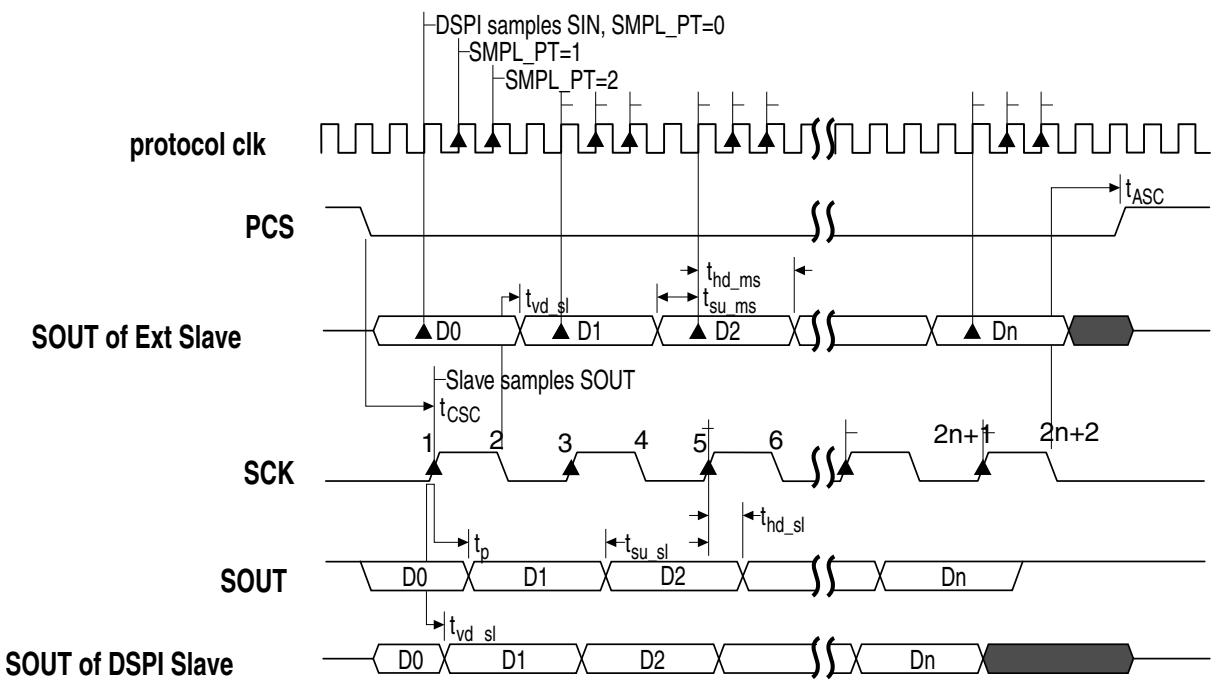

Figure 49-11. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)

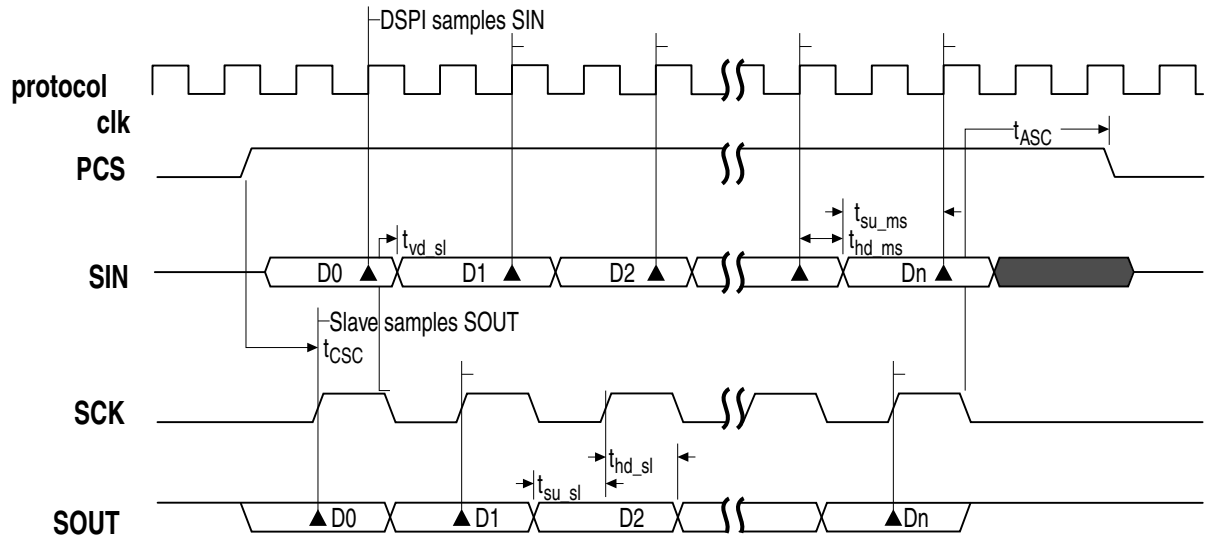

Figure 49-12. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

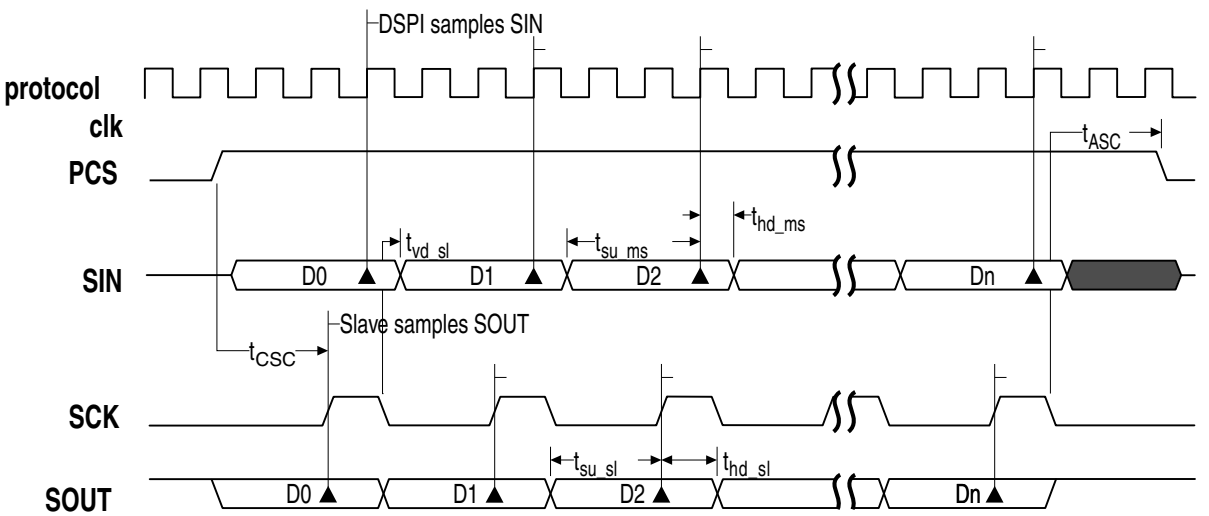

Figure 49-13. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

49.5.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT

bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The After SCK (tASC) delay must be greater or equal to half of the SCK period.**

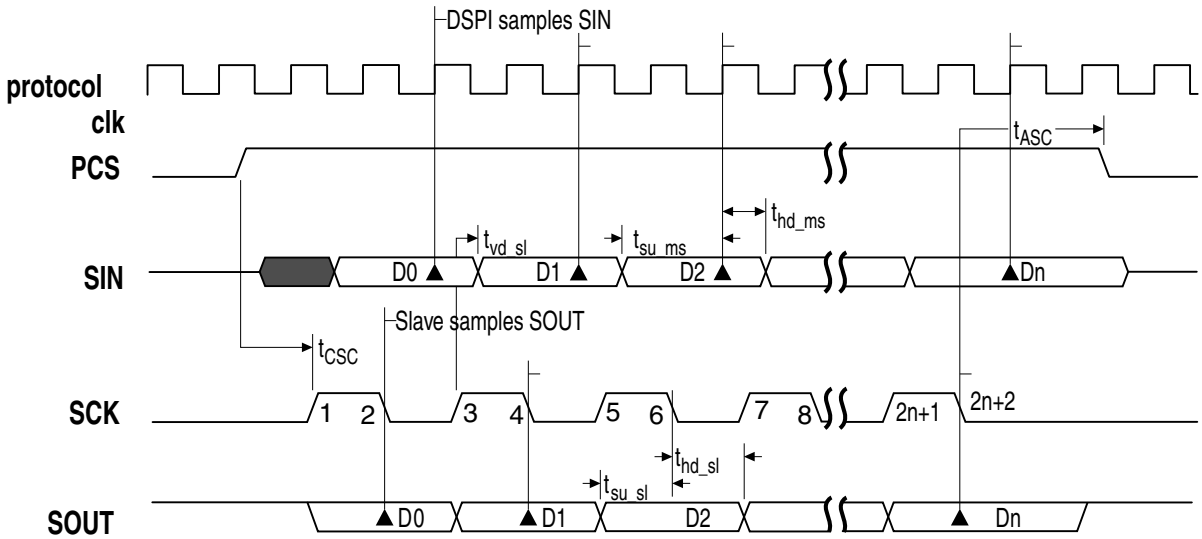

Figure 49-14. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

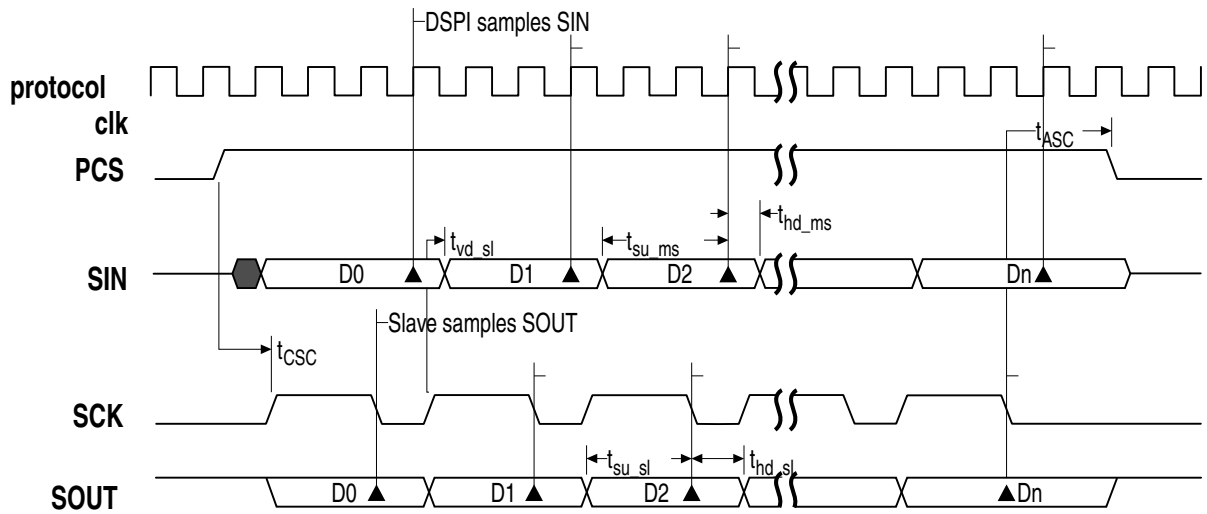

Figure 49-15. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)

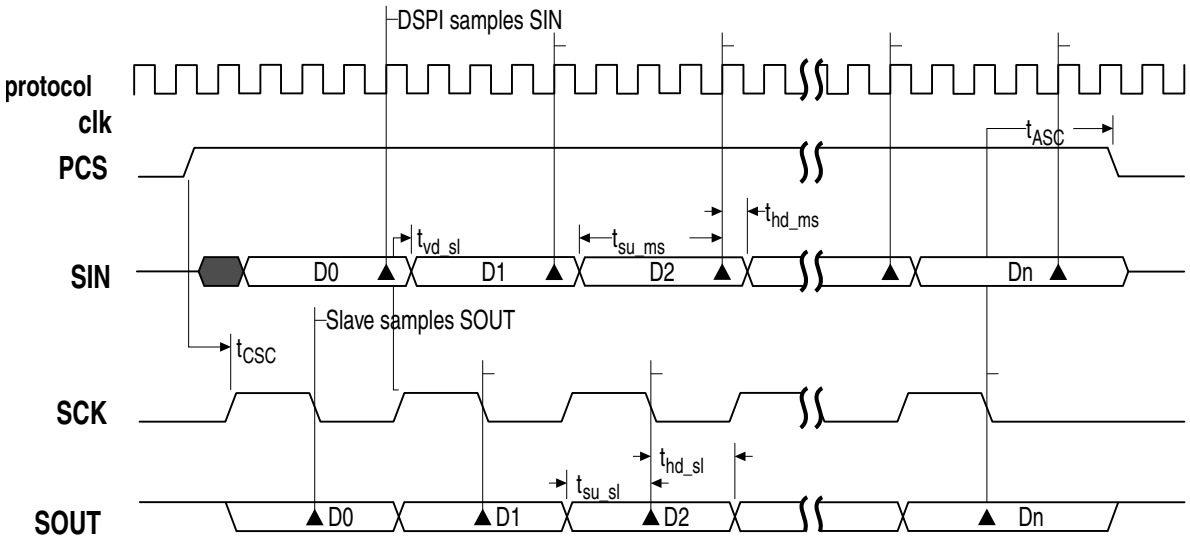

Figure 49-16. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

49.5.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI Configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.

The behavior of the PCS signals in the two configurations is identical so only SPI Configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The timing diagram in Figure 49-17 is for two four-bit transfers with CPHA = 1 and CONT = 0.

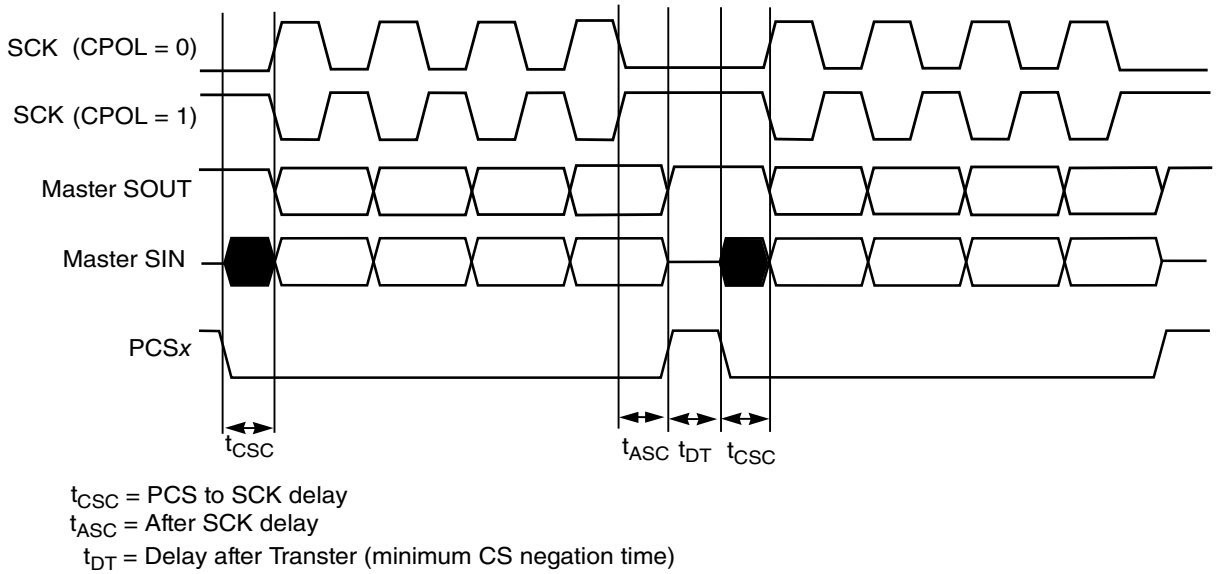

Figure 49-17. Example of non-continuous format (CPHA = 1, CONT = 0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. Figure 49-18 shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

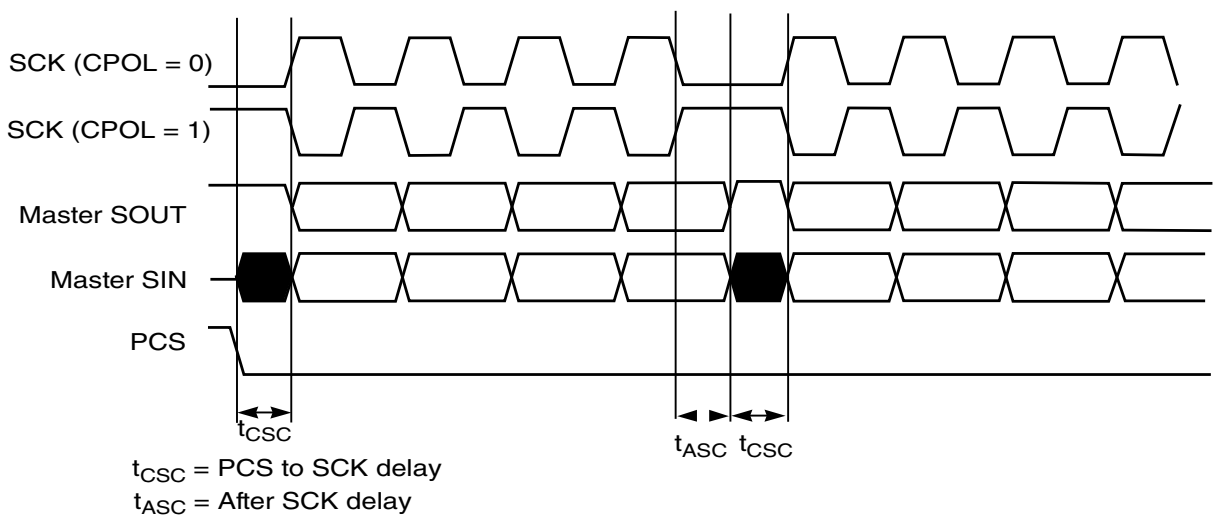

Figure 49-18. Example of continuous transfer (CPHA = 1, CONT = 1)

When using DSPI with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs selected by transmit commands must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit de-asserted (in master mode) and the user software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCSn at end of transmission of last frame.
- The PUSHR[CONT]/DSICR0[DCONT] bits must be de-asserted before asserting MCR[HALT] bit (in master mode). This ensures that the PCSn signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

Note

You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

49.5.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

Note

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing '1' into FCPCS bit of the MCR. When this bit is asserted, MASC and MCSC bits of the PUSHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the "After SCK" delay for the current frame.
- MCSC bit masks the "PCS to SCK" delay for the next frame.
- "After SCK" (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The "PCS to SCK" delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

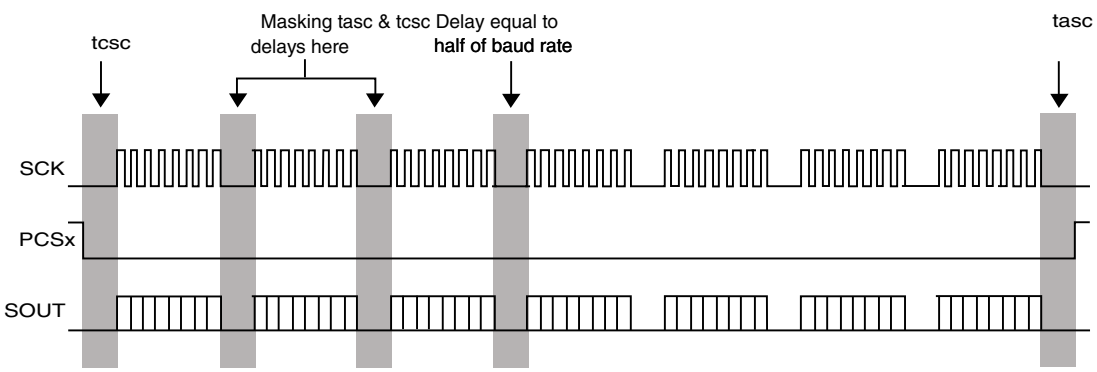

Figure 49-19. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

49.5.7 Continuous Serial Communications Clock

The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
    - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
    - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle.

When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. Figure 49-20 is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note

When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

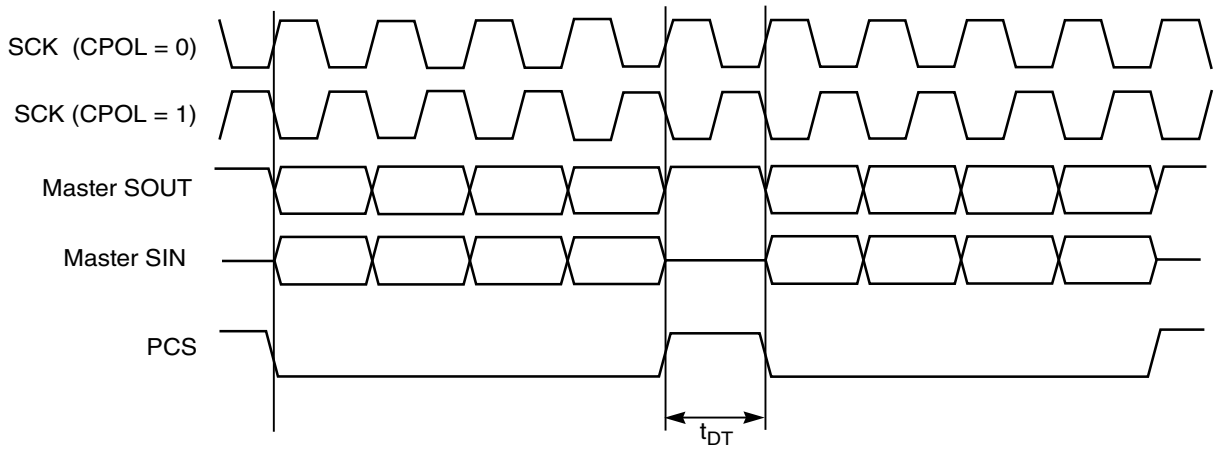

Figure 49-20. Continuous SCK timing diagram (CONT = 0)

If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to Start and Stop of DSPI transfers.
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

Figure 49-21 shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

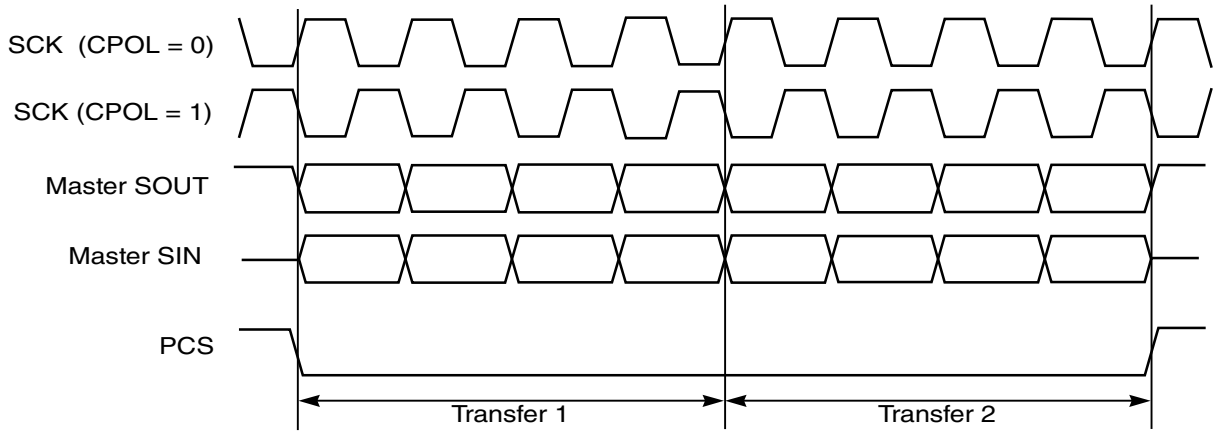

Figure 49-21. Continuous SCK Timing Diagram (CONT = 1)

49.5.8 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

49.5.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting DSICR0[TSBC] bit. See DSPI DSI Configuration Register 0 (DSPI_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the device.

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

Figure 49-22 shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 34 bits MSC data frames (4 to 32 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0), written by the host software,
- parallel input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR0).

DSPI_DSICR0 TXSS bit or DSPI_SSR0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

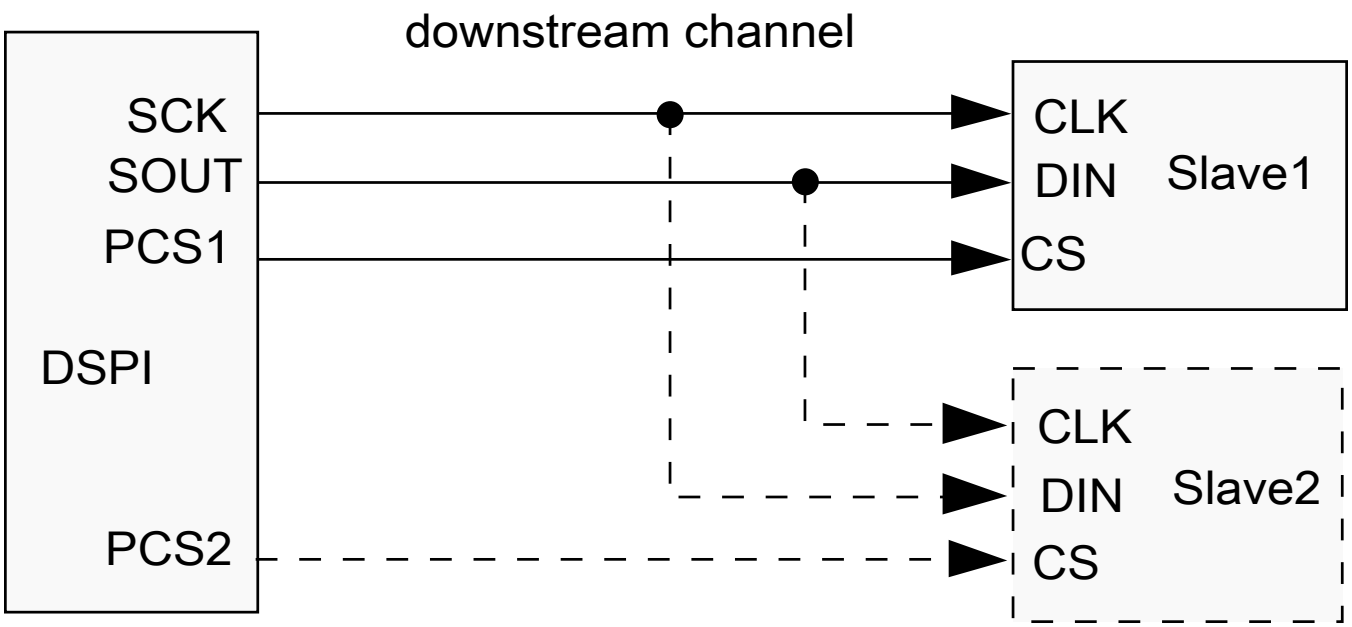

Figure 49-22. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

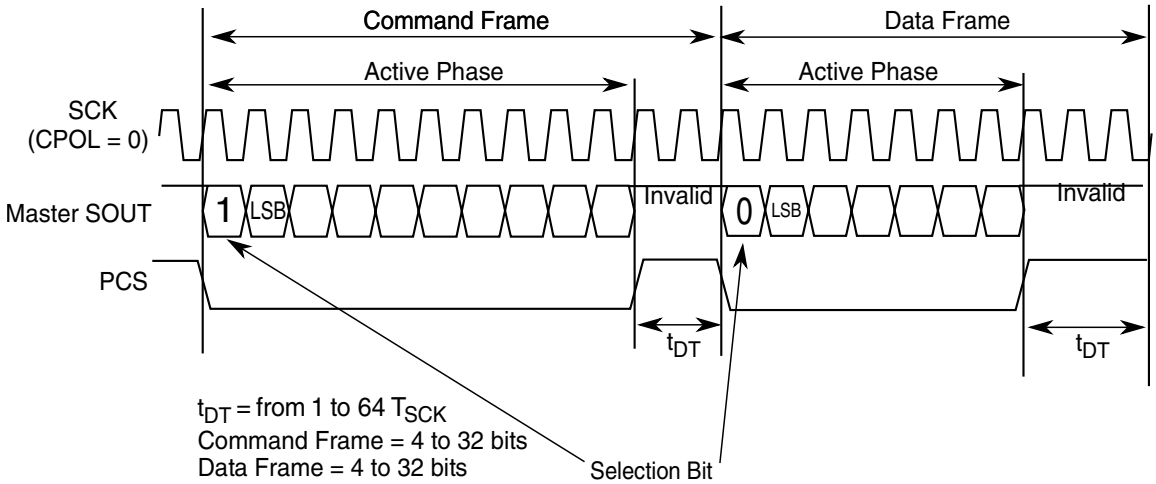

Figure 49-23. TSB Downstream Frames

The above figure shows the two types of MSC downstream frames: command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI].

The data frame consists of up to 32 bits from the SDR0 or ASDR0 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless of the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before the corresponding data subframes.

49.5.9.1 MSC Dual Receiver Support with PCS Switchover

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switchover occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register.

NOTE

When using Dual receiver support, it must be ensured that the number of bits to be transmitted to each slave must be at least 4.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCSn bits, after that by DSPI_DSICR1 DPCS1_n bits.

The PCS switchover occurs at the driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switchover if enabled.

The Data Frame with PCS switchover is shown in the following figure.

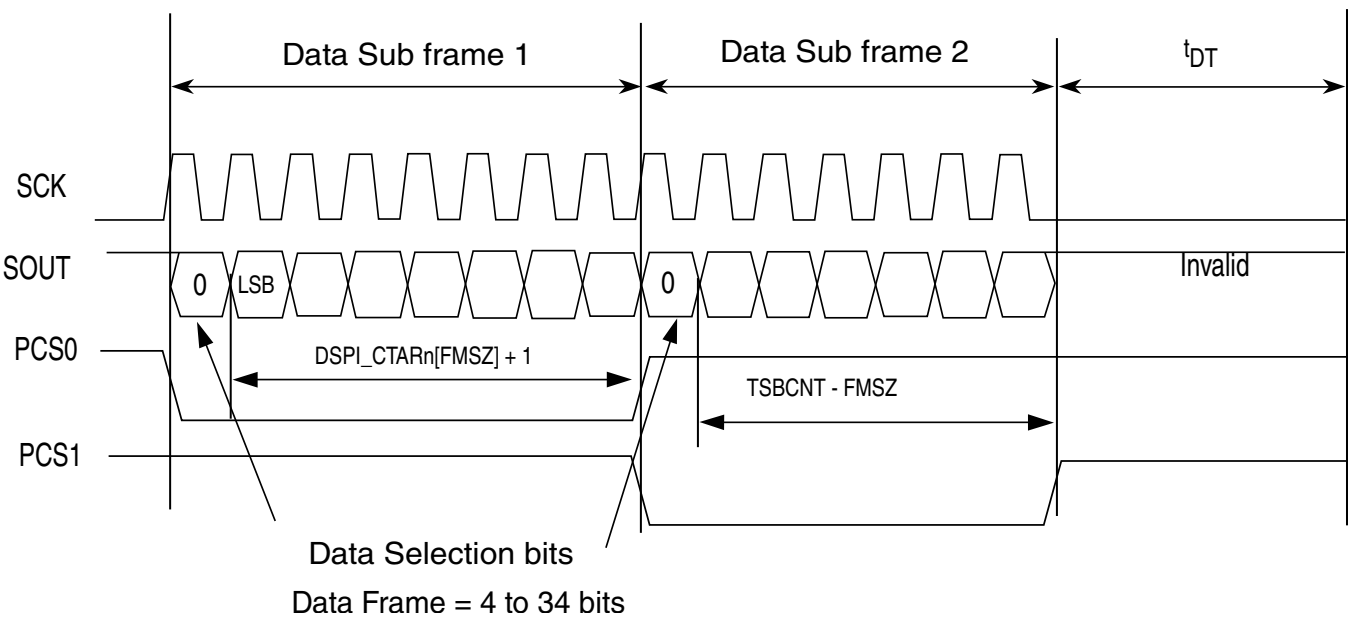

Figure 49-24. TSB Data Frame Format for MSC Dual Receiver Operation

49.5.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB in all aspects except for the differences mentioned in Table 49-11. In the Interleaved TSB or ITSB mode, frame transmission is governed by the following rules:

- Transmission of frames is executed on a periodic trigger that is generated internally to the DSPI. The trigger period is calculated as follows:
  - Trigger Period = 32 bits (maximum data frame size) + 2 selection bits (maximum bits in data frame) + t_{PT}
    - t_{PT} is the passive frame time or dead time inserted to have constant trigger period.
  - The user software shall configure the trigger period and trigger source.
- If the previously transmitted frame was a SPI frame or the TX FIFO (or CMD FIFO) is empty, the frame transmitted on subsequent trigger will always be a DSI frame.
- If the previously transmitted frame was not a SPI frame and the TX_FIFO (and CMD FIFO) is not empty, the frame transmitted on subsequent trigger will always be a SPI frame.

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) in such a way to prevent back to back SPI frames. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits cannot be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

Table 49-11 lists the differences between the TSB and ITSB modes.

Table 49-11. Differences between TSB and ITSB modes

Mode attribute	TSB mode	ITSB mode
Frame priority	Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Frame selection bit	Selection bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Frame transmission	Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Periodically triggered transmission (that is frames are transmitted continuously on every trigger).
Frame gap	Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is inserted automatically as the whole operation is based on a periodic trigger. If a frame has less than 32-bits to be transmitted, dead or passive time is automatically inserted by waiting for the next trigger pulse. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In TSB and ITSB mode, separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI. MSC dual receiver support with PCS switchover is also supported in ITSB mode. See MSC Dual Receiver Support with PCS Switchover for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the ITSB mode features listed in the table above.

49.5.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. DSICR0[CID] bit should be cleared. DSICR0[DCONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame completion (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in Interleaved TSB (ITSB) Mode.

49.5.10.2 Using ITSB mode for MSC downstream channel

MSC Downstream Channel uses two types of frames: command frames and data frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- If command frame has less bits than data frame, a gap is inserted to ensure next data frame starts at known reference time.

- In dual MSC ASIC, some bits of the data frame (which can be up to 64 bits) goes to first ASIC and remainder bits to second ASIC.
- In dual MSC ASIC, if a command frame is sent to one ASIC, it must not change the timing of the next data frame.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (See Configuring DSPI for ITSB mode), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in Combined Serial Interface (CSI) configuration.

The following figure shows a sample MSC Downstream transmission using the ITSB mode.

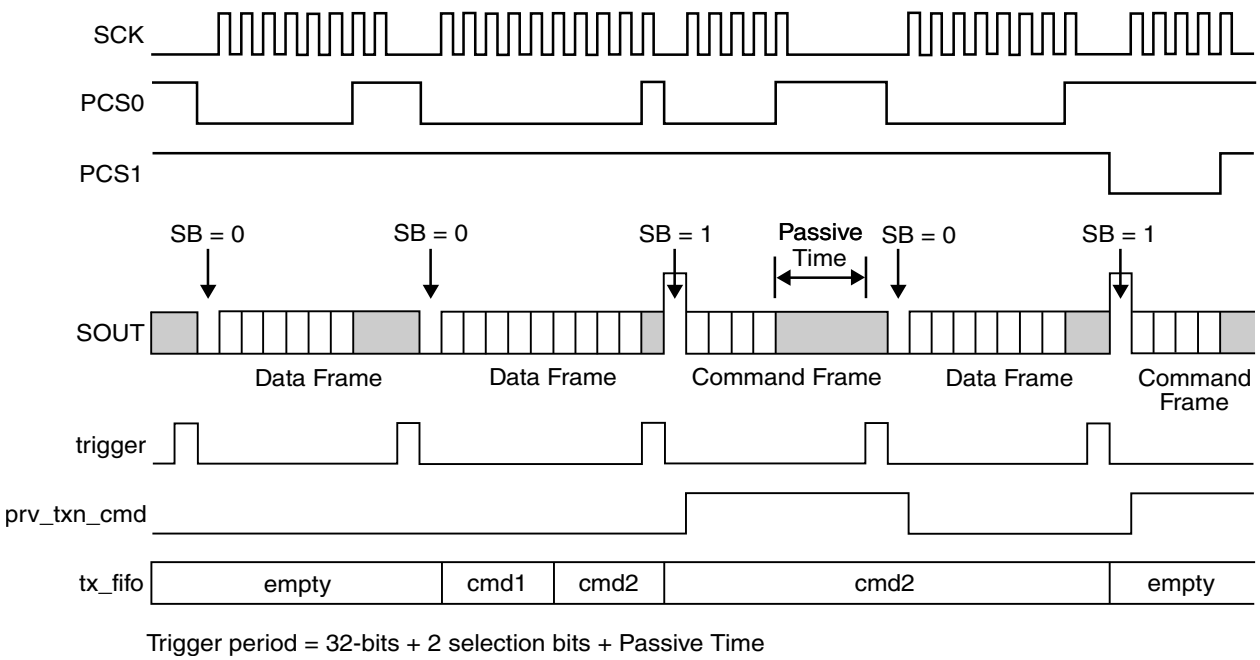

Figure 49-25. Sample MSC downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, since there are no command frames, a data frame is transmitted: to send a command frame at the start of operation, the user software must program a command frame in the TX_FIFO before enabling DSPI (MCR[HALT] = 0).
- The second trigger sets off the transmission of another data frame.
- Between second and third trigger, two command frames are pushed into the TX_FIFO.

- At third trigger, a command frame is transmitted as the TX_FIFO is not empty: since only 16 bits or less are transmitted, no transmission happens till next trigger. This is marked as the "Passive Time". The passive time is added in all frames after frame transmission completes and until next trigger pulse is detected.
- At fourth trigger, since the previous transmission was a command frame, a data frame is transmitted.
- At fifth trigger, since one command frame is pending in TX_FIFO and last transmitted frame was not a command frame, a command frame is transmitted.
- At sixth trigger (not shown), the process continues.

49.5.11 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programmed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

49.5.11.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

49.5.11.2 Parity for DSI frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. (DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode, the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation, clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

49.5.12 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. The following table lists these conditions.

Table 49-12. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
DSI Transfer Complete	DSITCF	Yes	—

Table continues on the next page...

Table 49-12. Interrupt and DMA request conditions (continued)

DSPI condition	Flag	Request type	
		Interrupt	DMA
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—
DSI Parity Error	DPEF	Yes	—
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

49.5.12.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note

This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

49.5.12.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note

TFFF flag clears automatically when DMA is used to fill TXFIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

1. Wait until TFFF = 1
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a '1' to its location. If TX FIFO is not full, this flag will not clear.

49.5.12.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note

CMDFFF flag clears automatically when DMA is used to fill CMD FIFO.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

1. Wait until CMDFFF = 1
2. Write data to Command field of PUSHR using CPU.
3. Clear CMDFFF by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.

49.5.12.4 Transmit FIFO Invalid Write interrupt request

The Transfer Fifo Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transfer Fifo Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

49.5.12.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

49.5.12.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

49.5.12.7 SPI Transfer Complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

49.5.12.8 DSI Transfer Complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

49.5.12.9 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

49.5.12.10 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

49.5.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

49.5.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

49.5.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

49.5.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR0 data, masked with DSPI_DIMR0, has been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

49.5.13 Power saving features

The DSPI supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

NOTE

When in Slave Mode, the module can only be put in Low Power Modes (such as STOP and HALT) once the Master module has transitioned to the Low Power Mode as well.

49.5.13.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter External Stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

If a DSPI block is configured in Slave mode, External Stop mode requests must be run after the last clock cycle or Low-power mode is not entered.

49.5.13.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting the MDIS bit in the MCR. The module disable mode can also be initiated by hardware.

When the MDIS bit is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state.

If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible.

Certain read or write operations have a different effect when the DSPI is in the module disable mode:

- Reading the RX FIFO Pop Register does not change the state of the RX FIFO.
- Writing to the FIFO Push Register does not change the state of the TX FIFO or CMD FIFO.
- Clearing of the FIFOs has no effect.
- Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect.
- All status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect.
- Writing to the TCR during module disable mode has no effect.
- Interrupt and DMA request signals cannot be cleared.

49.6 Initialization/application information

This section describes how to initialize the DSPI module.

49.6.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI Configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.

5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a '1' to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

49.6.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a '1' to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

49.6.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

49.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note

The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the clocking chapter for the frequency used to drive this module in the device.

Table 49-13. Baud rate values (bps)

		Baud rate divider prescaler values (DSPI*n*_CTAR[PBR])			
		2	**3**	**5**	**7**
Baud Rate scaler values (DSPI*n*_CTAR[BR])	**2**	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
	4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
	6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
	8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
	16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
	32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
	64	781 kHz	521 kHz	312 kHz	223 kHz
	128	391 kHz	260 kHz	156 kHz	112 kHz
	256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
	512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
	1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
	2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
	4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
	8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
	16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
	32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

49.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

Note

The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 49-14. Delay values

		Delay prescaler values (DSPI*n*_CTAR[PBR])			
		1	**3**	**5**	**7**
Delay scaler values	**2**	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

49.6.6 Calculation of FIFO pointer addresses

Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped.

- For TX FIFO, the first-in pointer is the Transmit Next Pointer (TXNXTPTR).
- For CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR).
- For RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR).

Figure 49-26 illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts are applicable to the CMD FIFO and RX FIFO.

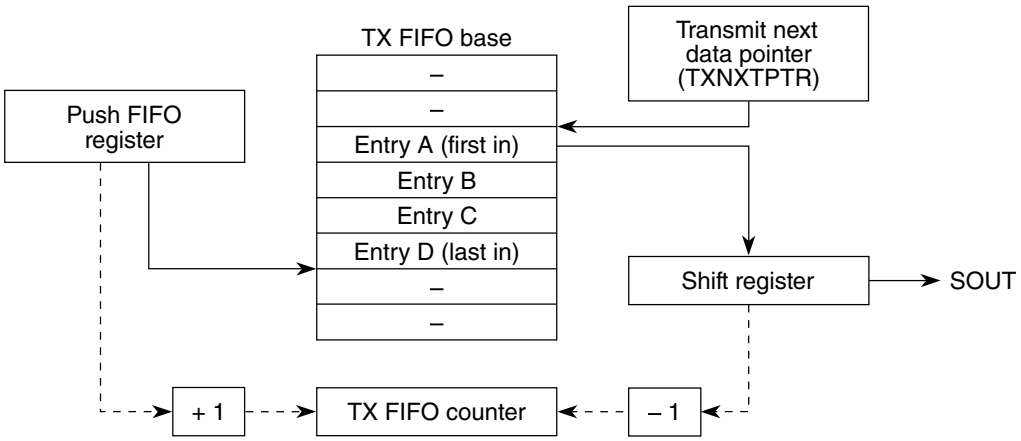

Figure 49-26. TX FIFO pointers and counter

See Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) buffering mechanism and Receive First In First Out (RX FIFO) Buffering Mechanism for details on the FIFO operation.

49.6.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in Entry Address} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

Equation 24. Equation for first-in entry address

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-in Entry Address} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFO depth})$$

Equation 25. Equation for last-in entry address

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXTPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

49.6.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in Entry Address} = \text{CMD FIFO Base} + (4 \times \text{CMD NXTPTR})$$

Equation 26. Equation for first-in entry address

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-in Entry Address} = \text{CMD FIFO Base} + 4 \times (\text{CMD CTR} + \text{CMD NXTPTR} - 1) \bmod (\text{CMD FIFO depth})$$

Equation 27. Equation for last-in entry address

CMD FIFO Base – Base address of CMD FIFO

CMDCTR – CMD FIFO Counter

CMDNXTPTR – Command Next Pointer

CMD FIFO Depth – Command FIFO depth, implementation specific

49.6.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in Entry Address} = \text{RX FIFO Base} + (4 \times \text{POPNXTPTR})$$

Equation 28. Equation for first-in entry address

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-in Entry Address} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFO depth})$$

Equation 29. Equation for last-in entry address

RX FIFO Base – Base address of RX FIFO

RXCTR – RX FIFO counter

POPNXTPTR – Pop Next Pointer RX FIFO Depth – Receive FIFO depth, implementation specific

Chapter 50
Zipwire

50.1 Overview

The SIPI and LFAST modules work together as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

50.2 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals and/or memories of another MCU or smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the intitiator or target node. Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and support multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.

Zipwire also supports a streaming mode for the transfer of large blocks of data.

In streaming mode Zipwire has a high transfer rate. For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

50.3 Zipwire Block Diagram

Figure 50-1 shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target mode transactions. The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST reference clock coming from MCU B clock system. The Ref_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

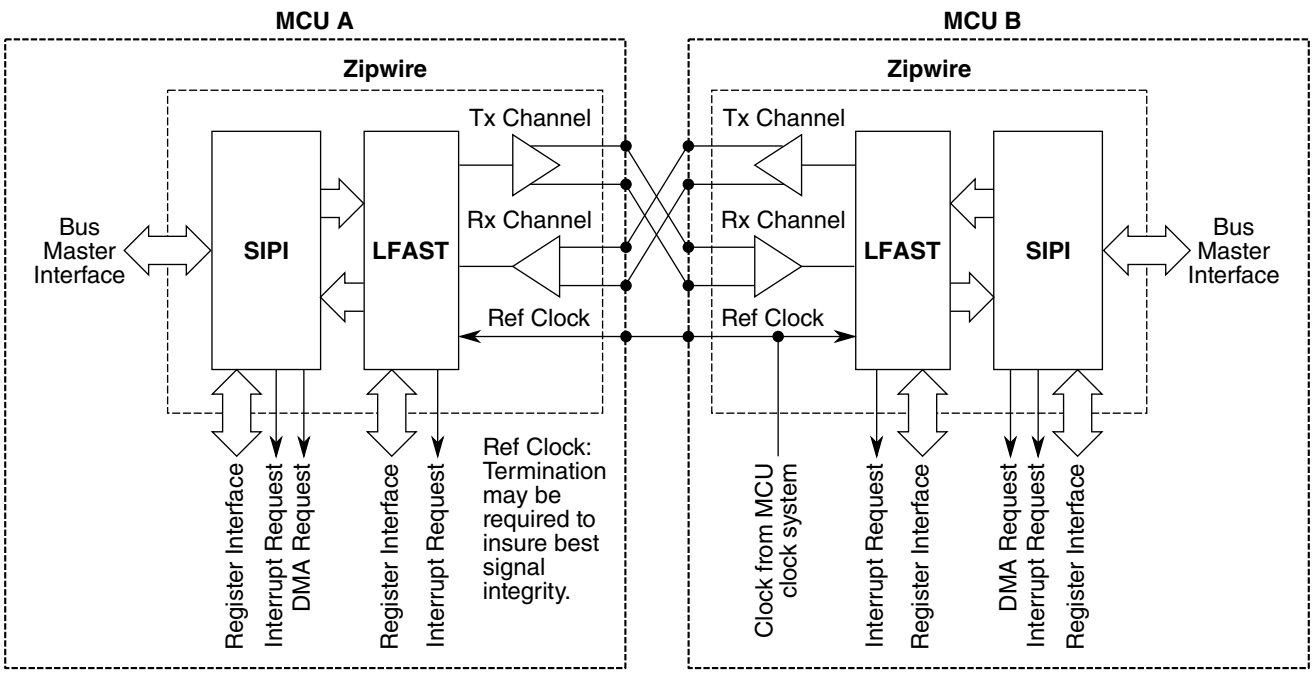

Figure 50-1. Zipwire connection diagram

50.4 Architecture

Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200mV swing.

The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.

- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). SIPI runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload in Zipwire:

- 32-bit
- 64-bit
- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated by one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently of each other and can run simultaneously. The SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Inititator MCU and executed by DMA and SIPI without CPU intervention at either Initiator or Target MCU.

50.5 Zipwire interconnections

LFAST has the following connections:

- Tx and Rx configuration is controlled by LFAST Control registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.

- Tx Data Port/Rx Data Port — Directly connected to the SIPI module. Allows received data to be efficiently transferred to SIPI and transmit data to be transferred from SIPI.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers.
- DMA connections — Allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

50.6 Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Inititator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

50.6.1 Read performance

A Zipwire read operation consists of three stages:

- Inititator sends SIPI Read command to Target.

- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in a LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 278 ns (= 89 × 3.13 ns).

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of 6 × slow XBAR cycles to read different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, time for SIPI to read an address location is:

(13 × 50 MHz clocks) + (6 × 100 MHz clocks) = 320 ns

50.6.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

Read Bandwidth = 4 bytes in 320 ns = 12.5 MB/second

50.6.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

Read Latency = 278 ns + 320 ns + 278 ns = 876 ns

50.6.2 Write performance

A Zipwire write operation consists of three stages:

- Initiator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address

- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header
- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 378 ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 178 ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of 5 × slow XBAR cycles to write different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, the time for SIPI to write an address location is:

(13 × 50 MHz clocks) + (5 × 100 MHz clocks) = 310 ns

50.6.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = 4 bytes in 378 ns = 10.6 MB/second

50.6.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = 378 ns + 310 ns + 178 ns = 866 ns

Chapter 51
Serial Interprocessor Interface (SIPI)

51.1 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

51.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between 2 devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:
  - Full Implementation = 4
  - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI which includes:

- Advanced High-Performance Bus (AHB-Lite) master interface

- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

51.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

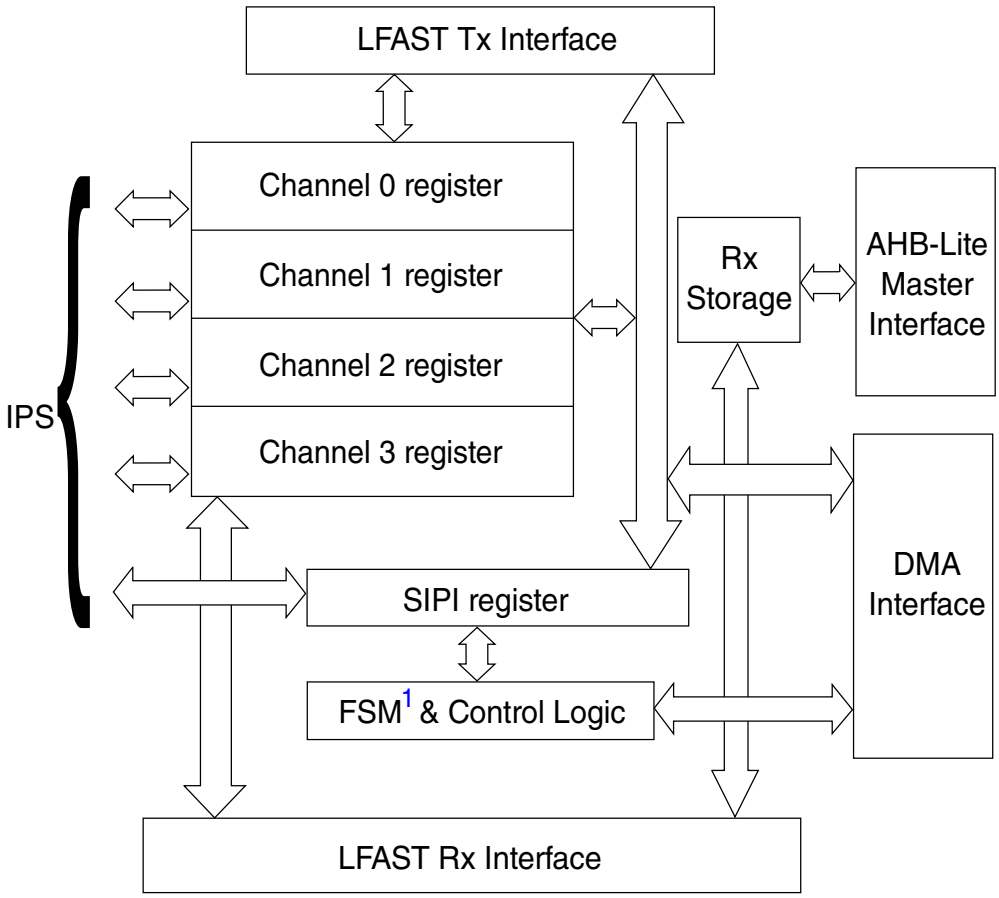
51.3 SIPI block diagram



[1] Finite State Machine

Figure 51-3. SIPI block diagram

51.4 Feature description

This section describes the features of the SIPI module.

51.4.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface which is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator

51.4.2 Standard features

- IPS bus interface (PBRIDGE)
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

51.5 SIPI operation from reset

When the SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

51.6 Functional description

51.6.1 External signals

The SIPI has no chip external signals.

51.6.2 Frame format

All frames have the same general format:

- 16 bit header
- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

51.6.2.1 Register read request

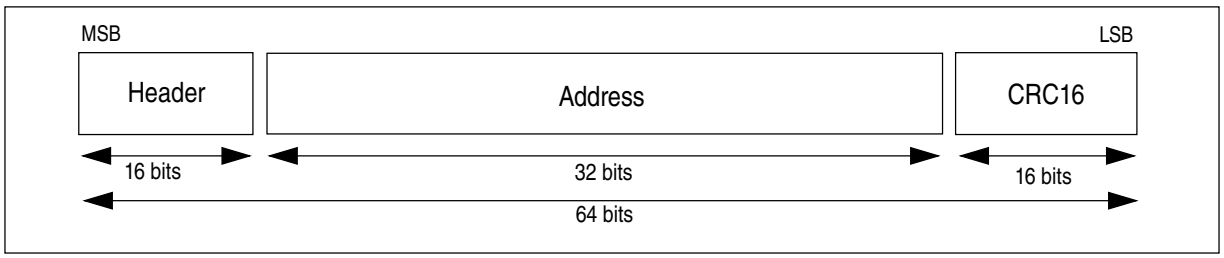


Figure 51-4. SIPI register read request

51.6.2.2 Register read response, ID request response

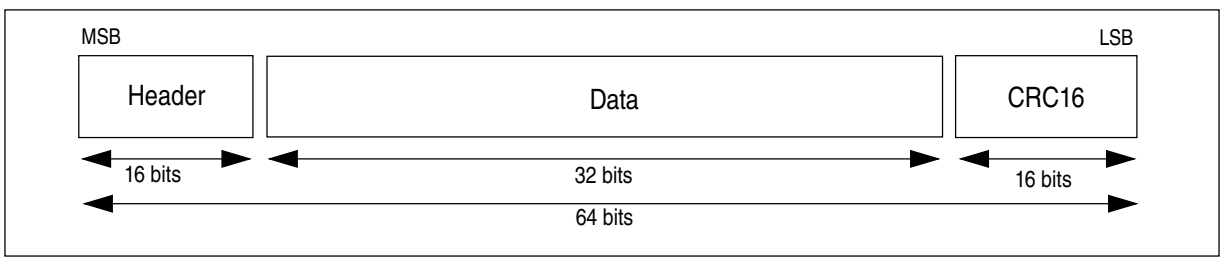

Figure 51-5. SIPI read response

51.6.2.3 Register write request

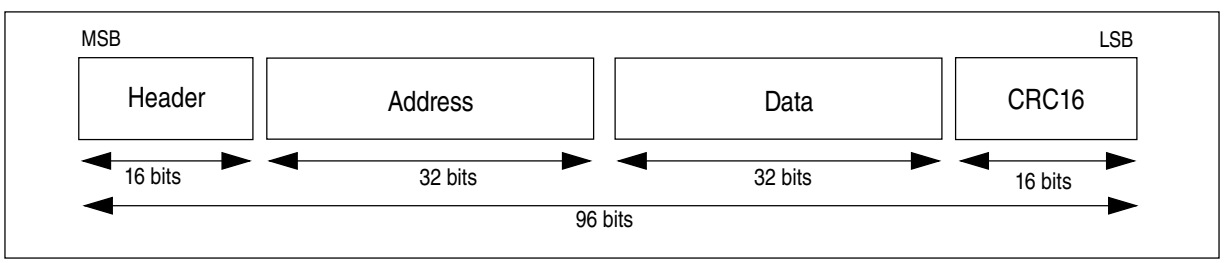

Figure 51-6. SIPI register write request

51.6.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

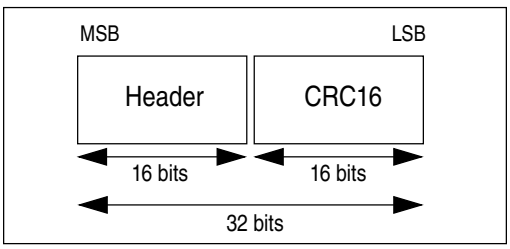

Figure 51-7. SIPI write acknowledge

51.6.2.5 Streaming write request

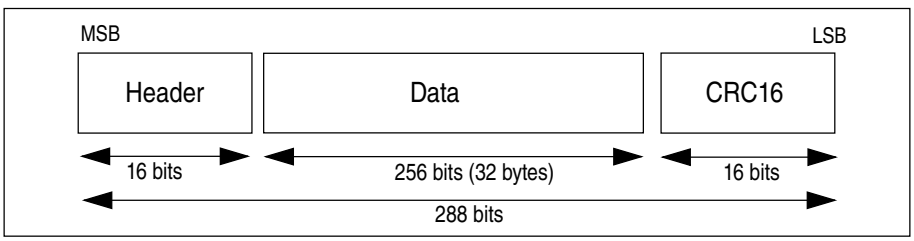

Figure 51-8. Streaming write request format

NOTE

Direct write operations are used to set the streaming address.

Streaming data write is performed using the format shown in Figure 51-8.

51.6.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

51.6.2.6.1 SIPI header coding

Figure 51-9, Table 51-1, Figure 51-10, and Table 51-2 show how the SIPI header bits are coded.

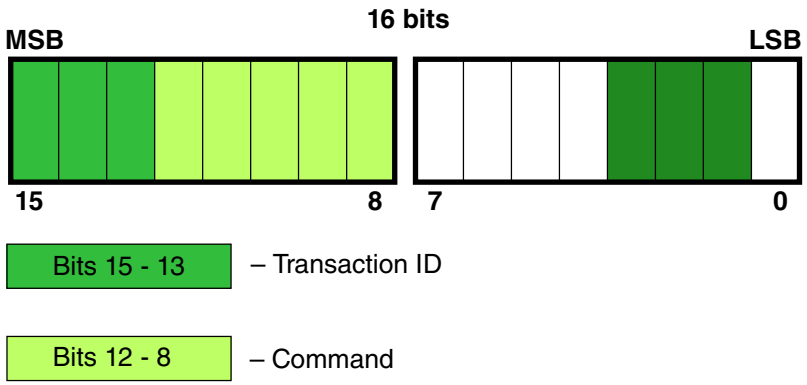

Figure 51-9. SIPI header coding

Table 51-1 shows the command coding for the bits[12:8] of the header.

Table 51-1. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—
04	Write 8 bits with ACK	96
05	Write 16 bits with ACK	96
06	Write 32 bits with ACK	96
07	Reserved	—
08	ACK – OK	32
09	ACK – Fault	32
0A	Read Answer – OK	64
0B	Reserved	—
0C	Trigger comm and with ACK	32
0D	Reserved	—
…	…	…
11	Reserved	—
12	ID Register Read Request	32
13	Reserved	—
…	…	…
16	Reserved	—
17	Stream Data with ACK (32 bytes)	288
18	Reserved	—
…	…	…
1F	Reserved	—

Figure 51-10 shows the channel number field in the header and Table 51-2 shows the channel number coding.

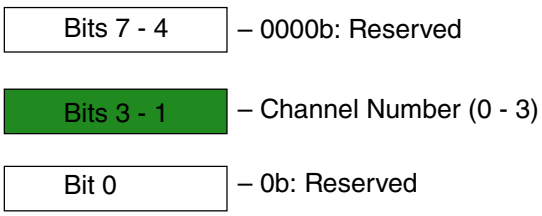

Figure 51-10. SIPI header channel field

Table 51-2. SIPI header channel number coding

SIPI channel name	Channel number coding in header(s)		Comment
	SIPI channel coding select field (SIPI_MCR[CHNSB])		
	Code table I (SIPI_MCR[CHNSB] = 1)	Code table II (SIPI_MCR[CHNSB] = 0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

51.6.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

51.6.2.8 Payload field

Table 51-3 shows the payload sizes of LFAST frames.

Table 51-3. Payload size of LFAST channel frame

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16

Table continues on the next page...

Table 51-3. Payload size of LFAST channel frame (continued)

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
101b	101b	256	32
110b	110b	512	64
111b	111b	288	36

Table 51-4 shows the converted coding of LFAST for a given SIPI code.

Table 51-4. Converted coding of LFAST channel code for SIPI headers

LFAST Code	SIPI Code	Channel (hex)[1]
0100b	100b	A
0101b	101b	B
0110b	110b	C
0111b	111b	D
1000b	000b	E (not used by SIPI)
1001b	001b	F (not used by SIPI)
1010b	010b	G (not used by SIPI)
1011b	011b	H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

51.6.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). MSB is sent first in the data stream.

51.6.2.9.1 CRC field examples

51.6.2.9.1.1 Example 1 – 32 bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

51.6.2.9.1.2 Example 2 – 32 bit read on channel 2 with ID2

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

51.6.2.9.1.3 Example 3 – Event command on channel 3 with ID3

- Header = 6C0Eh
- CRC = B286h

51.7 Transfer types

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

51.7.1 Read transfer

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

51.7.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in Figure 51-11.

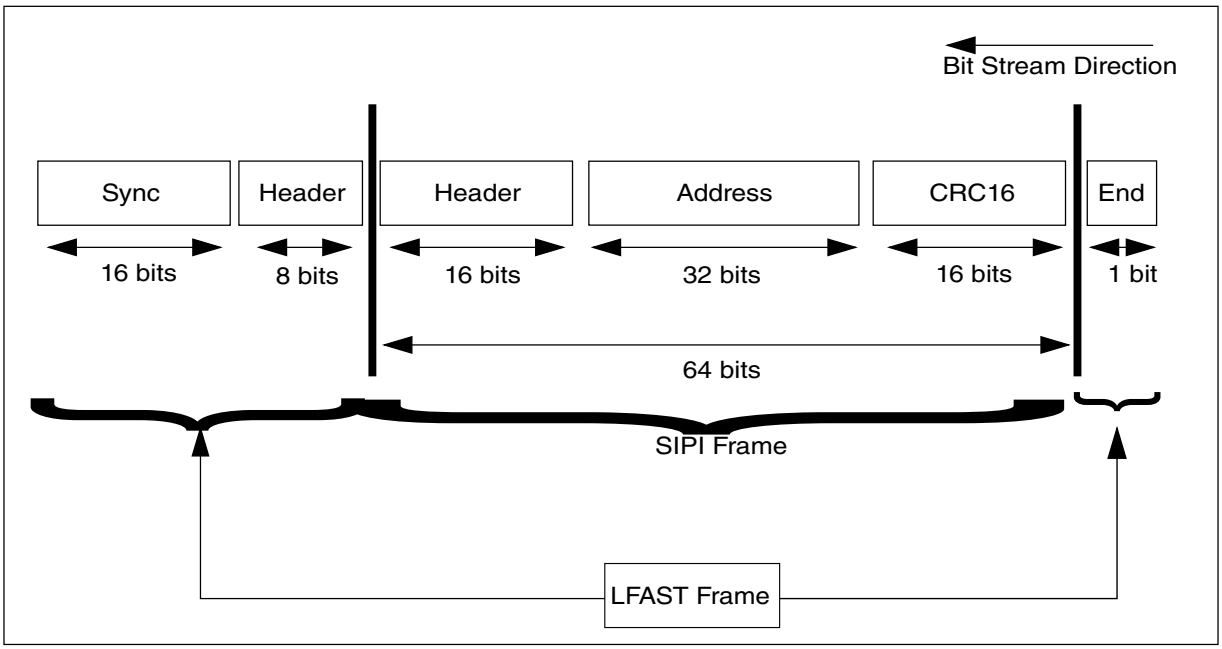

Figure 51-11. Read request transfer

51.7.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see Figure 51-12). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see Figure 51-13).

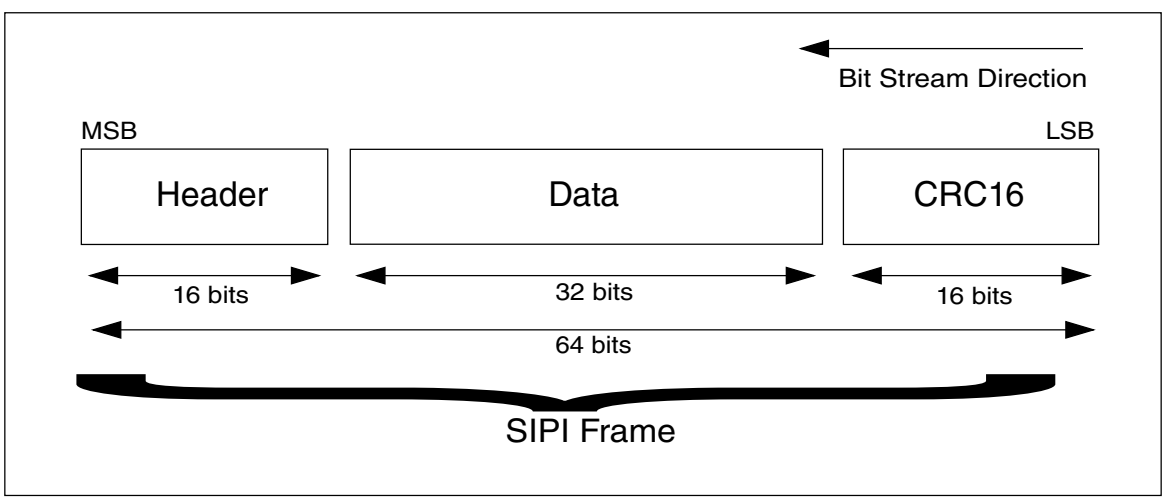

Figure 51-12. Read answer transfer

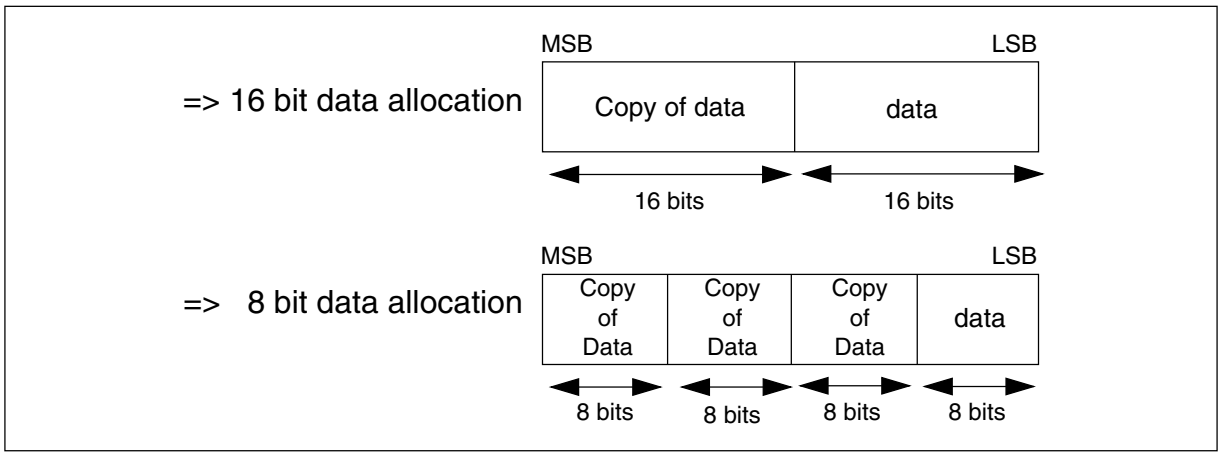

Figure 51-13. Data allocation

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
  - Bit[0]:
    - 0 - halfword 1 enabled (MSB)
    - 1 - halfword 0 enabled (LSB)

51.7.3 Register Write transfer

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see Normal write transfer) as shown in Figure 51-14.

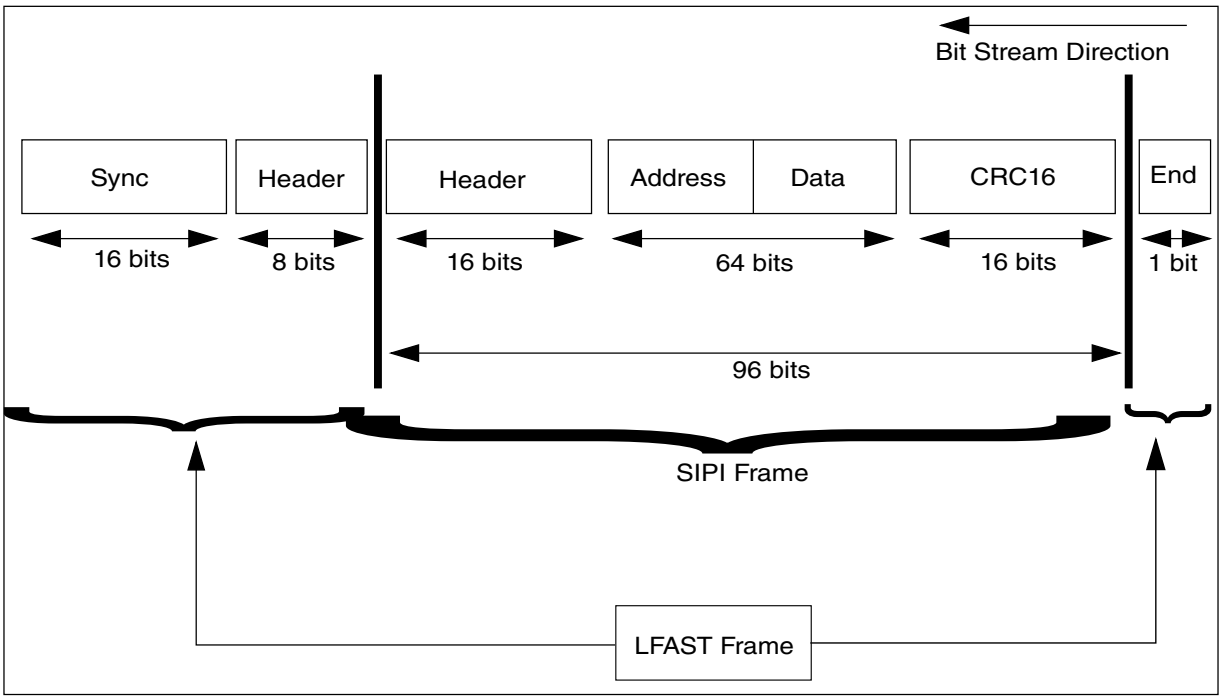

Figure 51-14. Register write transfer (showing LFAST frame encapsulation)

51.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in Figure 51-15.

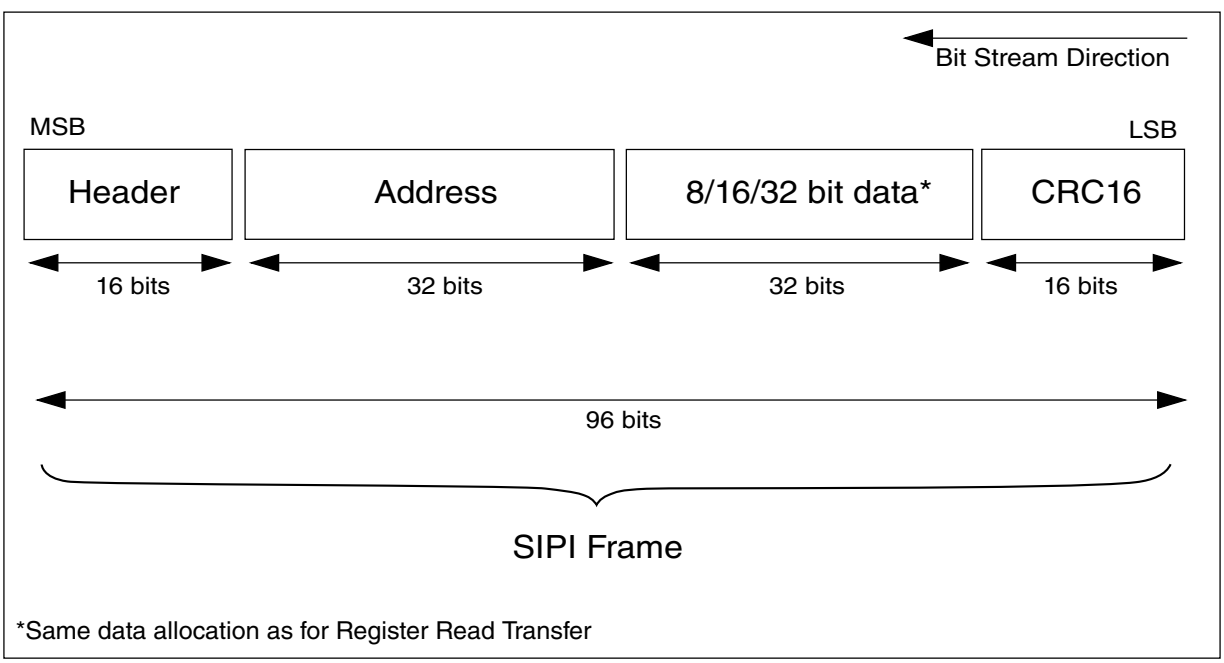

Figure 51-15. Write transfer (LFAST frame encapsulation is not shown)

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
  - Bit[0]:
    - 0 - half-word 1 enabled (MSB)
    - 1 - half-word 0 enabled (LSB)

51.7.3.2 Streaming write transfer

Streaming write transfer has 256 bits of payload.

51.7.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. The SIPI Maximum Count Register (SIPI_MAXCR) and SIPI Address Reload Register (SIPI_ARR) are written before the SIPI Address Count Register (SIPI_ACR). This is to avoid unwanted behavior of the SIPI attempting to access non-shared memory. This is only true for the very first streaming command, subsequent streaming command(s) may not need to write the SIPI_MAXCR and SIPI_ARR (see SIPI Max Count Register (SIPI_MAXCR), SIPI Address Count Register (SIPI_ACR) and SIPI Address Reload Register (SIPI_ARR)).

51.7.3.2.2 Streaming transfer with data

Figure 51-16 shows the packet structure of the streaming transfer containing data.

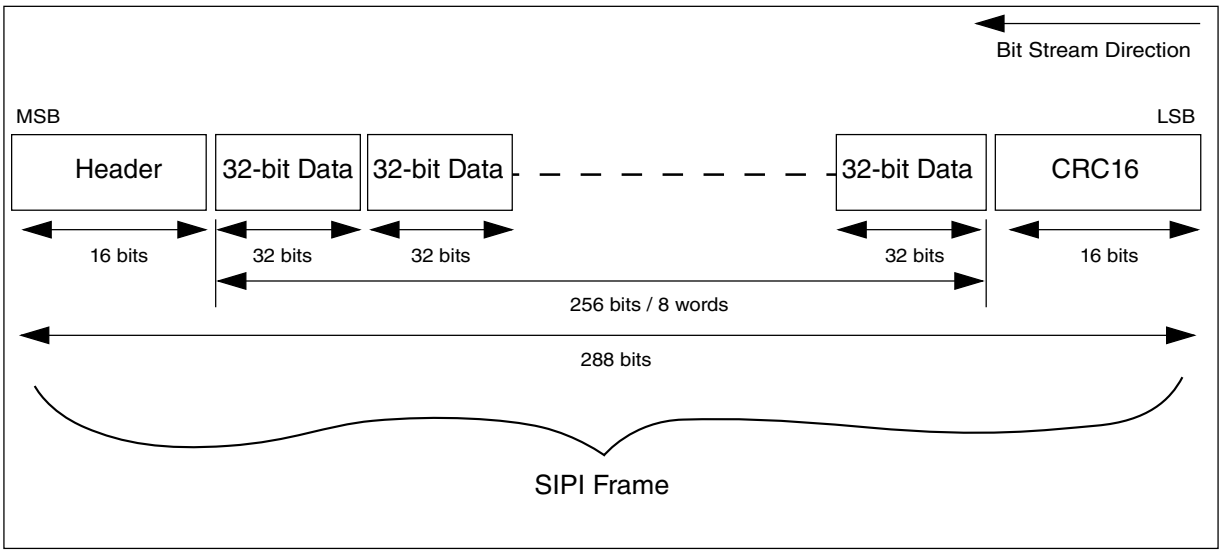

Figure 51-16. Streaming transfer with data

51.7.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see Write Aknowledge transfer. The CRC bits are calculated on the header field.

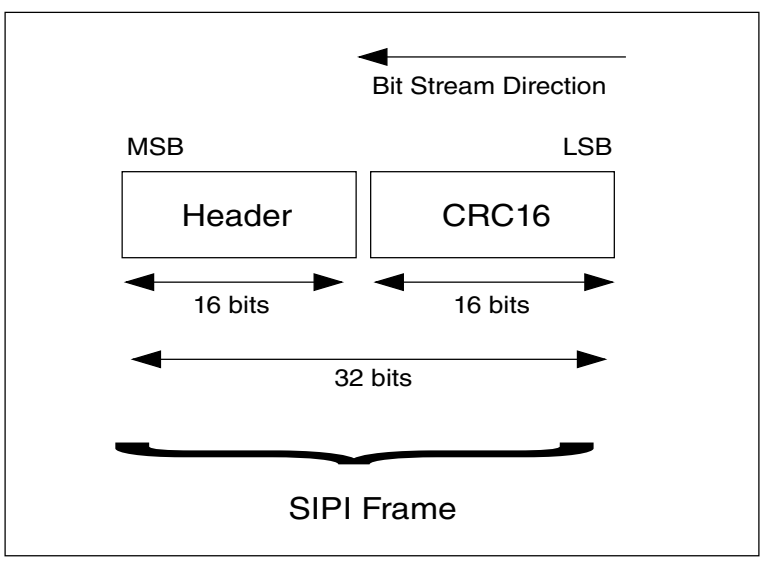

Figure 51-17. Write Aknowledge transfer (LFAST encapsulation is not shown)

51.7.5 ID request response

51.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in Figure 51-18.

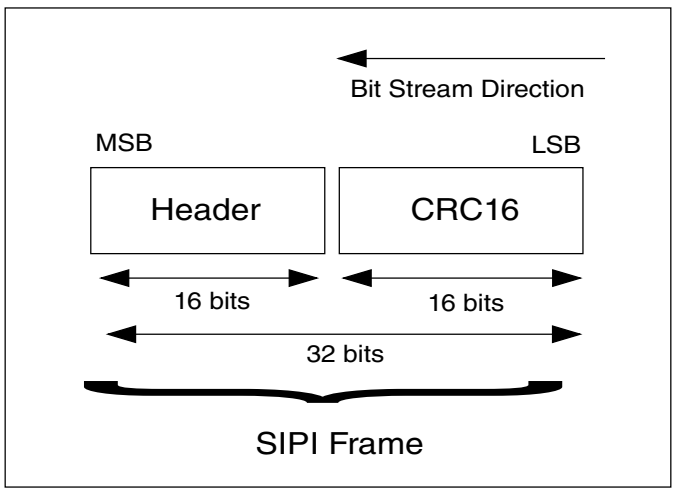

Figure 51-18. ID request transfer (LFAST encapsulation is not shown)

51.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in Figure 51-19.

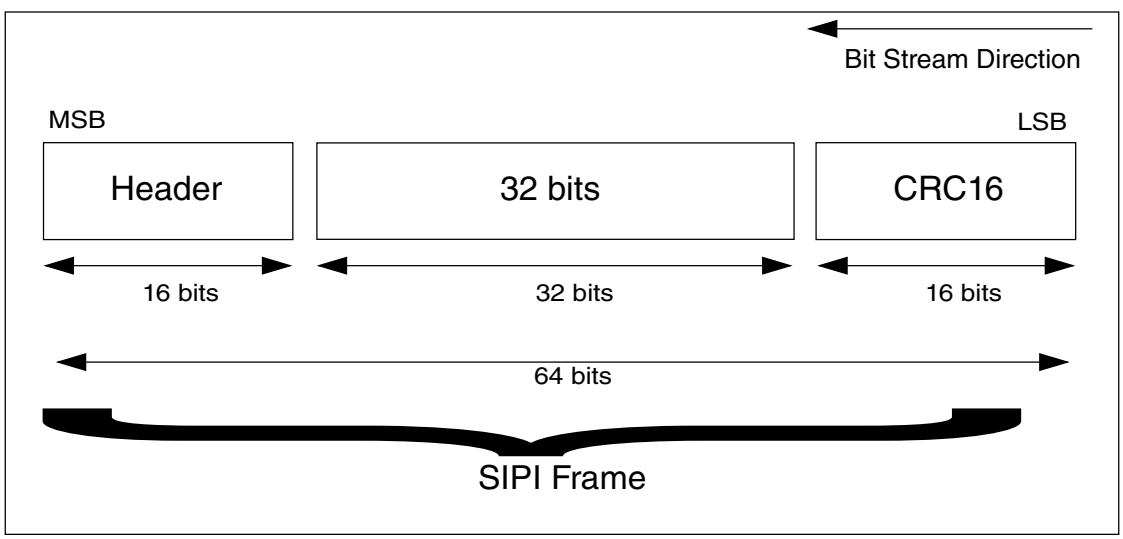

Figure 51-19. ID request response transfer

Note

The ID request response contains the value of the CHIP ID in place of data.

51.8 Transfer API and flow charts

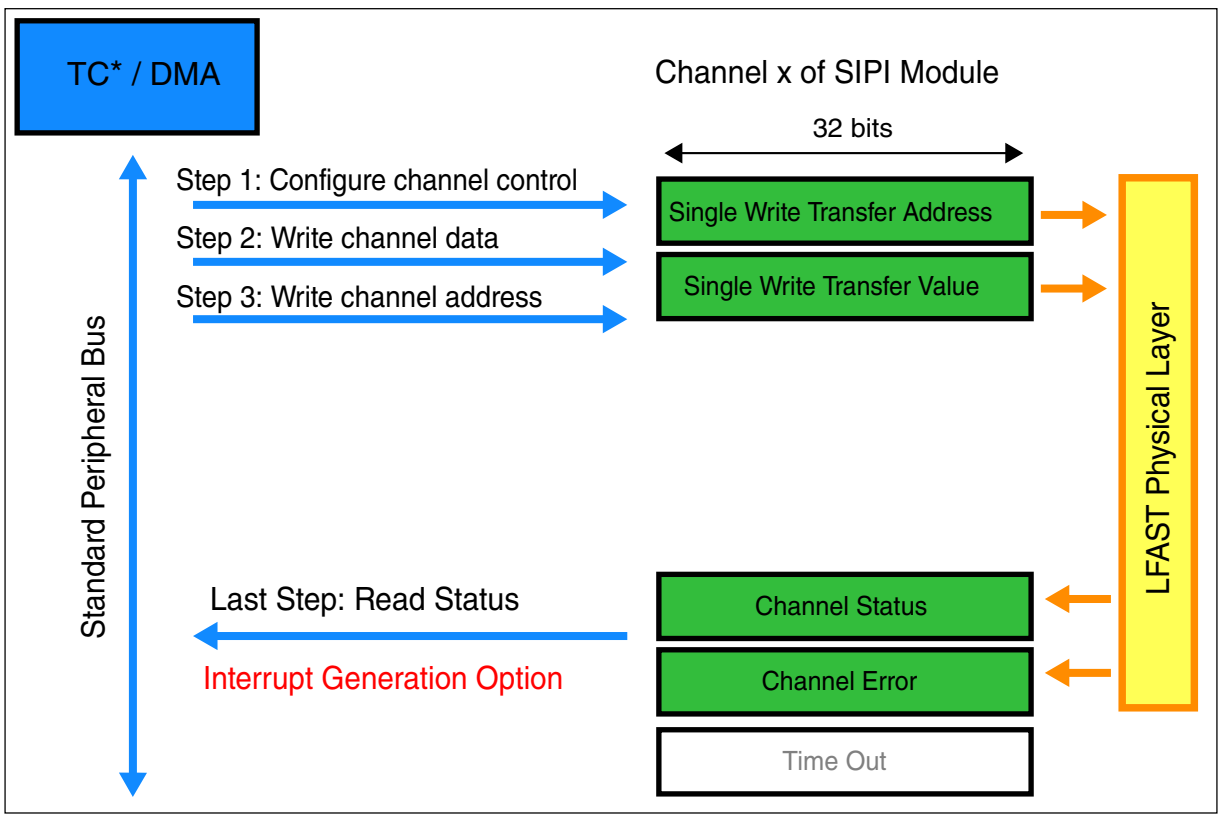

Figure 51-20. SIPI single register write API

Implement the following steps to generate a single Write Transfer Request (Figure 51-20):

1. Configure data and SIPI_CCR*n* at the initiator node.
2. Configure SIPI_CAR*n* at the initiator node.

   As soon as the channel address register (SIPI_CAR*n*) is written and if CCR*n*[CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.
3. Software polls the status register bits (SIPI_CSR*n*) to determine when the request completes, SIPI_CSR*n*[ACKR] = 1. An interrupt will be generated if the corresponding SIPI_CIR*n*[ACKIE] = 1.

On a single Write transfer request reception (Figure 51-21):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process in completed, the target node will generate an acknowledge frame and send it back to the LFAST.

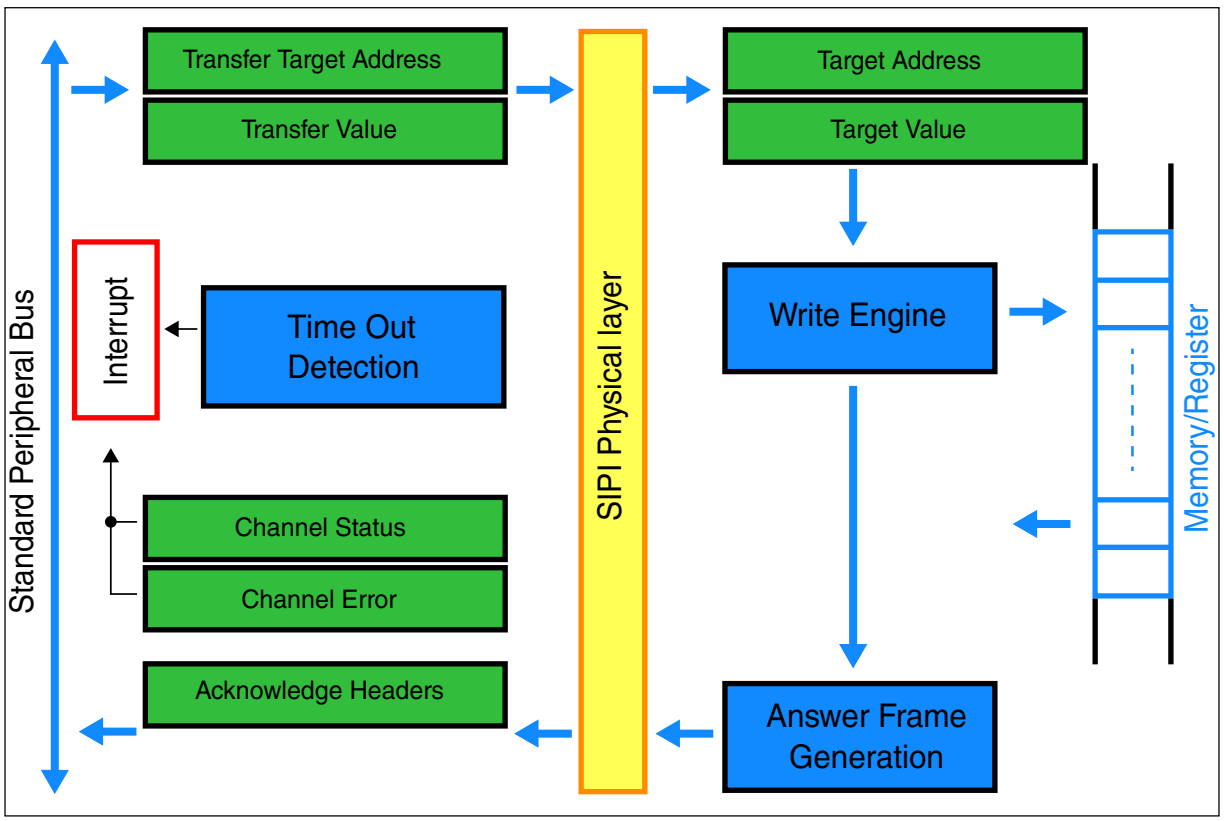

Figure 51-21. SIPI Single Register Write API – Flow Chart

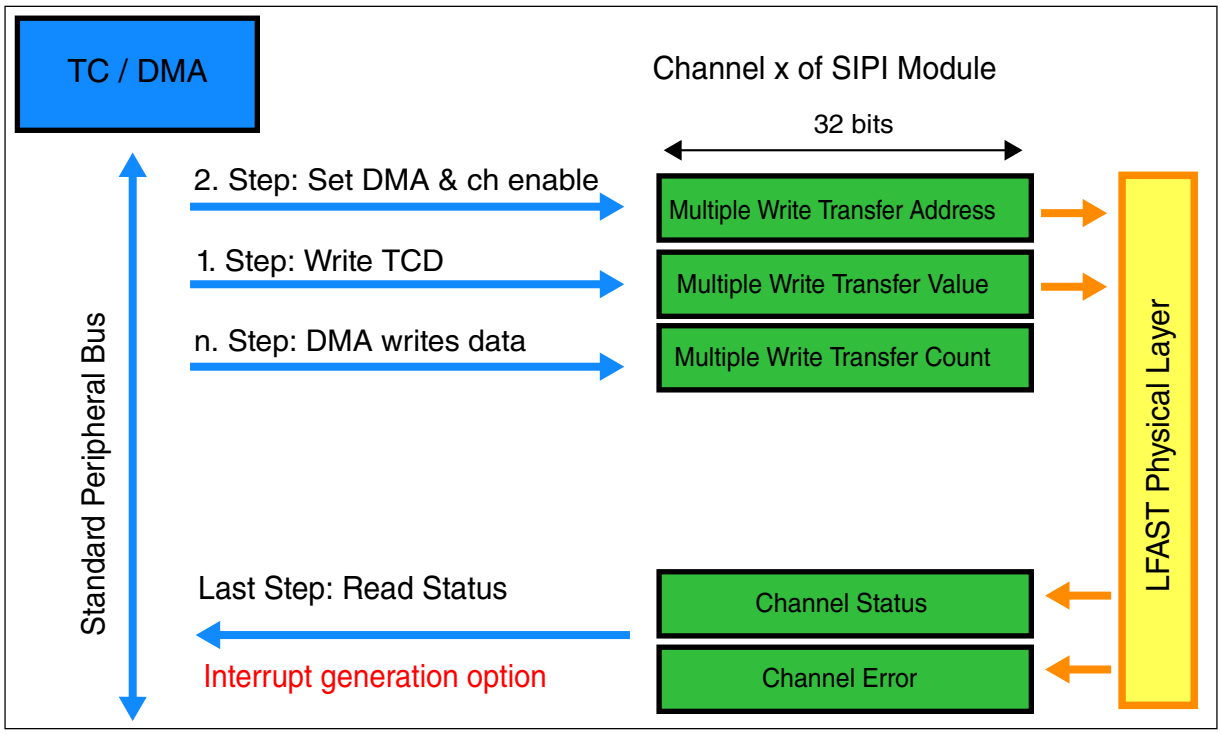

Figure 51-22. SIPI Multiple Register Write API

For multiple write transfer request generation (Figure 51-22):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write SIPI_CCR*n*[CHEN] = 1 and SIPI_CCR*n*[DAN] = 1.
3. SIPI will start copying data into the SIPI_CDR*n* through its DMA interface, depending on the transfer count and data registers size. SIPI_CDR2_0 should be written with the MSB.
4. When the copying process is completer, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
5. Software should poll the SIPI_CSR*n* status register bits to determine if the request has completed. If SIPI_CSR*n*[ACKR] = 1, an interrupt will be generated (if the corresponding SIPI_CIR*n*[ACKIE] = 1).
6. If SIPI_CCR*n*[DEN] = 1, the SIPI request will transfer to the DMA controller. If not, the state machine go idle.
7. Steps 4–7 will be repeated.

On Multiple Write transfer request reception (Figure 51-22):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, target node will generate an acknowledge frame and send it back to the LFAST.

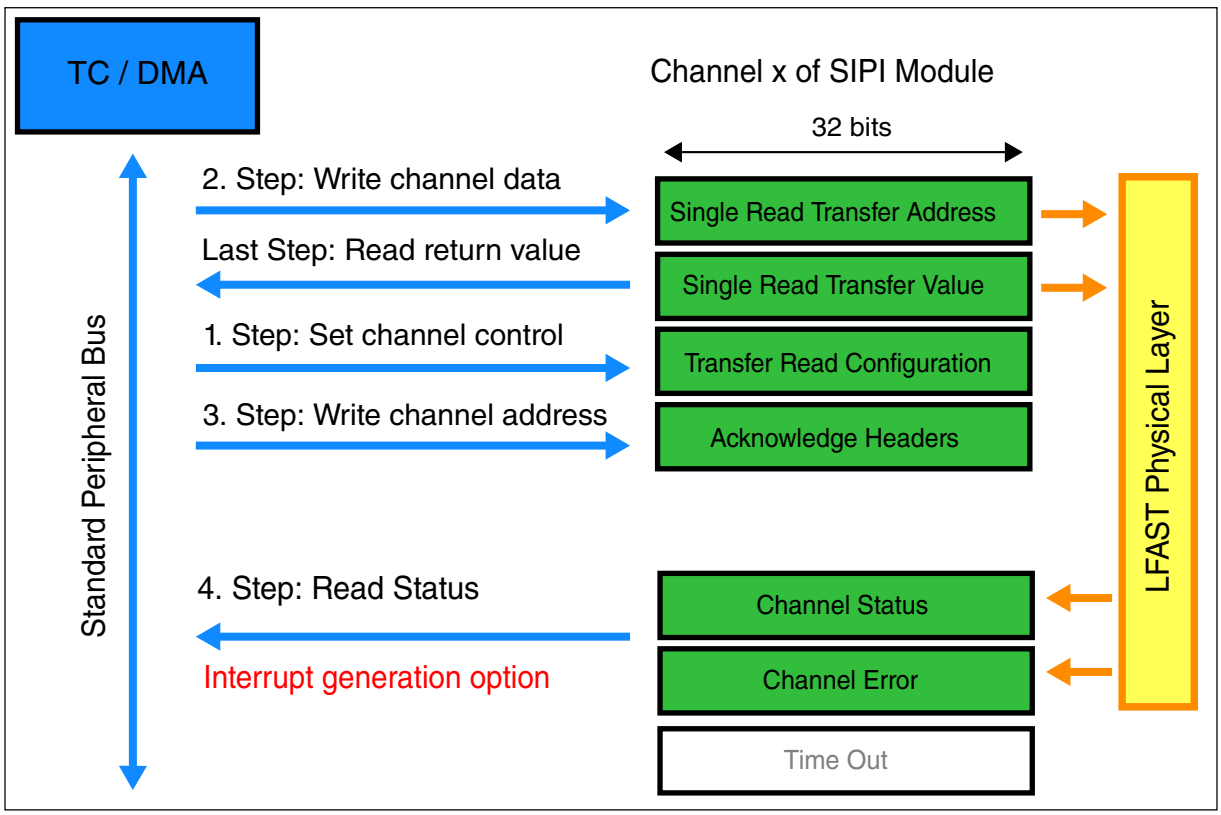

Figure 51-23. SIPI Single Register Read API

For Single Read Transfer Request generation (Figure 51-23):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing CAR*n*.
2. As soon as SIPI_CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1, an interrupt will be generated (if SIPI_CIR*n*[RAIE] = 1). If SIPI_CSR*n*[RAR] does not set then SIPI_ERR[TOE*n*] = 1 which indicates a timeout has occured.
4. If SIPI_CSR*n*[RAR] = 1 then software can read the data register, or can other necessary action if SIPI_CSR*n*[RAR] = 0.

On Single Read transfer request reception (Figure 51-23):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process in completed, target node will send read response back to LFAST.

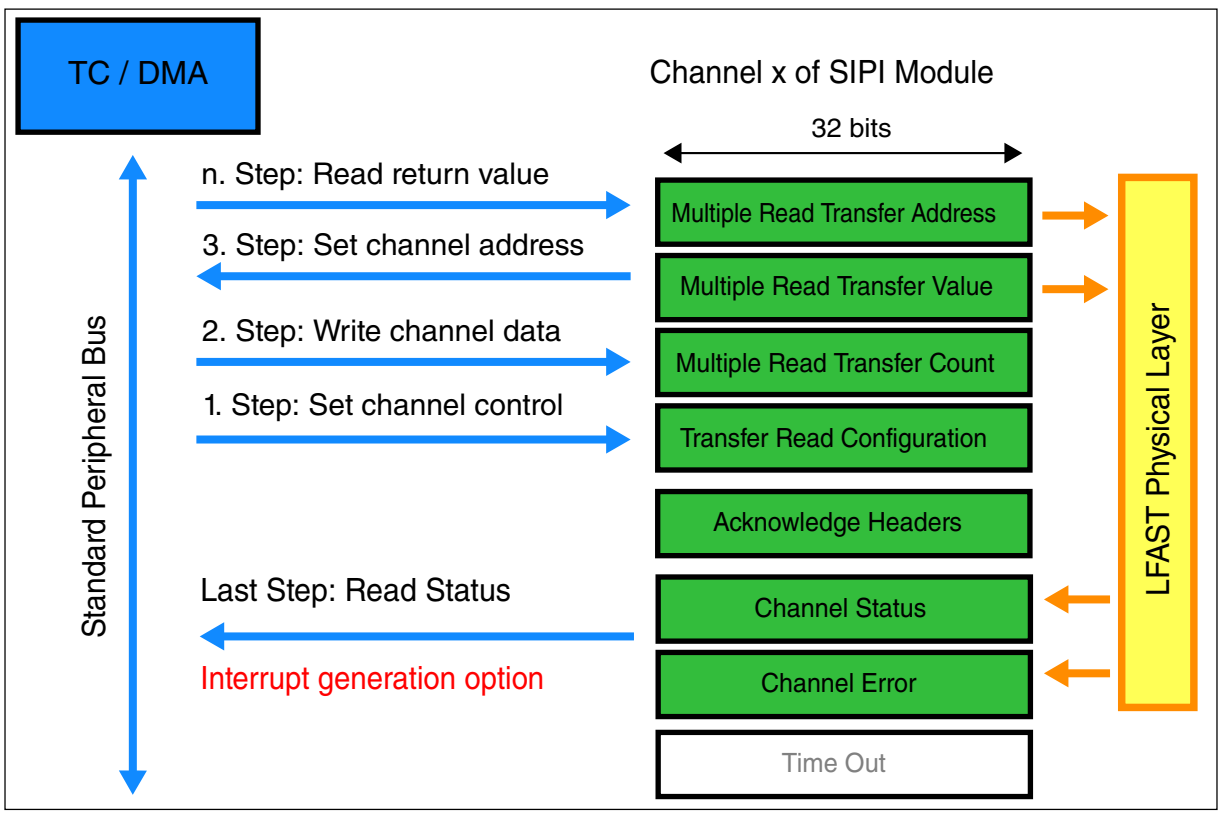

Figure 51-24. SIPI multiple register read API

For multiple read transfer request generation (Figure 51-24):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing SIPI_CAR*n*.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then starts transmitting data to the LFAST.
3. Software should poll SIPI_CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1 and SIPI_CIR*n*[RAIE] = 1 an interrupt will be generated. If SIPI_CSR*n*[RAR] does not set, then SIPI_ERR[TOE*n*] = 1 which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception (Figure 51-24):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

Figure 51-25, Figure 51-26, Figure 51-27 and Figure 51-28 show the SIPI data streaming of data.

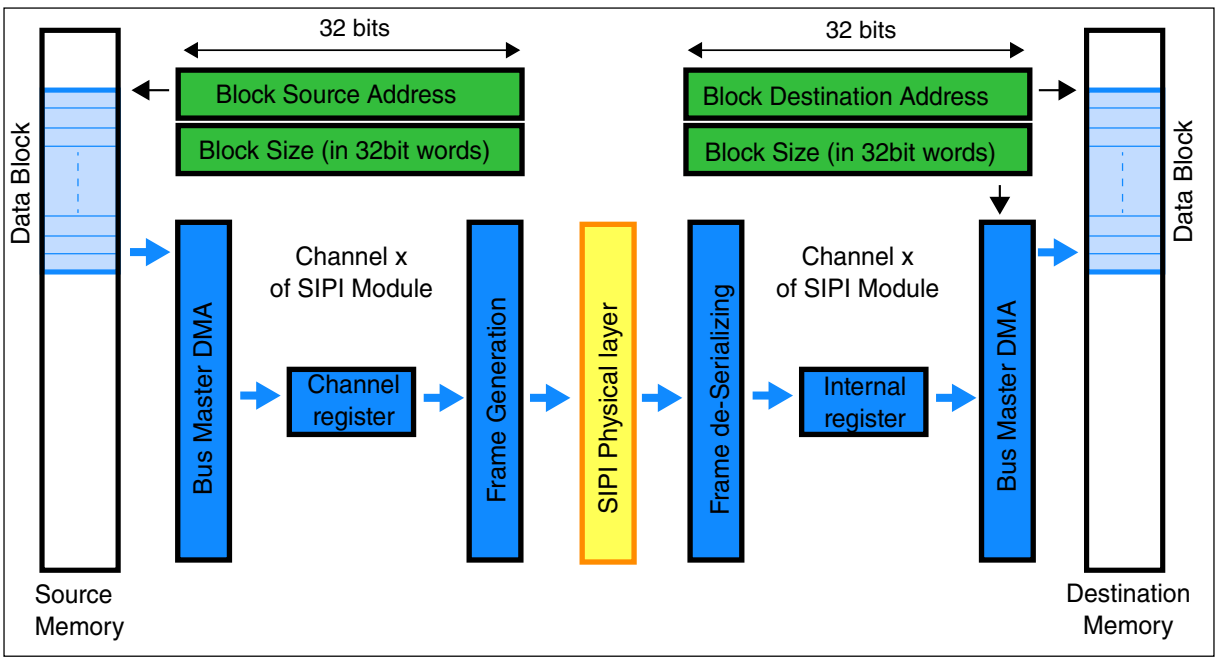

Figure 51-25. SIPI data stream model

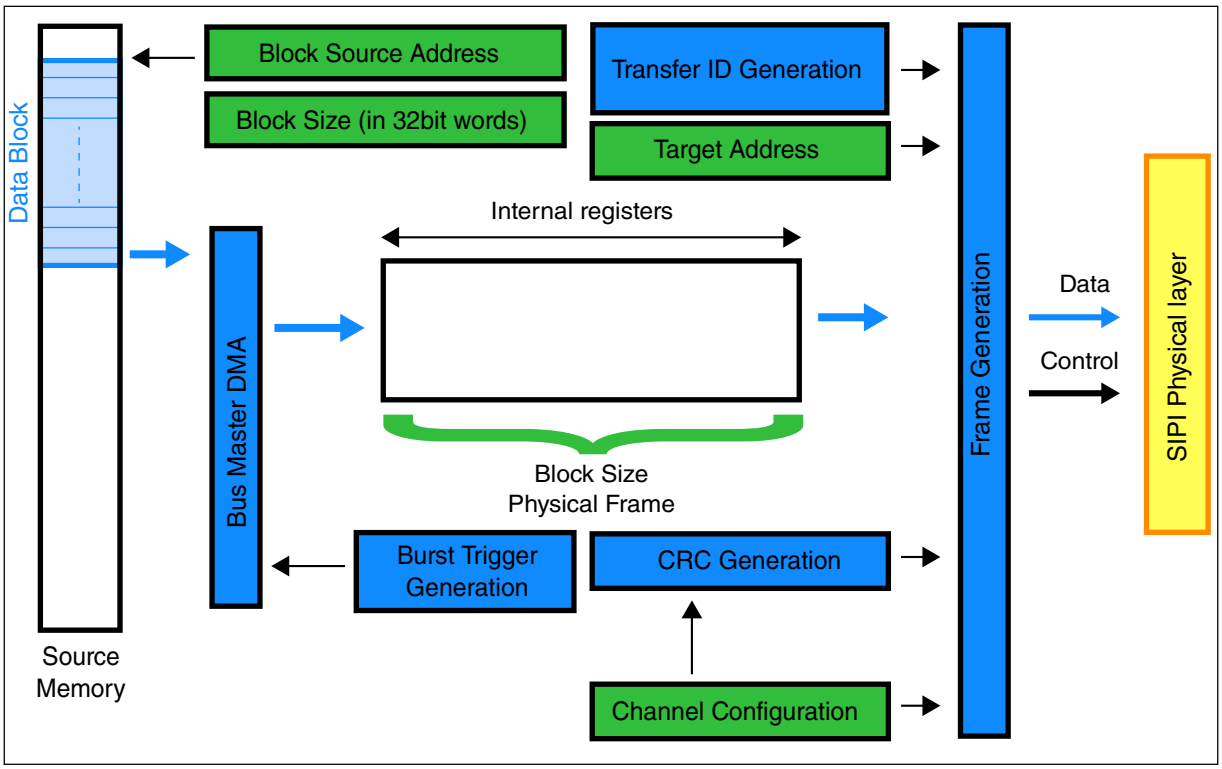

Figure 51-26. SIPI data stream model - Initiator

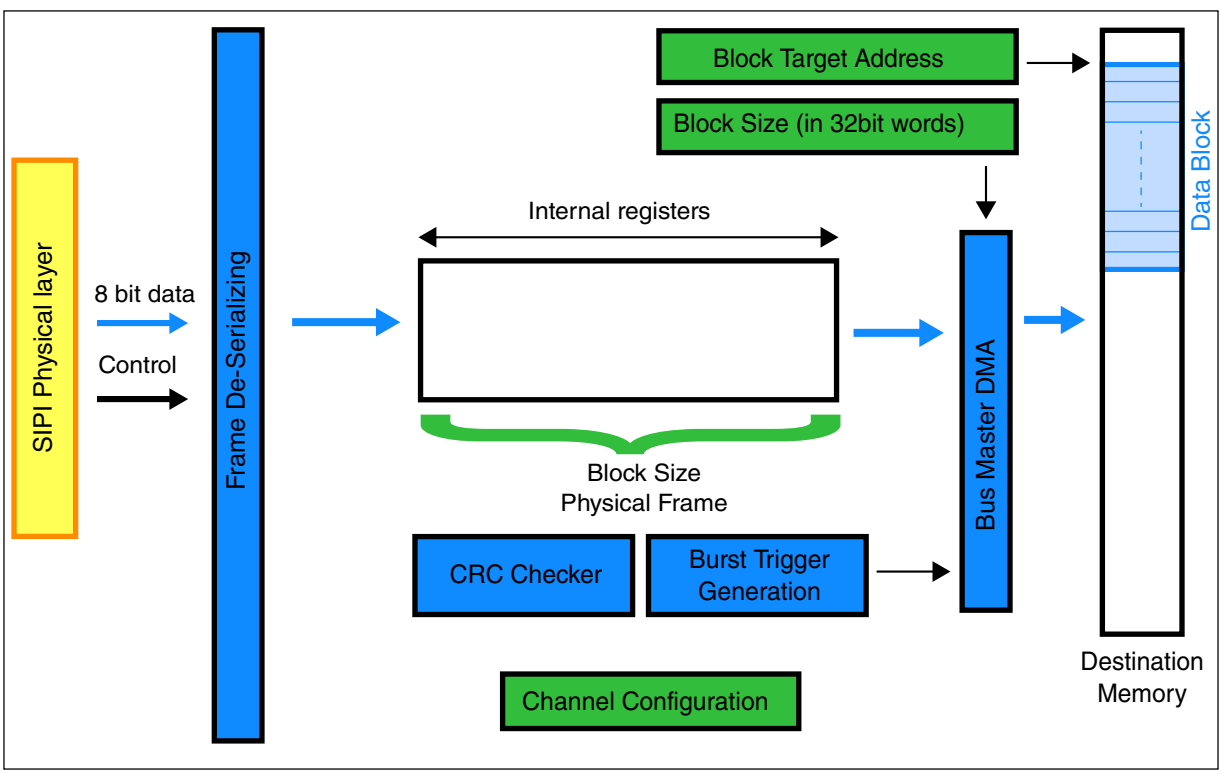

Figure 51-27. SIPI data stream model - Target

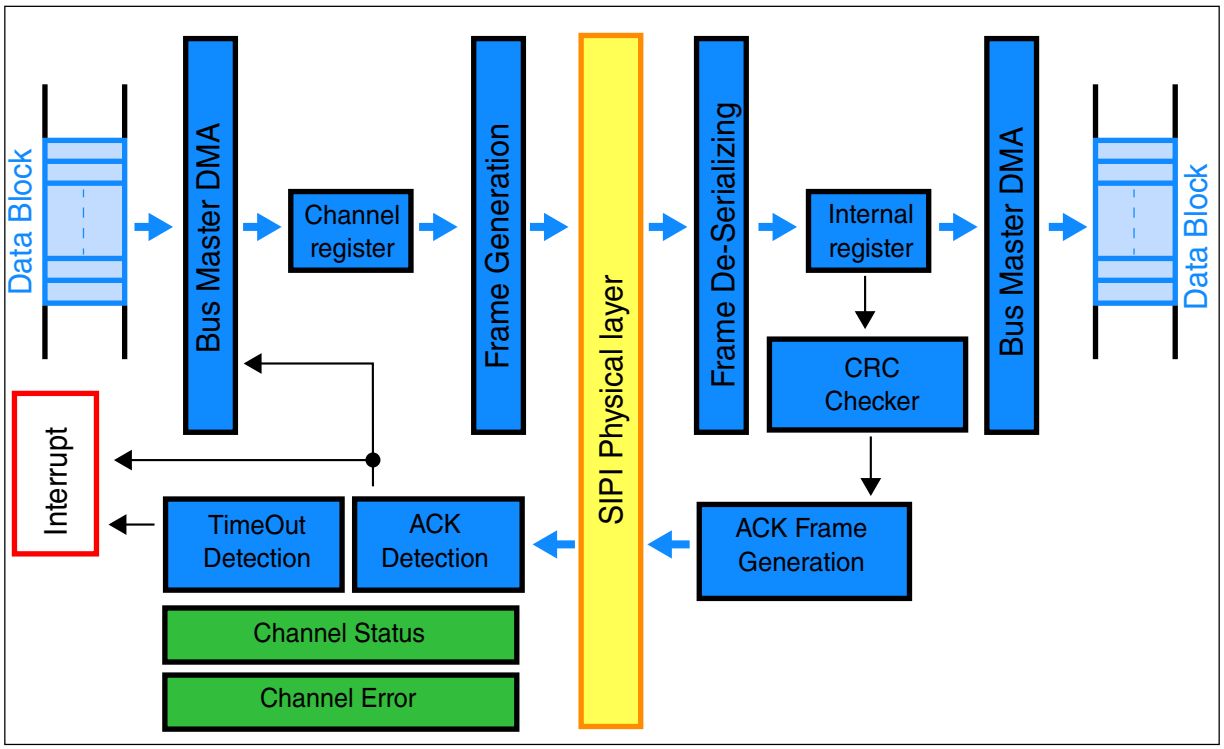

Figure 51-28. SIPI data stream with acknowledge trigger

51.9 DMA programming sequence

The DMA programming sequence is as follows:

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. If SIPI has received a read response, and error flags are not set on the LFAST Rx port, SIPI will assert ipd_request. In case of error, move to Step 8.
6. As soon as ipd_request is asserted, DMA transfer starts between the SIPI registers and RAM.
7. If DMA transfer minor loop/major loop is complete, and the request is negated, ipd_request is negated.
8. If an error occurs:

- The SIPI generates an interrupt
- Software takes control of the SIPI

9. Steps 5 – 8 are repeated until the transfer is finished.

51.10 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

51.10.1 Initialization mode

To enter Initialization mode software writes SIPI_MCR[INIT]=1 SIPI_MCR[MOEN] must be set before attempting to write SIPI_MCR[INIT]). To exit Initialization mode software writes SIPI_MCR[INIT]=0 (see SIPI Module Configuration Register (SIPI_MCR)).

All message transfers are stopped when in Initialization mode. If software invokes Initialization mode when a bus transfer is in progress, the transfer will be aborted immediately even if the transfer has not completed.

Note

It is recommended that software checks the state of SIPI (SIPI_MCR[MOEN]) before setting SIPI_MCR[INIT].

51.10.2 Normal mode

Once software has completed initialization of SIPI (SIPI_MCR[INIT]=1), it can enter Normal mode by writing SIPI_MCR[INIT]=0. SIPI needs to be in Normal mode for all data transfers (see SIPI Module Configuration Register (SIPI_MCR)).

Note

SIPI must be enabled before a attempting to write SIPI_MCR[INIT] (SIPI_MCR[MOEN]=1).

51.10.3 Module Disable (MD)

MD mode in the SIPI is used to help reduce power consumption. By default, SIPI is in Disable mode, SIPI_MCR[MOEN]=0, and is exited by writing SIPI_MCR[MOEN]=1 (see SIPI Module Configuration Register (SIPI_MCR)). All the activities on the SIPI Tx and Rx ports are immediately stopped in Module Disable mode.

51.11 Errors

This section describes the potential errors that can occur during SIPI operation.

51.11.1 Timeout error

A timeout error is generated at the initiator node when the acknowledge/response is not received within the time configured in the corresponding CTOR*n*[TOR] field setting (see SIPI Channel Timeout Register 0 (SIPI_CTOR0), SIPI Channel Timeout Register 1 (SIPI_CTOR1), SIPI Channel Timeout Register 2 (SIPI_CTOR2) and SIPI Channel Timeout Register 3 (SIPI_CTOR3)). A timeout error is indicated when ERR[TOE*n*]=1 (see SIPI Error Register (SIPI_ERR)).

Note

SIPI should not drop the response even after a timeout occurs. Software will poll both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may then be discarded.

51.11.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match the calculated CRC, and the SR[GCRCE] is set (see SIPI Status Register (SIPI_SR)). An interrupt will be asserted if MCR[CRCIE]=1 (see SIPI Module Configuration Register (SIPI_MCR)).

Note

The target node will not send an acknowledge to the initiator node when a CRC error is generated. An interrupt will be generated on the target side if the corresponding interrupt

enable bit is set. The initiator node will detect a timeout and take necessary action.

51.11.3 Maximum count reached error

The maximum count reached error is only generated at the target node. It is generated when the value of the SIPI_ACR is equal to the SIPI_MAXCR (see SIPI Max Count Register (SIPI_MAXCR) and SIPI Address Count Register (SIPI_ACR)). When the maximum count is reached, SIPI_SR[MCR] = 1 (see SIPI Status Register (SIPI_SR)). An interrupt will be generated if SIPI_MCR[MCRIE] = 1 (see SIPI Module Configuration Register (SIPI_MCR)).

51.11.4 Transaction ID error

The Transaction ID (TID) error is always generated at the initiator node only. It is generated when header bits 15–13 do not match SIPI_CSR*n*[TID] (transaction ID bits, see SIPI Channel Status Register 0 (SIPI_CSR0), SIPI Channel Status Register 1 (SIPI_CSR1), SIPI Channel Status Register 2 (SIPI_CSR2), and SIPI Channel Status Register 3 (SIPI_CSR3)). SIPI_CSR*n*[TIDE] = 1 when a TID error is detected, and an interrupt will be generated if SIPI_CIR*n*[TIDIE] = 1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

51.11.5 Acknowledge error

An incorrect acknowledge is received only from the initiator. When the acknowledge received is incorrect, SIPI_ERR[ACKR*n*] will be set (see SIPI Error Register (SIPI_ERR)). An interrupt will be generated if SIPI_CIR*n*[WAIE]=1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

51.12 CRC calculation

Example: If header is AABBh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

1) The CRC seed is initialized by FFFF_FFFFh.

2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).

3) So the header will be sent as DD55_0000h.

4) Address will be sent as 22CC_4488h.

5) Data will be sent as FF77_BB33h.

51.13 Interrupt logic

A description of the interrupt logic can be found in the following figure.

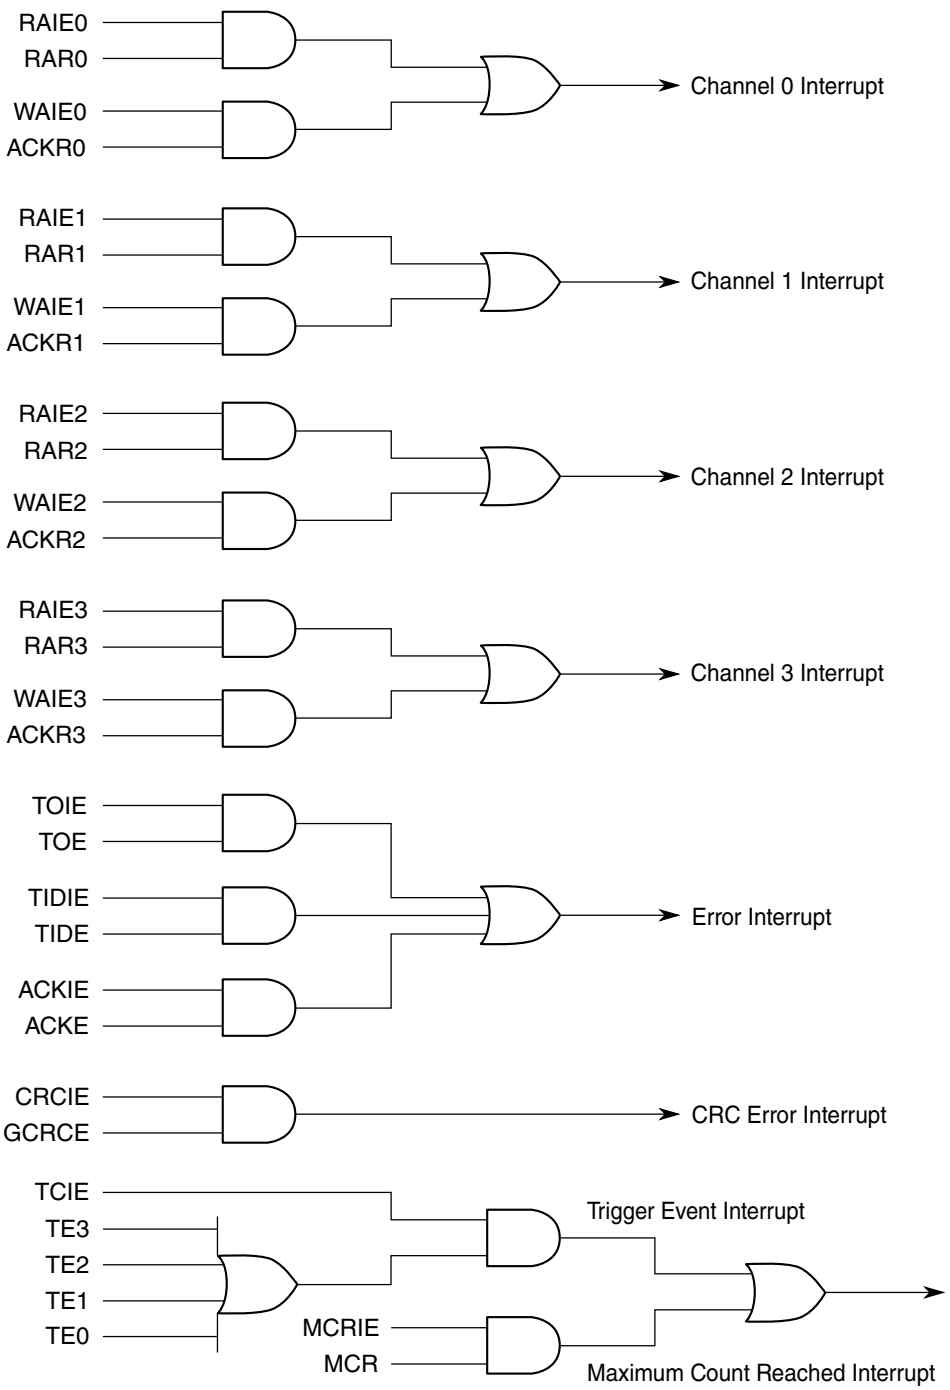

Figure 51-29. Interrupt description

51.14 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

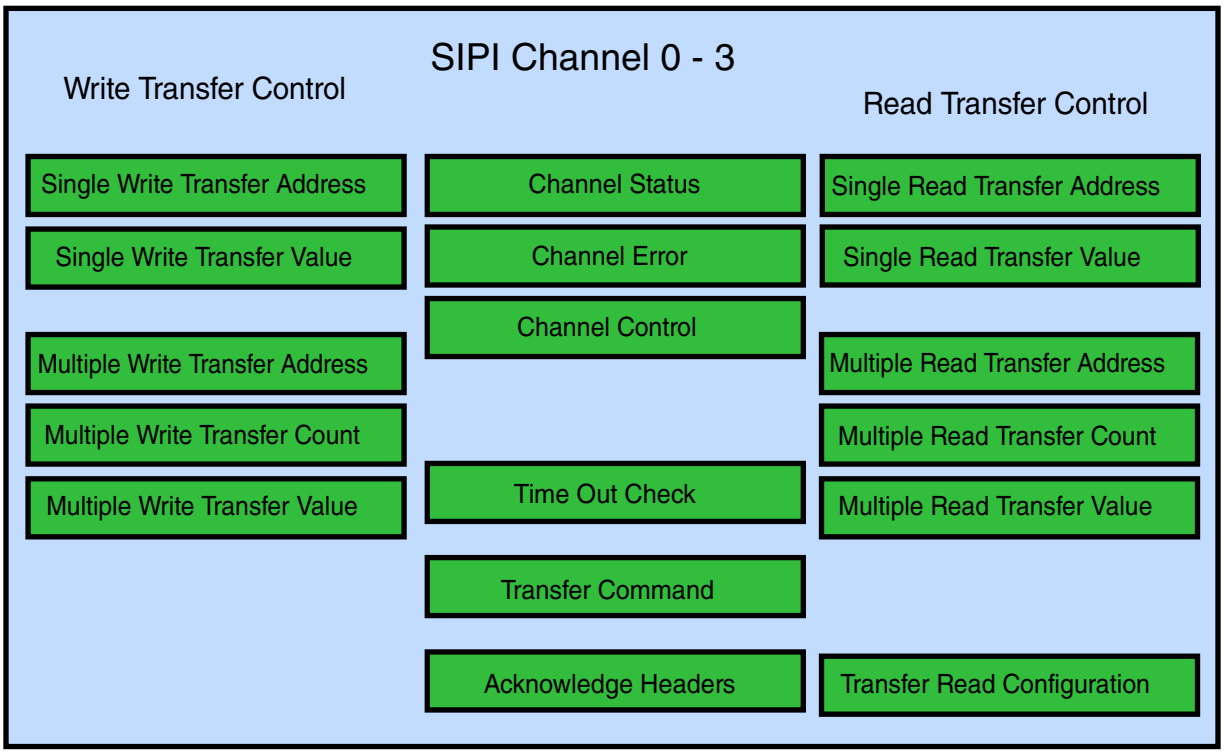

Figure 51-30. SIPI control and status overview – Register transfer

51.15 Memory map and register definition

SIPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SIPI Channel Control Register 0 (SIPI_CCR0)	32	R/W	0000_0000h	51.15.1/ 2213
4	SIPI Channel Status Register 0 (SIPI_CSR0)	32	R	0000_0000h	51.15.2/ 2216
C	SIPI Channel Interrupt Register 0 (SIPI_CIR0)	32	R/W	0000_0000h	51.15.3/ 2217
10	SIPI Channel Timeout Register 0 (SIPI_CTOR0)	32	R/W	0000_00FFh	51.15.4/ 2218

51.15.1 SIPI Channel Control Register 0 (SIPI_CCR0)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR0[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR0[CB] = 0).

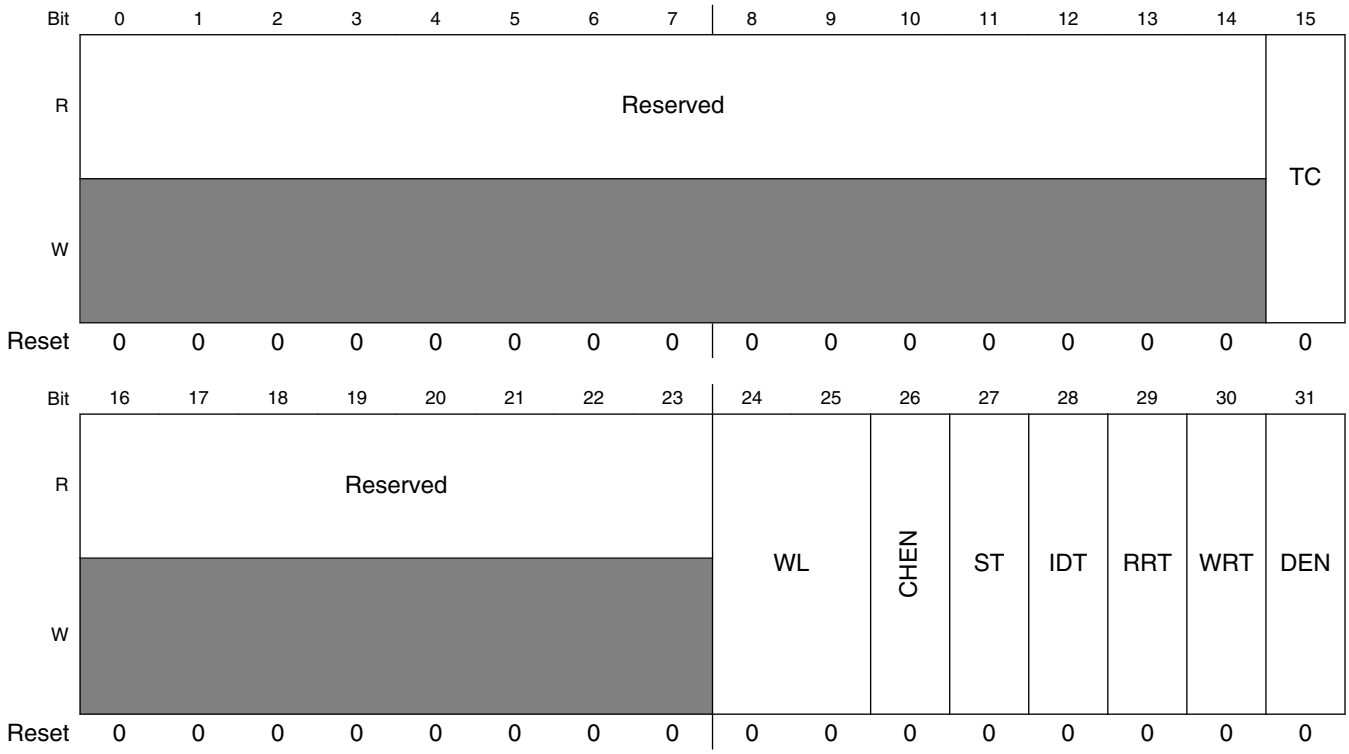
PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 0 (SIPI_CSR0)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 0 (SIPI_CAR0)).

Address: 0h base + 0h offset = 0h



SIPI_CCR0 field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR0. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority.

Table continues on the next page...

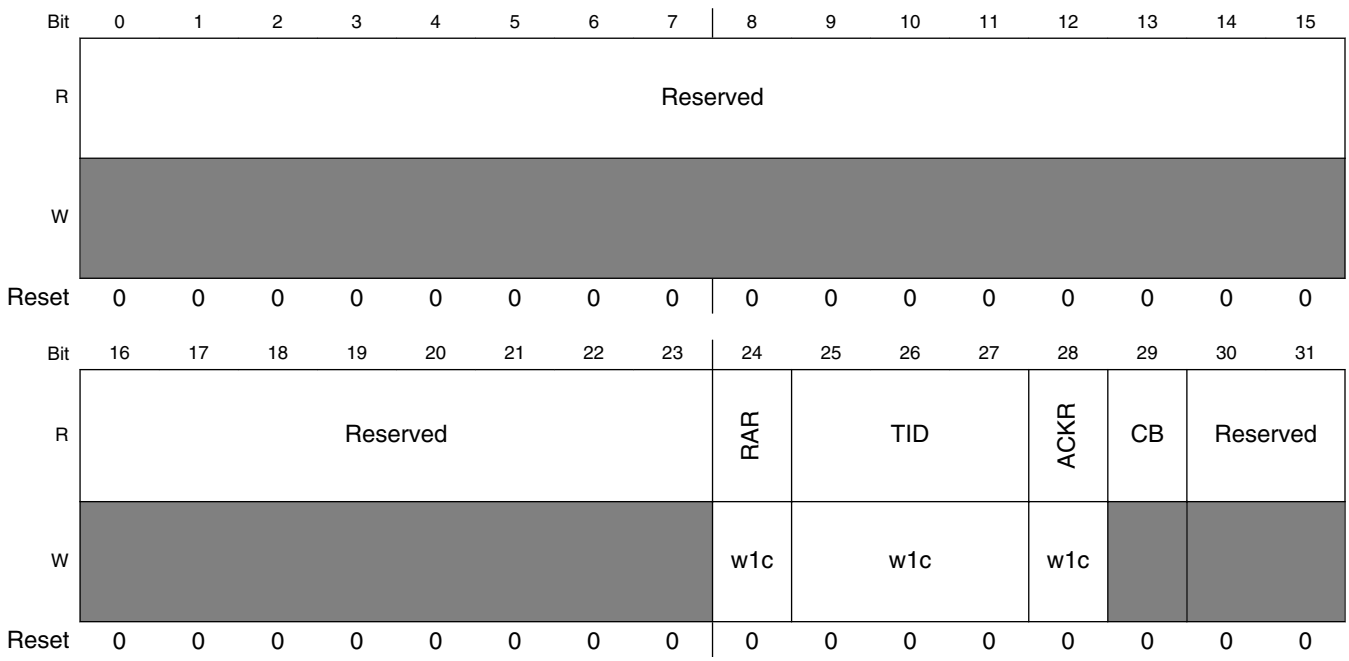
SIPI_CCR0 field descriptions (continued)

Field	Description
	0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1 or SIPI_CCR0[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

51.15.2 SIPI Channel Status Register 0 (SIPI_CSR0)

CSR0 contains the status bits for the current transfer.

Address: 0h base + 4h offset = 4h



SIPI_CSR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 0 status. 0 Channel 0 free 1 Channel 0 busy

Table continues on the next page...

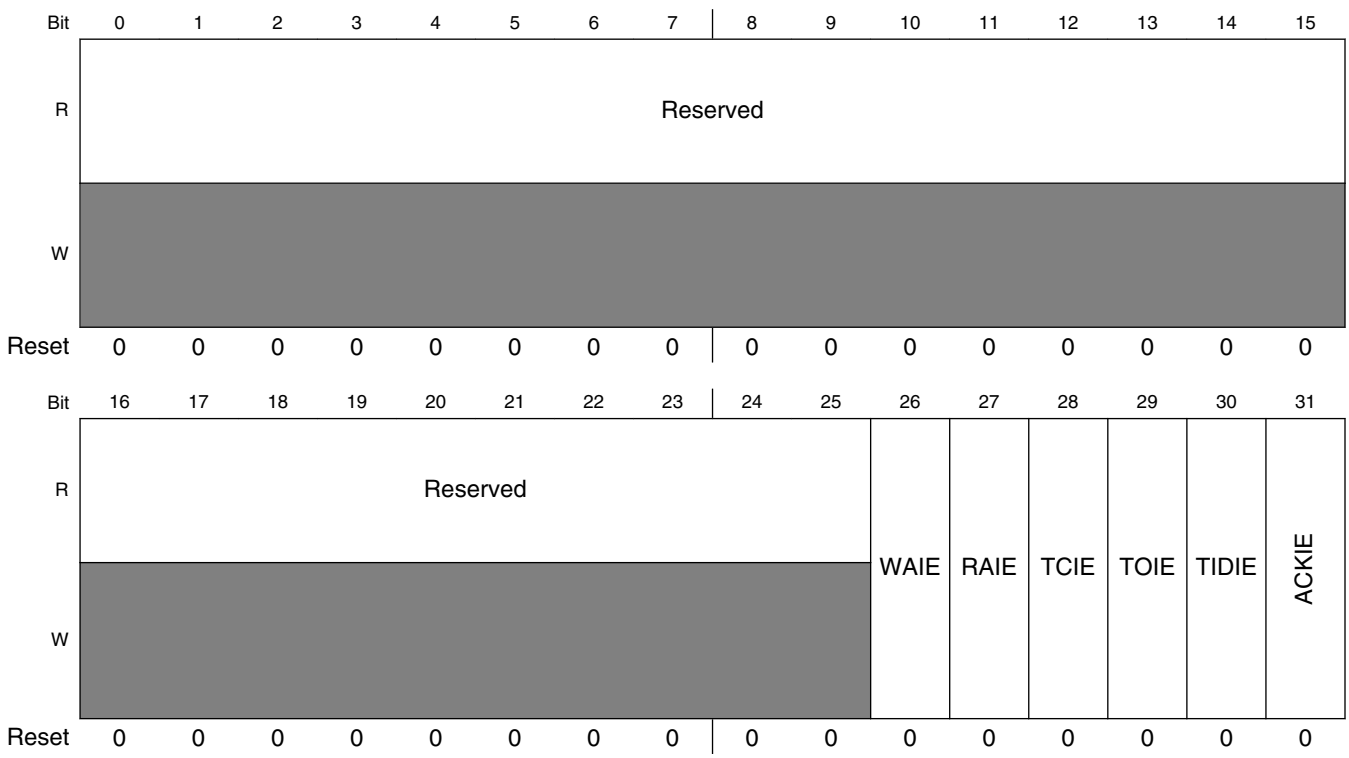
SIPI_CSR0 field descriptions (continued)

Field	Description
30–31 Reserved	This field is reserved.

51.15.3 SIPI Channel Interrupt Register 0 (SIPI_CIR0)

SIPI_CIR0 contains the interrupt enable bits for channel 0.

Address: 0h base + Ch offset = Ch



SIPI_CIR0 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

SIPI_CIR0 field descriptions (continued)

Field	Description
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled. 0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

51.15.4 SIPI Channel Timeout Register 0 (SIPI_CTOR0)

SIPI_CTOR0 contains the timeout value for Tx requests.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved																TOR															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

SIPI_CTOR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

51.15.5 SIPI Channel CRC Register 0 (SIPI_CCRC0)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIPI_CCRC0 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

51.15.6 SIPI Channel Address Register 0 (SIPI_CAR0)

SIPI_CAR0 is the address target for data transmission.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CAR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CAR0 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

51.15.7 SIPI Channel Data Register 0 (SIPI_CDR0)

SIPI_CDR0 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR0 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

51.15.8 SIPI Channel Control Register 1 (SIPI_CCR1)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR1[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR1[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 1 (SIPI_CSR1)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 1 (SIPI_CAR1)).

Address: 0h base + 20h offset = 20h

SIPI_CDR1 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

51.15.15 SIPI Channel Control Register 2 (SIPI_CCR2)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR2[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR2[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 2 (SIPI_CSR2)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 2 (SIPI_CAR2)).

SIPI_CCR2 field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR2. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT

Table continues on the next page...

SIPI_CCR2 field descriptions (continued)

Field	Description
	0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR2[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR2[IDT] = 1 or SIPI_CCR2[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

51.15.16 SIPI Channel Status Register 2 (SIPI_CSR2)

SIPI_CSR2 contains the status bits for the current transfer.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

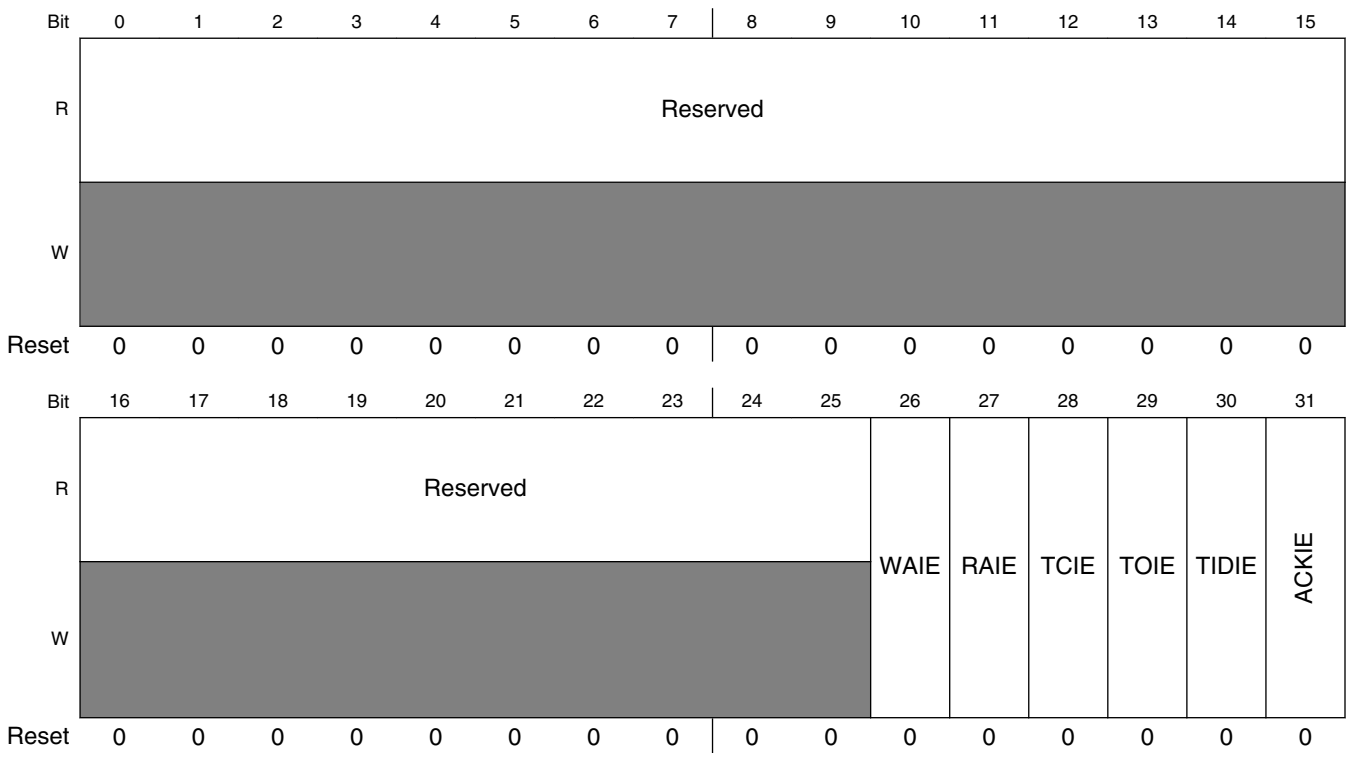
SIPI_CSR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 2 status. 0 Channel 2 free 1 Channel 2 busy
30–31 Reserved	This field is reserved.

51.15.17 SIPI Channel Interrupt Register 2 (SIPI_CIR2)

The SIPI_CIR2 contains the interrupt enable bits for channel 2.

Address: 0h base + 4Ch offset = 4Ch



SIPI_CIR2 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled.

Table continues on the next page...

SIPI_CIR2 field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

51.15.18 SIPI Channel Timeout Register 2 (SIPI_CTOR2)

SIPI_CTOR2 contains the timeout value for Tx requests.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

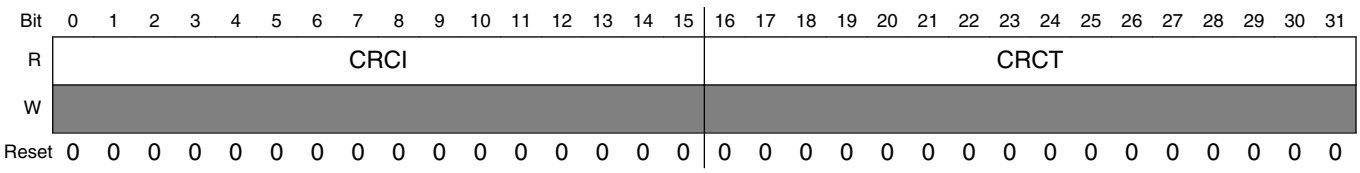
SIPI_CTOR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 TOR	Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

51.15.19 SIPI Channel CRC Register 2 (SIPI_CCRC2)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 54h offset = 54h



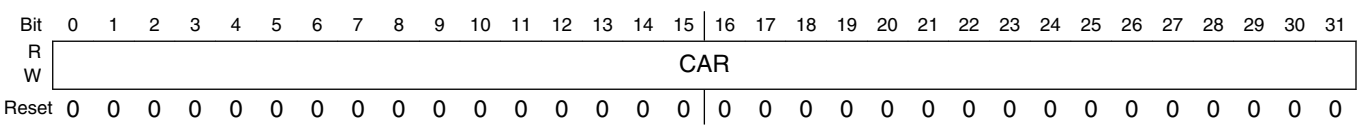
SIPI_CCRC2 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

51.15.20 SIPI Channel Address Register 2 (SIPI_CAR2)

SIPI_CAR2 is the address target for data transmission. For streaming operations this register is the start address.

Address: 0h base + 58h offset = 58h



SIPI_CAR2 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

51.15.21 SIPI Channel Data Register 2 (SIPI_CDR2_*n*)

SIPI_CDR2_*n*contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 5Ch offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR2																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR2_*n* field descriptions

Field	Description
0–31 CDR2	Data register bits. Contains the data that will be transmitted, or received.

51.15.22 SIPI Channel Control Register 3 (SIPI_CCR3)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR3[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR3[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 3 (SIPI_CSR3)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 3 (SIPI_CAR3)).

Address: 0h base + 7Ch offset = 7Ch

SIPI_CCR3 field descriptions

Field	Description
0–14 Reserved	This field is reserved.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR3. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved.
24–25 WL	Word Length Transfer. For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT

Table continues on the next page...

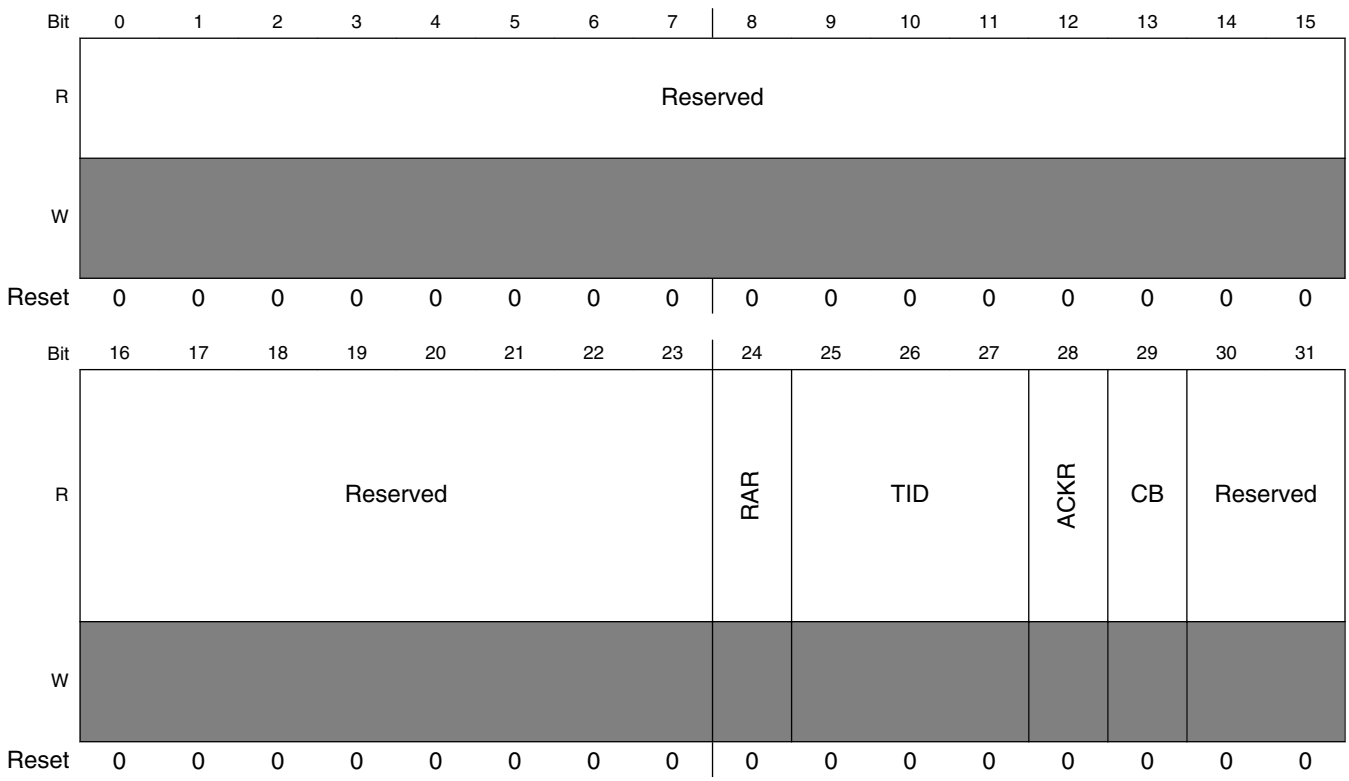
SIPI_CCR3 field descriptions (continued)

Field	Description
	3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1 or SIPI_CCR3[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

51.15.23 SIPI Channel Status Register 3 (SIPI_CSR3)

SIPI_CSR3 contains the status bits for the current transfer.

Address: 0h base + 80h offset = 80h



SIPI_CSR3 field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received

Table continues on the next page...

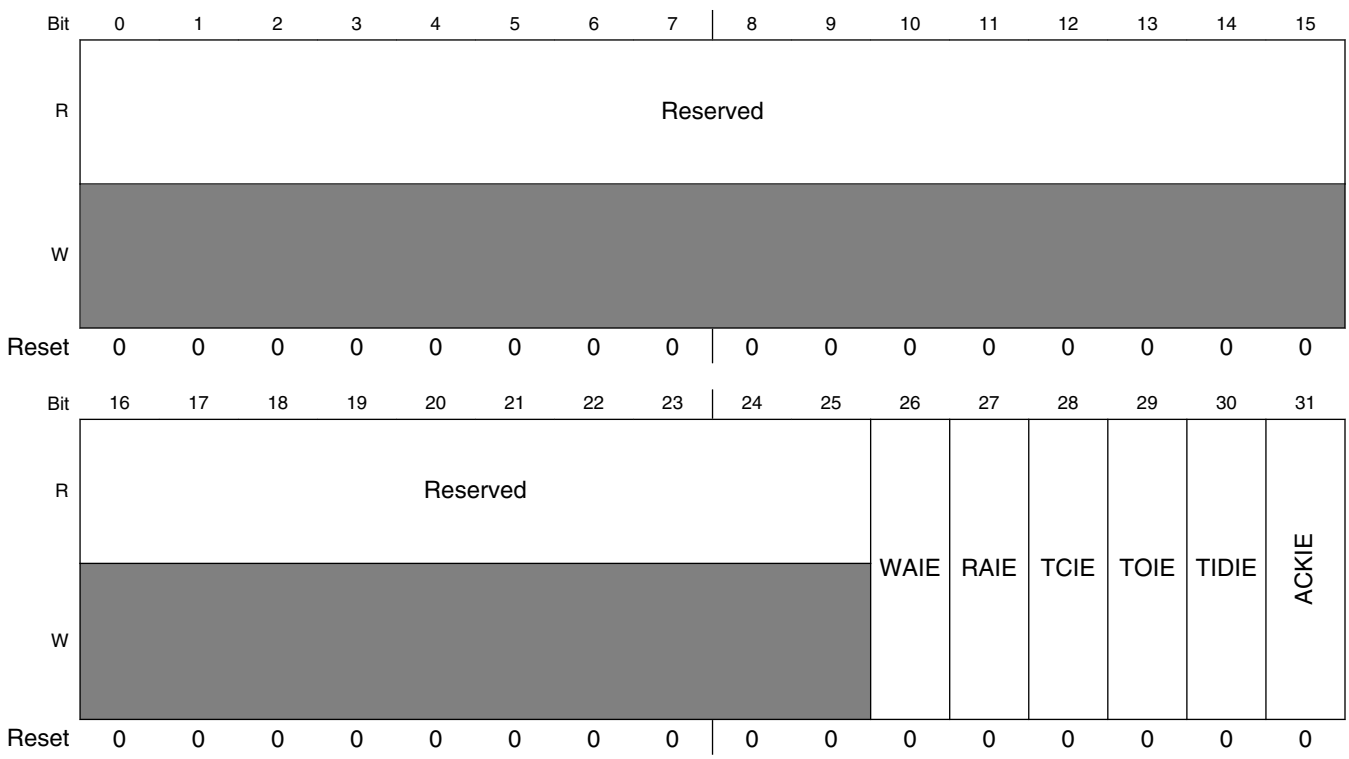
SIPI_CSR3 field descriptions (continued)

Field	Description
29 CB	Channel Busy. Indicates channel 3 status. 0 Channel 3 free 1 Channel 3 busy
30–31 Reserved	This field is reserved.

51.15.24 SIPI Channel Interrupt Register 3 (SIPI_CIR3)

SIPI_CIR3 contains the interrupt enable bits for channel 3.

Address: 0h base + 88h offset = 88h



SIPI_CIR3 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable.

Table continues on the next page...

SIPI_CIR3 field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

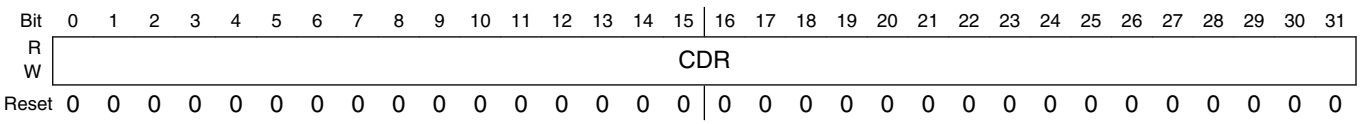
SIPI_CAR3 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

51.15.28 SIPI Channel Data Register 3 (SIPI_CDR3)

SIPI_CDR3 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 98h offset = 98h



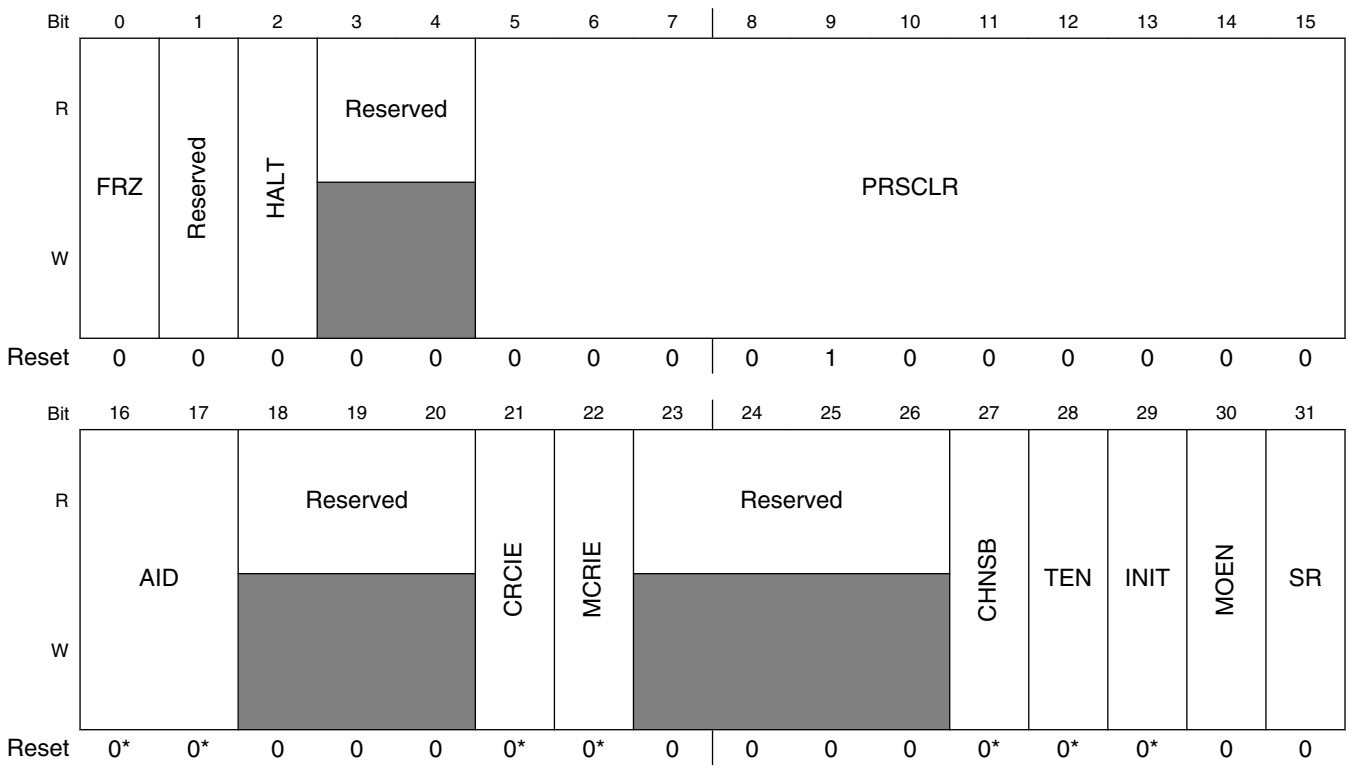
SIPI_CDR3 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

51.15.29 SIPI Module Configuration Register (SIPI_MCR)

The SIPI_MCR is a global 32-bit configuration register.

Address: 0h base + 9Ch offset = 9Ch



* Notes:
- INIT field: Can only be written when SIPI_MCR[MOEN] = 1.
- TEN field: Can only be written when SIPI_MCR[MOEN] = 1.
- CHNSB field: Can be written only once after reset.
- MCRIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- CRCIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- AID field: Can be written in initialization mode only (SIPI_MCR[INIT] = 1).

SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1.

Table continues on the next page...

SIPI_MCR field descriptions (continued)

Field	Description
	0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1 Reserved	This field is reserved. **Important:** Always write the default value to this field.
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–4 Reserved	This field is reserved.
5–15 PRSCLR	Timeout counter prescaler The timeout counter runs on the prescaled system clock. Default value is 64 (040h). The allowed programmable values are (all other values are ignored): 040h 64 (default) 080h 128 100h 256 200h 512 400h 1024 **NOTE:** This field should be programmed by software during initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. **NOTE:** Writes to SIPI_MCR[PRSCLR] can only be accomplished with 16-bit or 32-bit writes.
16–17 AID	Address Increment/Decrement These bits define the type of address change at the target node. **NOTE:** This bits should be programmed by software in initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. 00 no change. address stays same 01 address increments by 4 10 address decrements by 4 11 not used
18–20 Reserved	This field is reserved.
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable

Table continues on the next page...

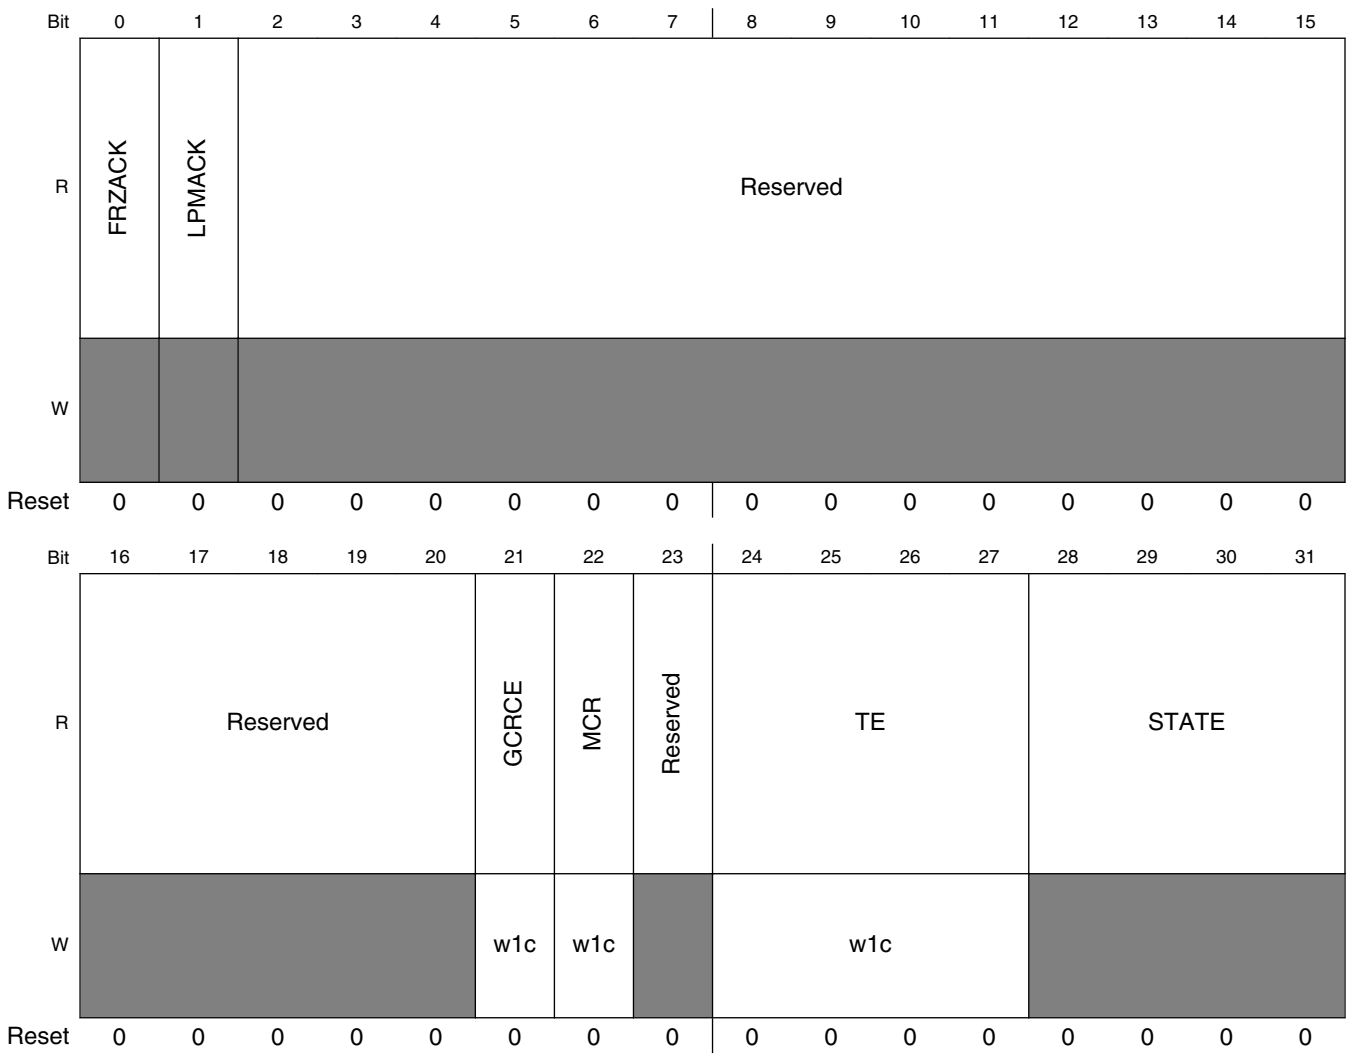
SIPI_MCR field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
23–26 Reserved	This field is reserved.
27 CHNSB	Channel coding select bit. 0 Code Table II (see Table 51-2) 1 Code Table I (see Table 51-2)
28 TEN	Target Enable Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in "streaming without ACK" mode. This bit has to be enabled for the transmission operations also.
29 INIT	Initialization Mode Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, all SIPI operations are immediately stopped.
31 SR	Soft Reset Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

51.15.30 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h



SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited.

Table continues on the next page...

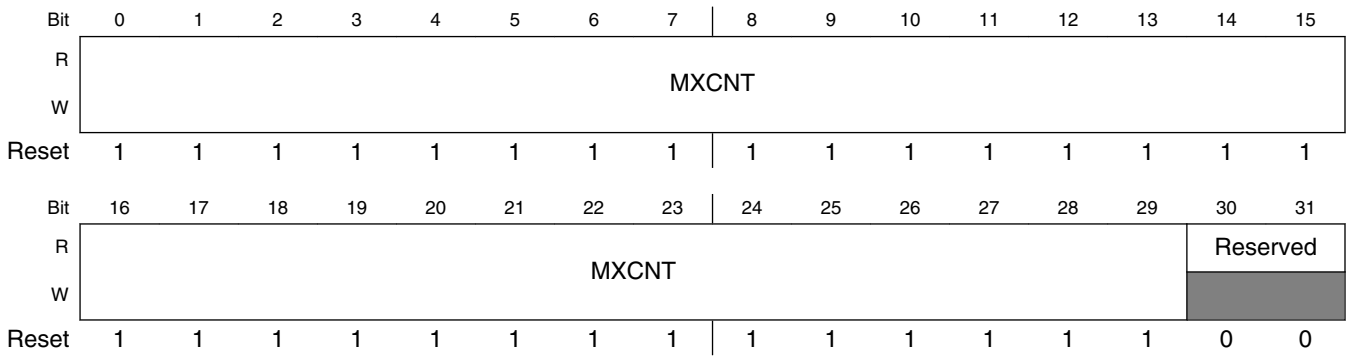
SIPI_SR field descriptions (continued)

Field	Description
	0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge. This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI is not in low power mode 1 SIPI is in Disable Mode.
2–20 Reserved	This field is reserved.
21 GCRCE	Global CRC Error Bit. 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached. This bit will be set whenever SIPI_ACR[ADCNT] = SIPI_MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPI_MCR[MCRIE] = 1. This it should be cleared by software.
23 Reserved	This field is reserved.
24–27 TE	Trigger Event on Respective Channels. This field enables interrupts for target nodes. xxx1 TE0 = 1 - Channel 0 trigger event xx1x TE1 = 1 - Channel 1 trigger event x1xx TE2 = 1 - Channel 2 trigger event 1xxx TE3 = 1 - Channel 3 trigger event
28–31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

51.15.31 SIPI Max Count Register (SIPI_MAXCR)

SIPI_MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

Address: 0h base + A4h offset = A4h



SIPI_MAXCR field descriptions

Field	Description
0–29 MXCNT	This field contains the maximum address count value at the target node. It should be programmed via direct write request through the initiator.
30–31 Reserved	This field is reserved.

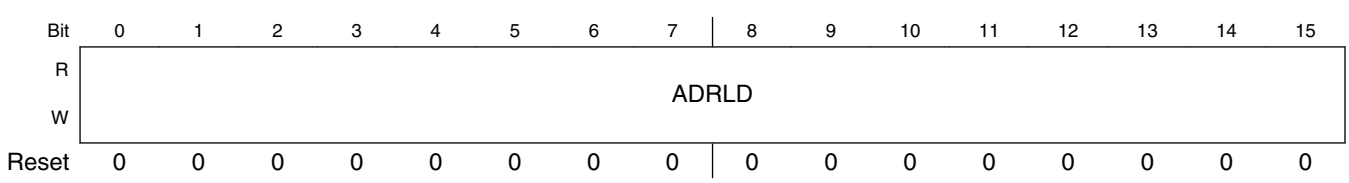
51.15.32 SIPI Address Reload Register (SIPI_ARR)

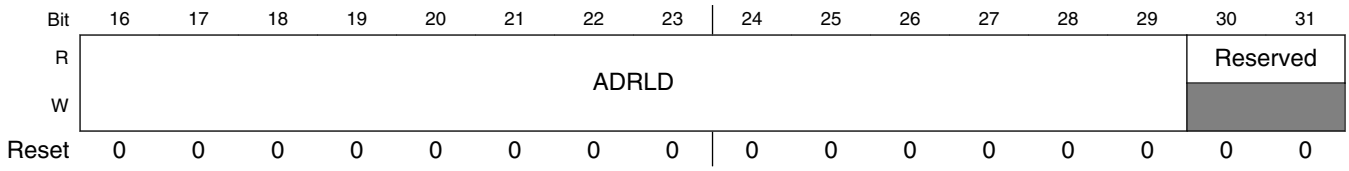
The SIPI_ARR contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.

NOTE

This register is writeable only when SIPI_MCR[INIT] = 1.

Address: 0h base + A8h offset = A8h





SIPI_ARR field descriptions

Field	Description
0–29 ADRLD	ADRLD contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.
30–31 Reserved	This field is reserved.

51.15.33 SIPI Address Count Register (SIPI_ACR)

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

NOTE

SIPI_ARR, SIPI_ACR and SIPI_MAXCR will be configured by direct write operation through the initiator.

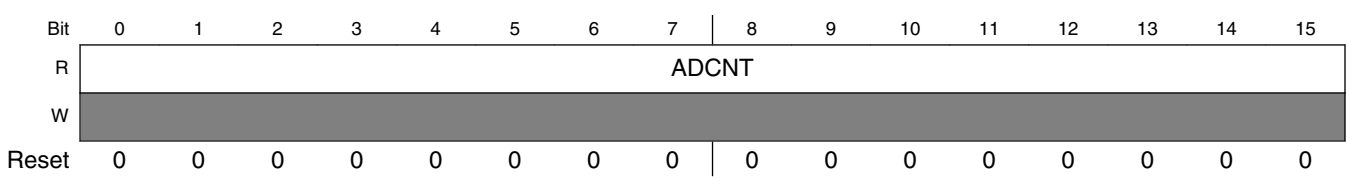
NOTE

When a streaming write command is received, the target will start the write operation from the address present in SIPI_ACR (address count register).

NOTE

After each 32-bit write has completed, SIPI_ACR[ADCNT] is compared against SIPI_MAXCR[MXCNT]. If they are equal, SIPI_ACR[ADCNT] is loaded with the value stored in SIPI_ARR[ADRLD]. If they are not equal, the SIPI_ACR[ADCNT] will increment by 4, decrement by 4 or remain the same (depending on configuration). In both cases, the SIPI_ACR[ADCNT] will contain the address at which the next streaming write will occur.

Address: 0h base + ACh offset = ACh



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ADCNT														Reserved	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_ACR field descriptions

Field	Description
0–29 ADCNT	Feflects the count value of address counter at target node. It should be configured by direct write request from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPI_ACR will point to the next address to be written.
30–31 Reserved	This field is reserved.

51.15.34 SIPI Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

Chapter 52
LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

52.1 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

52.2 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

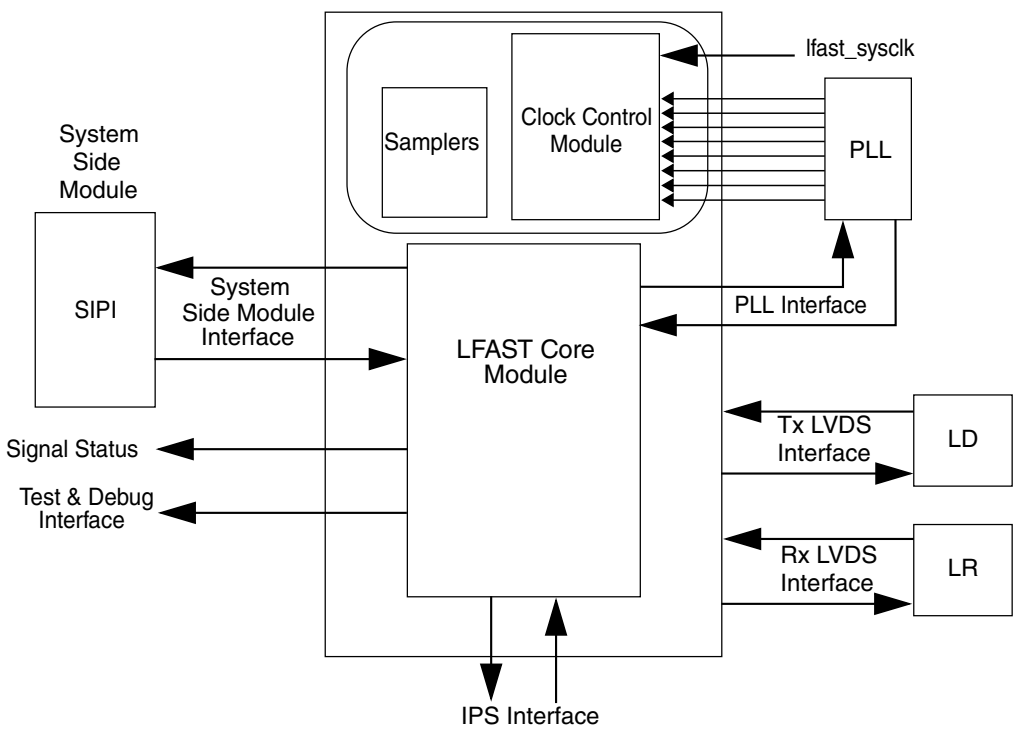

Figure 52-1. LFAST block diagram

52.3 External signals

LFAST is a five pin interface with the following signals :

- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

52.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

52.4 LFAST frame structure

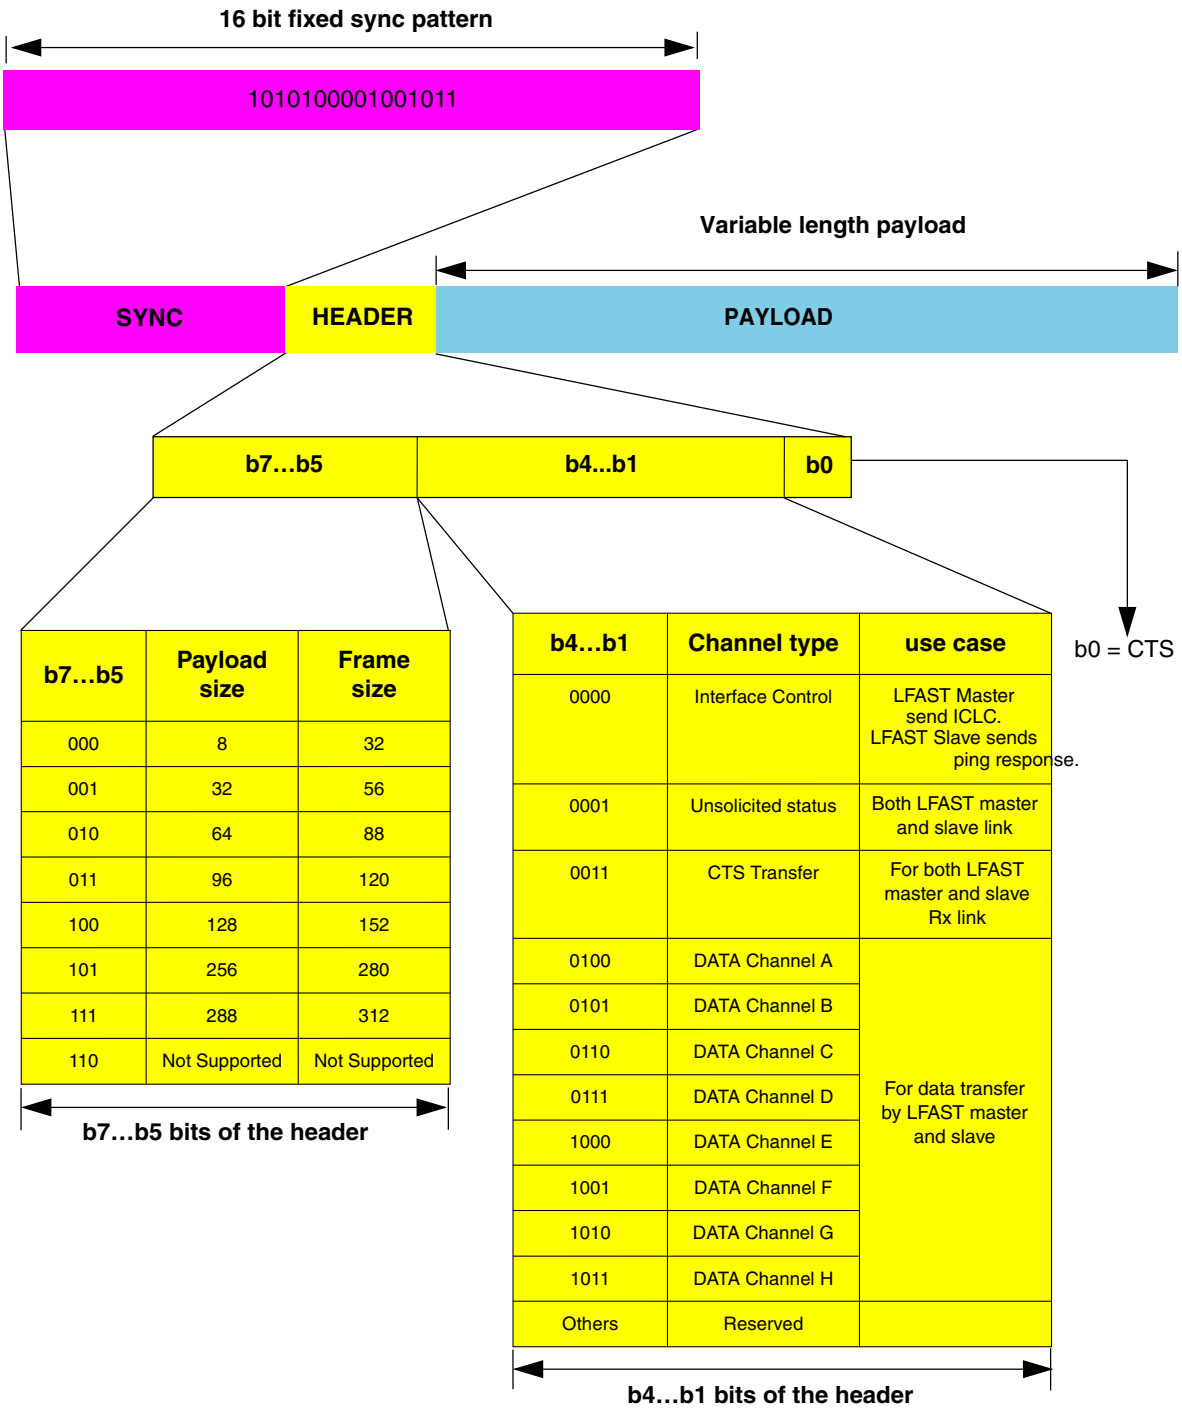
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See Figure 52-2 for details of the LFAST frame.



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	288	312
110	Not Supported	Not Supported

b4…b1	Channel type	use case
0000	Interface Control	LFAST Master send ICLC. LFAST Slave sends ping response.
0001	Unsolicited status	Both LFAST master and slave link
0011	CTS Transfer	For both LFAST master and slave Rx link
0100	DATA Channel A	For data transfer by LFAST master and slave
0101	DATA Channel B	
0110	DATA Channel C	
0111	DATA Channel D	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 52-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

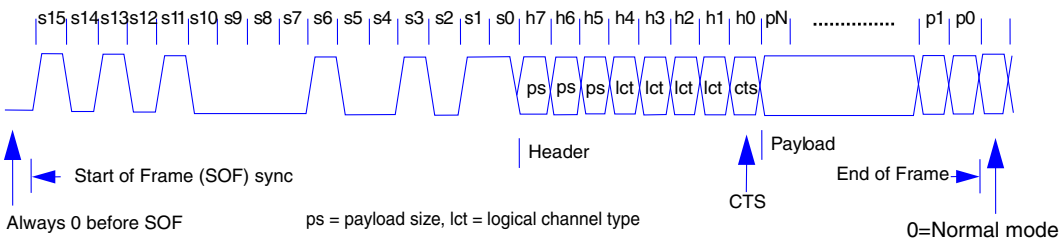


Figure 52-3. Serial frame structure

The frame structure is shown in Figure 52-3 and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in Table 52-1 :

Table 52-1. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.

- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

52.5 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer up to the maximum data rate shown in the product Data Sheet.
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Receives ICLC frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

52.6 Memory map and register definition

All registers are 32 bits wide.

LFAST memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	LFAST Mode Configuration Register (LFAST_MCR)	32	R/W	See section	52.6.1/2262

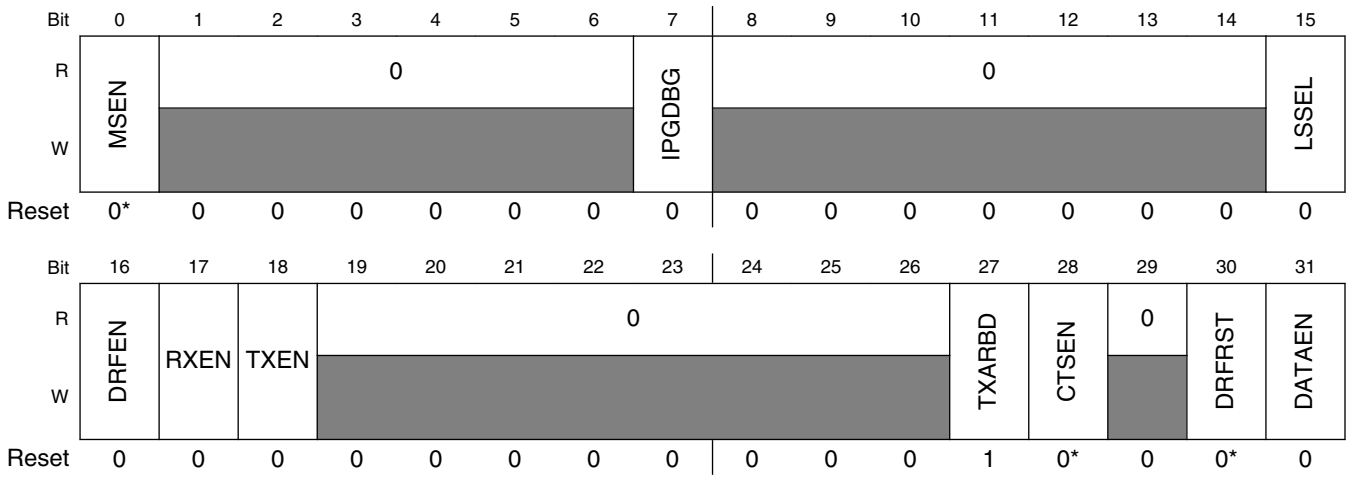
52.6.1 LFAST Mode Configuration Register (LFAST_MCR)

Address: 0h base + 0h offset = 0h



* Notes:
- DRFRST field: Set by user software and then cleared by system hardware.
- CTSEN field: Only writable when MCR[DRFEN] = 0.
- MSEN field: Writable only once after the asynchronous reset.

LFAST_MCR field descriptions

Field	Description
0 MSEN	LFAST Master or Slave mode Enable. This bit selects either the LFAST master or slave functionality. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable

Table continues on the next page...

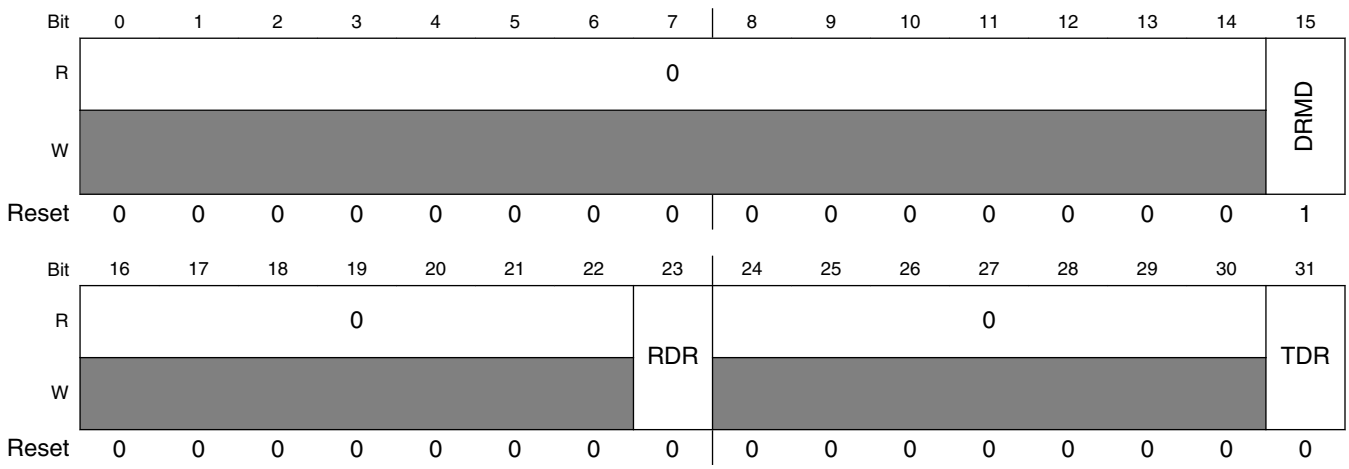
LFAST_MCR field descriptions (continued)

Field	Description
	registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be modified by LFAST slave H/W on reception of an ICLC command frame. This field can only be written in dual mode (LFAST_GSR[DUALMD] = 1). 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 LFAST transmitter Interface is enabled. New requests are accepted.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 CTSEN	CTS Enable. This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. This bit is only writable when MCR[DRFEN] = 0. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit doesn't represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset.. 0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

52.6.2 LFAST Speed Control Register (LFAST_SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 0h base + 4h offset = 4h



LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. 0 S/W controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no affect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is high speed.

Table continues on the next page...

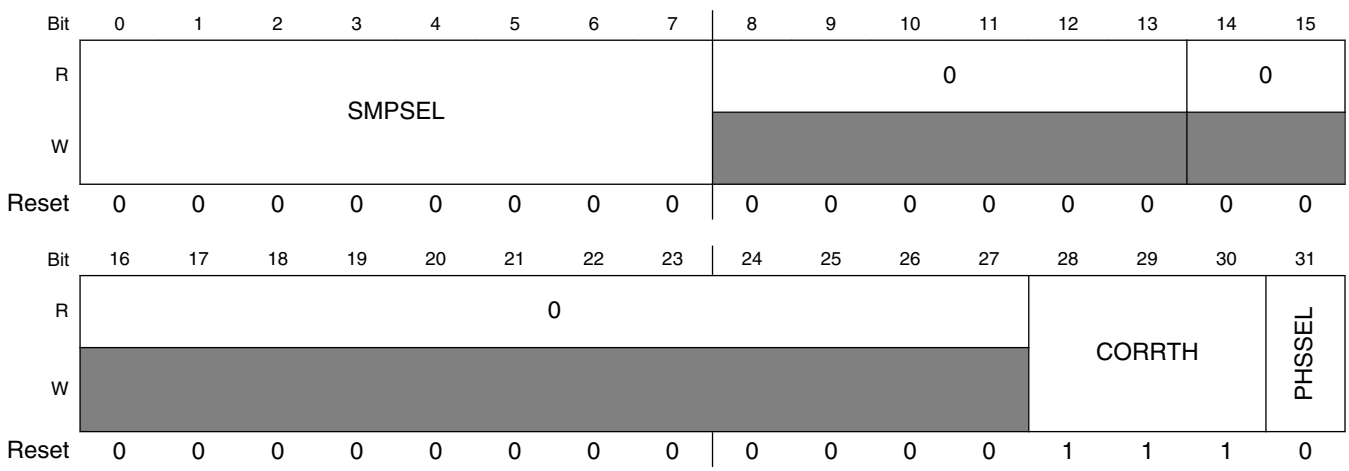
LFAST_SCR field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Tx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is high speed.

52.6.3 LFAST Correlator Control Register (LFAST_COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 0h base + 8h offset = 8h



LFAST_COCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0.

Table continues on the next page...

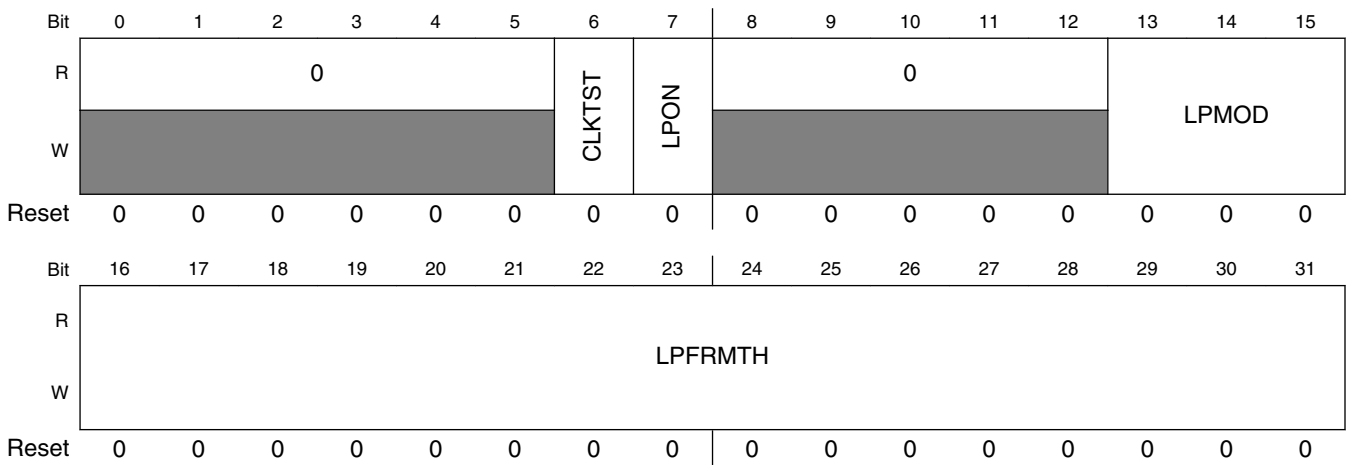
LFAST_COCR field descriptions (continued)

Field	Description
	00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

52.6.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 0h base + Ch offset = Ch



LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved

Table continues on the next page...

LFAST_TMCR field descriptions (continued)

Field	Description
	110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

52.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ...

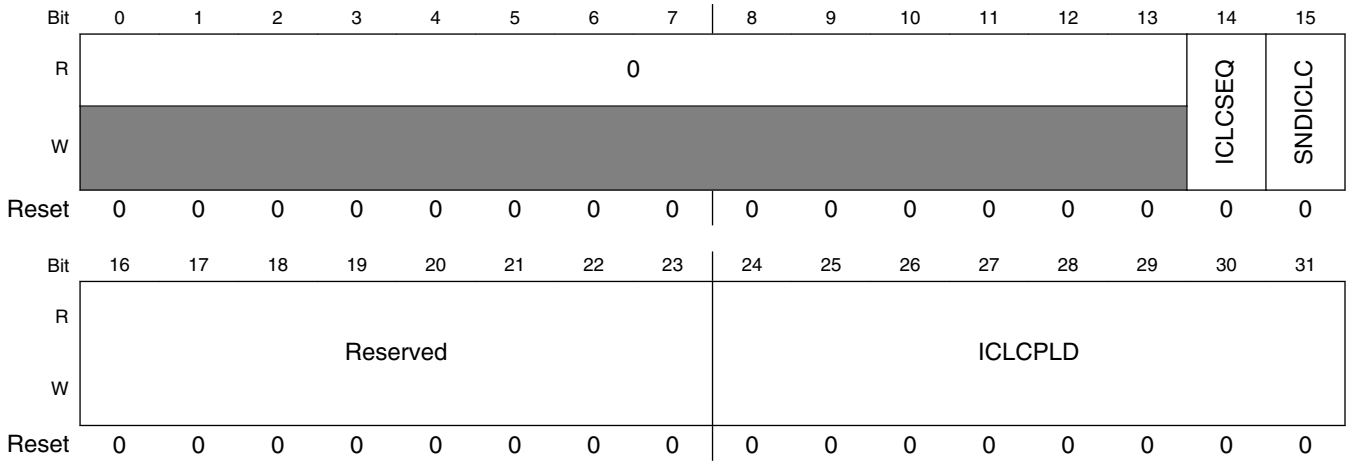
Table continues on the next page...

LFAST_SLCR field descriptions (continued)

Field	Description
	12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 µs) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 µs) ... Eh 14 cycles Fh 15 cycles

52.6.8 LFAST ICLC Control Register (LFAST_ICR)

Address: 0h base + 1Ch offset = 1Ch

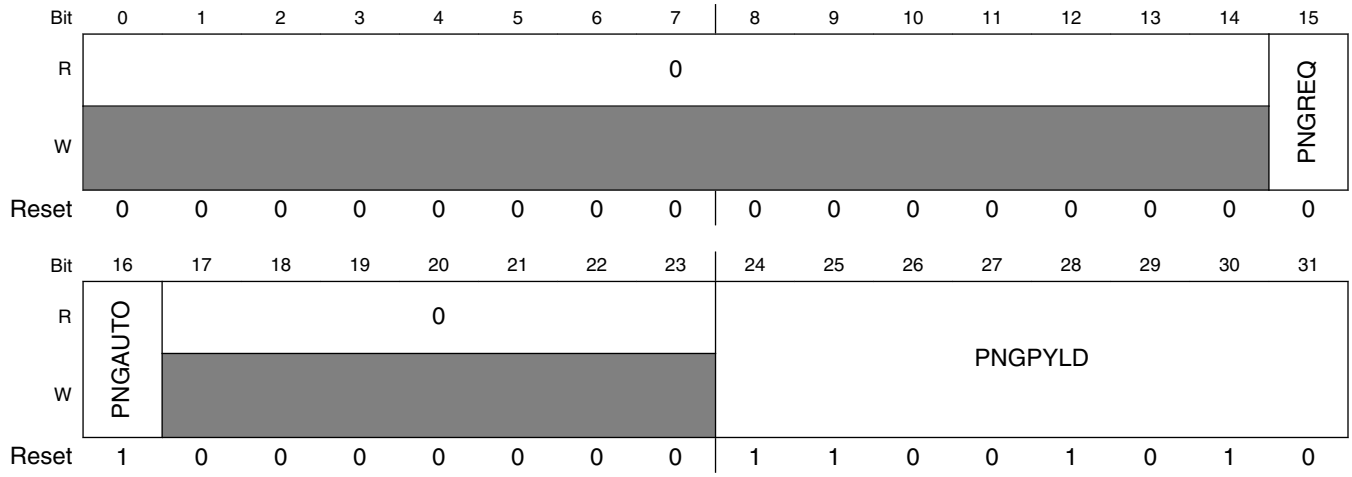


LFAST_ICR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ICLCSEQ	ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored. 0 Single ICLC frame transfer. 1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0.
15 SNDICLC	ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. Set by user software and cleared by system hardware. 0 No Valid ICLC frame for transfer. 1 Valid ICLC frame for transfer.
16–23 Reserved	This field is reserved.
24–31 ICLCPLD	ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. This field can only be written when ICR[SNDICLC] = 0 (see Table 52-8 for supported ICLC payloads).

52.6.9 LFAST Ping Control Register (LFAST_PICR)

Address: 0h base + 20h offset = 20h

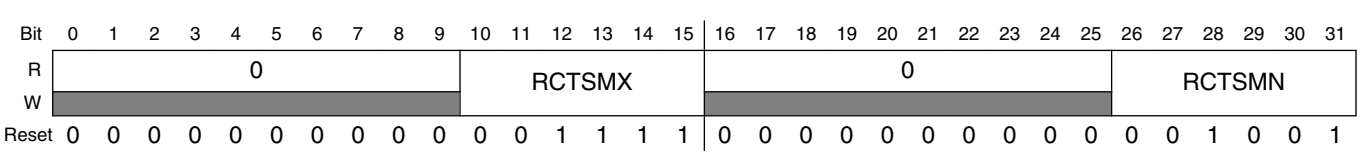


LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

52.6.10 LFAST Rx FIFO CTS Control Register (LFAST_RFCR)

Address: 0h base + 2Ch offset = 2Ch

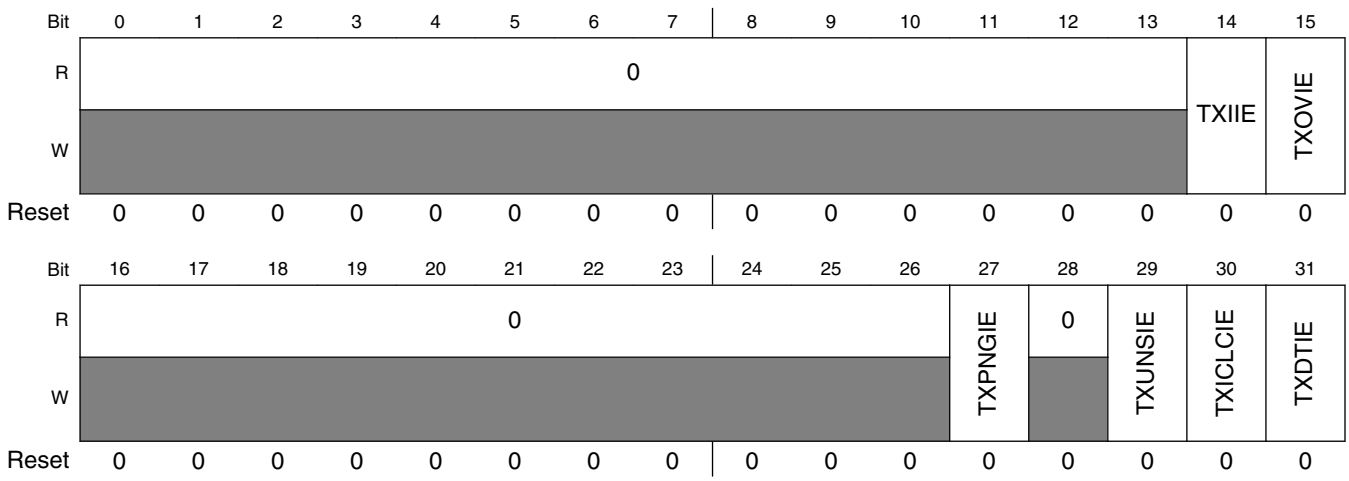


LFAST_RFCR field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 RCTSMX	Rx FIFO Maximum Threshold. Defines the condition for CTS bit of frames to be negated. This field can only be written when LFAST_MCR[DRFEN] = 0.
16–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 RCTSMN	Rx FIFO Minimum Threshold. Defines the condition for CTS bit of frames to be set. This field can only be written when LFAST_MCR[DRFEN] = 0.

52.6.11 LFAST Tx Interrupt Enable Register (LFAST_TIER)

Address: 0h base + 30h offset = 30h



LFAST_TIER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIIE	Tx Data Interface Not Enabled - (Mask) Enables or disables the interrupt. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt is disabled 1 Interrupt is enabled
15 TXOVIE	Transmit Data FIFO Overflow Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGIE	Ping Response Frame Transmitted Interrupt Enable.

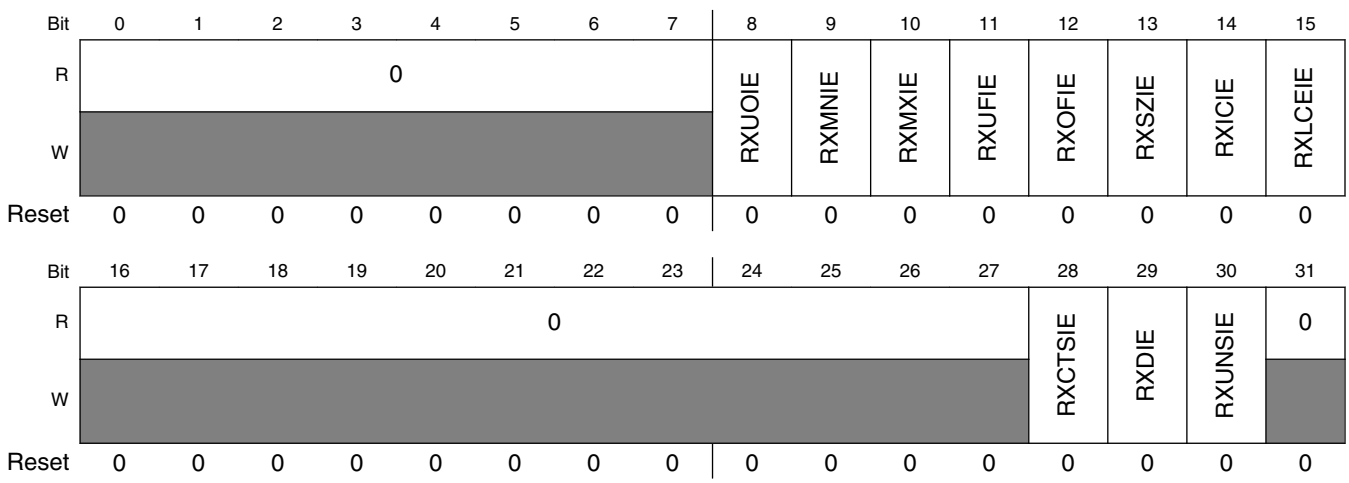
Table continues on the next page...

LFAST_TIER field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TXUNSIE	Unsolicited Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
30 TXICLCIE	ICLC Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
31 TXDTIE	Data Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled

52.6.12 LFAST Rx Interrupt Enable Register (LFAST_RIER)

Address: 0h base + 34h offset = 34h



LFAST_RIER field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RXUOIE	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt is disabled 1 Interrupt is enabled

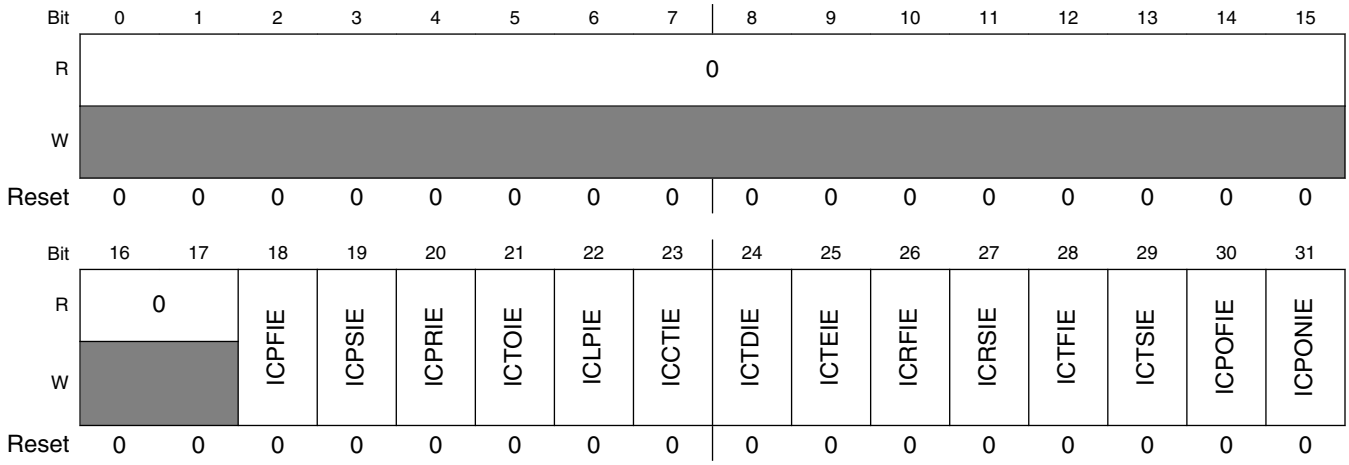
Table continues on the next page...

LFAST_RIER field descriptions (continued)

Field	Description
9 RXMNIE	Rx Data FIFO Min Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
10 RXMXIE	Rx Data FIFO Max Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
11 RXUFIE	Rx Data FIFO Underflow 0 Interrupt is disabled 1 Interrupt is enabled
12 RXOFIE	Rx Data FIFO Overflow 0 Interrupt is disabled 1 Interrupt is enabled
13 RXSZIE	Frame with unsupported frame size received. Valid frame sizes are defined in Table 52-12 0 Interrupt is disabled 1 Interrupt is enabled
14 RXICIE	Invalid ICLC code Received 0 Interrupt is disabled 1 Interrupt is enabled
15 RXLCEIE	Invalid Logical Channel Type 0 Interrupt is disabled 1 Interrupt is enabled
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSIE	Frame with CTS bit Low Received 0 Interrupt is disabled 1 Interrupt is enabled
29 RXDIE	Data frame received 0 Interrupt is disabled 1 Interrupt is enabled
30 RXUNSIE	Unsolicited Frame received 0 Interrupt is disabled 1 Interrupt is enabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.6.13 LFAST Rx ICLC Interrupt Enable Register (LFAST_RIIER)

Address: 0h base + 38h offset = 38h



LFAST_RIIER field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ICPFIE	Ping Frame Response failed 0 Interrupt is disabled 1 Interrupt is enabled
19 ICPSIE	Ping Frame Response successful 0 Interrupt is disabled 1 Interrupt is enabled
20 ICPRIE	ICLC frame for Ping Frame Request received 0 Interrupt is disabled 1 Interrupt is enabled
21 ICTOIE	ICLC frame for Test mode off received 0 Interrupt is disabled 1 Interrupt is enabled
22 ICLPIE	ICLC frame for Loopback On received 0 Interrupt is disabled 1 Interrupt is enabled
23 ICCTIE	ICLC frame for Clk Test mode on received 0 Interrupt is disabled 1 Interrupt is enabled
24 ICTDIE	ICLC frame for LFAST Slaves Tx Interface Disable received

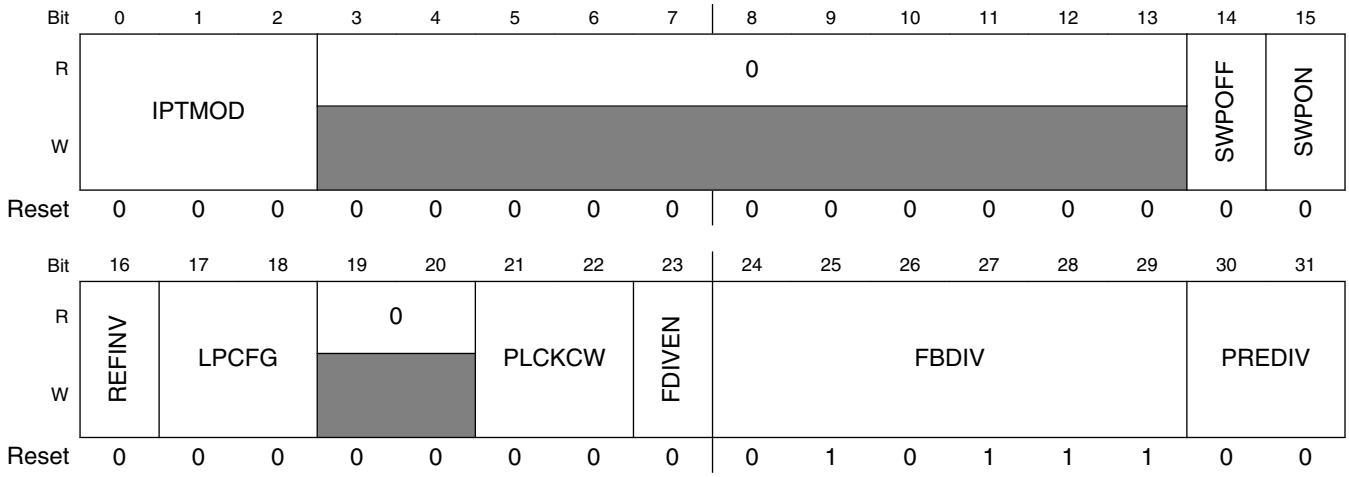
Table continues on the next page...

LFAST_RIIER field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
25 ICTEIE	ICLC frame for LFAST Slaves Tx Interface Enable received 0 Interrupt is disabled 1 Interrupt is enabled
26 ICRFIE	ICLC frame for LFAST Slaves Rx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
27 ICRSIE	ICLC frame for LFAST Slaves Rx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
28 ICTFIE	ICLC frame for LFAST Slaves Tx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
29 ICTSIE	ICLC frame for LFAST Slaves Tx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
30 ICPOFIE	ICLC frame for PLL OFF received 0 Interrupt is disabled 1 Interrupt is enabled
31 ICPONIE	ICLC frame for PLL ON received 0 Interrupt is disabled 1 Interrupt is enabled

52.6.14 LFAST PLL Control Register (LFAST_PLLCR)

Address: 0h base + 3Ch offset = 3Ch



LFAST_PLLCR field descriptions

Field	Description
0–2 IPTMOD	Test mode programmability 000 Functional mode 001 Closed Loop 1 010 Force Vctrl 011 Charge Pump Up 100 Charge Pump Up Internal Test 101 Charge Pump Idle 110 Charge Pump Down 111 Closed Loop 2
3–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SWPOFF	SW signal to turn OFF the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned OFF.
15 SWPON	SW signal to turn ON the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned ON
16 REFINV	Inverts reference clock edge to PFD. If System PLL PFD using same reference clock, enabling this feature will minimize noise injection crosstalk via the substrate. 0 Do not inverted 1 Invert

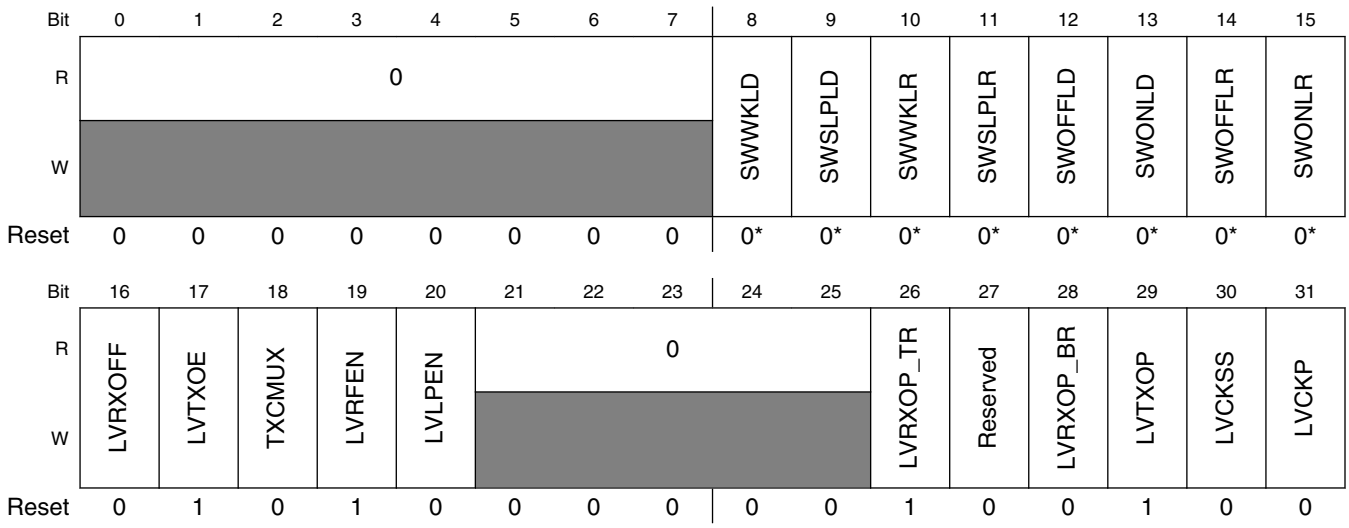
Table continues on the next page...

LFAST_PLLCR field descriptions (continued)

Field	Description
17–18 LPCFG	PLL Loop Optimization for sysclk frequency 00 1 × IBASE current 01 0.5 × IBASE current 10 1.5 × IBASE current 11 2 × IBASE current
19–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 PLCKCW	PLL Lock Ready Count Width. Defines the number of cycles PLL waits for before asserting lock_ready flag High 00 1040 cycles 01 520 cycles 10 320 cycles 11 200 cycles
23 FDIVEN	Enable fraction division mode in feedback divider. Enables the division of vco clock output by a factor of (FBDIV + 0.5). 0 Fraction division mode not enabled 1 Fraction division mode enabled
24–29 FBDIV	Feedback Division factor for VCO output clock. This field can only be written when LFAST_MCR[DRFEN] = 0. 00h No clock output 01h – 0Ah Reserved 0Bh Divide by 12 (11.5, if FDIVEN = 1) ... ... 1Fh Divide by 32 (31.5, if FDIVEN = 1) 20h – 3Fh Reserved
30–31 PREDIV	Division factor for PLL Reference Clock input. This field can only be written when LFAST_MCR[DRFEN] = 0. 00 Direct clock passed 01 Divide by 2 10 Divide by 3 11 Divide by 4

52.6.15 LFAST LVDS Control Register (LFAST_LCR)

Address: 0h base + 40h offset = 40h



* Notes:
- SWONLR field: Set by user software and cleared by system hardware.
- SWOFFLR field: Set by user software and cleared by system hardware.
- SWONLD field: Set by user software and cleared by system hardware.
- SWOFFLD field: Set by user software and cleared by system hardware.
- SWSLPLR field: Set by user software and cleared by system hardware.
- SWWKLR field: Set by user software and cleared by system hardware.
- SWSLPLD field: Set by user software and cleared by system hardware.
- SWWKLD field: Set by user software and cleared by system hardware.

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned OFF(provided no other source is trying to turn the LD ON)
13 SWONLD	SW signal to turn ON the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned ON
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned OFF (provided no other source is trying to turn the LR ON)
15 SWONLR	SW signal to turn ON the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned ON
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled

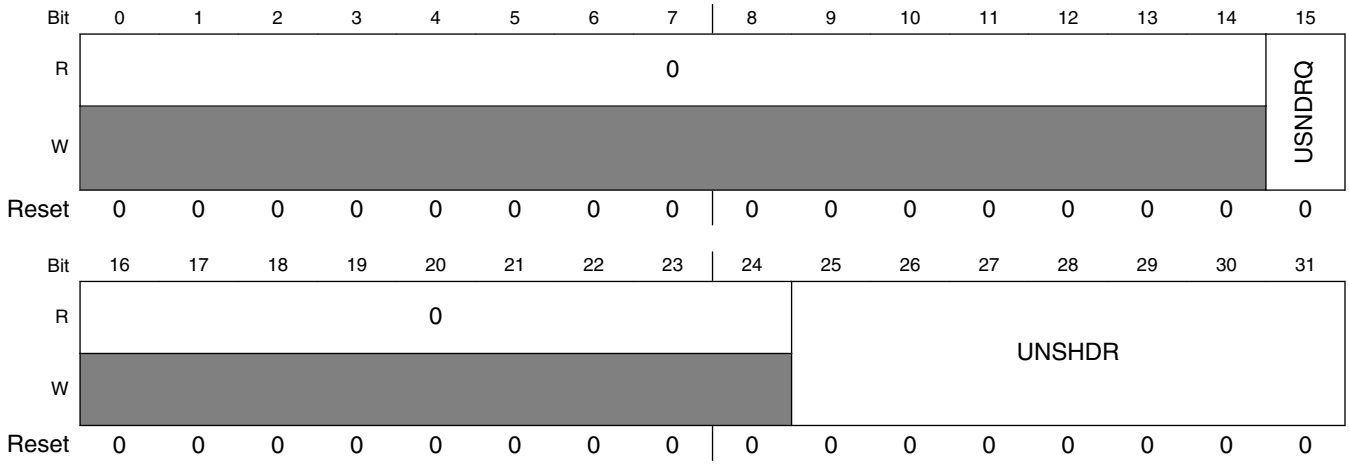
Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
20 LVLPEN	Tx LVDS internal loopback enable The bit is reflected by output signal ipp_digrf_lvds_lpbk_en.The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination
27 Reserved	This field is reserved.
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than the maximum baud rate. 1 Required for LFAST receiver maximum baud rate.
29 LVTXOP	Control signal for LFASTand Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 normal clock used to sample the LVDS data 1 adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

52.6.16 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 0h base + 44h offset = 44h

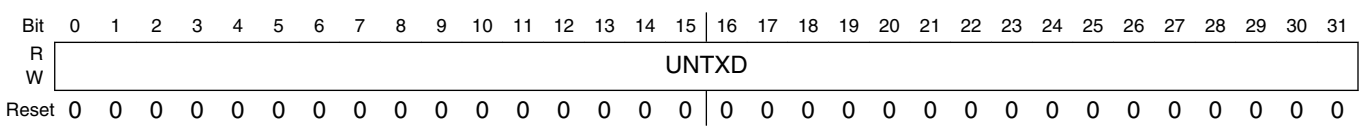


LFAST_UNSTCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 USNDRQ	Tx Unsolicited send request. Set by user software and cleared by system hardware. 0 No valid Unsolicited frame exists 1 Valid Unsolicited frame exists for transmission
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 UNSHDR	Tx Unsolicited message header. This field can only be written when LFAST_UNSTCR[USNDRQ] = 0

52.6.17 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)

Address: 0h base + 48h offset + (4d × i), where i=0d to 8d

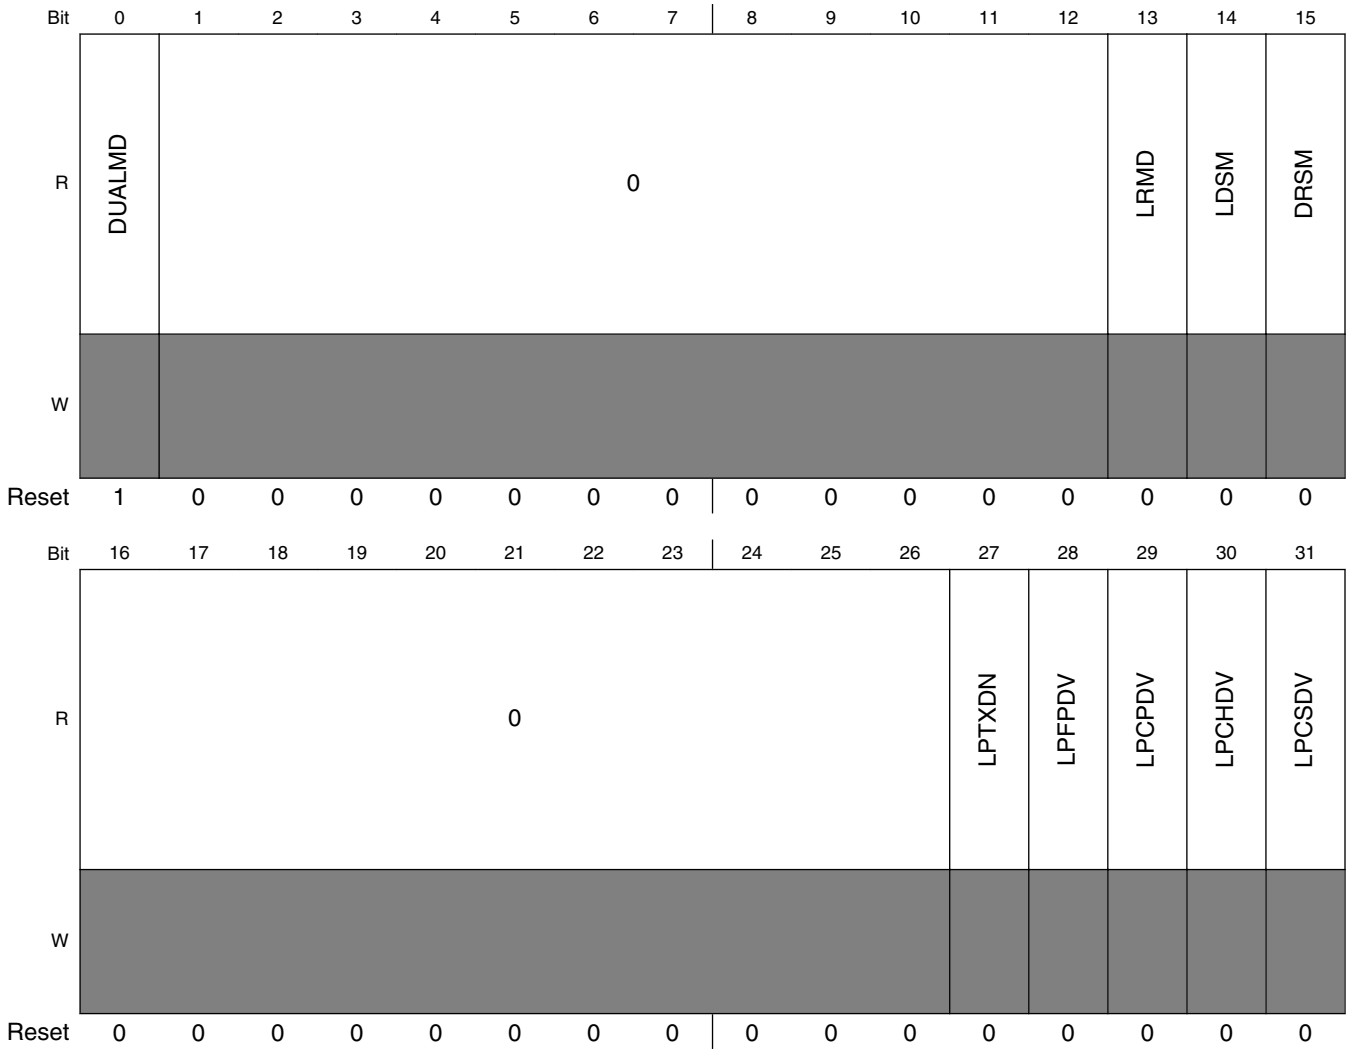


LFAST_UNSTDR*n* field descriptions

Field	Description
0–31 UNTXD	Unsolicited Transmit Data 8-0. This represents 9 registers for Unsolicited transmit data. The first bit to transmitted as part of the payload will be from UNTXD8[31], second bit from UNTXD8[30], and so on. So the last bit transmitted will be from UNTXD0[0] in case of 288 bit payload.

52.6.18 LFAST Global Status Register (LFAST_GSR)

Address: 0h base + 80h offset = 80h



LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode 0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active.

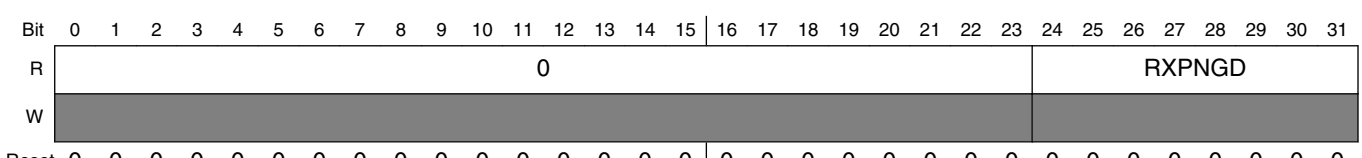
Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

52.6.19 LFAST Ping Status Register (LFAST_PISR)

Address: 0h base + 84h offset = 84h



LFAST_PISR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RXPNGD	Ping Data Register. In LFAST Master mode the Ping response ICLC frame received is stored into this register.

52.6.20 LFAST Data Frame Status Register (LFAST_DFSR)

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

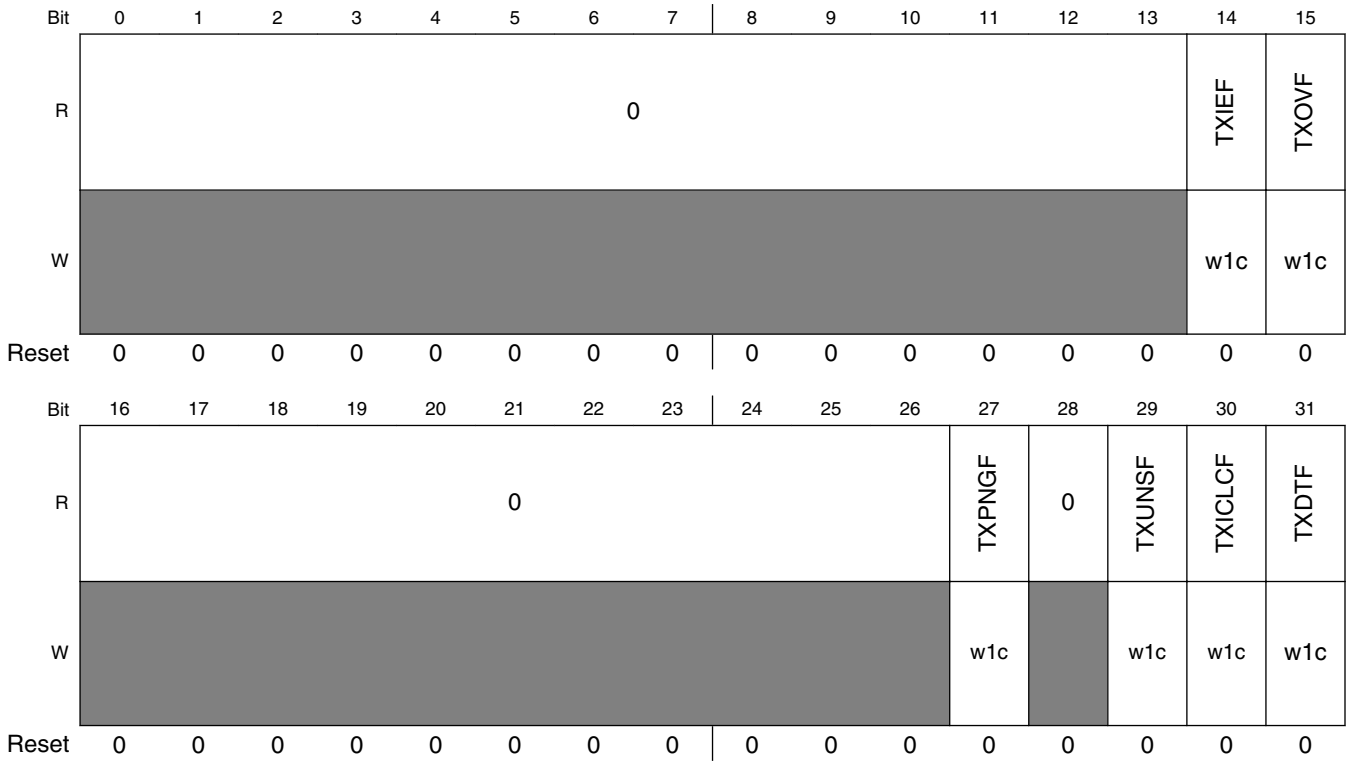
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_DFSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 RXDCNT	Unread Rx Frame Data Count. Indicates the number of unread data stored in the Rx Data FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 RXFCNT	Unread Rx Frame Count. Indicates the number of unread data frames stored in the Rx Data FIFO.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TXDCNT	Unread Tx Frame Data Count. Indicates the number of unread data stored in the Tx Data FIFO.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TXFCNT	Unread Tx Frame Count.Count of pending Data Frames programed by System Side Module.

52.6.21 LFAST Tx Interrupt Status Register (LFAST_TISR)

Address: 0h base + 98h offset = 98h



LFAST_TISR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIEF	TxData Interface not enabled. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 TXOVF	Transmit Data FIFO Overflow Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGF	Ping response frame transmitted interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_TISR field descriptions (continued)

Field	Description
29 TXUNSF	Unsolicited Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 TXICLCF	ICLC Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 TXDTF	Data Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred

52.6.22 LFAST Rx Interrupt Status Register (LFAST_RISR)

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_RISR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
8 RXUOF	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt event has not occurred 1 Interrupt event has occurred
9 RXMNF	Rx Data FIFO Min Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
10 RXMXF	Rx Data FIFO Max Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
11 RXUFF	Rx Data FIFO Underflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
12 RXOFF	Rx Data FIFO Overflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
13 RXSZF	Frame with unsupported frame size received. See "Frames Supported by LFAST interfaces" table for details. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame with payload size for a frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
14 RXICF	Invalid ICLC code Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 RXLCEF	Invalid Logical Channel Type. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSF	Frame with CTS bit Low Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 RXDF	Data frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 RXUNSF	Unsolicited Frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

52.6.23 LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)

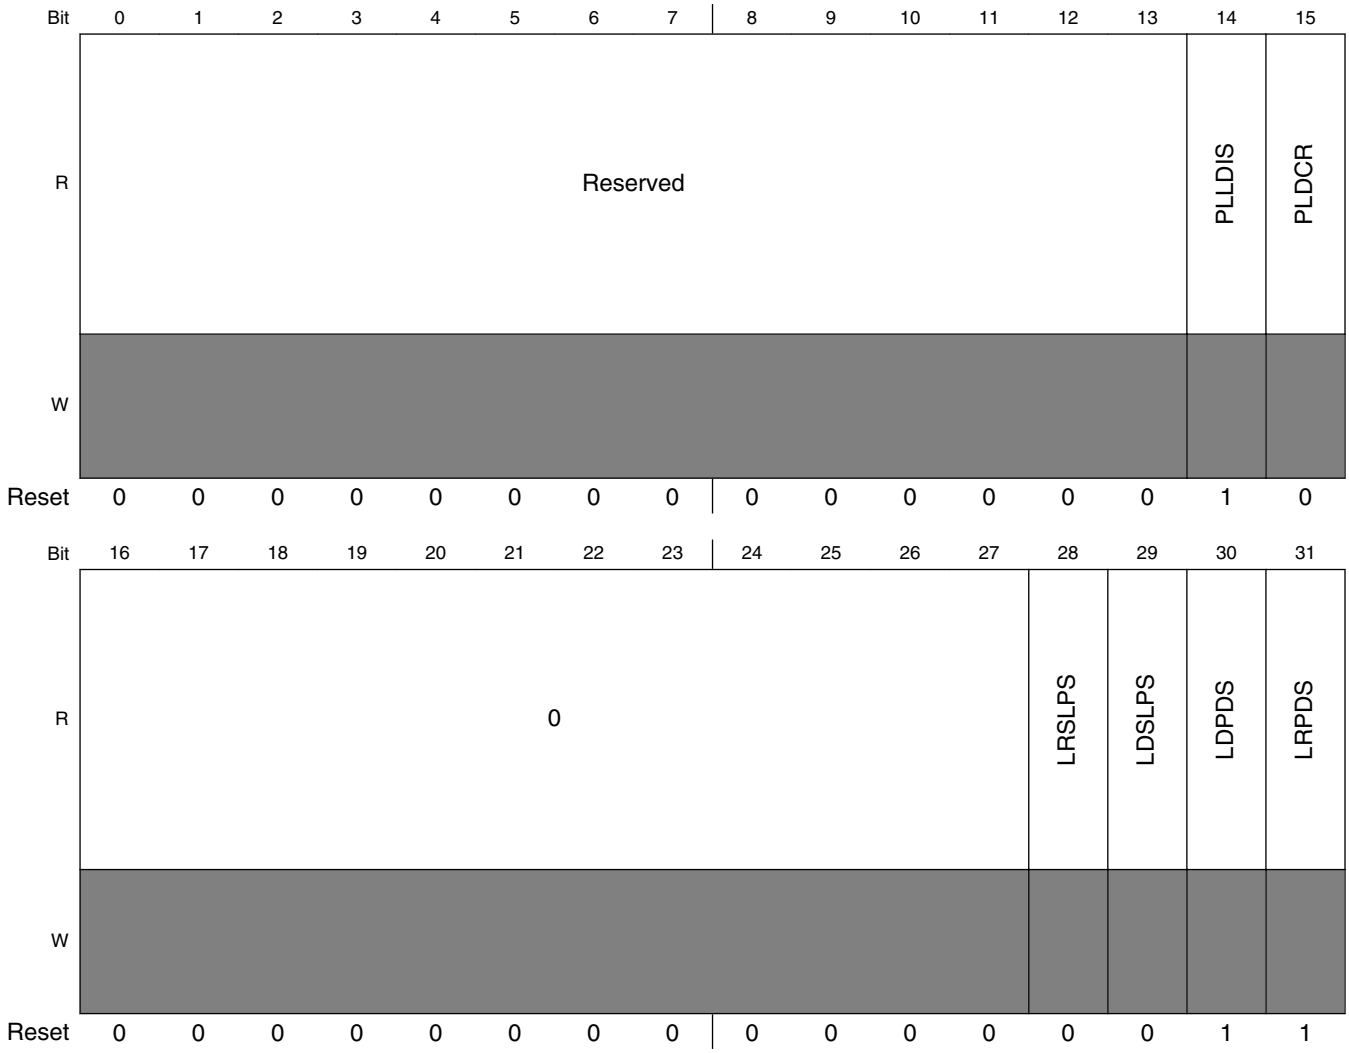
30 ICPOFF	ICLC frame for PLL OFF received 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 ICPONF	ICLC frame for PLL ON received 0 Interrupt event has not occurred 1 Interrupt event has occurred

52.6.24 LFAST PLL and LVDS Status Register (LFAST_PLLLSR)

Address: 0h base + A4h offset = A4h



LFAST_PLLLSR field descriptions

Field	Description
0–13 Reserved	This field is reserved.
14 PLLDIS	PLL disable Status. When asserted, PLL is put in the power down state. 0 PLL disable signal is negated. 1 PLL disable signal is asserted.
15 PLDCR	PLL Lock Delay Counter Ready. When asserted this bit indicates that the PLL is locked after N number of reference/PLLCR[PREDIV] cycles 0 PLL Lock delay counter is not decremented to 0 1 PLL Lock delay counter is decremented to 0

Table continues on the next page...

LFAST_PLLLSR field descriptions (continued)

Field	Description
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LRSLPS	This bit indicates the real time status of LR sleep signal 0 LR power sleep signal is negated. 1 LR power sleep signal is asserted.
29 LDSLPS	This bit indicates the real time status of LD sleep signal 0 LD sleep signal is negated. 1 LD sleep signal is asserted.
30 LDPDS	This bit indicates the real time status of LD power down signal When asserted, LD is put in the power down state. 0 LD power down signal is negated. 1 LD power down signal is asserted.
31 LRPDS	This bit indicates the real time status of LR power down signal When asserted, LR is put in the power down state. 0 LR power down signal is negated. 1 LR power down signal is asserted.

52.6.25 LFAST Unsolicited Rx Status Register (LFAST_UNSRSR)

Address: 0h base + A8h offset = A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

LFAST_UNSRDR*n* field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

52.7 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements[12]. All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

52.8 Functional description

12. See the “Functional Safety” chapter for register classification details.

52.8.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

52.8.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS parameters in the device data sheet.
2. The PLLCR is programmed with configuration parameters for the PLL.
3. The LCR is programed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN]and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurrence of one of the following:
    - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
    - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

Speed mode change:

14. Write PLLCR[SWPON] = 1 to enable the LFAST masters PLL.

15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:

Note

(The slaves Rx interface speed should be changed first.)

    - Write ICR[ICLCPLD] = 10h for Tx data fast frame.
    - Write ICR[SNDICLC] = 1.
19. Both of the following operations are performed to change the LFAST masters Rx interface speed:

Note

(The slaves Tx interface speed mode should be changed first)

    - Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
    - Write ICR[SNDICLC] = 1.
20. The ICLC transmission is confirmed by the occurrence of one of the following:
    - ICR[SNDICLC] = 0
    - TISR[TXICLCF] = 1.
21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.
22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.
23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.
24. Write ICR[SNDICLC] = 1

25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitation.
26. The LFAST slaves speed mode is confirmed by the occurrence of the following:
    - If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
    - If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.
27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:
    - Write ICR[ICLCSEQ] = 0.
    - Write MCR[TXARBD] = 0.
28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:
    - Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
    - Write MCR[TXARBD] = 0, to enable frame transmission.
    - The operations from step 14 need to be executed again.

52.8.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signaland LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
    - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
    - MCRMCR[TXEN] = 1.

8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received. H/W writes [ICRPF] = 1.
    - PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:
    - When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1.
    - Write PLLCR[SWPON] = 1.
10. The speed of the Tx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
    - SCR[TDR] = 1, when SCR[DRMD] = 0.
11. The speed of the Rx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
    - SCR[RDR] = 1, when SCR[DRMD] = 0.
12. A Ping Frame is sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received. H/W writes RIISR[ICRPF] = 1.
    - Write PICR[PNGREQ] = 1.
    - Write PICR[PNGREQ] = .

52.8.2 Line Receiver

This section describes the Line Receiver.

52.8.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 52-4 shows the block diagram of Uplink Controller.

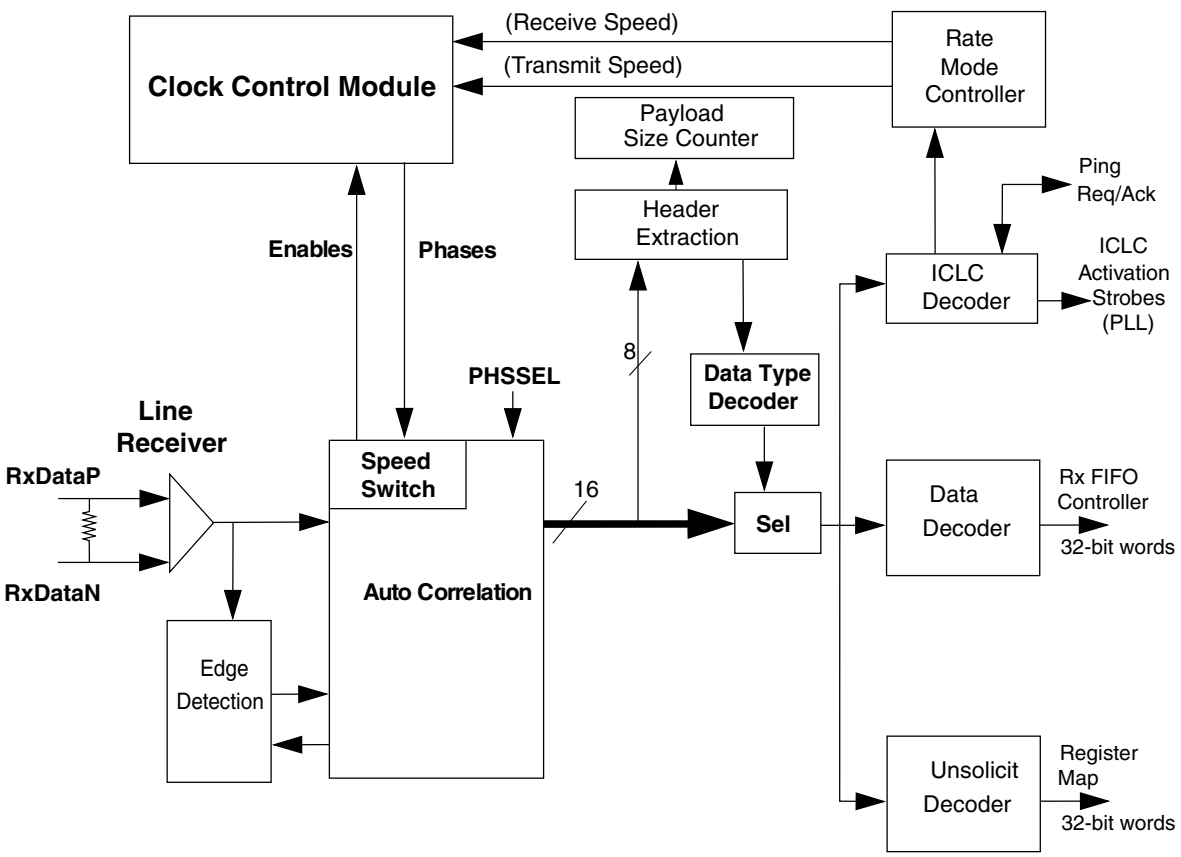

Figure 52-4. Top Level Receive Controller

52.8.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

52.8.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

52.8.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 52-5 shows the block diagram of Hunt Correlation mode.

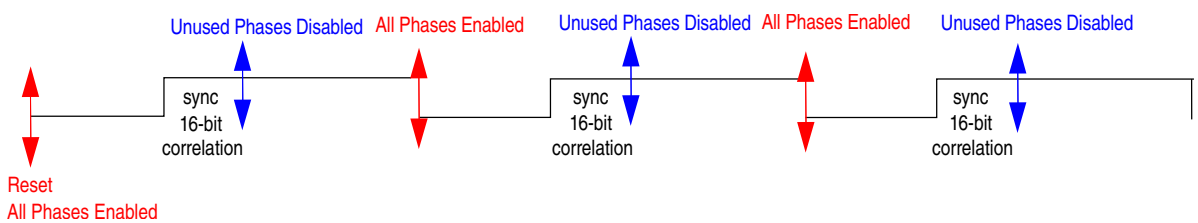

Figure 52-5. Hunt Correlation mode

52.8.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

52.8.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

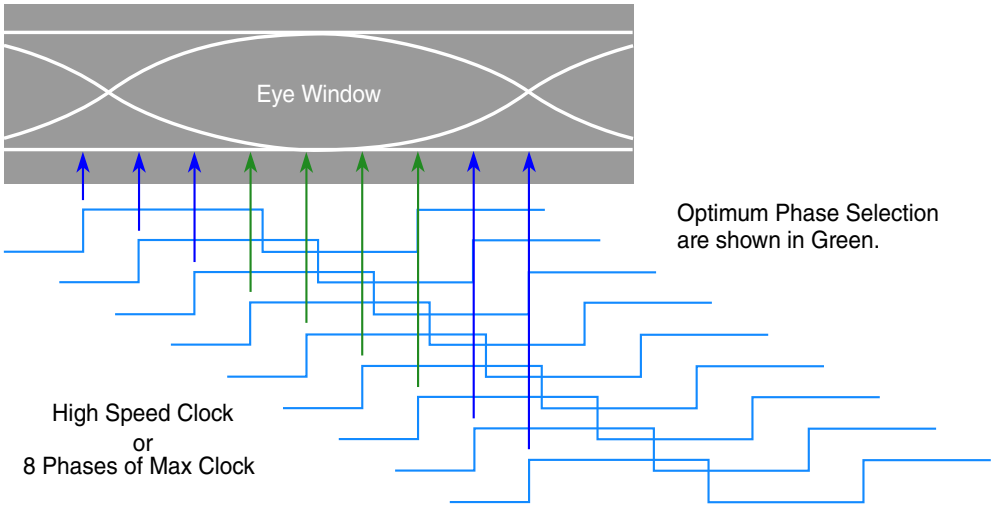

Figure 52-6. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

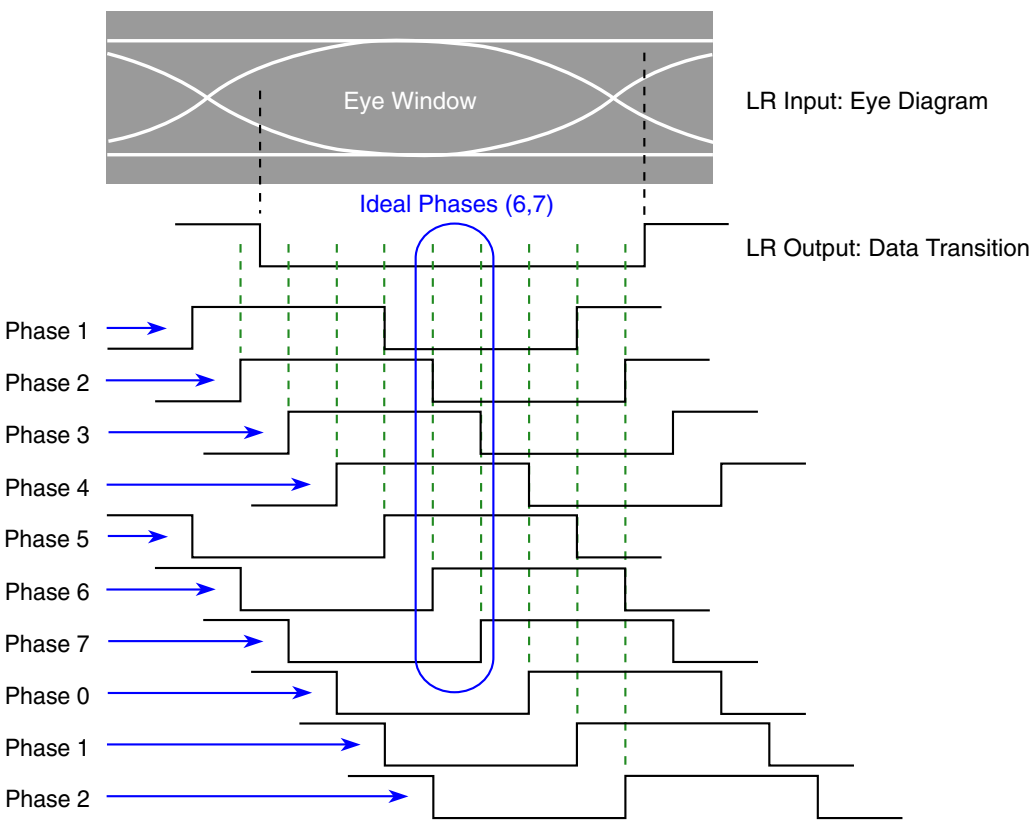

Figure 52-7. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in Figure 52-8 and Figure 52-9.

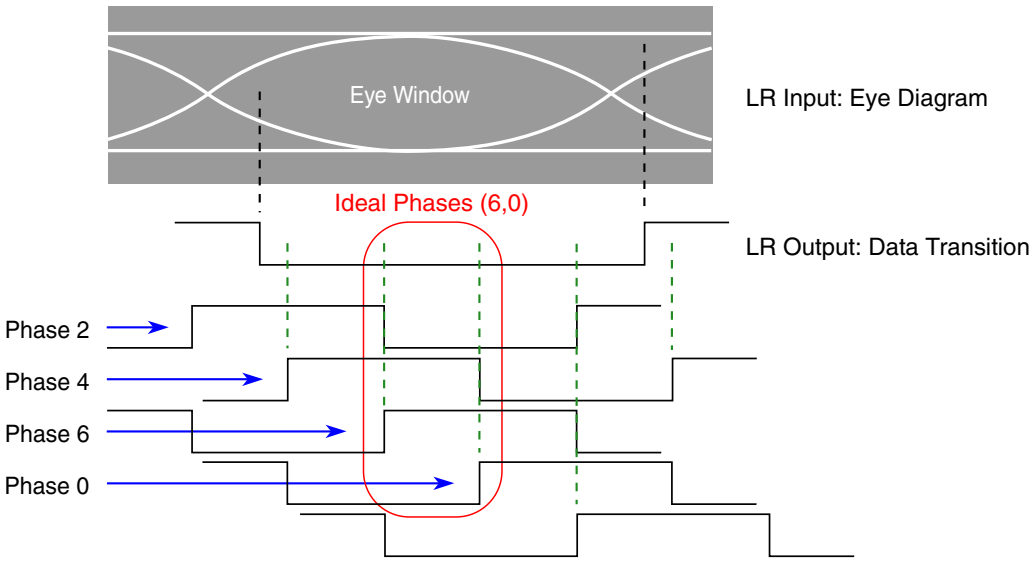

Figure 52-8. High Speed 4 Phase Clock Alignment Example

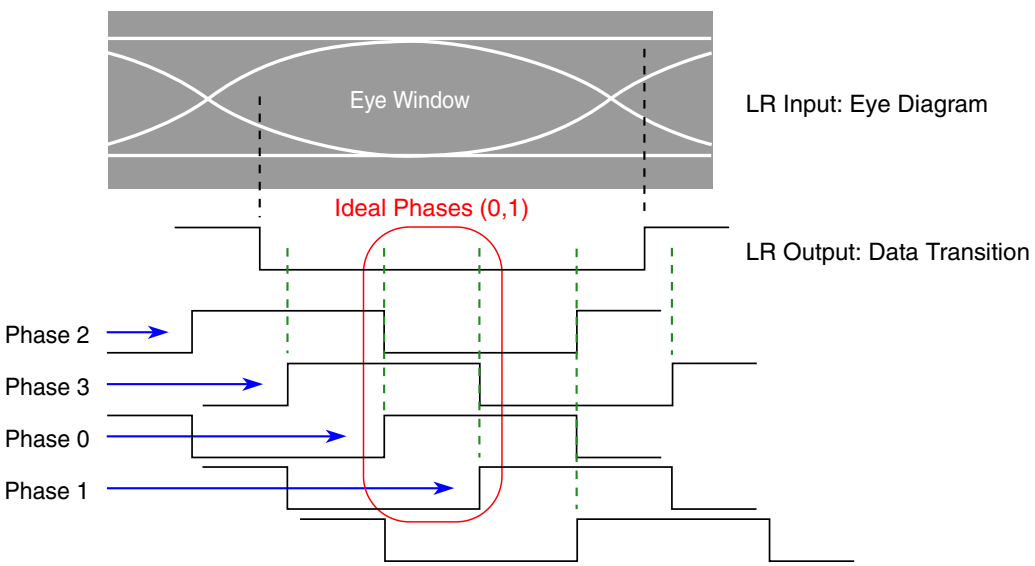

Figure 52-9. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in Table 52-2, Table 52-3, and Table 52-4 before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 52-2. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 52-3. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See Table 52-3, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 52-4. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 52-4. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See Table 52-4, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

52.8.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

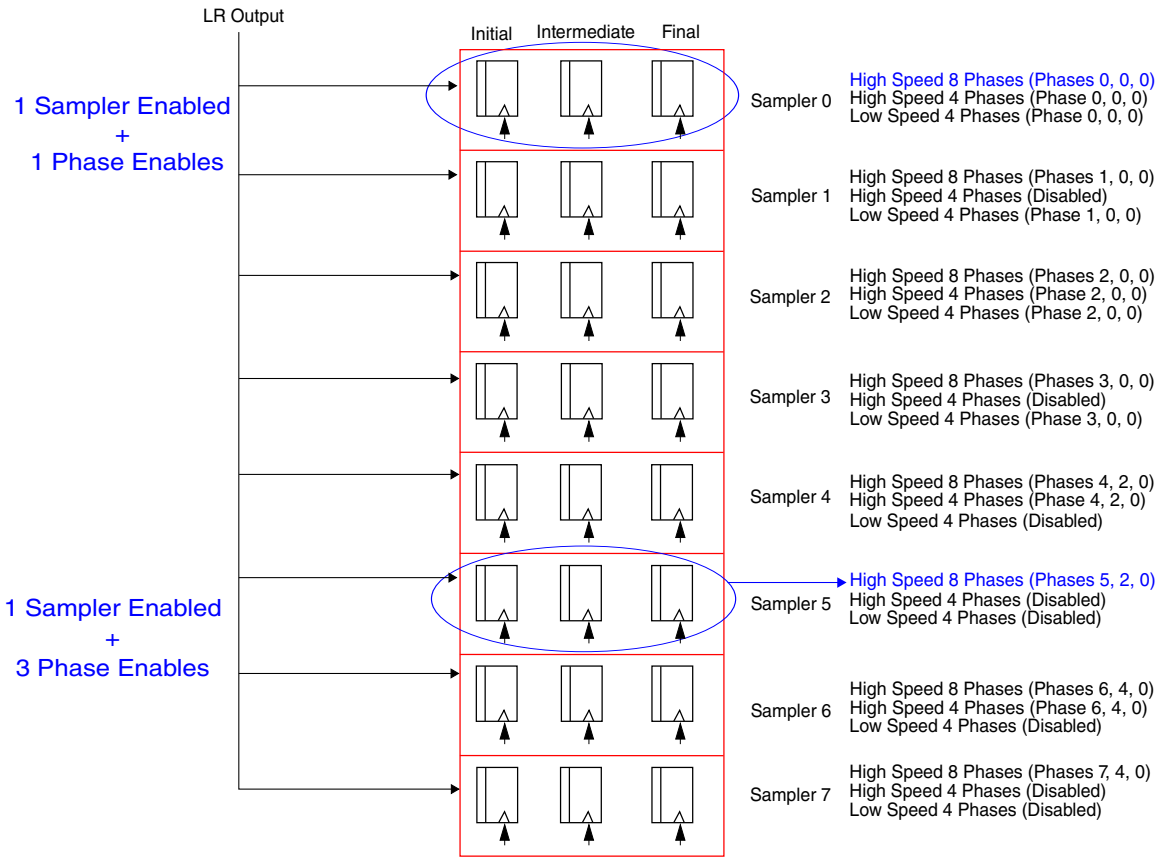

Figure 52-10. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

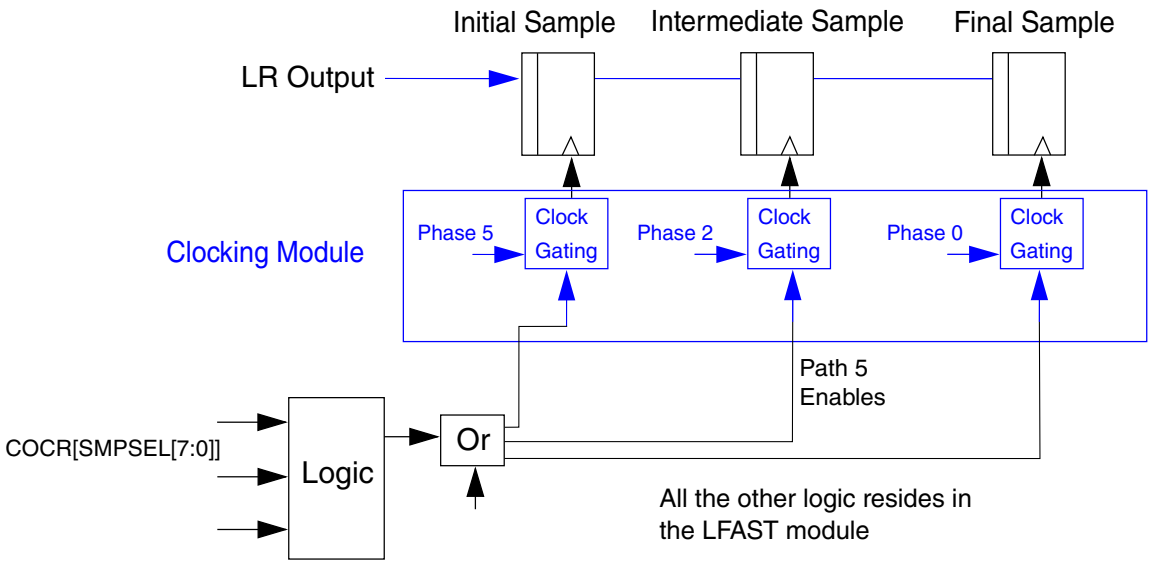

Figure 52-11. Sampler 5 Logic

52.8.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the Figure 52-12.

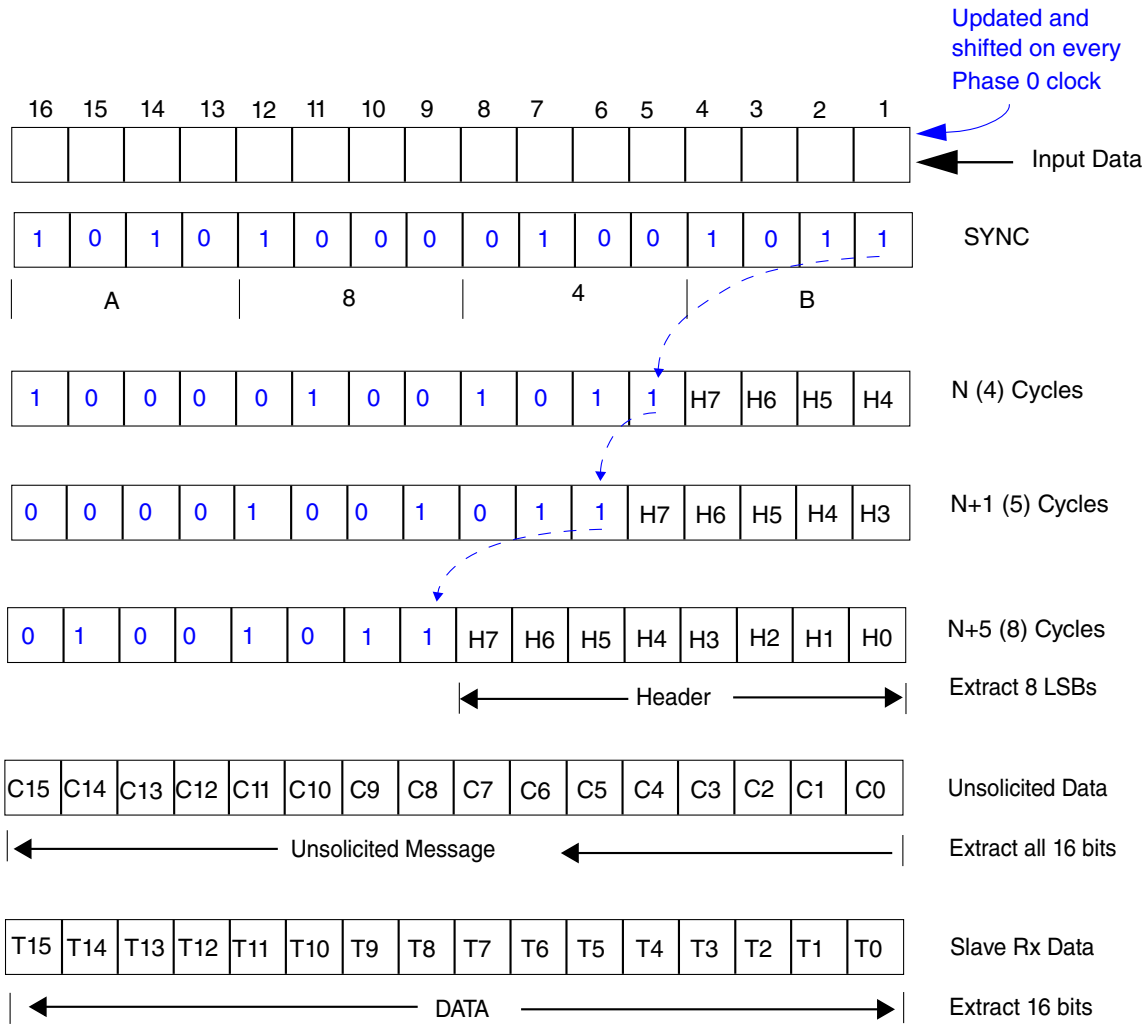

Figure 52-12. Extracting Header and Payload from the 16-bit output from Auto correlation.

52.8.3 Transmit Controller

This section describes the Transmit Controller.

52.8.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

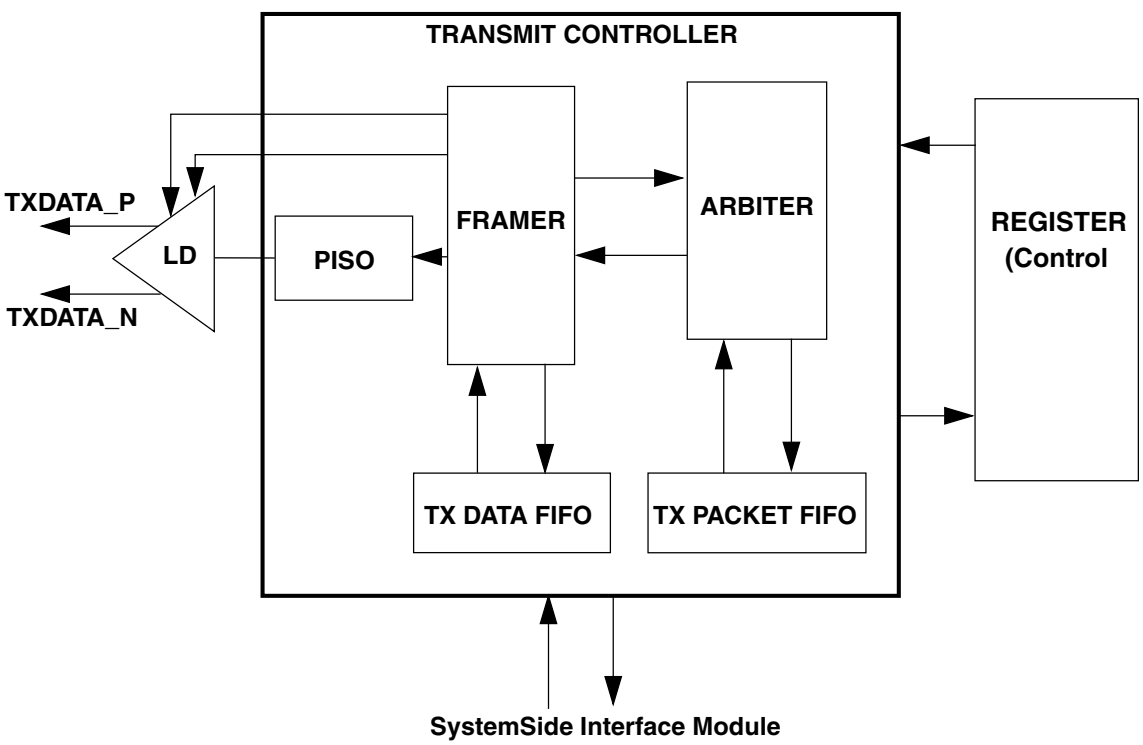

Figure 52-13. Transmit Controller Connections

52.8.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in Table 52-5

Table 52-5. Priority Levels for the Transmit Controller

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
LFAST interface enable	1	1	• LFAST interface enable is asserted • LFAST interface enable is negated
Tx Interface disabled	2	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	4	• TMCR[LPON] = 1Dig • RF Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	-	• LFAST Master: ICR[SNDICLC] = 1 • LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	-	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1

Table continues on the next page...

Table 52-5. Priority Levels for the Transmit Controller (continued)

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
Unsolicited frame request	6	6	• Last Frame with CTS = 1 received from the peer LFAST device • UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	• Tx FIFO contains one or more frames • Last Frame with CTS = 1 received from the peer LFAST device • MCR[DATAEN] = 1
CTSFrame	8	8	• MCR[CTSEN] = 1 • Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	• TMCR[CLKTST] = 0 • LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

52.8.3.3 Line Driver digital connections

52.8.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

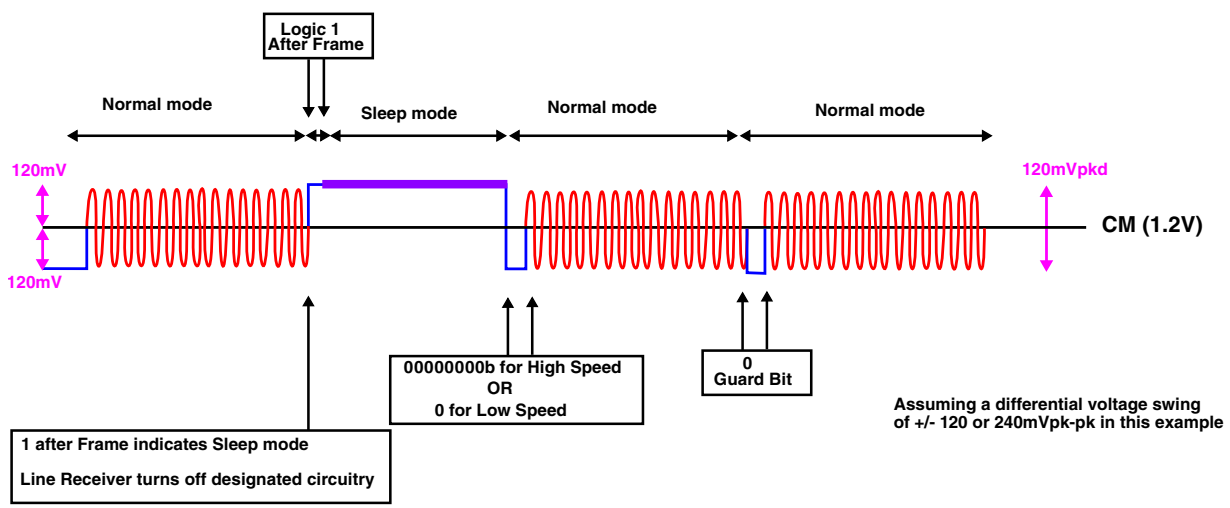

Figure 52-14. Example of Sleep mode

As shown in Figure 52-14 before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated,

and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 52-6. Line Driver States

LD State	LFAST Master Triggers	LFAST Slave Triggers
Shutdown	• Programing LVDS[SWOFFLD] and LVDS[SWONLD] • Programing MCR[TXEN] and MCR[DRFEN]	• LFAST interface enable negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]	• No pending frame for transmission • Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

52.8.4 CTS mode support

LFAST module supports flow control methods. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write MCR[CTSEN] = 1 then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device doesn't want the peer device to send data. The CTS bit of all frame are sent 0 untill the Rx FIFO pointer reaches the lower threshold, as described below.

- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 untill the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed untill a frame with CTS bit 1 is received.

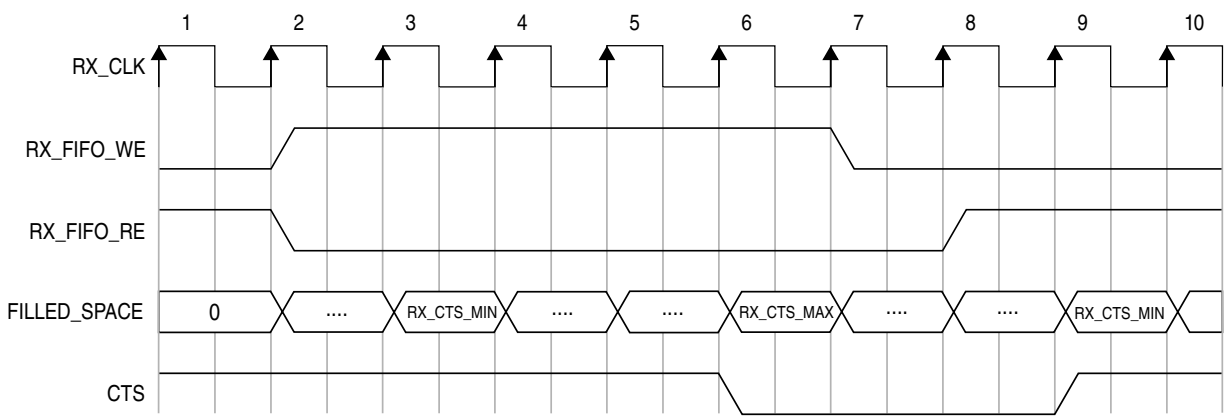

Figure 52-15. CTS generation

52.8.5 Frames supported

Table 52-7 provides the frames supported and their permissible payload sizes

Table 52-7. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO[1]	8
CTS Frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag RISR[RXLCEF] = 1. If the payload size received does not match any value in Table 52-7 then the flag RISR[RXSZF] = 1. In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

52.8.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

52.8.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

52.8.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

52.8.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

52.8.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

52.8.6.2 Unsolicited flow

52.8.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

52.8.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

52.8.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.

3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

52.8.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

52.8.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see Table 52-8 for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 52-8. Supported ICLC Payloads

ICLC Code(hex)	ICLC Function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLLIn preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010… continuously using the currently configured clock rate (slow, fast);
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional)
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the Table 52-8.
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

Note

ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in Table 52-8.

52.8.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in Table 52-8 will cause RISR[RXICF] = 1.

52.8.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

52.8.6.3.2.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

52.8.6.3.2.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

52.8.6.3.2.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

52.8.6.3.2.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

52.8.6.3.2.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

52.8.6.3.2.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable.

52.8.6.3.2.8 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

52.8.6.4 CTS flow

52.8.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

52.8.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

52.8.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

52.8.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 52-9. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.

- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

52.8.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

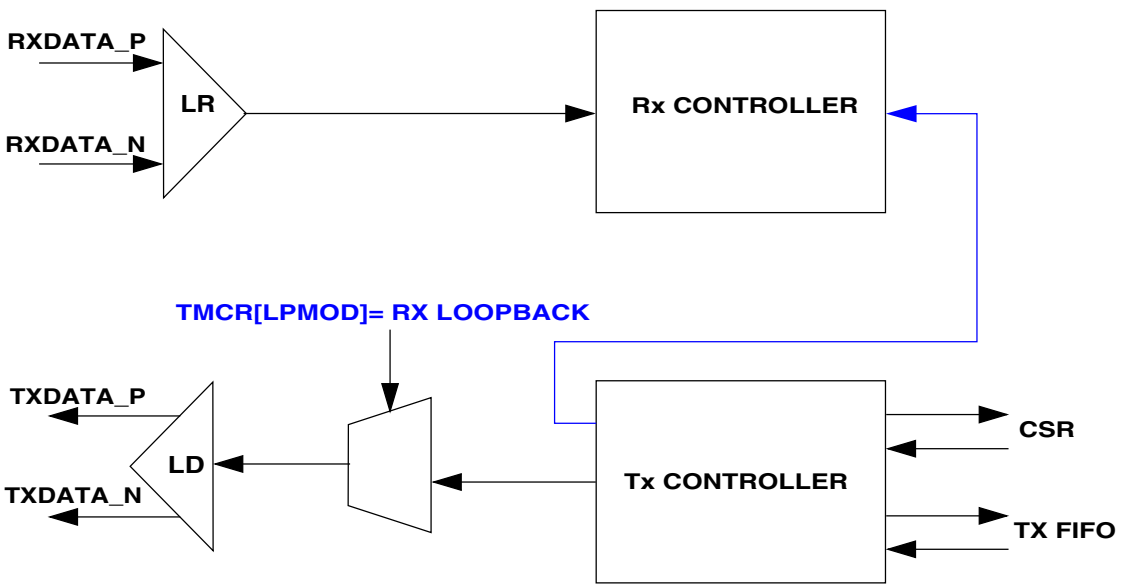

Figure 52-16. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

52.8.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

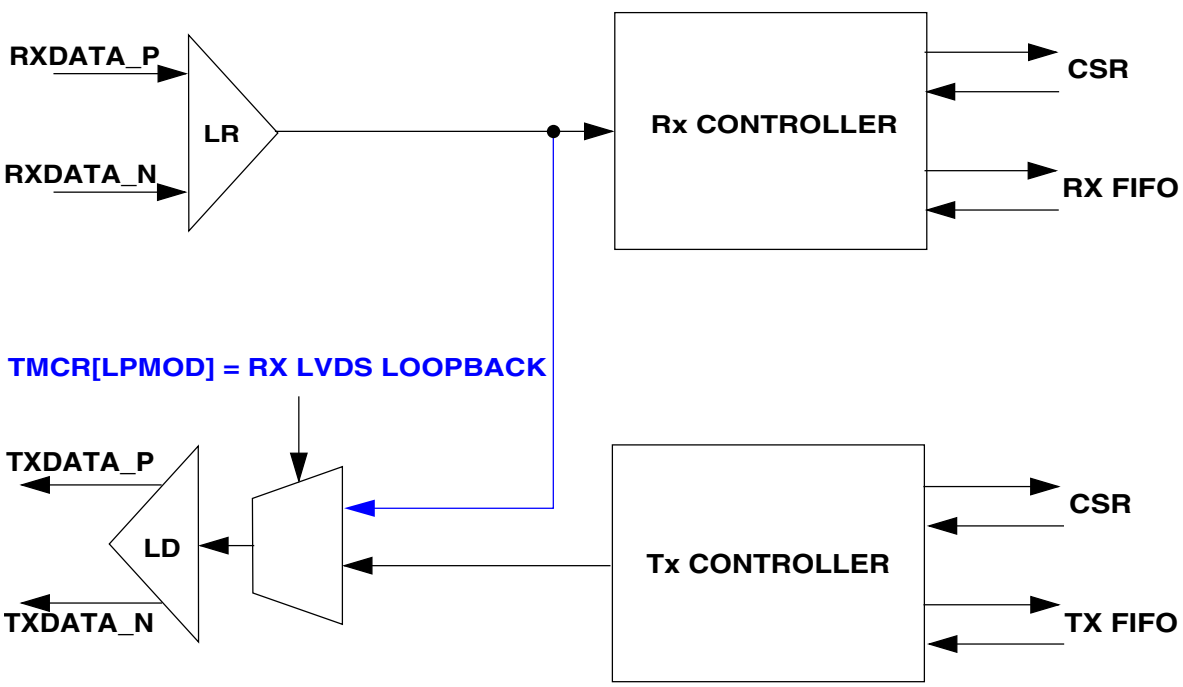

Figure 52-17. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:

- S/W writes TMCR[LPON] = 1.
- For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

52.8.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

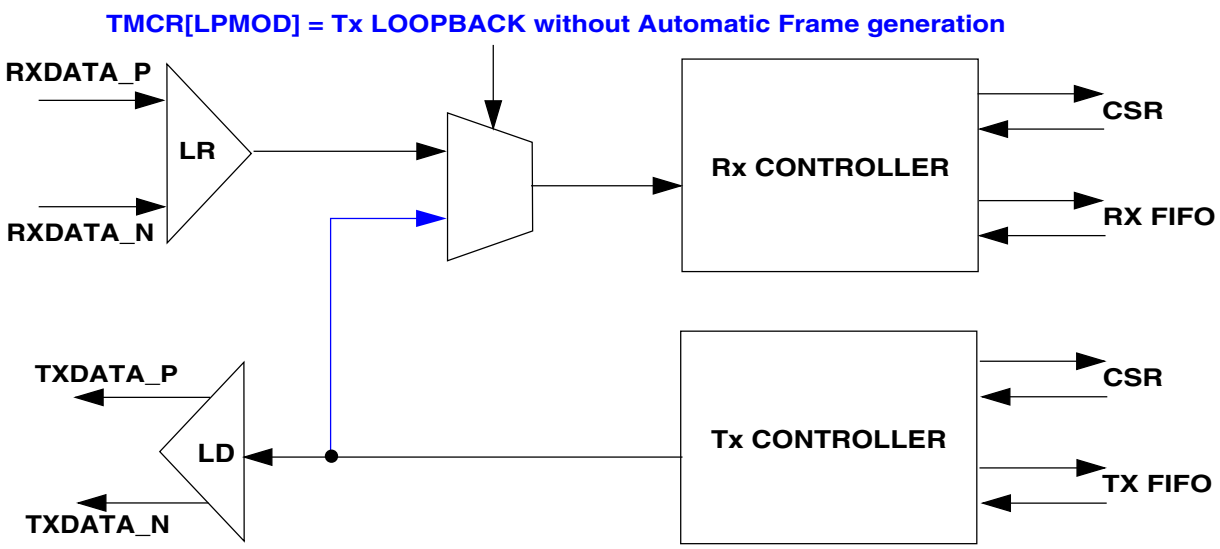

Figure 52-18. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

52.8.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

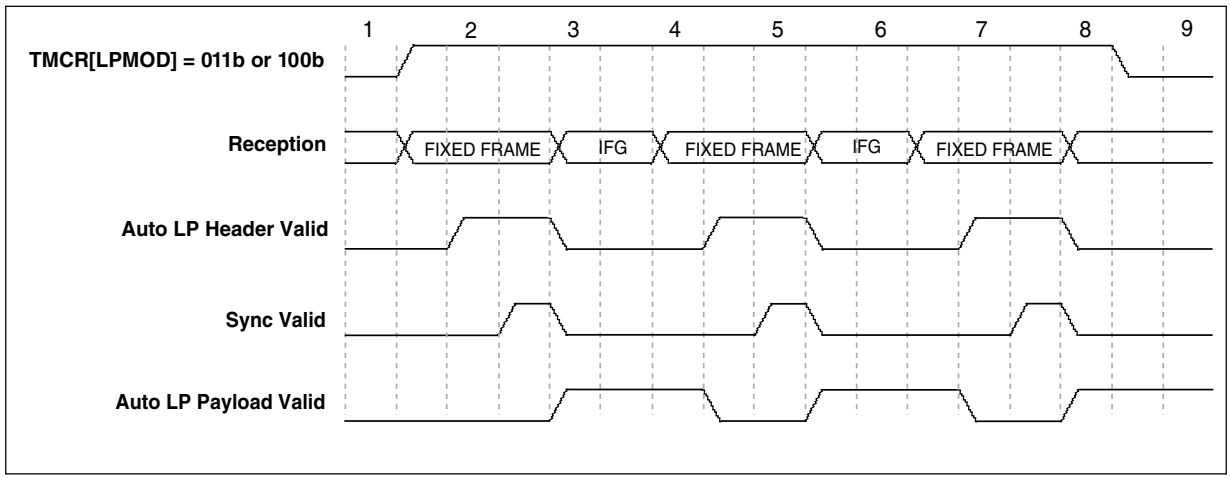

Figure 52-19. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

52.8.7.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

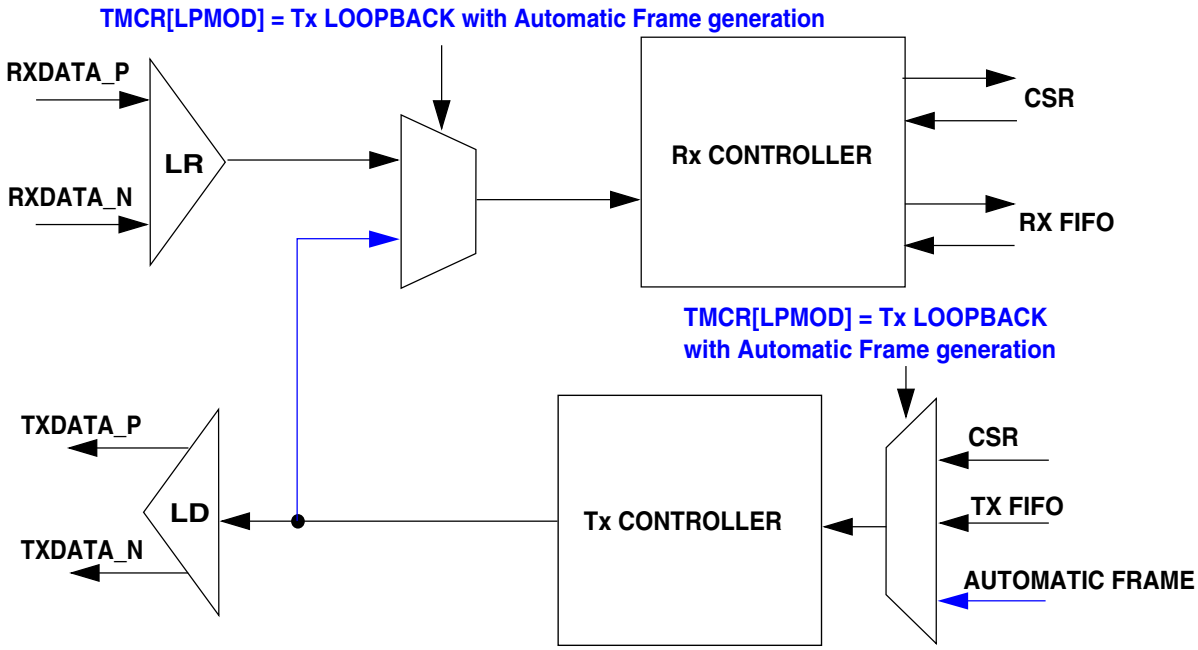

Figure 52-20. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

52.8.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

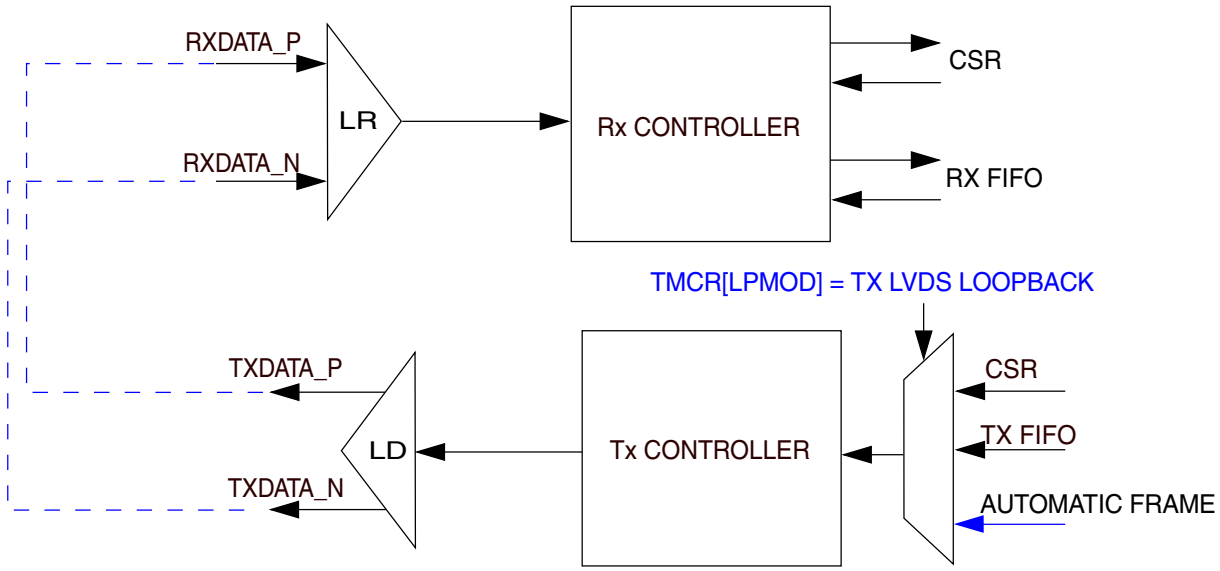

Figure 52-21. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by the following method:

- S/W programs TMCR[LPON] = 0.

52.8.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

52.8.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC recieve interrupt

Each interrupt is asserted when any one of their status conditions is met.

52.8.8.1 Transmit complete interrupt

This interrupt indicates a transfer compeletion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

52.8.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 52-10. Recommended transmit exception handling

Exception	Recommendation
TXOVF	• MCR[TXEN] = 0 • The system level interfaces transmit is reseted and enabled again • For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set • For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	• The MCR[TXEN] should be set

52.8.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

52.8.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 52-11. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	• The MCR[RXEN] may be cleared • The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RXMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

52.8.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

52.9 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 52-12. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	1 × 7 max 1 packet[1]	1 × 8 max 1 packet[2]	Registers ICR, PISR
CTS Frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1
2. Only for ping response data when MCR[MSEN] = 1

52.10 Resets

The various blocks in LFAST are reset as described in the table below.

Table 52-13. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ]

52.11 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

52.11.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

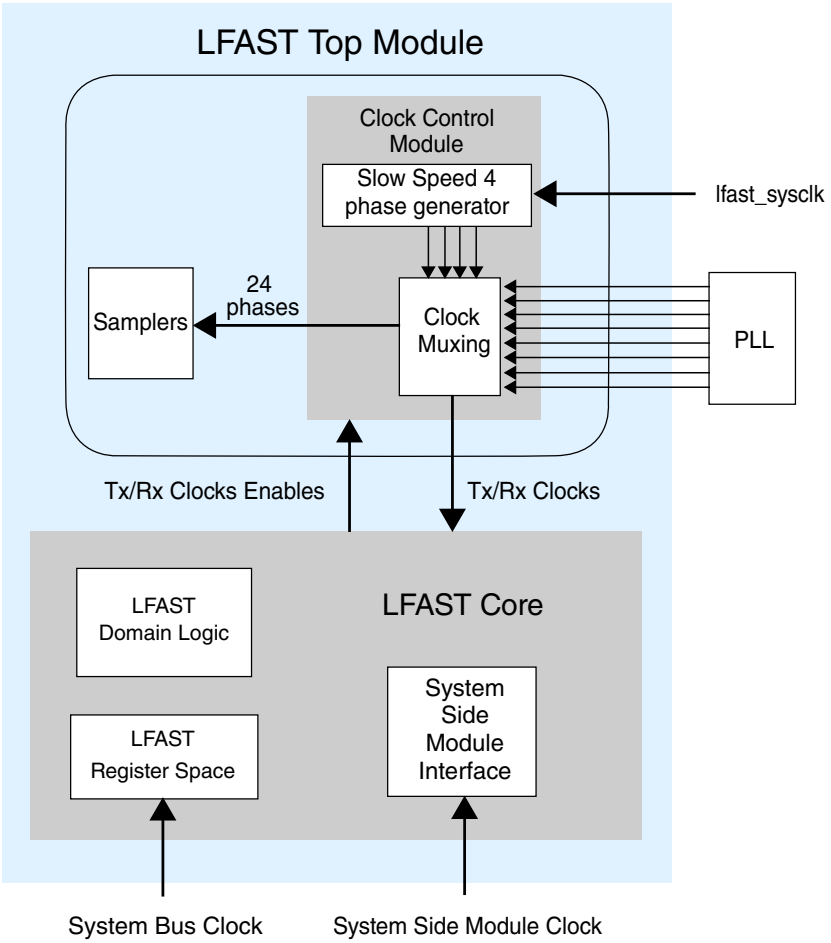

Figure 52-22. LFAST module clock domains

52.11.2 Slow speed clock

52.11.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in Figure 52-23, Figure 52-24 and Figure 52-25.

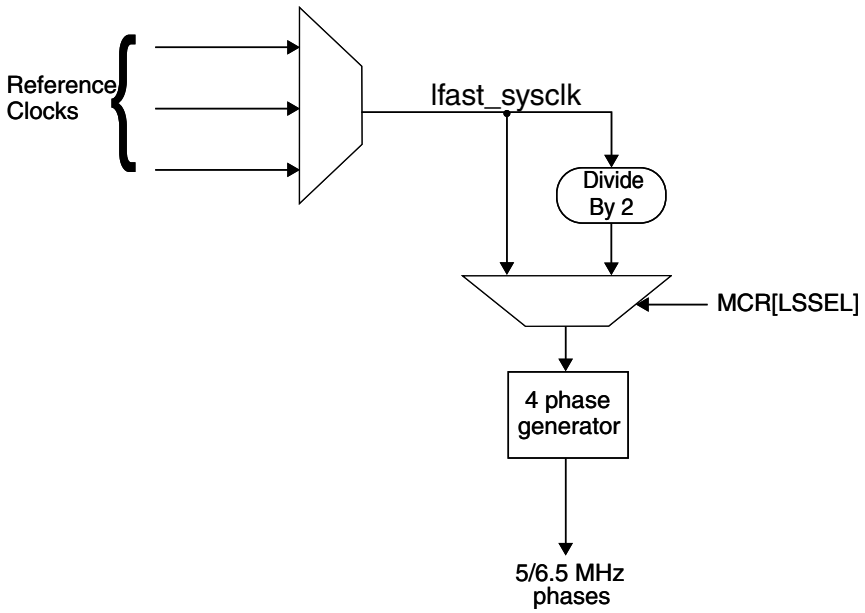

Figure 52-23. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in Figure 52-23.

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 52-24 (selected clock path shown in green).

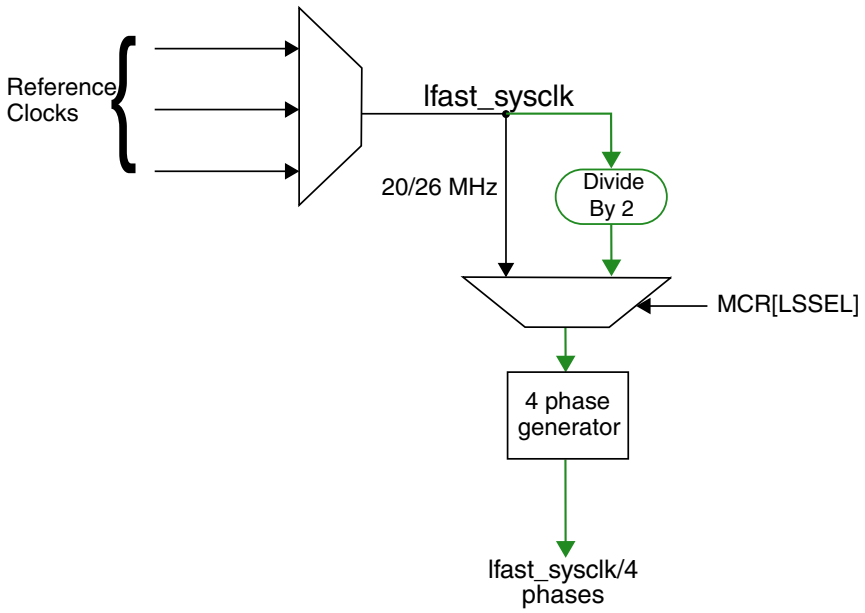

Figure 52-24. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 52-25 (selected clock path selected shown in magenta).

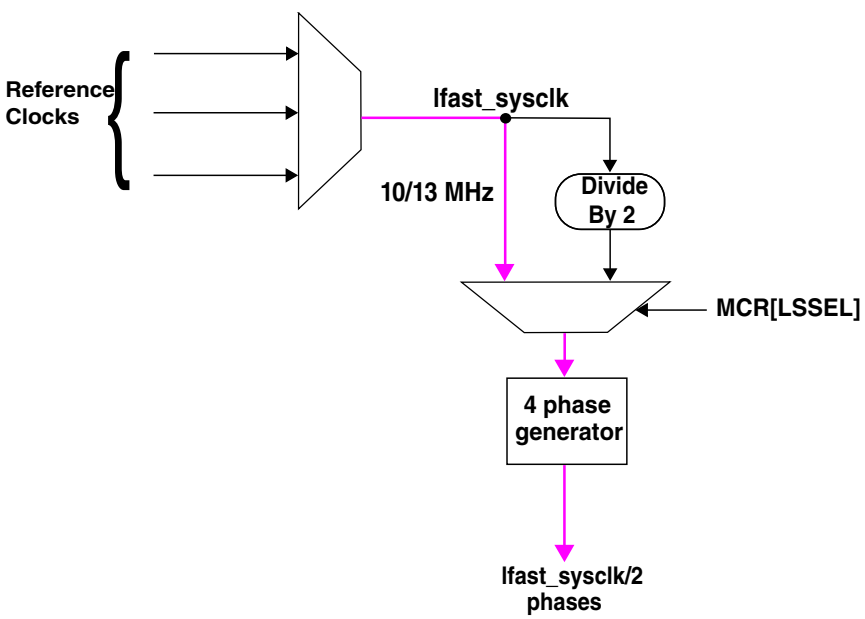

Figure 52-25. External clock muxing of lfast_sysclk of 10 MHz

52.11.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using lfast_sysclk.

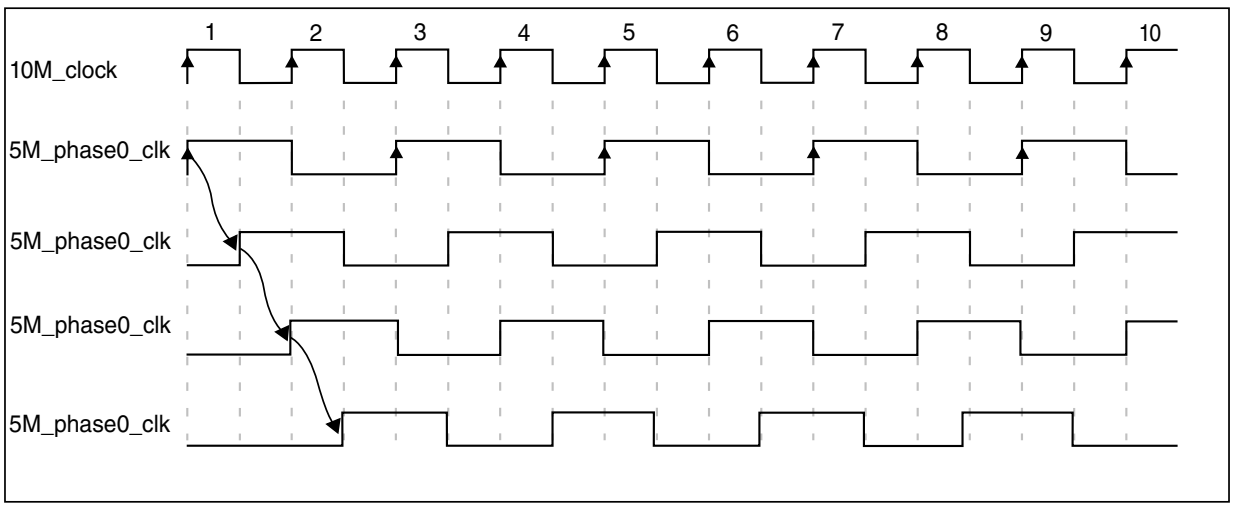

Figure 52-26. Slow speed 4 phases generation

52.11.3 Rx Controller Clocks

52.11.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

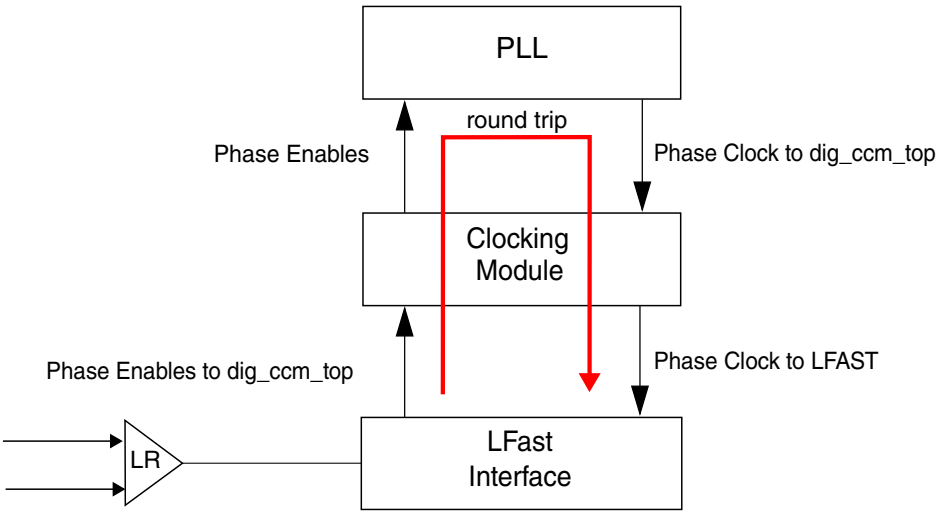

Figure 52-27. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

52.11.5 Clock module requirements for low speed phases

52.11.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 52-14. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

52.11.6 Tx Controller Clocks

52.11.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 52-15. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

52.11.6.2 Transmit Clock Muxing

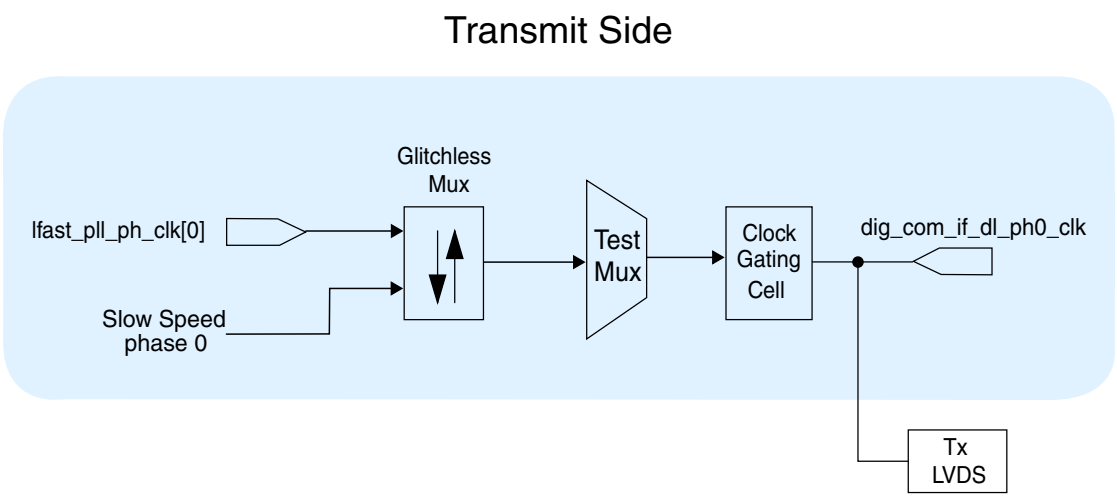

Figure 52-28. Transmit Clocks Muxing

52.11.6.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

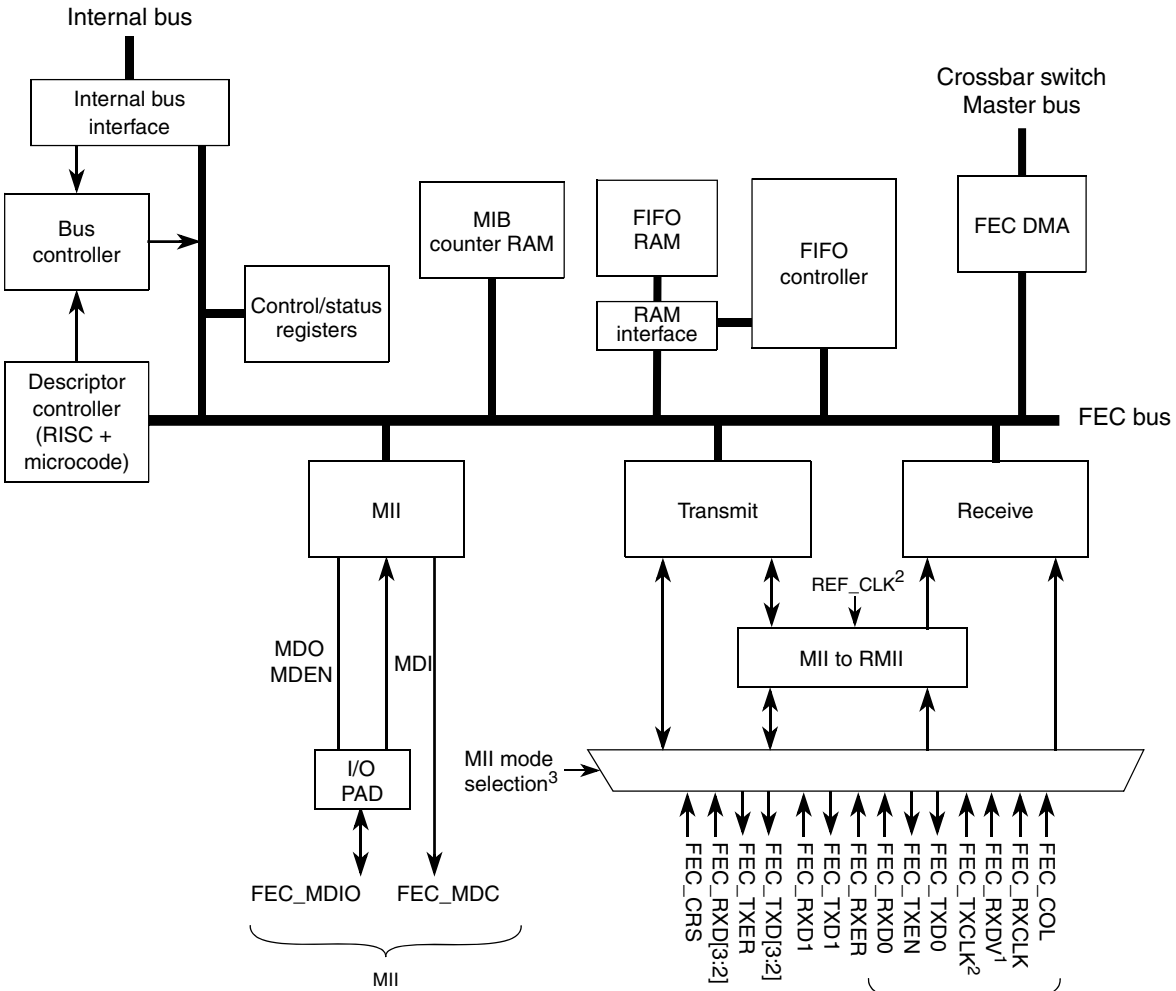
Chapter 53
Fast Ethernet Controller (FEC)

53.1 Introduction

The Fast Ethernet Controller (FEC) is a communication controller that supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports five different standard MAC-PHY (physical) interfaces for connection to an external Ethernet transceiver. The FEC supports the 10/100 Mbps MII, 10/100 Mbps reduced MII, and the 10 Mbps-only 7-wire interface.

53.1.1 Block diagram

Figure 53-1 shows the block diagram of the FEC. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.



Notes:
1. FEC_RXDV in RMII mode generates RXDV and CRS.
2. FEC_TXCLK in RMII mode is the reference clock for the RMII; the RMII supplies the FEC's receive and transmit clocks depending upon the assertion of RCR[RMII_10T].
3. Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.

Figure 53-1. FEC block diagram

The following table provides a brief description of the blocks in the previous figure.

Table 53-1. FEC sub-block descriptions

Block	Description
Control and status registers (CSR)	Provides global control (Ethernet reset and enable) and interrupt managing registers
Descriptor controller	A RISC-based controller providing these functions in the FEC: • Initialization (those internal registers not initialized by you or hardware) • High-level control of the DMA channels (initiating DMA transfers) • Interpreting buffer descriptors

Table continues on the next page...

Table 53-1. FEC sub-block descriptions (continued)

Block	Description
	• Address recognition for receive frames • Random number generation for transmit collision backoff timer
DMA block	Provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to all run independently **Note:** In this document, "DMA" refers to the DMA block within the FEC, and is not related to any other DMA controllers that may be present on the chip.
Media independent interface (MII)	Provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of: • The management data clock (FEC_MDC) • The management data input/output lines (FEC_MDIO) of the MII interface
Message information block (MIB)	Maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC, but provides valuable counters for network management. The counters supported are: • The RMON (RFC 1757) Ethernet Statistics group • Some of the IEEE 802.3 counters
RAM	Serves as the focal point of all data flow in the Fast Ethernet controller and divides into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to/from the DMA block from/to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO into the transmit block. Receive data flows from the receive block into the receive FIFO.
Transmit and receive blocks	Provide the Ethernet MAC functionality (with some assist from microcode)

53.1.2 Features

The FEC incorporates the following features:

- Support for the following Ethernet physical interfaces:[1]
  - 100-Mbps IEEE 802.3 MII
  - 10-Mbps IEEE 802.3 MII
  - 100-Mbps reduced media independent interface (RMII)
  - 10-Mbps reduced media independent interface (RMII)
  - 10-Mbps 7-wire interface (industry standard)

1. For interface selection options, see the chip-specific FEC information.

- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum internal bus clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum internal bus clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
    - Frames with broadcast address may be always accepted or always rejected
    - Exact match for single 48-bit individual (unicast) address
    - Hash (64-bit hash) check of individual (unicast) addresses
    - Hash (64-bit hash) check of group (multicast) addresses
    - Promiscuous mode

53.1.3 Clocking requirements

The FEC system clock frequency must be equal to or greater than the FEC protocol reference clock frequency (for example, 25 MHz system frequency for 100 Mbps protocol frequency). This requirement is true regardless of the reference selected by the application.

53.2 Modes of operation

This section describes the FEC operating modes.

53.2.1 Full and half duplex operation

Full duplex mode is for use on point-to-point links between switches or end node to switch. Half duplex mode works in connections between an end node and a repeater or between repeaters. TCR[FDEN] controls duplex mode selection.

When configured for full duplex mode, flow control may be enabled. For more details, see:

- The RFC_PAUSE and TFC_PAUSE fields in the TCR
- The RCR[FCE] field
- Full duplex flow control

53.2.2 Interface options

The following interface options are supported[2]. A detailed discussion of the interface configurations is provided in Network interface options.

53.2.2.1 10 Mbps and 100 Mbps MII interface

The IEEE 802.3 standard defines the media independent interface (MII) for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by programming RCR[MII_MODE]=1.

The operation speed is determined by the FEC_TXCLK and FEC_RXCLK pins driven by the external transceiver. The transceiver auto-negotiates the speed or software controls it via the serial management interface (FEC_MDC/FEC_MDIO pins) to the transceiver. Refer to the MMFR and MSCR register descriptions, as well as the section on the MII, for a description of how to read and write registers in the transceiver via this interface.

53.2.2.2 10 Mbps and 100 Mbps RMII interface

The reduced media independent interface (RMII) is a low-cost alternative to the IEEE802.3 MII standard. This interface provides the functionality of the MII interface on a total of 8 pins instead of 18. The RMII interface for 10/100 Ethernet MAC-PHY interface was defined by an industry consortium and is not currently included in the IEEE 802.3 standard. This functionality is selected as described in the chip configuration chapter, and is reflected in the read-only RCR[RMII_MODE] bit. The RCR[RMII_10T]

2. For interface selection options, see the chip-specific FEC information.

bit determines the speed of operation. The reference clock for RMII is always 50 MHz, but this clock can be divided by 10 within the RCR register to support 10 Mbps operation. The PHY must be configured accordingly.

53.2.2.3 10 Mbps 7-wire interface operation

The FEC supports 7-wire interface used by many 10 Mbps Ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is cleared, MII mode is disabled and the 10 Mbps 7-wire mode is enabled.

53.2.3 Address recognition options

The address options supported are:

- Promiscuous
- Broadcast reject
- Individual address (hash or exact match)
- Multicast hash match

Address recognition options are discussed in detail in Ethernet address recognition.

53.2.4 Internal loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in MII internal and external loopback.

53.3 External signal description

The following table describes the various FEC signals, as well as indicating which signals work in available modes.

Table 53-2. FEC signal descriptions

Signal name	MII	7-wire	RMII	Description
FEC_COL	X	X	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.
FEC_CRS	X	—	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle.

Table continues on the next page...

Table 53-2. FEC signal descriptions (continued)

Signal name	MII	7-wire	RMII	Description
				In RMII mode, this signal is present on the FEC_RXDV pin.
FEC_MDC	X	—	X	Output clock provides a timing reference to the PHY for data transfers on the FEC_MDIO signal.
FEC_MDIO	X	—	X	Transfers control information between the external PHY and the media-access controller. Data is synchronous to FEC_MDC. This signal is an input after reset. When the FEC operates in 10Mbps 7-wire interface mode, this signal should be connected to VSS.
FEC_RXCLK	X	X	—	Provides a timing reference for FEC_RXDV, FEC_RXD[3:0], and FEC_RXER.
FEC_RXDV	X	X	X	Asserting the FEC_RXDV input indicates PHY has valid nibbles present on the MII. FEC_RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Assertion of FEC_RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.
FEC_RXD0	X	X	X	This pin contains the Ethernet input data transferred from PHY to the media-access controller when FEC_RXDV is asserted.
FEC_RXD1	X	—	X	This pin contains the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXD[3:2]	X	—	—	These pins contain the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXER	X	—	X	When asserted with FEC_RXDV, indicates PHY detects an error in the current frame. When FEC_RXDV is not asserted, FEC_RXER has no effect.
FEC_TXCLK	X	X	X	Input clock which provides a timing reference for FEC_TXEN, FEC_TXD[3:0] and FEC_TXER. In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.
FEC_TXD0	X	X	X	The serial output Ethernet data and only valid during the assertion of FEC_TXEN.
FEC_TXD1	X	—	X	This pin contains the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXD[3:2]	X	—	—	These pins contain the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXEN	X	X	X	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is negated before the first FEC_TXCLK following the final nibble of the frame.
FEC_TXER	X	—	—	When asserted for one or more clock cycles while FEC_TXEN is also asserted, PHY sends one or more illegal symbols. FEC_TXER has no effect at 10 Mbps or when FEC_TXEN is negated.
Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.				

53.4 Memory map and register definition

The FEC is programmed by a combination of control/status registers (CSRs) and buffer descriptors. The CSRs control operation modes and extract global status information. The descriptors pass data buffers and related buffer information between the hardware and software.

Each FEC implementation requires a 1 KB memory map space, which is divided into two sections of 512 bytes each for:

- Control/status registers
- Event/statistic counters held in the MIB block

The following table defines the top-level memory map.

Table 53-3. FEC memory map

Address offset	Function
000h–1FFh	Control/status registers
200h–3FFh	MIB block counters

The following table shows the FEC register map. Any address offset not explicitly mentioned in this table is reserved. Do not modify the content of reserved fields. All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit. Accessing reserved or unimplemented register spaces in the FEC will not return transfer errors.

The MIB counters (shown in the following table) define the locations in the MIB RAM space where hardware-maintained counters reside. The counters are divided into two groups:

- RMON counters include the Ethernet statistics counters defined in RFC 1757
- Truncated frames counter (only frames with lengths up to 2047 bytes are supported)

The transmit and receive RMON counters are independent, which ensures accurate network statistics when operating in full duplex mode.

The included IEEE counters support the mandatory and recommended counter packages defined in Section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The FEC supports IEEE Basic Package objects, but these do not require counters in the MIB block. In addition, some of the recommended package objects supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are also included.

FEC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	Interrupt Event Register (FEC_EIR)	32	w1c	0000_0000h	53.4.1/2354

53.4.1 Interrupt Event Register (FEC_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

These interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC, and RL. Interrupts resulting from internal errors are HBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters:

- HBERR - IEEE_T_SQE
- BABR - RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
- BABT - RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
- LATE_COL - IEEE_T_LCOL
- COL_RETRY_LIM - IEEE_T_EXCOL
- XFIFO_UN - IEEE_T_MACERR

Software may choose to mask off these interrupts because these errors are visible to network management via the MIB counters.

Address: 0h base + 4h offset = 4h

FEC_EIR field descriptions

Field	Description
0 HBERR	Heartbeat error. Indicates TCR[HBC] is set and that the COL input was not asserted within the heartbeat window following a transmission.
1 BABR	Babbling receive error. Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling transmit error. Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused by a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful stop complete. Indicates the graceful stop is complete. During graceful stop the transmitter is placed into a pause state after completion of the frame currently being transmitted. This bit is set by one of these conditions: • A graceful stop initiated by the setting of the TCR[GTS] bit is now complete. • A graceful stop initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. • A graceful stop initiated by the reception of a valid full duplex flow control pause frame is now complete. See Full duplex flow control.
4 TXF	Transmit frame interrupt. Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit buffer interrupt. Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive frame interrupt. Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive buffer interrupt. Indicates a receive buffer descriptor not the last in the frame has been updated.
8 MII	MII interrupt. Indicates the MII has completed the data transfer requested.
9 EBERR	Ethernet bus error. Indicates a system bus error occurred when a DMA transaction is underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs, software needs to ensure that the FIFO controller and DMA also soft reset.

Table continues on the next page...

FEC_EIR field descriptions (continued)

Field	Description
10 LC	Late collision. Indicates a collision occurred beyond the collision window (slot time) in half duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision retry limit. Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half duplex mode.
12 UN	Transmit FIFO underrun. Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.2 Interrupt Mask Register (FEC_EIMR)

The EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

Each bit in this register corresponds to an interrupt source defined by the EIR. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every processor clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is set.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
	0 The interrupt source is masked. 1 The interrupt source is not masked.
13–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.3 Receive Descriptor Active Register (FEC_RDAR)

RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (if ECR[ETHER_EN] is also set). After the FEC polls a receive descriptor whose empty bit is not set, FEC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The RDAR is cleared at reset and when ECR[ETHER_EN] is cleared.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							RDAR	0

FEC_RDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC when no additional empty descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.4 Transmit Descriptor Active Register (FEC_TDAR)

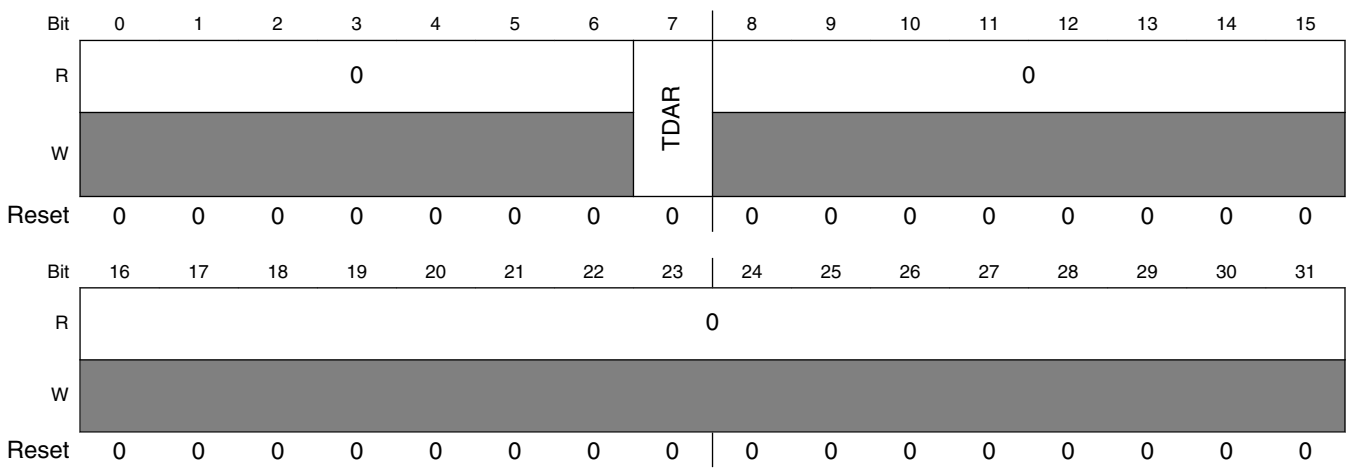
The TDAR is a command register which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR field is set. This value is independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and processes transmit frames (provided ECR[ETHER_EN] is also set). After the FEC polls a transmit descriptor that is a ready bit not set, FEC clears the TDAR field and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The TDAR field is cleared when any of the following events occur:

- Chip reset
- When ECR[ETHER_EN] is cleared
- When ECR[RESET] is set

Address: 0h base + 14h offset = 14h



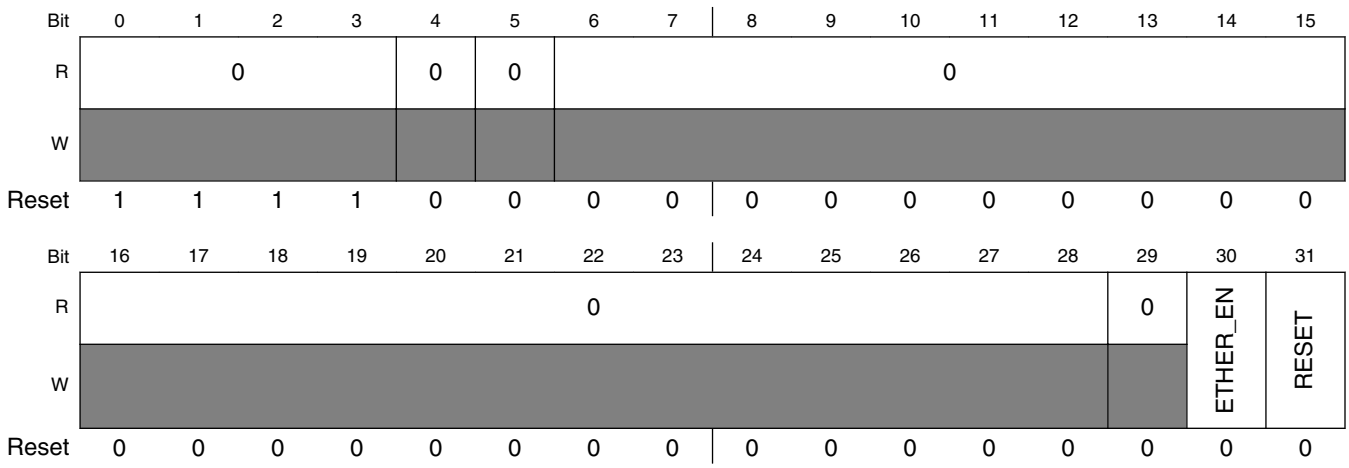
FEC_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHER_EN] is cleared.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.5 Ethernet Control Register (FEC_ECR)

ECR is a read/write user register, though hardware may alter fields in this register as well. The ECR enables/disables the FEC.

Address: 0h base + 24h offset = 24h



FEC_ECR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 ETHER_EN	When this bit is set, FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware alters the ETHER_EN bit under the following conditions: • ECR[RESET] is set by software, in which case ETHER_EN is cleared. • An error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN is cleared.
31 RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ECR[ETHER_EN] is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately eight internal bus clock cycles after this bit is set.

53.4.6 MII Management Frame Register (FEC_MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to the MMFR causes a management frame to be sourced unless the MSCR is programmed to 0. If MSCR is cleared while MMFR is written and then MSCR is written with a non-zero value, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

The MMFR does not reset to any predefined value.

To perform a read or write operation on the MII Management Interface, write the MMFR. To generate a valid read or write management frame, ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated, but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), write {01 01 PHYAD REGAD 10 DATA} to the MMFR. Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the write management frame operation completes, the MII interrupt is generated. At this time, contents of the MMFR match the original value written.

To generate an MII management interface read frame (read a PHY register), write {01 10 PHYAD REGAD 10 XXXX} to the MMFR (the content of the DATA field is unimportant). Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the read management frame operation completes, the MII interrupt is generated. At this time, the contents of the MMFR register match the original value written except for the DATA field whose contents are replaced by the value read from the PHY register.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- x = Undefined at reset.

FEC_MMFR field descriptions

Field	Description
0–1 ST	Start of frame delimiter. These bits must be programmed to 0b01 for a valid MII management frame.
2–3 OP	Operation code. 00 Write frame operation, but not MII compliant. 01 Write frame operation for a valid MII management frame. 10 Read frame operation for a valid MII management frame. 11 Read frame operation, but not MII compliant.
4–8 PA	PHY address. This field specifies one of up to 32 attached PHY devices.
9–13 RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
14–15 TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

53.4.7 MII Speed Control Register (FEC_MSCR)

The MSCR:

- Provides control of the MII clock (FEC_MDC pin) frequency
- Allows a preamble drop on the MII management frame

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be set to 0 to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED changes during operation (change takes effect following a rising or falling edge of FEC_MDC).

If the internal bus clock is 25 MHz, programming this register to 0000_0005h results in an FEC_MDC as stated the equation below.

$$25\,\mathrm{MHz} \times \frac{1}{5 \times 2} = 2.5\,\mathrm{MHz}$$

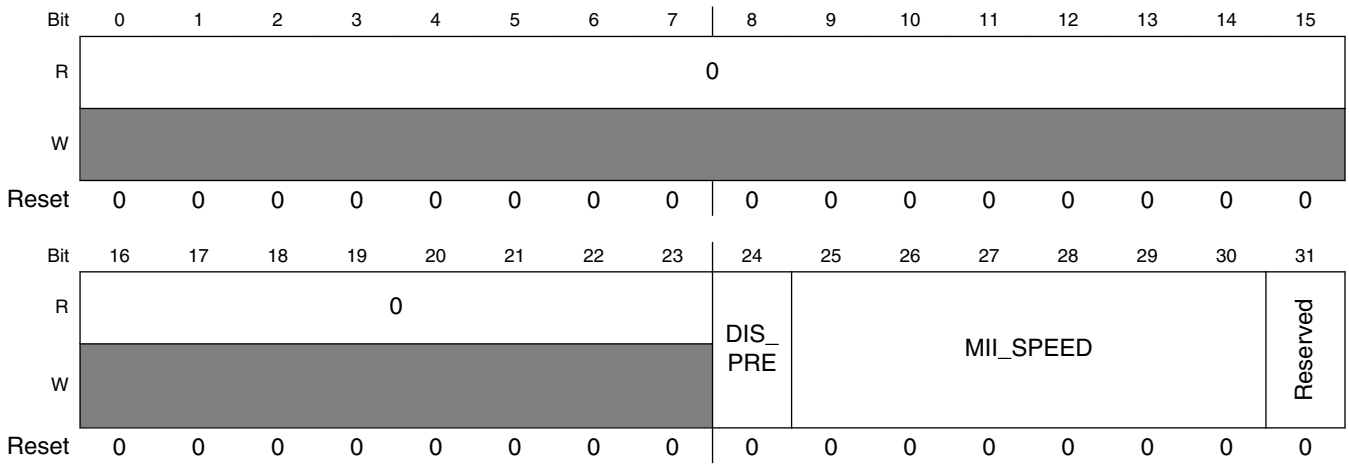
Equation 30. FEC_MDC example

Table 53-4 shows optimum values for MII_SPEED as a function of internal bus clock frequency.

Table 53-4. Programming examples for MSCR

Internal FEC clock frequency	MSCR[MII_SPEED]	FEC_MDC frequency
25 MHz	5h	2.50 MHz
33 MHz	7h	2.36 MHz
40 MHz	8h	2.50 MHz
50 MHz	Ah	2.50 MHz
66 MHz	Eh	2.36 MHz
80 MHz	10h	2.50 MHz
83 MHz	10h	2.59 MHz

Address: 0h base + 44h offset = 44h



FEC_MSCR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 DIS_PRE	Setting this bit causes the preamble (32 ones) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
25–30 MII_SPEED	Controls the frequency of the MII management interface clock (FEC_MDC) relative to the internal bus clock. A value of 0 in this field turns off the FEC_MDC and leaves it in low voltage state. Any non-zero value results in the FEC_MDC frequency of 1/(MII_SPEED x 2) of the internal bus frequency.
31 Reserved	This field is reserved. Reserved

53.4.8 MIB Control Register (FEC_MIBC)

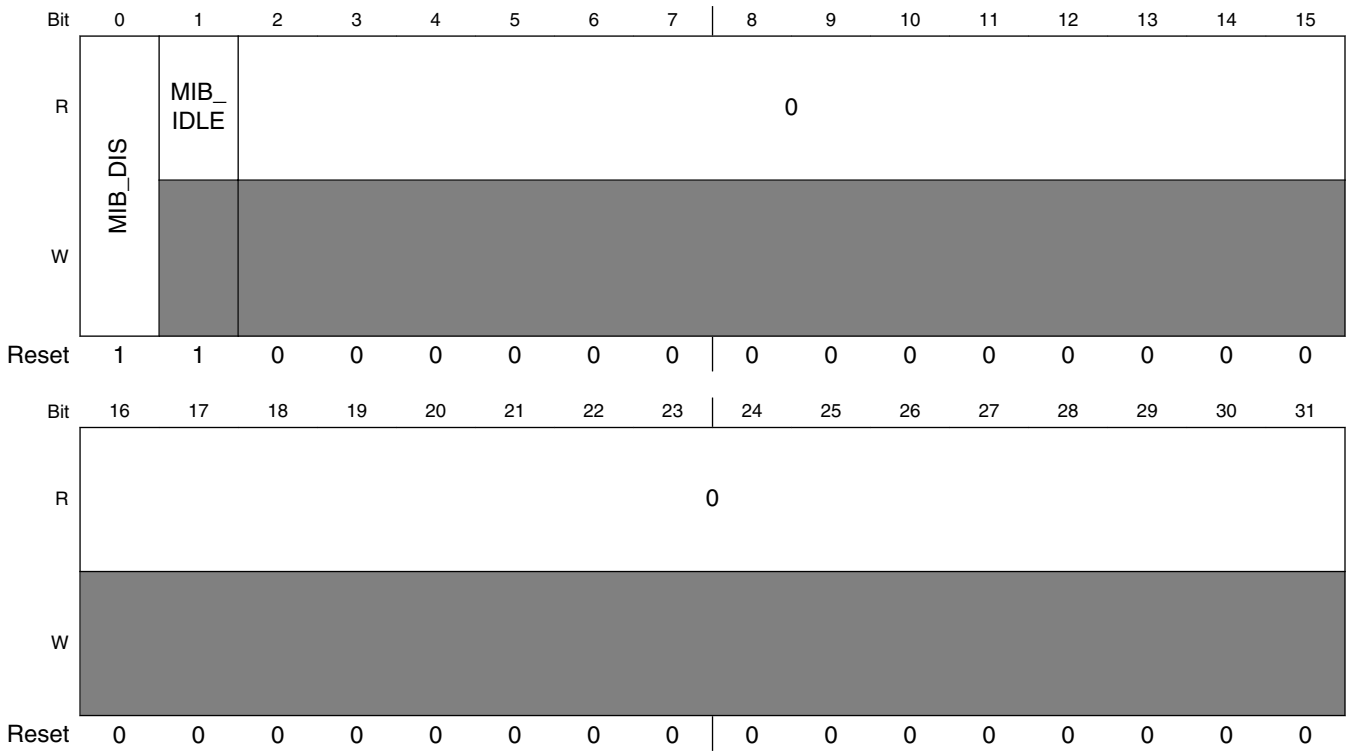
The MIBC is a read/write register controlling and observing the state of the MIB block. User software accesses this register if there is a need to disable the MIB block operation. For example, to clear all MIB counters in RAM:

1. Disable the MIB block

2. Clear all the MIB RAM locations
3. Enable the MIB block

The MIB_DIS bit is reset to 1. See the memory map for the locations of the MIB counters.

Address: 0h base + 64h offset = 64h



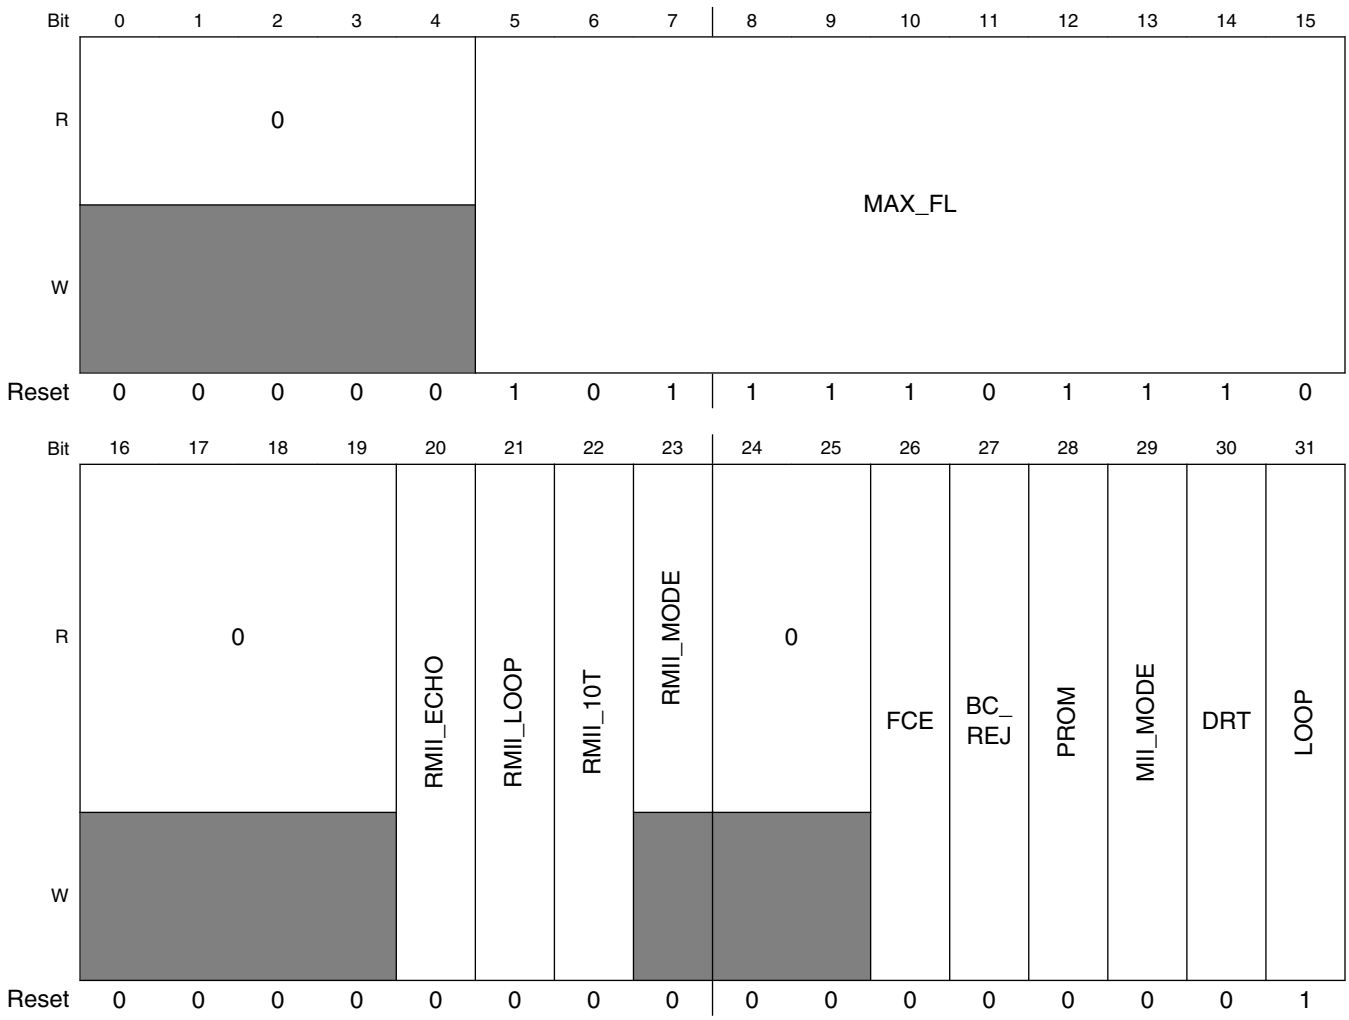
FEC_MIBC field descriptions

Field	Description
0 MIB_DIS	If MIB_DIS = 1, the MIB logic halts and not update any MIB counters.
1 MIB_IDLE	If MIB_IDLE = 1, the MIB block is not currently updating any MIB counters.
2–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.9 Receive Control Register (FEC_RCR)

RCR controls the operational mode of the receive block and must be written only when ECR[ETHER_EN] is cleared (initialization time).

Address: 0h base + 84h offset = 84h



FEC_RCR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 MAX_FL	Maximum frame length. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor.

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
	The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 RMII_ECHO	RMII Echo. Enables RMII echo mode. RMII 2-bit receive data is processed through the RMII receive logic to the FEC and also routes through the RMII's transmit logic to become RMII 2-bit transmit data out. 0 Normal operation. 1 RMII echo mode enabled. **NOTE:** When RMII_ECHO is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_LOOP = 0 and LOOP = 0.
21 RMII_LOOP	RMII loopback. Enables RMII loopback mode. Causes the MII transmit outputs from the Ethernet controller to loop back to the Ethernet controllers's MII receive inputs through the RMII transmit/receive logic. 0 Normal operation. 1 RMII loopback mode enabled. **NOTE:** When RMII_LOOP is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_ECHO = 0, LOOP = 0, and TCR *n* [FDEN] = 1.
22 RMII_10T	RMII 10-Base T. Enables 10Mbps mode of the RMII. Determines the clock frequency of the clock source to the FEC logic to support 10/100Mbps operations. 0 100 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is sent to the RMII, while a divided-by-2 version (25 MHz) is sent to the FEC. 1 10 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is divided by 10 (5 MHz) and sent to the RMII, while a divided-by-20 version (2.5 MHz) is sent to the FEC.
23 RMII_MODE	RMII Mode. Indicates if the FEC is in RMII or MII/7-wire mode. See the chip configuration chapter for more details. **NOTE:** Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 FEC is in true MII mode. 1 FEC is in RMII mode.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FCE	Flow control enable. If asserted, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast frame reject. If asserted, frames with DA (destination address) equal to FFFF_FFFF_FFFF are rejected unless the PROM bit is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the M (MISS) is set in the receive buffer descriptor.
28 PROM	Promiscuous mode. All frames are accepted regardless of address matching.
29 MII_MODE	Media independent interface mode. Selects the external interface mode for transmit and receive blocks. **NOTE:** Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. 0 7-wire mode (used only for serial 10 Mbps) 1 MII or RMII mode as indicated by the RMII_MODE bit

Table continues on the next page...

FEC_RCR field descriptions (continued)

Field	Description
30 DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode). 1 Disable reception of frames while transmitting (normally used for half duplex mode).
31 LOOP	Internal loopback. If set, transmitted frames are looped back internal to the device and transmit output signals are not asserted. The internal bus clock substitutes for the FEC_TXCLK when LOOP is asserted. DRT must be set to 0 when setting LOOP.

53.4.10 Transmit Control Register (FEC_TCR)

The TCR configures the transmit block.

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0											RFC_PAUSE	TFC_PAUSE	FDEN	HBC	GTS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_TCR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 RFC_PAUSE	Receive frame control pause. This read-only status bit is asserted when a full duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the MAC stops transmission of data frames after the current transmission is complete. At this time, GRA interrupt in the EIR is asserted. With transmission of data frames stopped, MAC transmits a MAC Control PAUSE frame. Next, the MAC clears the TFC_PAUSE bit and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC Control PAUSE frame.
29 FDEN	Full duplex enable. If set, frames transmit independent of carrier sense and collision inputs. This field must be modified only when ECR[ETHER_EN] = 0.
30 HBC	Heartbeat control. If set, the heartbeat check performs following end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This field must be modified only when ECR[ETHER_EN] = 0.
31 GTS	Graceful transmit stop. When this bit is set, MAC stops transmission after any frame currently transmitted is complete and GRA interrupt in the EIR is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this situation, program ECR[ETHER_EN] = 0 following the GRA interrupt.

53.4.11 Physical Address Low Register (FEC_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the 6-byte source address field when transmitting PAUSE frames.

This register is not reset and you must initialize it.

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_PALR field descriptions

Field	Description
0–31 PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

53.4.12 Physical Address High Register and Type Field (FEC_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (8808h) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize them.

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type field in PAUSE frames. These 16 read-only bits are a constant value of 8808h.

53.4.13 Opcode/Pause Duration (FEC_OPD)

The OPD contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0001h. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field.

The lower 16 bits of this register are not reset and you must initialize them.

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode field used in PAUSE frames. These read-only bits are a constant, 0001h.
16–31 PAUSE_DUR	Pause Duration field used in PAUSE frames.

53.4.14 Descriptor Individual Upper Address Register (FEC_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_GALR field descriptions

Field	Description
0–31 GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

53.4.18 Transmit FIFO Watermark (FEC_TFWR)

The TFWR controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

Address: 0h base + 144h offset = 144h

FEC_FRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_BOUND	Highest valid FIFO RAM address.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.20 FIFO Receive Start Register (FEC_FRSR)

FRSR indicates the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

Hardware initializes the FRSR at reset. FRSR only needs to be written to change the default value.

Address: 0h base + 150h offset = 150h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

21 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
22–29 R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs. For proper operation, ensure that R_FSTART is set to 48h or greater.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.21 Receive Descriptor Ring Start Register (FEC_ERDSR)

ERDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 180h offset = 180h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ERDSR field descriptions

Field	Description
0–29 R_DES_START	Pointer to start of receive buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.22 Transmit Buffer Descriptor Ring Start Register (FEC_ETDSR)

ETSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FEC_ETDSR field descriptions

Field	Description
0–29 X_DES_START	Pointer to start of transmit buffer descriptor queue.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.23 Receive Buffer Size Register (FEC_EMRBR)

The EMRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. To properly align the buffer, EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR is undefined at reset and must be initialized by the user.

Address: 0h base + 188h offset = 188h

Bit	0–20	21–27	28–31
R	0	R_BUF_SIZE	0
W			
Reset	u*	u*	u*

* Notes:
- u = Unaffected by reset.

FEC_EMRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–27 R_BUF_SIZE	Maximum size of receive buffer size in bytes. To minimize bus utilization (descriptor fetches), set this field to 256 bytes (10h) or larger. 10h: 256 + 15 bytes (minimum size recommended) 11h: 272 + 15 bytes ... 7Fh: 2032 + 15 bytes. The FEC writes up to 2047 bytes in the receive buffer. If data larger than 2047 is received, the FEC truncates it and shows 7FFh in the receive descriptor
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.24 Count of frames not counted correctly (FEC_RMON_T_DROP)

53.4.79 Using the RMON and IEEE registers

In order to use the RMON and IEEE registers to monitor FEC performance, you must prepare them using the sequence below:

1. Write zeros to the registers.
2. Enable the FEC.

Until you complete this sequence, the registers are read/write, and their reset value is undefined. After you complete this sequence, the registers become read-only, and you may read them as necessary.

53.5 Functional description

This section describes the operation of the FEC, beginning with the description of two different types of MII frames, the buffer descriptors, the hardware and software initialization sequence, then the software (Ethernet driver) interface for transmitting and receiving frames.

Following the software initialization and operation sections are sections providing a detailed description of the functions of the FEC.

53.5.1 MII data frame

Ethernet/802.3 data frames transmitted across the MII have the format specified in Figure 53-2 and Table 53-5.

<inter-frame> <preamble> <sfd> <data> <efd>

Figure 53-2. MII data frame format

Table 53-5. MII data frame components

Component	Description
<inter-frame>	Inter-frame period. This is an unspecified amount of time during which no data activity occurs on the MII. The de-assertion of RX_DV and TX_EN indicate the absence of data activity.
<preamble>	Preamble that begins a frame. It has the following value: 10101010 10101010 10101010 10101010 10101010 10101010 10101010 The leftmost 1 represents the LSB of the byte.
<sfd>	Start of a frame. It has the value 10101011.
<data>	Data portion of the frame. It consists of N octets which corresponds to 2N nibbles being transmitted. The order of each nibble is defined in Figure 53-3.
<efd>	End-of-frame delimiter.

Table 53-5. MII data frame components

Component	Description
	For TXD data, it is indicated by the de-assertion of the TX_EN signal. For RXD data, it is indicated by the de-assertion of the RX_DV signal.

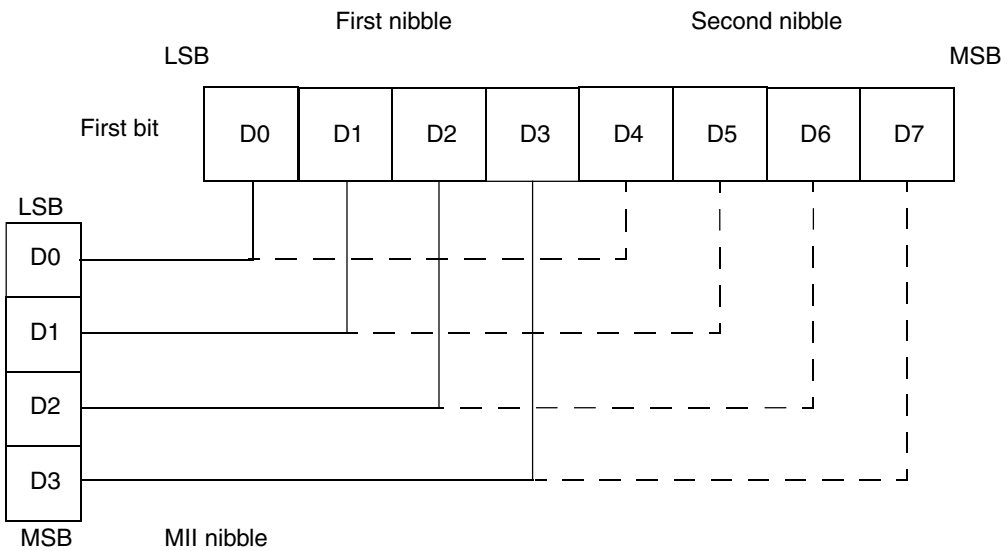

Figure 53-3. MII nibble/octet to octet/nibble mapping

53.5.2 MII management frame structure

A transceiver management frame being transmitted on the MII management interface uses the MDIO and MDC pins. A transaction or frame on this serial interface has the format specified in Figure 53-4 and Table 53-6.

<preamble> <st> <op> <phyad> <regad> <ta> <data> <idle>

Figure 53-4. MII management frame format

Table 53-6. MII management frame components

Component	Description
<preamble>	Optional preamble, consisting of a sequence of 32 continuous logic 1's.
<st>	Start of frame, consisting of a 01 pattern.
<op>	Operation code. 01 Write operation 10 Read instruction
<phyad>	Five-bit field that allows up to 32 PHYs to be addressed. The first address bit transmitted is the MSB of the address.

Table continues on the next page...

Table 53-6. MII management frame components (continued)

Component	Description
<regad>	Five-bit field that allows for 32 registers to be addressed within each PHY. The first register bit transmitted is the MSB of the address.
<ta>	Two-bit field that provides spacing between the register address field and the data field to avoid contention on the MDIO signal during a read operation.
<data>	16-bit data field. Bit 15 is the first data bit transmitted and received.
<idle>	Idle condition (MDIO is in the high-impedance state).

The MII management register set located in the PHY may consist of a basic register set and an extended register set as defined in Table 53-7.

Table 53-7. MII management register set

Register address	Register name	Register set
0	Control	Basic
1	Status	
2-3	PHY identifier	Extended
4	Auto-negotiation advertisement	
5	AN link partner ability	
6	AN expansion	
7	AN next page transmit	
8-15	Reserved	
16-31	Vendor-specific	

53.5.3 Buffer descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

53.5.3.1 Driver/DMA operation with buffer descriptors

The data for the FEC frames resides in one or more memory buffers external to the FEC. Associated with each buffer is a buffer descriptor (BD), which contains a starting address (32-bit aligned pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read by the FEC DMA engine.

Software produces buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit produces the buffer. Software writing to TDAR or RDAR tells the FEC that a buffer is placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and consumes the buffers after they have been produced. After the data DMA is complete and the DMA engine writes the buffer descriptor status bits, hardware clears RxBD[E] or TxBD[R] to signal the buffer has been consumed. Software may poll the BDs to detect when the buffers are consumed or may rely on the buffer/frame interrupts. The driver may process these buffers, and they can return to the free list.

The ECR[ETHER_EN] bit operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is cleared, the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before ECR[ETHER_EN] is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The wrap (W) bit defines the last buffer descriptor in each ring. When W is set, the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively. Buffer descriptor rings must start on a 32-bit boundary; however, it is recommended they be 128-bit aligned.

53.5.3.1.1 Driver/DMA operation with transmit BDs

Typically, a transmit frame is divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a second buffer, IP header in a third buffer, and Ethernet/IEEE 802.3 header in a fourth buffer. The Ethernet MAC does not prepend the Ethernet header (destination address, source address, length/type field(s)), so the driver must provide this in one of the transmit buffers. The Ethernet MAC can append the Ethernet CRC to the frame. TxBD[TC], which must be set by the driver, determines whether the MAC or driver appends the CRC.

The driver (TxBD software producer) should set up Tx BDs so a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length, and control (W, L, TC, ABC) and then the TxBD[R] bit should be set in reverse order (third, second, then first BD) to ensure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the second was made available, potentially causing a transmit FIFO underrun.

In the FEC, the driver notifies the DMA that new transmit frame(s) are available by writing to TDAR. When this register is written to (data value is not significant), the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers until a transmit BD is encountered with the R bit cleared. At this point, the FEC polls this BD one more time. If the R bit is cleared the second time, RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

53.5.3.1.2 Driver/DMA operation with receive BDs

Unlike transmit, the length of the receive frame is unknown by the driver ahead of time. Therefore, the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of empty buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L is set), and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end-of-frame buffers, the receive BD is written with L set and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not only the length of the last buffer.

For simplicity, the driver may assign a large enough default receive buffer length to contain an entire frame, keeping in mind that a malfunction on the network or out-of-spec implementation could result in giant frames. Frames of 2K (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received, the FEC fills receive buffers and updates the associated BDs, then reads the next BD in the receive

descriptor ring. If the FEC reads a receive BD and finds the E bit cleared, it polls this BD once more. If RxBD[E] is clear a second time, FEC stops reading receive BDs until the driver writes to RDAR.

53.5.3.2 Ethernet Receive Buffer Descriptor (RxBD)

In the RxBD, the user initializes the E and W bits in the first longword and the pointer in the second longword. When the buffer has been DMA'd, the Ethernet controller modifies the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and writes the length of the used portion of the buffer in the first longword. The M, BC, MC, LG, NO, CR, OV, and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

Table 53-8. Receive Buffer Descriptor (RxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset+2	Data Length															
Offset+4	Rx Data Buffer Pointer - A[31:16]															
Offset+6	Rx Data Buffer Pointer - A[15:0]															

Table 53-9. Receive Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	E	Empty. Written by the FEC (=0) and user (=1). 0: The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1: The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ERDSR.
Offset + 0	RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by the FEC. 0: The buffer is not the last in a frame. 1: The buffer is the last in a frame.
Offset + 0	M	Miss. Written by the FEC. This bit is set by the FEC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0: The frame was received because of an address recognition hit.

Table continues on the next page...

Table 53-9. Receive Buffer Descriptor field descriptions (continued)

Word	Field	Description
		1: The frame was received because of promiscuous mode.
Offset + 0	BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	MC	Set if the DA is multicast and not BC.
Offset + 0	LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
Offset + 0	NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set, the CR bit is not set.
Offset + 0	CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
Offset + 0	OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and are zero. This bit is valid only if the L-bit is set.
Offset + 0	TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set, the frame must be discarded and the other error bits must be ignored as they may be incorrect.
Offset + 2	Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L equals 0 (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the FEC once as the BD is closed.
0ffset + 4	A[31:16]	RX data buffer pointer, bits [31:16][1]
Offset + 6	A[15:0]	RX data buffer pointer, bits [15:0]

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the FEC. The Ethernet controller never modifies this value.

Note

When the software driver sets an E bit in one or more receive descriptors, the driver should follow with a write to RDAR.

53.5.3.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (TxBD[R]) when DMA of the buffer is complete. In the TxBD, the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword and the buffer pointer in the second longword.

The FEC clears the R bit when the buffer is transferred. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block.

Table 53-10. Transmit Buffer Descriptor (TxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset+0	R	TO1	W	TO2	L	TC	ABC	—	—	—	—	—	—	—	—	—
Offset+2	Data Length															
Offset+4	Tx Data Buffer Pointer - A[31:16]															
Offset+6	Tx Data Buffer Pointer - A[15:0]															

Table 53-11. Transmit Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	R	Ready. Written by the FEC and you. 0: The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1: The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this bit is set.
Offset + 0	TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0: The next buffer descriptor is found in the consecutive location 1: The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by user. 0: The buffer is not the last in the transmit frame 1: The buffer is the last in the transmit frame
Offset + 0	TC	Transmit CRC. Written by user (only valid if L is set). 0: End transmission immediately after the last data byte 1: Transmit the CRC sequence after the last data byte
Offset + 0	ABC	Append bad CRC. Written by user (only valid if L is set). 0: No effect 1: Transmit the CRC sequence inverted after the last data byte (regardless of TC value)
Offset + 2	Data Length	Data length, written by user. Data length is the number of octets the FEC should transmit from this BD's data buffer. It is never modified by the FEC.
Offset + 4	A[31:16]	Tx data buffer pointer, bits [31:16] [1]
Offset + 6	A[15:0]	Tx data buffer pointer, bits [15:0]

1. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 4. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

Note

After the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame is setting the R bit in the first BD for the frame. The driver must follow that with a write to TDAR that triggers the FEC to poll the next BD in the ring.

53.5.4 Initialization sequence

This section describes which registers are reset due to hardware reset, which registers are reset by the FEC RISC, and what locations you must initialize prior to enabling the FEC.

53.5.4.1 Hardware Controlled Initialization

In the FEC, hardware resets registers and control logic that generate interrupts. A hardware reset negates output signals and resets general configuration bits.

Other registers reset when the ECR[ETHER_EN] bit is cleared (which is accomplished by a hard reset or software to halt operation). By clearing ECR[ETHER_EN], configuration control registers such as the TCR and RCR are not reset, but the entire data path is reset.

Table 53-12. ECR[ETHER_EN] De-Assertion Effect on FEC

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

53.5.5 User initialization (Prior to Setting ECR[ETHER_EN])

You need to initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values depend on the particular application. The sequence is not important.

The following registers require initialization:

- EIMR
- EIR (clear by writing FFFF_FFFFh)
- TFWR (optional)
- IALR / IAUR
- GAUR / GALR
- PALR / PAUR (only needed for full duplex flow control)
- OPD (only needed for full duplex flow control)
- RCR
- TCR
- MSCR (optional)
- MIB_RAM (clear)
- FRSR (optional)
- EMRBR
- ERDSR
- ETDSR
- Transmit Descriptor ring (empty)
- Receive Descriptor ring (empty)

53.5.6 Microcontroller initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, hardware is ready for operation.

The sequence is as follows:

1. Initialize the backoff random number seed.
2. Activate receiver.
3. Activate transmitter.
4. Clear transmit FIFO.

5. Clear receive FIFO.
6. Initialize the transmit ring pointer.
7. Initialize the receive ring pointer.
8. Initialize FIFO count registers.

53.5.7 User initialization (after setting ECR[ETHER_EN])

After setting ECR[ETHER_EN], you can set up the buffer/frame descriptors and write to TDAR and RDAR. See Buffer descriptors, for more details.

53.5.8 Network interface options

The FEC supports an MII and reduced MII interface for 10/100 Mbps Ethernet, as well as a 7-wire serial interface for 10 Mbps Ethernet. The RCR[MII_MODE] and RCR [RMII_MODE] bits select the interface mode. In MII mode (RCR[MII_MODE]=1 and RCR [RMII_MODE]=0), there are 18 signals defined by the IEEE 802.3 standard and supported by the EMAC. The following table shows these signals.

Table 53-13. MII mode

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[3:0]
Transmit Error	FEC_TXER
Collision	FEC_COL
Carrier Sense	FEC_CRS
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[3:0]
Receive Error	FEC_RXER
Management Data Clock	FEC_MDC
Management Data Input/Output	FEC_MDIO

In RMII mode (RCR[MII_MODE]=1 and RCR[RMII_MODE]=1), the EMAC supports 8 external signals. These signals are shown in the table below.

Table 53-14. RMII mode configuration

Signal description	EMAC pin
Reference Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[1:0]
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[1:0]
Receive Error	FEC_RXER

The 7-wire serial mode interface (RCR[MII_MODE]=1 and RCR[RMII_MODE]=0 or 1) is generally referred to as AMD mode. The following table shows the 7-wire mode connections to the external transceiver.

Table 53-15. 7-Wire mode configuration

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[0]
Collision	FEC_COL
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[0]

53.5.9 FEC frame transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER_EN] is set and data appears in the transmit FIFO, the Ethernet MAC can transmit onto the network. The Ethernet controller transmits bytes least significant bit (lsb) first.

When the transmit FIFO fills to the watermark (defined by TFWR), MAC transmit logic asserts FEC_TXEN and starts transmitting the (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See "Transmission errors" for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data is transmitted, FCS (frame check sequence) or 32-bit cyclic redundancy check (CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Transmit logic automatically pads short frames (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set).

Settings in the EIMR determine interrupts generated to the buffer (TXB) and frame (TXF).

The transmit error interrupts are HBERR, BABT, LC, RL, and UN. If the transmit frame length exceeds MAX_FL bytes, BABT interrupt is asserted. However, the entire frame is transmitted (no truncation).

To pause transmission, set TCR[GTS] (graceful transmit stop). The FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame finishes or terminates with a collision. After the transmitter has stopped, the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

53.5.9.1 Duplicate frame transmission

The FEC fetches transmit buffer descriptors (TxBDs) and the corresponding transmit data continuously until the transmit FIFO is full. It does not determine whether the TxBD to be fetched is already being processed internally (as a result of a wrap). As the FEC nears the end of the transmission of one frame, it begins to DMA the data for the next frame. To remain one BD ahead of the DMA, it also fetches the TxBD for the next frame. It is possible that the FEC fetches from memory a BD that has already been processed but not yet written back (it is read a second time with the R bit remains set). In this case, the data is fetched and transmitted again.

Using at least three TxBDs fixes this problem for large frames, but not for small frames. To ensure correct operation for large or small frames, one of the following must be true:

- The FEC software driver ensures that there is always at least one TxBD with the ready bit cleared.
- Every frame uses more than one TxBD and every TxBD but the last is written back immediately after the data is fetched.
- The FEC software driver ensures a minimum frame size, *n.* The minimum number of TxBDs is then (Tx FIFO Size ÷ (*n*+4)) rounded up to the nearest integer (though the result cannot be less than three). The default Tx FIFO size is 192 bytes; this size is programmable.

53.5.10 FEC frame reception

The FEC receiver works with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking. The Ethernet controller receives serial data lsb first.

When the driver enables the FEC receiver by setting ECR[ETHER_EN], it immediately starts processing receive frames. When FEC_RXDV is asserted, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the receiver processes the frame. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit times of RX_D0 following assertion of FEC_RXDV are ignored. Following the first 16 bit times, the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame are received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data is received and if address recognition has not rejected the frame, the receive FIFO signals the frame is accepted and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Therefore, no collision fragments are presented to you except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV, and TR status bits, and the frame length. See "Reception errors" for more details.

Receive buffer (RXB) and frame interrupts (RFINT) may be generated if enabled by the EIMR register. A receive error interrupt is a babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See Ethernet Receive Buffer Descriptor (RxBD), for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RFINT bit in EIR, maskable by RFIEN bit in EIMR), indicating that a frame is received and is in memory. The Ethernet controller then waits for a new frame.

53.5.11 Ethernet address recognition

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames appears in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 53-5 illustrates the address recognition decisions made by the receive block, while Figure 53-6 illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in Figure 53-5. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 53-6.

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.

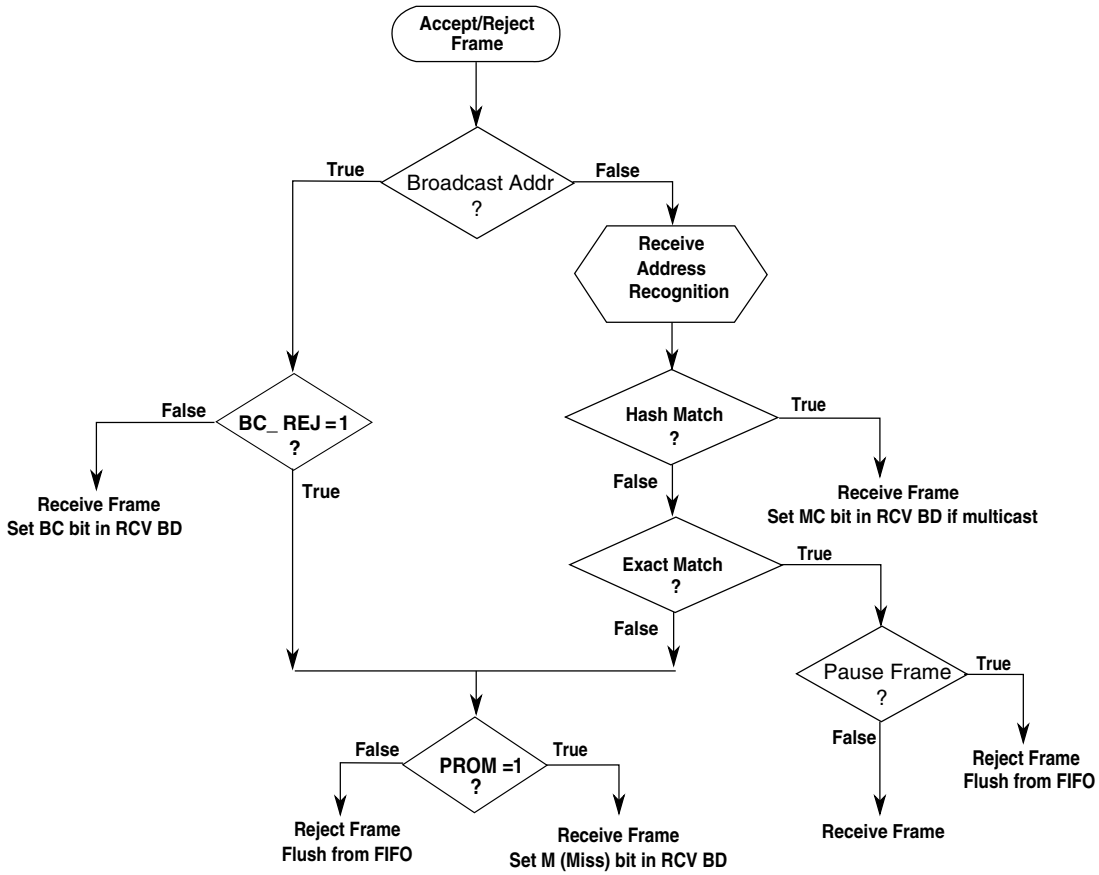
If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines the received frame is a valid PAUSE frame, the frame is rejected. The receiver detects a PAUSE frame with the DA field set to the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that you program in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on PAUSE frame detection, shown in Figure 53-5.

If neither a hash match (group or individual) nor an exact match (group or individual) occur, and if promiscuous mode is enabled (RCR[PROM] set), the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

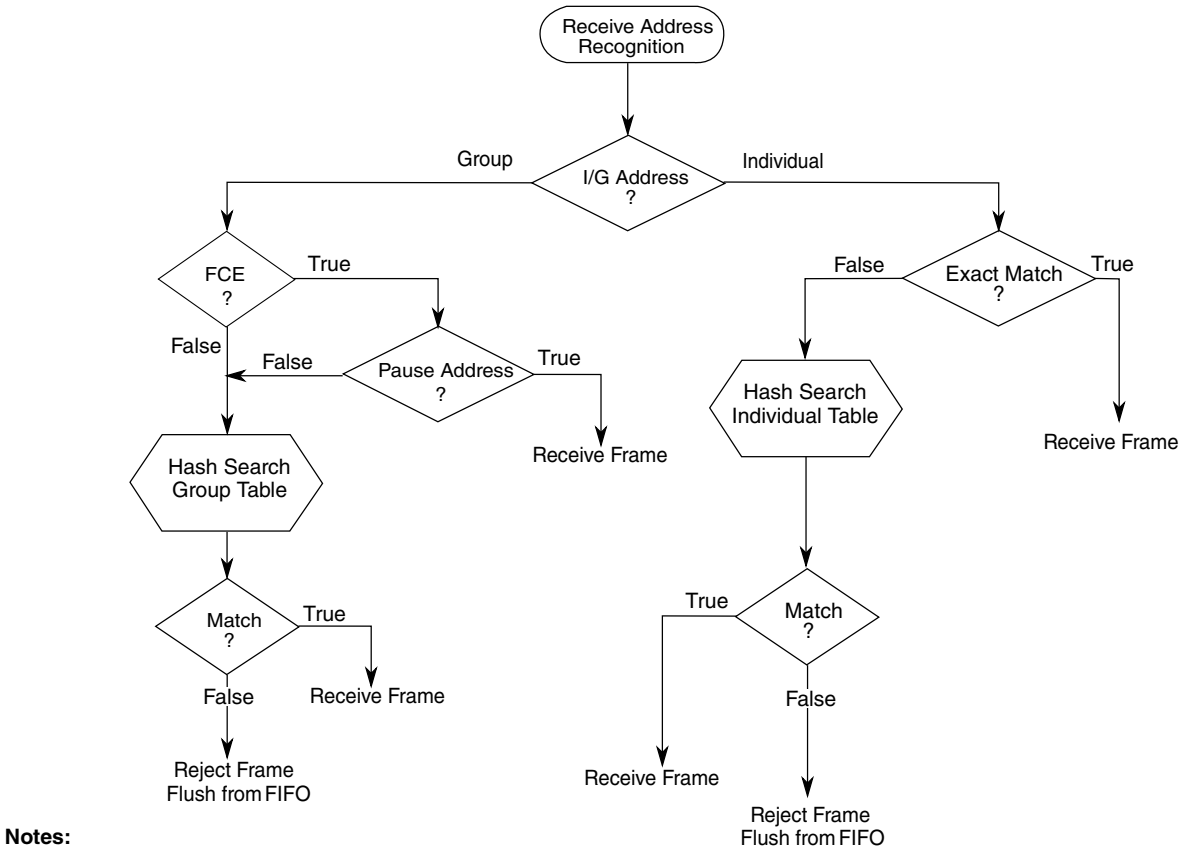
Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.



Notes:
BC_REJ - field in RCR register (BroadCast REJect)
PROM - field in RCR register (PROMiscous mode)
Pause Frame - valid PAUSE frame received

Figure 53-5. Ethernet address recognition—receive block decisions



Notes:
FCE - field in RCR register (flow control enable)
I/G - Individual/Group bit in destination address (lsb in first byte received in MAC frame)

Figure 53-6. Ethernet address recognition—microcode decisions

53.5.12 Hash algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits stored in GAUR, GALR (group address hash match), or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The msb of the CRC result selects GAUR (msb = 1) or GALR (msb = 0). The five least significant bits of the hash result select the bit within the selected register. If the CRC generator selects a bit set in the hash table, the frame is accepted; otherwise, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

$$X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^{8}+X^{7}+X^{5}+X^{4}+X^{2}+X+1$$

Equation 31. CRC32 polynomial for hash computation

The following table contains example destination addresses and corresponding hash values.

Table 53-16. Destination address to 6-bit hash

48-BIT DA	6-bit hash (in hex)	Hash decimal value
65FF_FFFF_FFFF	0h	0
55FF_FFFF_FFFF	1h	1

53.5.13 Full duplex flow control

Full-duplex flow control allows you to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, MAC data frame transmission stops for a given pause duration.

To enable PAUSE frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] set) with flow control (RCR[FCE] set). The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in the following table. In addition, the receive status associated with the frame should indicate that the frame is valid.

Table 53-17. PAUSE frame field specification

48-bit destination address	0180_C200_0001h or Physical Address
48-bit source address	Any
16-bit type	8808h
16-bit opcode	0001h
16-bit PAUSE duration	0000h — FFFFh

The receiver and microcontroller modules perform PAUSE frame detection. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is set by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. The pause timer uses the transmit backoff timer hardware for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is cleared allowing MAC data frame transmission to resume. The receive flow control pause status bit (TCR[RFC_PAUSE]) is set while the transmitter pauses due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and you must set flow control pause (TCR[TFC_PAUSE]). After TCR[TFC_PAUSE] is set, the transmitter sets TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts and the pause frame is transmitted. TCR[TFC_PAUSE,GTS] are then cleared internally.

You must specify the desired pause duration in the OPD register.

When the transmitter pauses due to receiver/microcontroller pause frame detection, TCR[TFC_PAUSE] may remain set and cause the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

53.5.14 Inter-Packet Gap (IPG) time

The minimum inter-packet gap time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it is ignored and a collision occurs.

The receiver accepts back-to-back frames with a minimum spacing of at least 28 bit times. If an inter-packet gap between receive frames is less than 28 bit times, the receiver may discard the following frame.

53.5.15 Collision managing

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the sequence, a JAM pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit times (one slot time), the retry process is initiated. The transmitter waits a random number of slot times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

53.5.16 MII internal and external loopback

Internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Internal and external loopback are configured using combinations of the RCR[LOOP, DRT] and TCR[FDEN] bits.

Set FDEN for internal and external loopback.

For internal loopback, set RCR[LOOP] and clear RCR[DRT]. FEC_TXEN and FEC_TXER do not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the transmit and receive blocks use the internal bus clock instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit

and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underruns and receive FIFO overflows.

For external loopback, clear RCR[LOOP] and RCR[DRT], and configure the external transceiver for loopback.

53.5.17 RMII loopback

The FEC also supports RMII loopback. In this mode, transmit data is sent to the RMII receive logic and out the FEC_TXD[1:0] pins. To enable RMII loopback mode, set RCR[RMII_MODE, RMII_LOOP] and TCR[FDEN] and clear RCR[RMII_ECHO, LOOP].

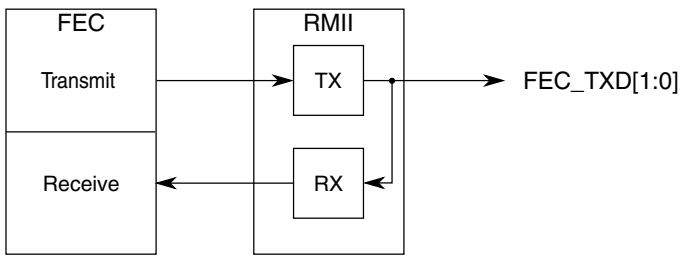

Figure 53-7. RMII loopback mode

53.5.18 RMII echo

The Ethernet controller also supports RMII echo mode, which transmits data on FEC_TXD[1:0] as it is received on FEC_RXD[1:0]. To enable RMII echo mode, set RCR[RMII_MODE, RMII_ECHO] bits and clear RCR[RMII_LOOP, LOOP].

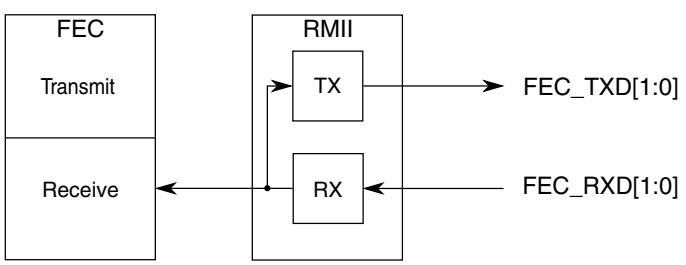

Figure 53-8. RMII echo mode

53.5.19 Ethernet error-managing procedure

The Ethernet controller reports frame reception and transmission error conditions using the MIB block counters, the FEC RxBDs, and the EIR register.

53.5.19.1 Transmission errors

53.5.19.1.1 Transmitter underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed, and EIR[UN] is set. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame. The UN interrupt is asserted if enabled in the EIMR register.

53.5.19.1.2 Retransmission attempts limit expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[RL] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The RL interrupt is asserted if enabled in the EIMR register.

53.5.19.1.3 Late collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[LC] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The LC interrupt is asserted if enabled in the EIMR register.

53.5.19.1.4 Heartbeat

Some transceivers have a self-test feature called heartbeat or signal quality error. To signify a good self-test, the transceiver indicates a collision to the FEC within four microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver continues to function properly. This is the heartbeat condition.

If TCR[HBC] is set and the heartbeat condition is not detected by the FEC after a frame transmission, a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets EIR[HB], and generates the HBERR interrupt if it is enabled.

53.5.19.2 Reception errors

53.5.19.2.1 Overrun error

If the receive block has data to put into the receive FIFO and the receive FIFO is full, FEC sets RxBD[OV]. All subsequent data in the frame is discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. The driver must discard this frame.

53.5.19.2.2 Non-octet error (dribbling bits)

The Ethernet controller manages up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, no error is reported.

53.5.19.2.3 CRC error

When a CRC error occurs with no dribble bits, FEC closes the buffer and sets RxBD[CR]. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

53.5.19.2.4 Frame length violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and RxBD[LG] is set. The frame is not truncated unless the frame length exceeds 2047 bytes.

53.5.19.2.5 Truncation

When the receive frame length exceeds 2047 bytes, frame is truncated and RxBD[TR] is set.

Chapter 54
FlexRay Communication Controller (FlexRay)

54.1 Introduction

This section provides a high-level summary of module features.

54.1.1 Reference

The following documents are referenced.

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*[1]
  - Refer to this document for the all of the FlexRay related informaton including the configuration parameters and the allowed parameter ranges.
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0*

54.1.2 Glossary

This section provides a list of terms used in this chapter.

Table 54-1. List of terms

Term	Definition
BCU	Buffer Control Unit. Handles message buffer access.
BMIF	Bus Master Interface. Provides master access to FlexRay memory area.
CC	Communication Controller
CDC	Clock Domain Crosser
CHI	Controller Host Interface

Table continues on the next page...

1. The FlexRay Specifications have been developed for automotive applications.The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Table 54-1. List of terms (continued)

Term	Definition
Cycle length in µT	The actual length of a cycle in µT for the ideal controller (+/- 0 ppm)
EBI	External Bus Interface
FlexRay Memory Area	Memory area to store the physical message buffer payload data, frame header, frame and slot status, and synchronization frame related tables.
FSS	Frame Start Sequence
HIF	Host Interface. Provides host access to controller.
Host	The FlexRay CC host MCU
Keyslot	Key slot is used to transmit the startup frame, sync frame, or designated single slot frame.
LUT	Look Up Table. Stores message buffer header index value.
LRAM	Look Up Table RAM. Module internal memory to store message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers.
MB	Message Buffer
Mini-slot	An interval of time within the dynamic segment of the communication cycle that is of constant duration (in terms of macroticks) and that is used by the synchronized FTDMA media access scheme to manage media arbitration
MBIDX	Message Buffer Index: the position of a header field entry within the header area. If the header area is accessed as an array, this is the same as the array index of the entry.
MBNum	Message Buffer Number: Position of message buffer configuration registers within the register map. For example, Message Buffer Number 5 corresponds to the MBCCS5 register.
MCU	Microcontroller Unit
µT	Microtick
MT	Macrotick
MTS	Media Access Test Symbol
message frame	Frame with *Null Frame Indicator* set to 1
normal frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 0
null frame	frame with *Null Frame Indicator* set to 0
NIT	Network Idle Time
PE	Protocol Engine
POC	Protocol Operation Control. Each state of the POC is denoted by POC:state
Rx	Reception
Slot	An interval of time during which access to a communication channel is granted exclusively to a specific node for the transmission of a frame with a frame ID corresponding to the slot.
SEQ	Sequencer Engine
SU	Status update
SECDED	Single-bit error correction, double-bit error detection
System Memory	Memory that contains the FlexRay Memory Area.
System Bus	Bus that connects the controller and System Memory

Table continues on the next page...

Table 54-1. List of terms (continued)

Term	Definition
sync frame	null frame or message frame with *Sync Frame Indicator* set to 1
startup frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 1
TCU	Time Control Unit
Tx	Transmission

54.1.3 Overview

The CC is a FlexRay communication controller that implements the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

The CC has three main components:

- *Controller host interface (CHI)*
- *Protocol engine (PE)*
- *Clock domain crossing unit (CDC)*

A block diagram of the CC with its surrounding modules is given in the below figure.

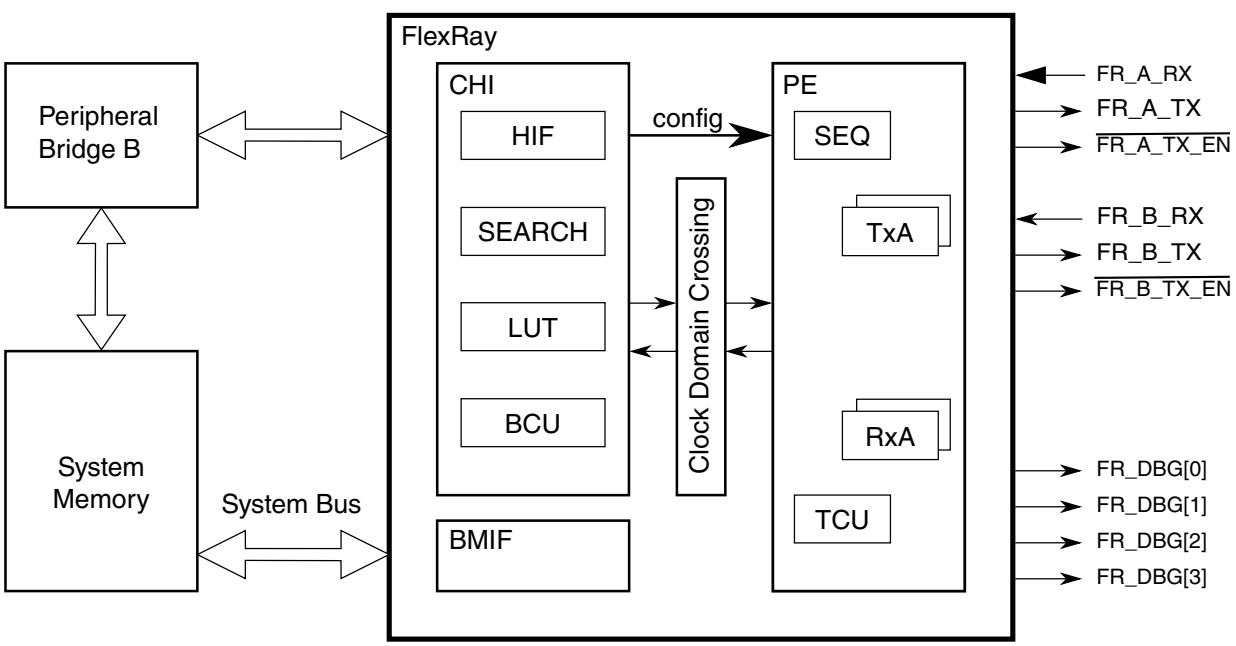

Figure 54-1. FlexRay block diagram

The protocol engine has two transmitter units TxA and TxB and two receiver units RxA and RxB for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the PE is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, and the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the CHI clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the System Memory Base Address Register (FR_SYMBADHR and FR_SYMBADLR). All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note

The CC does not provide a memory protection scheme for the FlexRay memory area.

54.1.4 Features

The CC provides the following features:

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A compliant protocol implementation*
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0 compliant bus driver interface*

- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- Dual channel support
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 128 configurable message buffers with
  - individual frame ID filtering
  - individual channel ID filtering
  - individual cycle counter filtering
- Message buffer header, status and payload data stored in dedicated FlexRay memory area
  - allows for flexible and efficient message buffer implementation
  - consistent data access ensured by means of buffer locking scheme
  - application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0 up to 254 bytes
- Two independent message buffer segments with configurable size of payload data section
  - each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
  - applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
  - receive message buffer
  - transmit message buffer
- Individual message buffer reconfiguration supported
  - means provided to safely disable individual message buffers
  - disabled message buffers can be reconfigured

- Two independent receive FIFOs
  - one receive FIFO per channel
  - up to 255 entries for each FIFO
  - global frame ID filtering, based on both value/mask filters and range filters
  - global channel ID filtering
  - global message ID filtering for the dynamic segment
- 4 configurable slot error counters
- 4 dedicated slot status indicators
  - used to observe slots without using receive message buffers
- Measured value indicators for the clock synchronization
  - internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- 1 absolute timer
- 1 timer that can be configured to absolute or relative
- Error correction and error detection (SECDED ECC) for protocol engine data RAM
- Error detection (SECDED ECC) for CHI lookup table RAM

54.1.5 Modes of Operation

This section describes the basic operational power modes of the CC.

54.1.5.1 Disabled Mode

The CC enters the Disabled Mode during hard reset or when the host clears the ‘MEN’ field in the Module Configuration Register (FR_MCR). The host can clear this field by writing ‘0’ and only when the module is in POC:default config mode. The Disabled mode can be checked by reading the module enable field, MEN, in the Module Configuration Register (FR_MCR).

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled Mode* can be accessed for writing as stated in the Memory Map and Register Description section.

The application configures the CC by accessing the configuration bits and fields in the Module Configuration Register (FR_MCR) as described in Module Initialization .

54.1.5.1.1 Leave Disabled Mode

The CC leaves the Disabled Mode and enters the Normal Mode, when the application writes 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

Note

Once the CC is enabled, it can only be disabled during POC: default config.

54.1.5.2 Normal Mode

In this mode the CC is fully functional. The CC indicates that it is in Normal Mode by asserting the module enable bit MEN in the Module Configuration Register (FR_MCR).

54.1.5.2.1 Enter Normal Mode

This mode is entered when the application requests the CC to leave the Disabled Mode. If the Normal Mode was entered by leaving the Disabled Mode, the application has to perform the protocol initialization described in Protocol Initialization to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB bits in the Module Configuration Register (FR_MCR), the corresponding FlexRay bus driver ports are enabled and driven.

54.2 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in the following table and described in detail in the Detailed Signal Descriptions section below.

NOTE

Please refer the device configuration of the reference manual for the exact module pin names.

NOTE

The off chip signals FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 54-2. External Signal Properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR\_A\_TX\_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR\_B\_TX\_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

54.2.1 Detailed Signal Descriptions

This section provides a detailed description of the CC signals, connected to external pins.

54.2.1.1 FR_A_RX — Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

54.2.1.2 FR_A_TX — Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

54.2.1.3 $\overline{\text{FR\_A\_TX\_EN}}$ — Transmit Enable Channel A

The $\overline{\text{FR\_A\_TX\_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

54.2.1.4 FR_B_RX — Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

54.2.1.5 FR_B_TX — Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

54.2.1.6 $\overline{\text{FR\_B\_TX\_EN}}$ — Transmit Enable Channel B

The $\overline{\text{FR\_B\_TX\_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

54.2.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] — Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection refer to the Strobe Signal Support.

54.3 Controller Host Interface Clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

The first constraint corresponds to the number of utilized message buffers and is specified in Number of Usable Message Buffers.

The second constraint corresponds to the value of the TIMEOUT field in the System Memory Access Time-Out Register (FR_SYMATOR) and is specified in Configure System Memory Access Time-Out Register (FR_SYMATOR).

54.4 Protocol Engine Clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select bit CLKSEL in the Module Configuration Register (FR_MCR).

Note

See the Device clocking details for the exact clock sources used.

54.4.1 Oscillator Clocking

If the protocol engine is clocked by the internal crystal oscillator, a crystal or CMOS compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version* 2.1 Rev A.

54.4.2 PLL Clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately and provided to the PE.

For more details, see the clocking chapter of the device reference manual.

54.5 Register Descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

Table 54-3. Register Access Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
R*	Reserved bit or field, will not be changed. Application must not write any value different from the reset value.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 54-4. Register Field Types

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A flag bit that can be read, is cleared by writing a one, writing 0 has no effect.
Reset Value	
0	Resets to zero.
1	Resets to one.
-	Not defined after reset and not affected by reset.

54.5.1 Register Reset

All registers except the Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*), Message Buffer Frame ID Register (FR_MBFIDR*n*), and Message Buffer Index Register (FR_MBIDXR*n*) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are mentioned in the detailed description of the register. The additional reset conditions are explained in the table below.

Table 54-5. Additional Register Reset Conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes to RUN command "0101" to the POCCMD field in the Protocol Operation Control Register (FR_POCR).
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants the disable to the application by clearing the FR_MBCCSRn[EDS] bit.

54.5.2 Register Write Access

This section describes the write access restriction terms that apply to all registers.

54.5.2.1 Register Write Access Restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the table below. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 54-6. Register Write Access Restrictions

Condition	Indication	Description
Any Time	-	No write access restriction.
Disabled Mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled Mode.
Normal Mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal Mode.
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when Protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSR[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.

54.5.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

54.5.2.3 Internal Register Access

The following memory mapped registers are used to access multiple internal registers.

- *Strobe Signal Control Register (FR_STBSCR)*
- *Slot Status Selection Register (FR_SSSR)*

- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Configuration Data*

Each of these memory mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If the WMD bit is set to 0 during the write access, all fields of the internal register are updated. If the WMD bit set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

54.6 Memory map and register definition

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU.

NOTE

The following registers are 16-bit write accessible only.

Strobe Signal Control Register (FR_STBSCR)

PE DRAM Access Register (FR_PEDRAR)

PE DRAM Data Register (FR_PEDRDR)

Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Slot Status Selection Register (FR_SSSR)

Slot Status Counter Condition Register (FR_SSCCR)

Receive Shadow Buffer Index Register (FR_RSBIR)

Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)

Message Buffer Frame ID Register (FR_MBFIDRn)

Message Buffer Index Register (FR_MBIDXRn)

Message Buffer Data Field Offset Register (FR_MBDORn)

LRAM ECC Error Test Register (FR_LEETRn)

FR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Version Register (FR_MVR)	16	R	A568h	54.6.1/2477

1056	Message Buffer Data Field Offset Register (FR_MBDOR43)	16	R/W	See section	54.6.117/ 2579
1058	Message Buffer Data Field Offset Register (FR_MBDOR44)	16	R/W	See section	54.6.117/ 2579
105A	Message Buffer Data Field Offset Register (FR_MBDOR45)	16	R/W	See section	54.6.117/ 2579

Table continues on the next page...

FR memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
105C	Message Buffer Data Field Offset Register (FR_MBDOR46)	16	R/W	See section	54.6.117/ 2579
105E	Message Buffer Data Field Offset Register (FR_MBDOR47)	16	R/W	See section	54.6.117/ 2579
1060	Message Buffer Data Field Offset Register (FR_MBDOR48)	16	R/W	See section	54.6.117/ 2579
1062	Message Buffer Data Field Offset Register (FR_MBDOR49)	16	R/W	See section	54.6.117/ 2579
1064	Message Buffer Data Field Offset Register (FR_MBDOR50)	16	R/W	See section	54.6.117/ 2579
1066	Message Buffer Data Field Offset Register (FR_MBDOR51)	16	R/W	See section	54.6.117/ 2579
1068	Message Buffer Data Field Offset Register (FR_MBDOR52)	16	R/W	See section	54.6.117/ 2579
106A	Message Buffer Data Field Offset Register (FR_MBDOR53)	16	R/W	See section	54.6.117/ 2579
106C	Message Buffer Data Field Offset Register (FR_MBDOR54)	16	R/W	See section	54.6.117/ 2579
106E	Message Buffer Data Field Offset Register (FR_MBDOR55)	16	R/W	See section	54.6.117/ 2579
1070	Message Buffer Data Field Offset Register (FR_MBDOR56)	16	R/W	See section	54.6.117/ 2579
1072	Message Buffer Data Field Offset Register (FR_MBDOR57)	16	R/W	See section	54.6.117/ 2579
1074	Message Buffer Data Field Offset Register (FR_MBDOR58)	16	R/W	See section	54.6.117/ 2579
1076	Message Buffer Data Field Offset Register (FR_MBDOR59)	16	R/W	See section	54.6.117/ 2579
1078	Message Buffer Data Field Offset Register (FR_MBDOR60)	16	R/W	See section	54.6.117/ 2579
107A	Message Buffer Data Field Offset Register (FR_MBDOR61)	16	R/W	See section	54.6.117/ 2579
107C	Message Buffer Data Field Offset Register (FR_MBDOR62)	16	R/W	See section	54.6.117/ 2579
107E	Message Buffer Data Field Offset Register (FR_MBDOR63)	16	R/W	See section	54.6.117/ 2579
1080	Message Buffer Data Field Offset Register (FR_MBDOR64)	16	R/W	See section	54.6.117/ 2579
1082	Message Buffer Data Field Offset Register (FR_MBDOR65)	16	R/W	See section	54.6.117/ 2579
1084	Message Buffer Data Field Offset Register (FR_MBDOR66)	16	R/W	See section	54.6.117/ 2579
1086	Message Buffer Data Field Offset Register (FR_MBDOR67)	16	R/W	See section	54.6.117/ 2579
