54.6.1 Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CHIVER								PEVER							
Write																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

FR_MVR field descriptions

Field	Description
0–7 CHIVER	CHI Version Number. This field provides the version number of the controller host interface.
8–15 PEVER	PE Version Number. This field provides the version number of the protocol engine.

54.6.2 Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Write: SBFF, SCM, CHB, CHA, ECCE, FUM, FAM , CLKSEL , BITRATE: Disabled Mode and SFFE, MEN: Disabled Mode or POC: config

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read Write	MEN	SBFF	SCM	CHB	CHA	SFFE	ECCE	Reserved
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	FUM	FAM	0	CLKSEL	BITRATE			0
Write								
Reset	0	0	0	0	0	0	0	0

FR_MCR field descriptions

Field	Description
0 MEN	Module Enable. This bit indicates whether or not the CC is in the Disabled Mode. The application requests the CC to leave the Disabled Mode by writing 1 to this bit Before leaving the Disabled Mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, BITRATE values. For details see Modes of Operation. **NOTE:** If the CC is enabled it can only be disabled during mode: POC:default config. 0 Write: only during POC:default config, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled
1 SBFF	System Bus Failure Freeze This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to freeze mode
2 SCM	Single Channel Device Mode. This control bit defines the channel device mode of the CC as described in Channel Device Modes. 0 CC works in dual channel device mode 1 CC works in single channel device mode
3 CHB	Channel B Enable. protocol related parameter: pChannels The semantic of these control bits depends on the channel device mode controlled by the SCM bit and is given in the following table.

Table 54-7. FlexRay channel selection

SCM	CHB	CHA	Description
Dual Channel Device Modes			
0	0	0	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC
	0	1	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC
	1	0	reserved
	1	1	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel B
Single Channel Device Mode

</table>

Table continues on the next page...

FR_MCR field descriptions (continued)

Field	Description
12–14 BITRATE	FlexRay Bus Bit Rate. This bit field defines the FlexRay Bus Bit Rate. 000 10.0 Mbit/sec 001 5.0 Mbit/sec 010 2.5 Mbit/sec 011 8.0 Mbit/sec 100 reserved 101 reserved 110 reserved 111 reserved
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.6.3 System Memory Base Address High Register (FR_SYMBADHR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADHR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADHR register contains the most significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address high. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

54.6.4 System Memory Base Address Low Register (FR_SYMBADLR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADLR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADLR register contains the least significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SMBA												0			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address low. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.6.5 Strobe Signal Control Register (FR_STBSCR)

Write: Anytime

This register is used to assign the individual protocol timing related strobe signals given in Table 54-8 to the external strobe ports. Each strobe signal can be assigned to at most one strobe port . Each write access to registers overwrites the previously written ENB and STBPSEL values for the signal indicated by SEL . If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port . If no strobe signal is assigned to a strobe port, the strobe port carries logic 0 . For more detailed and timing information refer to Strobe Signal Support .

NOTE

In single channel device mode, channel B related strobe signals are undefined and should not be assigned to the strobe ports.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0			SEL				0			ENB	0		STBPSEL	
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_STBSCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SEL	Strobe Signal Select. This control field selects one of the strobe signals given in Table 54-8 to be enabled or disabled and assigned to one of the four strobe ports given in the following table.

Table 54-8. Strobe Signal Mapping

SEL		Description	Channel	Type	Offset (Given in PE clock cycles)	Reference
dec	hex					
0	0x0	arm	-	value	+1	MT start
1	0x1	mt	-	value	+1	MT start
2	0x2	cycle start	-	pulse	0	MT start

</table>

54.6.6 Message Buffer Data Size Register (FR_MBDSR)

Write: POC:config

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	MBSEG2DS							0	MBSEG1DS						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBDSR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 MBSEG2DS	Message Buffer Segment 2 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the second message buffer segment.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBSEG1DS	Message Buffer Segment 1 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the first message buffer segment.

54.6.7 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Write: POC:config

This register is used to define the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Address: 0h base + Eh offset = Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	LAST_MB_SEG1							0	LAST_MB_UTIL						
Write																
Reset	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

FR_MBSSUTR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 LAST_MB_SEG1	Last Message Buffer In Segment 1. This field defines the message buffer number of the last individual message buffer that is assigned to the first message buffer segment. The individual message buffers in the first segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with n <= LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1+1 individual message buffers. **NOTE:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the second message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 128 .

Table continues on the next page...

FR_MBSSUTR field descriptions (continued)

Field	Description
	NOTE: If LAST_MB_SEG1 = 127 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LAST_MB_UTIL	Last Message Buffer Utilized. This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n <= LAST_MB_UTIL. **NOTE:** If LAST_MB_UTIL=LAST_MB_SEG1 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

54.6.8 PE DRAM Access Register (FR_PEDRAR)

The PEDRAR register is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this registers initiates a read or write operation on the PE DRAM. The access done status bit DAD is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR are written into the PE DRAM, read back from the PE DRAM and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data are read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description refer to Memory Content Fault Detection

Address: 0h base + 10h offset = 10h

FR_PEDRAR field descriptions

Field	Description
0–3 INST	PE DRAM Access Instruction. This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16 bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16 bit) into FR_PEDRDR[DATA] other reserved

Table continues on the next page...

FR_PEDRAR field descriptions (continued)

Field	Description
4–14 ADDR	PE DRAM Access Address. This field defines the address in the PE DRAM to be written to or read from.
15 DAD	PE DRAM Access Done. This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done

54.6.9 PE DRAM Data Register (FR_PEDRDR)

This register provides the data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

Address: 0h base + 12h offset = 12h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PEDRDR field descriptions

Field	Description
0–15 DATA	Data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

54.6.10 Protocol Operation Control Register (FR_POCR)

The application uses this register to issue

- protocol control commands
- external clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see Protocol Control Command Execution .

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to External Clock Synchronization .

Write: Normal Mode

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0			EOC_AP		ERC_AP		BSY_WMC	0			POCCMD			
Write	WME															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_POCR field descriptions

Field	Description
0 WME	Write Mode External Correction. This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write. 1 No write to EOC_AP and ERC_AP fields on register write.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 EOC_AP	External Offset Correction Application. This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 do not apply external offset correction value 01 reserved 10 subtract external offset correction value 11 add external offset correction value
6–7 ERC_AP	External Rate Correction Application. This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21) 00 do not apply external rate correction value 01 reserved 10 subtract external rate correction value 11 add external rate correction value
8 BSY_WMC	**NOTE:** The name and function of this field varies depending on whether it is being read or written. BSY (Read-Only). Protocol Control Command Busy. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. WMC (Write-Only) Protocol Control Command Write. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. 0 (Write-Only) Write to POCCMD field on register write. 1 (Write-Only) Do not write to POCCMD field on register write. 0 (Read-Only) Command write idle, command accepted and ready to receive new protocol command. 1 (Read-Only) Command write busy, command not yet accepted, not ready to receive new protocol command.

Table continues on the next page...

FR_POCR field descriptions (continued)

Field	Description
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 POCCMD	Protocol Control Command. The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTART. Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS. Delayed transition to the all slots transmission mode. (Delayed means on completion of current communication cycle.) 0010 CONFIG. Immediately transition to the POC:config state. 0011 FREEZE. Immediately transition to the POC:halt state. 0100 READY, CONFIG_COMPLETE. Immediately transition to the POC:ready state. 0101 RUN. Immediately transition to the POC:startup start state. 0110 DEFAULT_CONFIG. Immediately transition to the POC:default config state. 0111 HALT. Delayed transition to the POC:halt state 1000 WAKEUP. Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

54.6.11 Global Interrupt Flag and Enable Register (FR_GIFER)

Write: Normal Mode

This register provides the means to control some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables . The generation scheme for these flags is depicted in Figure 54-33 . For more details on interrupt generation, see Interrupt Support . These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Address: 0h base + 16h offset = 16h

Bit	0	1	2	3	4	5	6	7
Read	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
Write				w1c	w1c	w1c		
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	MIE	PRIE	CHIE	WUPIE	FAFBIE	FAFAIE	RBIE	TBIE
Reset	0	0	0	0	0	0	0	0

FR_GIFER field descriptions

Field	Description
0 MIF	Module Interrupt Flag. This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set.
1 PRIF	Protocol Interrupt Flag. This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set. 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set.
2 CHIF	CHI Interrupt Flag. This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the chi error interrupt enable bit FR_GIFER[CHIE] are set . 0 All CHI error flags are equal to 0 or the chi error interrupt is disabled. 1 At least one CHI error flag and the chi error interrupt enable are is set.
3 WUPIF	Wakeup Interrupt Flag. This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No Wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus
4 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO B almost full event has occurred
5 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO A almost full event has occurred

Table continues on the next page...

FR_GIFER field descriptions (continued)

Field	Description
6 RBIF	Receive Message Buffer Interrupt Flag. This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly, instead it is cleared by the CC when all of the interrupt flags MBIF of the individual receive message buffers are cleared by the application or if the application has cleared the related interrupt enables bit MBIE. 0 None of the individual receive message buffers has the MBIF and MBIE flag set. 1 At least one individual receive message buffer has the MBIF and MBIE flag set.
7 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application can not clear this interrupt flag directly, instead, this interrupt flag is cleared by the CC when either all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application or the application has cleared the related interrupt enables bit MBIE. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set. 1 At least one individual transmit message buffer has the MBIF and MBIE flag set.
8 MIE	Module Interrupt Enable. This bit controls if the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	Protocol Interrupt Enable. This bit controls if the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
10 CHIE	CHI Interrupt Enable. This bit controls if the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	Wakeup Interrupt Enable. This bit controls if the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
12 FAFBIE	Receive FIFO Channel B Almost Full Interrupt Enable. This bit controls if the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	Receive FIFO Channel A Almost Full Interrupt Enable. This bit controls if the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	Receive Message Buffer Interrupt Enable. This bit controls if the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table continues on the next page...

FR_GIFER field descriptions (continued)

Field	Description
15 TBIE	Transmit Message Buffer Interrupt Enable. This bit controls if the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

54.6.12 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	FATL_IF	INTL_IF	ILCF_IF	CSA_IF	MRC_IF	MOC_IF	CCL_IF	MXS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	MTX_IF	LTXB_IF	LTXA_IF	TBVB_IF	TBVA_IF	TI2_IF	TI1_IF	CYS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	Fatal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. The fatal protocol errors are: 1) pLatestTx violation, as described in the MAC process of the FlexRay protocol 2) transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event. 1 Fatal protocol error detected.
1 INTL_IF	Internal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event. 1 Internal protocol error detected.
2 ILCF_IF	Illegal Protocol Configuration Interrupt Flag. This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the POC:halt state immediately.

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
	The protocol engine checks the listen_timeout value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of listen_timeout is equal to zero, the protocol configuration setting is considered as illegal. 0 No such event. 1 Illegal protocol configuration detected.
3 CSA_IF	Cold Start Abort Interrupt Flag. This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event. 1 Cold start aborted and no more coldstart attempts allowed.
4 MRC_IF	Missing Rate Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	Missing Offset Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event. 1 Insufficient number of measurements for offset correction detected.
6 CCL_IF	Clock Correction Limit Reached Interrupt Flag. This flag is set when the internal calculated offset or rate calculation values have reached or exceeded its configured thresholds as given by the offset_coorection_out field in the Protocol Configuration Register 9 (FR_PCR9) and the rate_correction_out field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event. 1 Offset or rate correction limit reached.
7 MXS_IF	Max Sync Frames Detected Interrupt Flag. This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the node_sync_max field in the Protocol Configuration Register 30 (FR_PCR30). **NOTE:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account. 0 No such event. 1 More than node_sync_max sync frames detected.
8 MTX_IF	Media Access Test Symbol Received Interrupt Flag. This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event. 1 MTS symbol received.
9 LTXB_IF	pLatestTx Violation on Channel B Interrupt Flag. This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation, as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel B.

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
10 LTXA_IF	pLatestTx Violation on Channel A Interrupt Flag. This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel A.
11 TBVB_IF	Transmission across boundary on channel B Interrupt Flag. This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event. 1 Transmission across boundary violation occurred on channel B.
12 TBVA_IF	Transmission across boundary on channel A Interrupt Flag. This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event. 1 Transmission across boundary violation occurred on channel A.
13 TI2_IF	Timer 2 Expired Interrupt Flag. This flag is set whenever timer 2 expires. 0 No such event. 1 Timer 2 has reached its time limit.
14 TI1_IF	Timer 1 Expired Interrupt Flag. This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	Cycle Start Interrupt Flag. This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started.

54.6.13 Protocol Interrupt Flag Register 1 (FR_PIFR1)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	EMC_IF	IPC_IF	PECF_IF	PSC_IF	SSI3_IF	SSI2_IF	SSI1_IF	SSI0_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0		EVT_IF	ODT_IF	0			
Write			w1c	w1c				
Reset	0	0	0	0	0	0	0	0

FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	Error Mode Changed Interrupt Flag. This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event. 1 ERRMODE field changed.
1 IPC_IF	Illegal Protocol Control Command Interrupt Flag. This flag is set when the PE tries to execute a protocol control command, which was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case the command is not executed. For more details, see Protocol Control Command Execution . 0 No such event. 1 Illegal protocol control command detected.
2 PECF_IF	Protocol Engine Communication Failure Interrupt Flag. This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event. 1 Protocol Engine Communication Failure detected.
3 PSC_IF	Protocol State Changed Interrupt Flag. This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event. 1 Protocol state changed.
4 SSI3_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
5 SSI2_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
6 SSI1_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
7 SSI0_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_PIFR1 field descriptions (continued)

Field	Description
10 EVT_IF	Even Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the even cycle. 0 No such event. 1 Sync frame measurement table written
11 ODT_IF	Odd Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the odd cycle. 0 No such event. 1 Sync frame measurement table written
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.6.14 Protocol Interrupt Enable Register 0 (FR_PIER0)

Write: Anytime

This register defines whether or not the individual interrupt flags defined in the Protocol Interrupt Flag Register 0 (FR_PIFR0) can generate a protocol interrupt request.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7

Reset	0	0	0	0	0	0	0	0

FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	Frame Lost Channel B Error Flag. This flag is set if a complete frame was received on channel B but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	Frame Lost Channel A Error Flag. This flag is set if a complete frame was received on channel A but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected
2 PCMI_EF	Protocol Command Ignored Error Flag. This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	Receive FIFO Overrun Channel B Error Flag. This flag is set when an overrun of the FIFO for channel B occurred. This error occurs if a semantically valid frame was received on channel B and matches the all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	Receive FIFO Overrun Channel A Error Flag. This flag is set when an overrun of the FIFO for channel A occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	Message Buffer Search Error Flag. This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 131 is detected in the FR_MBIDXR[MBIDX] field of an found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to Message Buffer Search Error for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
6 MBU_EF	Message Buffer Utilization Error Flag. This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	Lock Error Flag. This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SBCF_EF	System Bus Communication Failure Error Flag. This flag is set if a system bus access was not finished within the required amount of time (see System Bus Access Timeout). 0 No such event 1 System bus access not finished in time
10 FID_EF	Frame ID Error Flag. This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register . 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	Dynamic Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding protocol configuration register field max_payload_length_dynamic in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	Static Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding protocol configuration register field payload_length_static in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	Network Management Length Error Flag. This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
14 NMF_EF	Network Management Frame Error Flag. This flag is set if a received message in the static segment with a Preamble Indicator flag PP asserted has its Null Frame indicator flag NF asserted as well. In this case, the

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
	Global Network Management Registers (see Network Management Vector Registers (FR_NMVR0-FR_NMVR5)) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	Illegal System Bus Address Error Flag. This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see System Bus Illegal Address Access). 0 No such event 1 Illegal system bus address accessed

54.6.17 Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their interrupt status flag MBIF and interrupt enable MBIE bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Address: 0h base + 22h offset = 22h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	TBIVEC							0	RBIVEC						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBIVEC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 TBIVEC	Transmit Buffer Interrupt Vector. This field provides the number of the lowest numbered enabled transmit message buffer that has its interrupt status flag MBIF and its interrupt enable bit MBIE set. If there is no transmit message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 RBIVEC	Receive Buffer Interrupt Vector. This field provides the message buffer number of the lowest numbered receive message buffer which has its interrupt flag MBIF and its interrupt enable bit MBIE asserted. If there is no receive message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.

54.6.18 Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see Slot Status Monitoring.

Address: 0h base + 24h offset = 24h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_CASERCR field descriptions

Field	Description
0–15 CHAERSCNT	Channel A Status Error Counter. This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

54.6.19 Channel B Status Error Counter Register (FR_CBSERCR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring see Slot Status Monitoring.

Address: 0h base + 26h offset = 26h

FR_PSR1 field descriptions

Field	Description
0 CSAA	Cold Start Attempt Aborted Flag. protocol related event: 'set coldstart abort indicator in CHI' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	Leading Cold Start Path. This status bit is set when the CC has reached the POC:normal active state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 POC:normal active reached from POC:startup state via leading cold start path
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 REMCSAT	Remaining Coldstart Attempts. protocol related variable: vRemainingColdstartAttempts This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	Leading Cold Start Path Noise. protocol related variable: vPOC!ColdstartNoise This status bit is set if the CC has reached the POC:normal active state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 POC:normal active state was reached from POC:startup state via noisy leading cold start path
9 HHR	Host Halt Request Pending. protocol related variable: vPOC!CHIHaltRequest This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 HALT command received

Table continues on the next page...

FR_PSR1 field descriptions (continued)

Field	Description
10 FRZ	Freeze Occurred. protocol related variable: vPOC!Freeze This status bit is set when the CC has reached the POC:halt state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11–15 APTAC	Allow Passive to Active Counter. protocol related variable: vPOC!vAllowPassivetoActive This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the POC:normal passive state due to an application configured delay to enter POC:normal active state. This delay is defined by the allow_passive_to_active field in the Protocol Configuration Register 12 (FR_PCR12).

54.6.22 Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the Network Idle Time NIT, the Symbol Window and the clock synchronization. The NIT related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The Symbol Window related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol window related status bits remain in their reset state. The clock synchronization related CLKCORRFAILCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Address: 0h base + 2Ch offset = 2Ch

Reset	0	0	0	0	0	0	0	0

FR_PSR2 field descriptions

Field	Description
0 NBVB	NIT Boundary Violation on Channel B. protocol related variable: vSS!BViolation for NIT on channel B This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	NIT Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for NIT on channel B This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	Symbol Window Transmit Conflict on Channel B. protocol related variable: vSS!TxConflict for symbol window on channel B This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	Symbol Window Boundary Violation on Channel B. protocol related variable: vSS!BViolation for symbol window on channel B This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
4 SSEB	Symbol Window Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for symbol window on channel B This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	Media Access Test Symbol MTS Received on Channel B. protocol related variable: vSS!ValidMTS for Symbol Window on channel B This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	NIT Boundary Violation on Channel A. protocol related variable: vSS!BViolation for NIT on channel A This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	NIT Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected

Table continues on the next page...

FR_PSR2 field descriptions (continued)

Field	Description
8 STCA	Symbol Window Transmit Conflict on Channel A. protocol related variable: vSS!TxConflict for symbol window on channel A This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	Symbol Window Boundary Violation on Channel A. protocol related variable: vSS!BViolation for symbol window on channel A This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	Symbol Window Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for symbol window on channel A This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected
11 MTA	Media Access Test Symbol MTS Received on Channel A. protocol related variable: vSS!ValidMTS for symbol window on channel A This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel A. 1 MTS symbol received 0 No such event
12–15 CKCORFCNT	Clock Correction Failed Counter. protocol related variable: vClockCorrectionFailed This field provides the number of consecutive even/odd communication cycle pairs that have passed without clock synchronization having performed an offset or a rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in the Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the POC:normal active state, or when both the rate and offset correction terms have been calculated successfully.

54.6.23 Protocol Status Register 3 (FR_PSR3)

Write: Normal Mode

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Address: 0h base + 2Eh offset = 2Eh

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SLTCTBR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTCNTB	Slot Counter Value for Channel B. protocol related variable: vSlotCounter for channel B This field provides the number of the current slot in the current communication cycle.

54.6.28 Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	RATECORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RTCORVR field descriptions

Field	Description
0–15 RATECORR	Rate Correction Value. protocol related variable: vRateCorrection (before value limitation and external rate correction) This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

54.6.29 Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Address: 0h base + 3Ah offset = 3Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	OFFSETCORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_OFCORVR field descriptions

Field	Description
0–15 OFFSETCORR	Offset Correction Value. protocol related variable: vOffsetCorrection (before value limitation and external offset correction) This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

54.6.30 Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in Figure 54-35 . The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

NOTE

The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

FR_CIFR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MIF	Module Interrupt Flag. This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	Protocol Interrupt Flag. This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	CHI Interrupt Flag. This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1.

Table continues on the next page...

FR_CIFR field descriptions (continued)

Field	Description
	0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	Wakeup Interrupt Flag. Provides the same value as FR_GIFER[WUPIF]
12 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFBIF]
13 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFAIF]
14 RBIF	Receive Message Buffer Interrupt Flag. This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted. 1 At least one individual receive message buffers has the MBIF flag asserted.
15 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted. 1 At least one individual transmit message buffers has the MBIF flag asserted.

54.6.31 System Memory Access Time-Out Register (FR_SYMATOR)

Write: Disabled Mode

Address: 0h base + 3Eh offset = 3Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								TIMEOUT							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

FR_SYMATOR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 TIMEOUT	System Memory Access Time-Out. This value defines when a system bus access timout is detected. For a detailed description see Configure System Memory Access Time-Out Register (FR_SYMATOR) and System Bus Access Timeout .

54.6.32 Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 MT after offset correction start.

NOTE

If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

NOTE

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the values SFODB and SFODA.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFEVB				SFEVA				SFODB				SFODA			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFCNTR field descriptions

Field	Description
0–3 SFEVB	Sync Frames Channel B, even cycle. protocol related variable: size of (vsSyncIdListB for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4–7 SFEVA	Sync Frames Channel A, even cycle. protocol related variable: size of (vsSyncIdListA for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8–11 SFODB	Sync Frames Channel B, odd cycle. protocol related variable: size of (vsSyncIdListB for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .
12–15 SFODA	Sync Frames Channel A, odd cycle. protocol related variable: size of (vsSyncIdListA for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .

54.6.33 Sync Frame Table Offset Register (FR_SFTOR)

Write: POC:config

This register defines the FlexRay memory area related offset for sync frame tables. For more details, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 42h offset = 42h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFT_OFFSET															0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFTOR field descriptions

Field	Description
0–14 SFT_OFFSET	Sync Frame Table Offset. The offset of the Sync Frame Tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus STF_OFFSET[0] is always 0.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.6.34 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Write: Normal Mode

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7
Read	0	0	CYCNUM					
Write	ELKT	OLKT						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
Write						OPT		
Reset	0	0	0	0	0	0	0	0

FR_SFTCCSR field descriptions

Field	Description
0 ELKT	Even Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables.
1 OLKT	Odd Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables.

Table continues on the next page...

FR_SFTCCSR field descriptions (continued)

Field	Description
2–7 CYCNUM	Cycle Number. This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	Even Cycle Tables Lock Status. This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables. 1 Application has locked the even cycle tables.
9 OLKS	Odd Cycle Tables Lock Status. This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables. 1 Application has locked the odd cycle tables.
10 EVAL	Even Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
11 OVAL	Odd Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 OPT	One Pair Trigger. This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.
14 SDVEN	Sync Frame Deviation Table Enable. This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. **NOTE:** If SDVEN is set to 1, then SIDEN must also be set to 1. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area
15 SIDEN	Sync Frame ID Table Enable. This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

54.6.35 Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Write: Normal Mode

This register defines the Sync Frame Rejection Filter ID. The application must update this register outside of the static segment. If the application updates this register in the static segment, it can appear that the CC accepts the sync frame in the current cycle.

Address: 0h base + 46h offset = 46h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								SYNFRID							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDRFR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SYNFRID	Sync Frame Rejection ID. This field defines the frame ID of a frame that must not be used for clock synchronization. For details see Sync Frame Rejection Filtering .

54.6.36 Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)

Write: POC:config

This register defines the sync frame acceptance filter value. For details on filtering, see Sync Frame Filtering .

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								FVAL							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFVR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FVAL	Filter Value. This field defines the value for the sync frame acceptance filtering.

54.6.37 Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)

Write: POC:config

This register defines the sync frame acceptance filter mask. For details on filtering see Sync Frame Acceptance Filtering .

Address: 0h base + 4Ah offset = 4Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						FMSK									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFMR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FMSK	Filter Mask. This field defines the mask for the sync frame acceptance filtering.

54.6.38 Network Management Vector Register (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0-FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Address: 0h base + 4Ch offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	NMVP															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVR*n* field descriptions

Field	Description
0–15 NMVP	Network Management Vector Part. The mapping between the Network Management Vector Registers (FR_NMVR0-FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in the following table.

Table 54-9. Mapping of NMVRn to the Received Payload Bytes NMVn

NMVRn Register	NMVn Received Payload
FR_NMVR0[NMVP[15:8]]	NMV0
FR_NMVR0[NMVP[7:0]]	NMV1
FR_NMVR1[NMVP[15:8]]	NMV2
FR_NMVR1[NMVP[7:0]]	NMV3
...	
FR_NMVR5[NMVP[15:8]]	NMV10
FR_NMVR5[NMVP[7:0]]	NMV11

54.6.39 Network Management Vector Length Register (FR_NMVLR)

Write: POC:config

This register defines the length of the network management vector in bytes.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0												NMVL			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVLR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 NMVL	Network Management Vector Length. protocol related variable: gNetworkManagementVectorLength This field defines the length of the Network Management Vector in bytes. Legal values are between 0 and 12.

54.6.40 Timer Configuration and Control Register (FR_TICCR)

Write: T2_CFG: POC:config T2_REP, T1_REP, T1SP, T2SP, T1TR, T2TR: Normal Mode

This register is used to configure and control the two timers T1 and T2. For timer details, see Timer Support . The Timer T1 is an absolute timer. The Timer T2 can be configured as an absolute or relative timer.

NOTE

Both timers are deactivated immediately when the protocol enters a state different from POC:normal active or POC:normal passive.

Address: 0h base + 5Ah offset = 5Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T2_ CFG	T2_ REP	0	0	0	T2ST	0			T1_ REP	0	0	0	T1ST
Write						T2SP	T2TR							T1SP	T1TR	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TICCR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 T2_CFG	Timer T2 Configuration. This bit configures the timebase mode of Timer T2. 0 T2 is absolute timer. 1 T2 is relative timer.
3 T2_REP	Timer T2 Repetitive Mode. This bit configures the repetition mode of Timer T2. 0 T2 is non repetitive 1 T2 is repetitive
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 T2SP	Timer T2 Stop. This trigger bit is used to stop timer T2. 0 no effect 1 stop timer T2
6 T2TR	Timer T2 Trigger. This trigger bit is used to start timer T2. 0 no effect 1 start timer T2
7 T2ST	Timer T2 State. This status bit provides the current state of timer T2. 0 timer T2 is idle 1 timer T2 is running
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 T1_REP	Timer T1 Repetitive Mode. This bit configures the repetition mode of timer T1. 0 T1 is non repetitive 1 T1 is repetitive

Table continues on the next page...

FR_TICCR field descriptions (continued)

Field	Description
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 T1SP	Timer T1 Stop. This trigger bit is used to stop timer T1. 0 no effect 1 stop timer T1
14 T1TR	Timer T1 Trigger. This trigger bit is used to start timer T1. 0 no effect 1 start timer T1
15 T1ST	Timer T1 State. This status bit provides the current state of timer T1. 0 timer T1 is idle 1 timer T1 is running

54.6.41 Timer 1 Cycle Set Register (FR_TI1CYSR)

Write: Anytime

This register defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

Address: 0h base + 5Ch offset = 5Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T1_CYC_VAL						0		T1_CYC_MSK					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI1CYSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T1_CYC_VAL	Timer T1 Cycle Filter Value. This field defines the cycle filter value for timer T1.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T1_CYC_MSK	Timer T1 Cycle Filter Mask. This field defines the cycle filter mask for timer T1.

54.6.42 Timer 1 Macrotick Offset Register (FR_TI1MTOR)

Write: Anytime

This register holds the macrotick offset value for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

Address: 0h base + 5Eh offset = 5Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T1_MTOFFSET													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI1MTOR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 T1_MTOFFSET	Timer 1 Macrotick Offset. This field defines the macrotick offset value for timer 1.

54.6.43 Timer 2 Configuration Register 0 (Absolute Timer Configuration) (FR_TI2CR0_ABS)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, .

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T2CYCVAL						0		T2CYCMSK					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR0_ABS field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T2CYCVAL	Timer T2 Cycle Filter Mask
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T2CYCMSK	Timer T2 Cycle Filter Mask

54.6.44 Timer 2 Configuration Register 0 (Relative Timer Configuration) (FR_TI2CR0_REL)

Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Relative Timer T2.

NOTE

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	T2MTCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR0_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick High Word

54.6.45 Timer 2 Configuration Register 1 (Absolute Timer Configuration) (FR_TI2CR1_ABS)

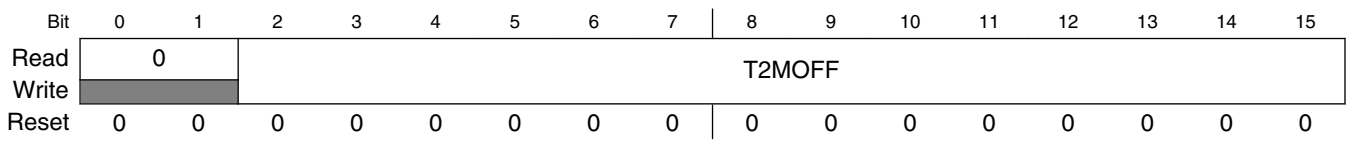
Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Absolute Timer T2

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

Address: 0h base + 62h offset = 62h



FR_TI2CR1_ABS field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 T2MOFF	Timer T2 Macrotick Offset

54.6.46 Timer 2 Configuration Register 1 (Relative Timer Configuration) (FR_TI2CR1_REL)

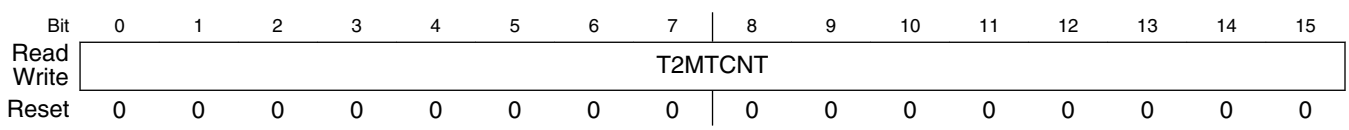
Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Relative Timer T2.

NOTE

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

Address: 0h base + 62h offset = 62h



FR_TI2CR1_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick Low Word

54.6.47 Slot Status Selection Register (FR_SSSR)

Write: Anytime

This register is used to access the four internal non-memory mapped slot status selection registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR_SSR0-FR_SSR7) according to Slot Status Selection Register (FR_SSSR) . For a detailed description of slot status monitoring, refer to Slot Status Monitoring .

Table 54-10. Mapping Between FR_SSSRn and FR_SSRn

Internal Slot Status Selection Register	Write the Slot Status of the Slot Selected by FR_SSSRn for each			
	Even Communication Cycle		Odd Communication Cycle	
	For Channel B to	For Channel A to	For Channel B to	For Channel A to
FR_SSSR0	FR_SSR0[15:8]	FR_SSR0[7:0]	FR_SSR1[15:8]	FR_SSR1[7:0]
FR_SSSR1	FR_SSR2[15:8]	FR_SSR2[7:0]	FR_SSR3[15:8]	FR_SSR3[7:0]
FR_SSSR2	FR_SSR4[15:8]	FR_SSR4[7:0]	FR_SSR5[15:8]	FR_SSR5[7:0]
FR_SSSR3	FR_SSR6[15:8]	FR_SSR6[7:0]	FR_SSR7[15:8]	FR_SSR7[7:0]

Address: 0h base + 64h offset = 64h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0	SEL		0	SLOTNUMBER										
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SSSR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_SSSR field descriptions (continued)

Field	Description
2–3 SEL	Selector. This field selects one of the four internal slot status selection registers for access. 00 select FR_SSSR0. 01 select FR_SSSR1. 10 select FR_SSSR2. 11 select FR_SSSR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTNUMBER	Slot Number. This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. **NOTE:** If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.

54.6.48 Slot Status Counter Condition Register (FR_SSCCR)

Write: Anytime

This register is used to access and program the four internal non-memory mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal slot status counter condition registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0-FR_SSCR3). The correspondence is given in Slot Status Counter Condition Register (FR_SSCCR) . For a detailed description of slot status counters, refer to Slot Status Counter Registers .

Table 54-11. Mapping between internal FR_SSCCRn and FR_SSCRn

Condition Register	Condition Defined for Register
FR_SSCCR0	FR_SSCR0
FR_SSCCR1	FR_SSCR1
FR_SSCCR2	FR_SSCR2
FR_SSCCR3	FR_SSCR3

Address: 0h base + 66h offset = 66h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SSCCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SEL	Selector. This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0. 01 select FR_SSCCR1. 10 select FR_SSCCR2. 11 select FR_SSCCR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–6 CNTCFG	Counter Configuration. These bit field controls the channel related incrementing of the slot status counter. 00 increment by 1 if condition is fulfilled on channel A. 01 increment by 1 if condition is fulfilled on channel B. 10 increment by 1 if condition is fulfilled on at least one channel. 11 increment by 2 if condition is fulfilled on both channels channel; increment by 1 if condition is fulfilled on only one channel.
7 MCY	Multi Cycle Selection. This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	Valid Frame Restriction. This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	Sync Frame Restriction. This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	Null Frame Restriction. This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.
11 SUF	Startup Frame Restriction. This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12–15 STATUSMASK	Slot Status Mask. This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3] - This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2] - This bit enables the counting for slots with the content error indicator bit set to 1.

Table continues on the next page...

FR_SSCCR field descriptions (continued)

Field	Description
	STATUSMASK[1] - This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0] - This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

54.6.49 Slot Status Register (FR_SSR*n*)

Each Slot Status Register (SSR) holds the status vector of the slot specified in the corresponding internal slot status selection register, which can be programmed using the Slot Status Selection Register (FR_SSSR). Each register is updated after the end of the corresponding slot as shown in Figure 54-31 . The register bits are directly related to the protocol variables and described in more detail in Slot Status Monitoring .

Address: 0h base + 68h offset + (2d × i), where i=0d to 7d

54.6.50 Slot Status Counter Register (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal slot status counter condition register FR_SSCCRn, which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, see Slot Status Counter Registers .

NOTE

If the counter has reached its maximum value 0xFFFF and is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be set into the multicycle mode again.

NOTE

Address: 0h base + 78h offset + (2d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SLOTSTATUSCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SSCR*n* field descriptions

Field	Description
0–15 SLOTSTATUSCNT	Slot Status Counter. This field provides the current value of the Slot Status Counter.

54.6.51 MTS A Configuration Register (FR_MTSACFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel A. For more details, see MTS Generation .

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSACFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

54.6.52 MTS B Configuration Register (FR_MTSBCFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel B. For more details, see MTS Generation .

Address: 0h base + 82h offset = 82h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSBCFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

54.6.53 Receive Shadow Buffer Index Register (FR_RSBIR)

Write: WMD, SEL: Any Time; RSBIDX: POC:config

This register is used to provide and retrieve the indices of the message buffer header fields currently associated with the receive shadow buffers . For more details on the receive shadow buffer concept, refer to Receive Shadow Buffers Concept .

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7
Read Write	WMD	Reserved	SEL		Reserved			
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	RSBIDX							
Reset	0	0	0	0	0	0	0	0

FR_RSBIR field descriptions

Field	Description
0 WMD	Write Mode. This bit controls the write mode for this register. 0 update SEL and RSBIDX field on register write 1 update only SEL field on register write
1 Reserved	This field is reserved.
2–3 SEL	Selector. This field is used to select the internal receive shadow buffer index register for access. 00 FR_RSBIR_A1. receive shadow buffer index register for channel A, segment 1 01 FR_RSBIR_A2. receive shadow buffer index register for channel A, segment 2 10 FR_RSBIR_B1. receive shadow buffer index register for channel B, segment 1 11 FR_RSBIR_B2. receive shadow buffer index register for channel B, segment 2
4–7 Reserved	This field is reserved.
8–15 RSBIDX	RSBIDXA1/RSBIDXA2/RSBIDXB1/RSBIDXB2- Receive Shadow Buffer Index Receive Shadow Buffer Index. This field contains the current index of the message buffer header field of the receive shadow message buffer selected by the SEL field. The CC uses this index to determine the physical location of the shadow buffer header field in the FlexRay memory area. The CC will update this field during receive operation.The application provides initial message buffer header index value in the configuration phase. CC: Updates the message buffer header index after successful reception. Application: Provides initial message buffer header index. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

54.6.54 Receive FIFO Watermark and Selection Register (FR_RFWMSR)

Write: WMA/WMB: POC:config, SEL: Anytime

This register is used to

- select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in Receive FIFO Watermark and Selection Register (FR_RFWMSR) .
- to define the watermark for the selected FIFO.

Table 54-12. SEL Controlled Receiver FIFO Registers

Register
Receive FIFO Start Index Register (FR_RFSIR)
Receive FIFO Depth and Size Register (FR_RFDSR)
Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)
Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Address: 0h base + 86h offset = 86h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	WM								0							SEL
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFWMSR field descriptions

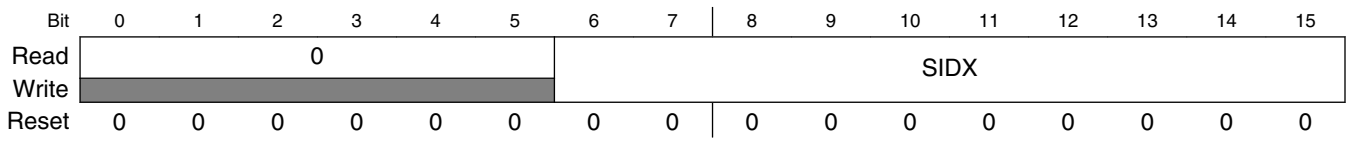
Field	Description
0–7 WM	WMA/WMB - Watermark This field defines the watermark value for the selected FIFO. This value is used to control the generation of the almost full interrupt flags.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 SEL	Select. This control bit selects the receiver FIFO for subsequent programming. 0 Receiver FIFO for channel A selected 1 Receiver FIFO for channel B selected

54.6.55 Receive FIFO Start Index Register (FR_RFSIR)

Write: POC:config

This register defines the message buffer header index of the first message buffer of the selected FIFO.

Address: 0h base + 88h offset = 88h



FR_RFSIR field descriptions

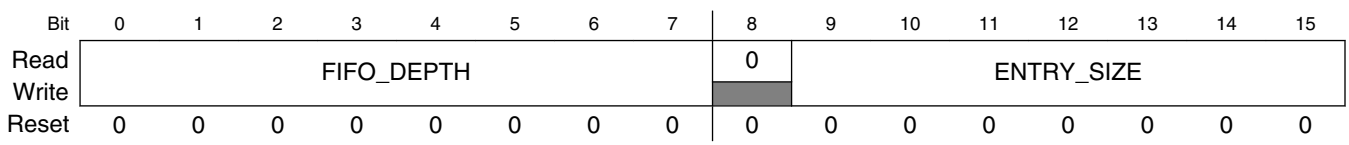
Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SIDX	SIDXA/SIDXB - Start Index This field defines the number of the message buffer header field of the first message buffer of the selected FIFO. The CC uses the value of the SIDX field to determine the physical location of the receiver FIFO's first message buffer header field.

54.6.56 Receive FIFO Depth and Size Register (FR_RFDSR)

Write: POC:config

This register defines the structure of the selected FIFO, i.e. the number of entries and the size of each entry .

Address: 0h base + 8Ah offset = 8Ah



FR_RFDSR field descriptions

Field	Description
0–7 FIFO_DEPTH	FIFO_DEPTHA/FIFO_DEPTHB - FIFO Depth FIFO Depth. This field defines the depth of the selected FIFO, i.e. the number of entries. Note: If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 too, to ensure that no frames are received into the FIFO.

Table continues on the next page...

FR_RFDSR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 ENTRY_SIZE	ENTRY_SIZEA/ENTRY_SIZEB - Entry Size This field defines the size of the frame data sections for the selected FIFO in 2 byte entities.

54.6.57 Receive FIFO A Read Index Register (FR_RFARIR)

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Ch offset = 8Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						RDIDX									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFARIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

54.6.58 Receive FIFO B Read Index Register (FR_RFBRIR)

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Eh offset = 8Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								RDIDX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFBRIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

54.6.59 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Write: POC:config

This register defines the filter value for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFVR field descriptions

Field	Description
0–15 MIDAFVAL	MIDAFVALA/MIDAFVALB - Message ID Acceptance Filter Value Filter value for the message ID acceptance filter.

54.6.60 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

Write: POC:config

This register defines the filter mask for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 92h offset = 92h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFMSK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFMR field descriptions

Field	Description
0–15 MIDAFMSK	MIDAFMSKA/MIDAFMSKB - Message ID Acceptance Filter Mask Filter mask for the message ID acceptance filter.

54.6.61 Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)

Write: POC:config

This register defines the filter value for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FIDRFVAL										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFIDRFVR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFVAL	FIDRFVALA/FIDRFVALB - Frame ID Rejection Filter Value Filter value for the frame ID rejection filter.

54.6.62 Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)

Write: POC:config

This register defines the filter mask for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 96h offset = 96h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FIDRFMSK										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFIDRFMR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFMSK	Frame ID Rejection Filter Mask. Filter mask for the frame ID rejection filter.

54.6.63 Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Write: WMD, IBD, SEL: Any Time; SID: POC:config

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter see FIFO Filtering .

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	IBD	SEL		0	SID										
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFRFCFR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL and IBD field only on write access.
1 IBD	Interval Boundary. This control bit selects the interval boundary to be programmed with the SID value. 0 program lower interval boundary 1 program upper interval boundary
2–3 SEL	Filter Selector. This control field selects the frame ID range filter to be accessed. 00 select frame ID range filter 0. 01 select frame ID range filter 1. 10 select frame ID range filter 2. 11 select frame ID range filter 3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCFR field descriptions (continued)

Field	Description
5–15 SID	Slot ID Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

54.6.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Write: Anytime

This register is used to enable and disable each frame ID range filter and to define whether it is running as acceptance or rejection filter.

Address: 0h base + 9Ah offset = 9Ah

Bit	0	1	2	3	4	5	6	7
Read	0				F3MD	F2MD	F1MD	F0MD
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0				F3EN	F2EN	F1EN	F0EN
Write								
Reset	0	0	0	0	0	0	0	0

FR_RFRFCTR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 F3MD	Range Filter 3 Mode. This control bit defines the filter mode of the frame ID range filter 3. 0 range filter 3 runs as acceptance filter 1 range filter 3 runs as rejection filter
5 F2MD	Range Filter 2 Mode. This control bit defines the filter mode of the frame ID range filter 2. 0 range filter 2 runs as acceptance filter 1 range filter 2 runs as rejection filter
6 F1MD	Range Filter 1 Mode. This control bit defines the filter mode of the frame ID range filter 1. 0 range filter 1 runs as acceptance filter 1 range filter 1 runs as rejection filter
7 F0MD	Range Filter 0 Mode. This control bit defines the filter mode of the frame ID range filter 0. 0 range filter 0 runs as acceptance filter 1 range filter 0 runs as rejection filter
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCTR field descriptions (continued)

Field	Description
12 F3EN	Range Filter 3 Enable. This control bit is used to enable and disable the frame ID range filter 3. 0 range filter 3 disabled 1 range filter 3 enabled
13 F2EN	Range Filter 2 Enable. This control bit is used to enable and disable the frame ID range filter 2. 0 range filter 2 disabled 1 range filter 2 enabled
14 F1EN	Range Filter 1 Enable. This control bit is used to enable and disable the frame ID range filter 1. 0 range filter 1 disabled 1 range filter 1 enabled
15 F0EN	Range Filter 0 Enable. This control bit is used to enable and disable the frame ID range filter 0. 0 range filter 0 disabled 1 range filter 0 enabled

54.6.65 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

This register provides the number of the last transmission slot in the dynamic segment for channel A. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					LDYNTXSLOTA										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_LDTXSLAR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 LDYNTXSLOTA	Last Dynamic Transmission Slot Channel A. protocol related variable: zLastDynTxSlot channel A Number of the last transmission slot in the dynamic segment for channel A. If no frame was transmitted during the dynamic segment on channel A, the value of this field is set to 0.

54.6.66 Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Eh offset = 9Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					LDYNTXSLOTB										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_LDTXSLBR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 LDYNTXSLOTB	Last Dynamic Transmission Slot Channel B. protocol related variable: zLastDynTxSlot channel B Number of the last transmission slot in the dynamic segment for channel B. If no frame was transmitted during the dynamic segment on channel B the value of this field is set to 0.

54.6.67 Protocol Configuration Register 0 (FR_PCR0)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Table 54-13. Protocol Configuration Register (PCR0-30) Fields

Name	Description	Min	Max	Unit	FR_PCR
coldstart_attempts	gColdstartAttempts			number	3
action_point_offset	gdActionPointOffset - 1			MT	0
cas_rx_low_max	gdCASRxLowMax - 1			gdBit	4

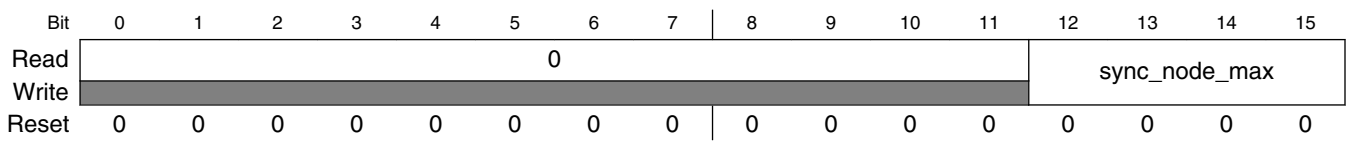
54.6.97 Protocol Configuration Register 30 (FR_PCR30)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + DCh offset = DCh

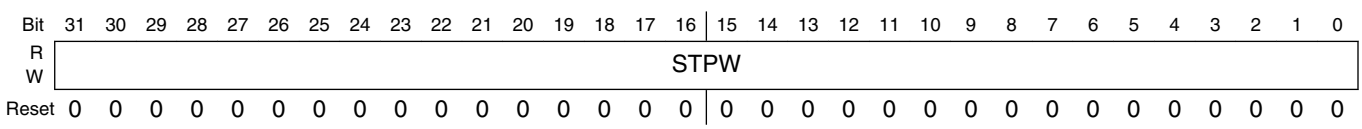


FR_PCR30 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 sync_node_max	gSyncNodeMax

54.6.98 StopWatch Count Register (FR_STPWR)

Address: 0h base + DEh offset = DEh



FR_STPWR field descriptions

Field	Description
STPW	StopWatch Count Register This is the value of the stopwatch counter running on system clock. This starts on cycle start even and stops on an external event “OS_tick”. This is a read reset type register, which means that when all the 32 bits are read, it automatically clears. For details, please see the "StopWatch Function" section.

54.6.99 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Write: Anytime

This register defines whether or not the Event output ports are enabled based on the events such as Cycle start and Timer1 and Timer2 expiry (see Timer Support for details).

Address: 0h base + E2h offset = E2h

Bit	0	1	2	3	4	5	6	7
Read	1							STPW_EN
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0					TIM2_EE	TIM1_EE	CYC_EE
Write								
Reset	0	0	0	0	0	0	0	0

FR_PEOER field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
7 STPW_EN	Stopwatch count Enable This bit controls the stopwatch counter. 0 Stopwatch counter disabled 1 Stopwatch counter enabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 TIM2_EE	Timer 2 expired Event Output Enable- This bit controls the event on port "fr_evt_tim2" 0 Timer 2 expired event out disabled 1 Timer 2 expired event out enabled
14 TIM1_EE	Timer 1 expired Event Output Enable- This bit controls the event on port "fr_evt_tim1" 0 Timer 1 expired event out disabled 1 Timer 1 expired event out enabled
15 CYC_EE	Cycle Start Event Output Enable- This bit controls the event on port "fr_evt_cyc" 0 Cycle start event out disabled 1 Cycle start event out enabled

54.6.100 Receive FIFO Start Data Offset Register (FR_RFSDOR)

Write: POC:config

NOTE

Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses the content of the FR_RFSDOR corresponds to the start address of payload area of the selected FIFO.

Address: 0h base + E6h offset = E6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SDO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSDOR field descriptions

Field	Description
0–15 SDO	SDOA/SDOB - Start Data Field Offset Start Data Field Offset. This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO's first message buffer header field. For configuration constraints see Configure Data Field Offsets .

54.6.101 Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

54.6.102 Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + EAh offset = EAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SMBA												0			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.6.103 Receive FIFO Periodic Timer Register (FR_RFPTR)

Write: POC:config

This register holds periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see FIFO Periodic Timer).

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		PTD													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFPTR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFPTR field descriptions (continued)

Field	Description
2–15 PTD	Periodic Timer Duration. This value defines the periodic timer duration in terms of macroticks. 0000 timer stays expired 3FFF timer never expires other timer expires after specified number of macroticks, expires and is restarted at each cycle start

54.6.104 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs

If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, than the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

.

Address: 0h base + EEh offset = EEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	FLB_or_PCB								FLA_or_PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFLPCR field descriptions

Field	Description
0–7 FLB_or_PCB	**NOTE:** The name and function of the fields in this register vary depending on whether they are being read or written. See the following table for details.

Operation	Sub-Field	Description
Read	0-7 FLB	Fill Level FIFO B. This field provides the current number of entries in the FIFO B.
	-	-
Write	0-7 PCB	Pop Count FIFO B. This field defines the number of entries to be removed from FIFO B.
	-	-

Field	Description
8–15 FLA_or_PCA	

Operation	Sub-Field	Description
Read	-	-

Table continues on the next page...

FR_RFFLPCR field descriptions (continued)

Field	Description		
	Operation	**Sub-Field**	**Description**
		8-15 FLA	Fill Level FIFO A- This field provides the current number of entries in the FIFO A.
	Write	-	-
		8-15 PCA	Pop Count FIFO A - This field defines the number of entries to be removed from FIFO A.

54.6.105 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description see Memory Error Reporting .

Address: 0h base + F0h offset = F0h

Bit	0	1	2	3	4	5	6	7
Read	LRNE_OF	LRCE_OF	DRNE_OF	DRCE_OF	LRNE_IF	LRCE_IF	DRNE_IF	DRCE_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0				LRNE_IE	LRCE_IE	DRNE_IE	DRCE_IE
Write								
Reset	0	0	0	0	0	0	0	0

FR_EEIFER field descriptions

Field	Description
0 LRNE_OF	LRAM Non-Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected but not corrected on CHI LRAM and interrupt flag LRNE_IF is already 1. b) memory errors are detected but not corrected on at least two banks of CHI LRAM 0 no such event 1 Non-Corrected Error overflow detected on CHI LRAM
1 LRCE_OF	LRAM Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears a) memory errors are detected and corrected on CHI LRAM and interrupt flag LRCE_IF is already 1.

Table continues on the next page...

FR_EEIFER field descriptions (continued)

Field	Description
	b) memory errors are detected and corrected on at least two banks of CHI LRAM **NOTE:** Error Correction not implemented on CHI LRAM, flag will never be asserted. 0 no such event 1 Corrected Error overflow detected on CHI LRAM
2 DRNE_OF	DRAM Non-Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected but not corrected on PE DRAM and interrupt flag DRNE_IF is already 1. b) memory errors are detected but not corrected on at least two banks of the PE DRAM 0 no such event 1 Non-Corrected Error overflow detected on PE DRAM
3 DRCE_OF	DRAM Corrected Error Overflow Flag. This flag is set to 1 when at least one of the following events appears: a) memory errors are detected and corrected on PE DRAM and interrupt flag DRCE_IF is already 1. b) memory errors are detected and corrected on at least two banks of PE DRAM 0 no such event 1 Corrected Error overflow detected on PE DRAM
4 LRNE_IF	LRAM Non-Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected but not corrected on the CHI LRAM. 0 no such event 1 Non-Corrected Error detected on CHI LRAM
5 LRCE_IF	LRAM Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected and corrected on the CHI LRAM. **NOTE:** Error Correction not implemented on CHI LRAM, flag will never be asserted. 0 no such event 1 Corrected Error detected on CHI LRAM
6 DRNE_IF	DRAM Non-Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected but not corrected on PE DRAM. 0 no such event 1 Non-Corrected Error detected on PE DRAM
7 DRCE_IF	DRAM Corrected Error Interrupt Flag. This interrupt flag is set to 1 when a memory error is detected and corrected on PE DRAM. 0 no such event 1 Corrected Error detected on PE DRAM
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LRNE_IE	LRAM Non-Corrected Error Interrupt Enable. This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table continues on the next page...

FR_EEIFER field descriptions (continued)

Field	Description
13 LRCE_IE	LRAM Corrected Error Interrupt Enable. This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 DRNE_IE	DRAM Non-Corrected Error Interrupt Enable. This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 DRCE_IE	DRAM Corrected Error Interrupt Enable. This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

54.6.106 ECC Error Report and Injection Control Register (FR_EERICR)

This register configures the error injection and error reporting and provides the selector for the content of the report registers.

Address: 0h base + F2h offset = F2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	BSY	0					ERS		0			ERM	0		EIM	EIE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERICR field descriptions

Field	Description
0 BSY	Register Update Busy- This field indicates the current state of the ECC configuration update and controls the register write access condition IDL specified in " Register Write Access 0 ECC configuration is idle 1 ECC configuration is running
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 ERS	Error Report Select. This field selects the content of the ECC Error reporting registers. 00 show PE DRAM non-corrected error information 01 show PE DRAM corrected error information

Table continues on the next page...

FR_EERICR field descriptions (continued)

Field	Description
	10 show CHI LRAM non-corrected error information 11 show CHI LRAM corrected error information
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERM	Error Report Mode. This bit configures the type of data written into the internal error report registers on the detection of a memory error. 0 store data and code as delivered by ecc decoding logic. 1 store data and code as read from the memory.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 EIM	Error Injection Mode. This bit configures the ECC error injection mode. 0 use FR_EEIDR[DATA] and FR_EEICR[CODE] as XOR distortion pattern for error injection. 1 use FR_EEIDR[DATA] and FR_EEICR[CODE] as write value for error injection.
15 EIE	Error Injection Enable. This bit configures the ECC error injection on the memories. 0 Error injection disabled 1 Error injection enabled

54.6.107 ECC Error Report Address Register (FR_EERAR)

This register provides the memory identifier, bank, and address for which the memory error is reported.

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MID	BANK			ADDR											
Write																
Reset	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag provides the memory instance for which the memory error is reported. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field provides the BANK for which the memory error is reported. 111 reset value, indicates no error found after reset. For MID=0:

Table continues on the next page...

FR_EERAR field descriptions (continued)

Field	Description
	000 PE DRAM [7:0] 001 PE DRAM [15:8] others - not used For MID=1: Refer to the following table for the assignment of the LRAM banks.

Table 54-15. LRAM Bank Value for MID = 1

BANK	Register		
000	FR_MBCCFR(2n)	FR_MBDOR(6n)	FR_LEETR0
001	FR_MBFIDR(2n)	FR_MBDOR(6n + 1)	FR_LEETR1
010	FR_MBIDXR(2n)	FR_MBDOR(6n + 2)	FR_LEETR2
011	FR_MBCCFR(2n+1)	FR_MBDOR(6n + 3)	FR_LEETR3
100	FR_MBFIDR(2n+1)	FR_MBDOR(6n + 4)	FR_LEETR4
101	FR_MBIDXR(2n+1)	FR_MBDOR(6n + 5)	FR_LEETR5
110	Not Used	Not Used	Not Used
111			

4–15 ADDR	Memory Address. This field provides the address of the failing memory location.

54.6.108 ECC Error Report Data Register (FR_EERDR)

This register provides the data related information of the reported memory read access. The assignment of the bits depends on the selected memory and memory bank as shown in ECC Error Report Data Register (FR_EERDR) .

Table 54-16. Valid Bits in FR_EERDR[DATA] / FR_EEIDR[DATA] field

MEM	BANK	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CHI LRAM	5	FR_LEETR5															

Address: 0h base + F6h offset = F6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	DATA															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Ecc Data, shows data as generated by the ecc decoding logic. ERM=1: Memory Data, shows data as read from the memory.

54.6.109 ECC Error Report Code Register (FR_EERCR)

This register provides the ECC related information of the reported memory read access.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERCR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_EERCR field descriptions (continued)

Field	Description
11–15 CODE	Code. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Syndrome. Shows the ecc syndrome generated by the ecc decoding logic. The coding of the PE DRAM syndrome is shown in PE DRAM Syndrome . The coding of the CHI LRAM syndrome is shown in CHI LRAM Syndrome . ERM=1: Checkbits. Shows the ecc checkbits read from the memory.

54.6.110 ECC Error Injection Address Register (FR_EEIAR)

This register defines the memory module, bank, and address where the ECC error has to be injected.

Address: 0h base + FAh offset = FAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MID	BANK			ADDR											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag defines the memory instance for ECC error injection. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field defines the memory bank for ECC error injection. For MID=0: 000 BANK0: PE DRAM [7:0] 001 BANK1: PE DRAM [15:8] others reserved For MID=1: Refer to ECC Error Report Address Register (FR_EERAR) for the assignment of the LRAM banks.
4–15 ADDR	Memory Address. This flag defines the memory address for ECC error injection.

54.6.111 ECC Error Injection Data Register (FR_EEIDR)

This register defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in ECC Error Report Data Register (FR_EERDR) .

NOTE

The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. Refer to Memory Error Response for details.

Address: 0h base + FCh offset = FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the data written into the memory. EIM=1: This field defines the data to be written into the memory.

54.6.112 ECC Error Injection Code Register (FR_EEICR)

This register defines the ECC code distortion pattern for the error injection write.

Address: 0h base + FEh offset = FEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEICR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CODE	Code. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the ecc checkbits written into the memory. EIM=1: This field defines the ecc checkbits written into the memory.

54.6.113 Message Buffer Configuration, Control, Status Register (FR_MBCCSR*n*)

Write: MTD: POC:config or MB_DIS CMT: MB_LCK or MB_DIS EDT, LCKT, MBIE, MBIF: Normal Mode

The content of these registers is composed of message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in Individual Message Buffer Functional Description.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Address: 0h base + 800h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read	0			MTD	CMT		0	MBIE
Write						EDT	LCKT	
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0			DUP	DVAL	EDS	LCKS	MBIF
Write								w1c
Reset	0	0	0	0	0	0	0	0

FR_MBCCSR*n* field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 MTD	Message Buffer Transfer Direction. This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
4 CMT	Commit for Transmission. This bit indicates if the transmit message buffer data are ready for transmission. **NOTE:** This bit is read/write but may be modified by hardware other than by a reset. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger. If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger. If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable. This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set.

Table continues on the next page...

FR_MBCCSR*n* field descriptions (continued)

Field	Description
	0 Interrupt request generation disabled 1 Interrupt request generation enabled
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 DUP	Data Updated. This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and Message buffer data field not updated 1 Frame Header and Message buffer data field updated
12 DVAL	Data Valid. For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 receive message buffer contains no valid frame data / message is transmitted for the first time 1 receive message buffer contains valid frame data / message will be transferred again
13 EDS	Enable/Disable Status. This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled. 1 Message buffer is enabled.
14 LCKS	Lock Status. This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application. 1 Message buffer is locked by the application.
15 MBIF	Message Buffer Interrupt Flag. This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled

54.6.114 Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to Message Buffer Cycle Counter Filtering .

NOTE

If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.

Table 54-17. Channel Assignment Description

CHA	CHB	Transmit Message Buffer		Receive Message Buffer	
		static segment	dynamic segment	static segment	dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Address: 0h base + 802h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read Write	MTM	CHA	CHB	CCFE	CCFMSK			
Reset	0*	0*	0*	0*	0*	0*	0*	0*

Bit	8	9	10	11	12	13	14	15
Read Write	CCFMSK		CCFVAL					
Reset	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode. This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event transmission mode 1 State transmission mode
1 CHA	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .
2 CHB	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .

Table continues on the next page...

FR_MBCCFR*n* field descriptions (continued)

Field	Description
3 CCFE	Cycle Counter Filtering Enable. This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled
4–9 CCFMSK	Cycle Counter Filtering Mask. This field defines the filter mask for the cycle counter filtering.
10–15 CCFVAL	Cycle Counter Filtering Value. This field defines the filter value for the cycle counter filtering.

54.6.115 Message Buffer Frame ID Register (FR_MBFIDR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 804h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FID										
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBFIDR*n* field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FID	Frame ID. The semantic of this field depends on the message buffer transfer type. • Receive Message Buffer: This field is used as a filter value to determine if the message buffer is used for reception of a message received in a slot with the slot ID equal to FID. • Transmit Message Buffer: This field is used to determine the slot in which the message in this message buffer should be transmitted.

54.6.116 Message Buffer Index Register (FR_MBIDXR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 806h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBIDXR*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 MBIDX	Message Buffer Index. This field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer. The application writes the index of the initially associated message buffer header field into this register. The CC updates this register after frame reception or transmission. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

54.6.117 Message Buffer Data Field Offset Register (FR_MBDOR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config

Address: 0h base + 1000h offset + (2d × i), where i=0d to 131d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MBDO															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:

- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBDOR*n* field descriptions

Field	Description
0–15 MBDO	Message Buffer Data Field Offset. This field provides the data field offset belonging to a particular Message Buffer Index. For configuration constraints see Configure Data Field Offsets .

54.6.118 LRAM ECC Error Test Register (FR_LEETR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Address: 0h base + 1108h offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	LEETD															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_LEETR*n* field descriptions

Field	Description
0–15 LEETD	LRAM ECC Error Test Data. This field contains the LRAM data belonging to the test register located in LRAM Bank n.

54.7 Functional Description

This section provides a detailed description of the functionality implemented in the CC.

54.7.1 Message Buffer Concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts, the *message buffer control data* and the *physical message buffer*. The message buffer control data are located in dedicated registers. The structure of the message buffer control data depends on the

message buffer type and is described in the Message Buffer Types section. The physical message buffer is located in the FlexRay memory area and is described in the next section.

54.7.2 Physical Message Buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area.The structure of a physical message buffer is depicted in the figure below.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

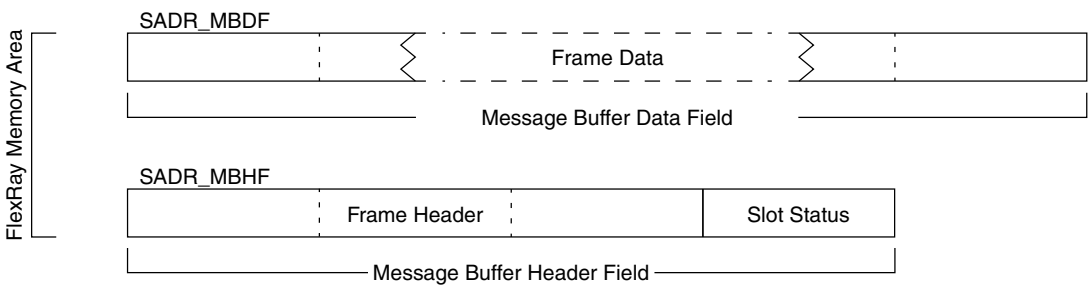

Figure 54-2. Physical Message Buffer Structure

54.7.2.1 Message Buffer Header Field

The message buffer header field is a contiguous region in the FlexRay memory area and occupies eight bytes. It contains the frame header, and the slot status. Its structure is shown in the above figure. The physical start address *SADR_MBHF* of the message buffer header field must be 16-bit aligned.

54.7.2.1.1 Frame Header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header related information according to the *FlexRay Communications System Protocol Specification, Version*2.1 Rev A. A detailed description of the usage and the content of the frame header is provided in Frame Header Description section.

54.7.2.1.2 Slot Status

The slot status occupies the last two bytes of the message buffer header field. It provides the slot and frame status related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in the Slot Status Description section.

54.7.2.2 Message Buffer Data Field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in the following section.

54.7.3 Message Buffer Types

The CC provides three different types of message buffers.

- *Individual Message Buffers*
- *Receive Shadow Buffers*
- *Receive FIFO Buffers*

For each message buffer type the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

54.7.3.1 Individual Message Buffers

The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in the Individual Message Buffer Functional Description section.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in the figure below.

Each individual message buffer has a message buffer number n assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field MBIDX in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR\_MBHF = (FR\_MBIDXRn[MBIDX] \times 8) + SMBA$$

Equation 32

The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to this equation:

$$SADR\_MBDF = [DataFieldOffset] + SMBA$$

Equation 33

The FR_MBDORn are stored in the module internal memory LRAM. Refer to CHI LRAM Initialization for the setup of the data field offset values.

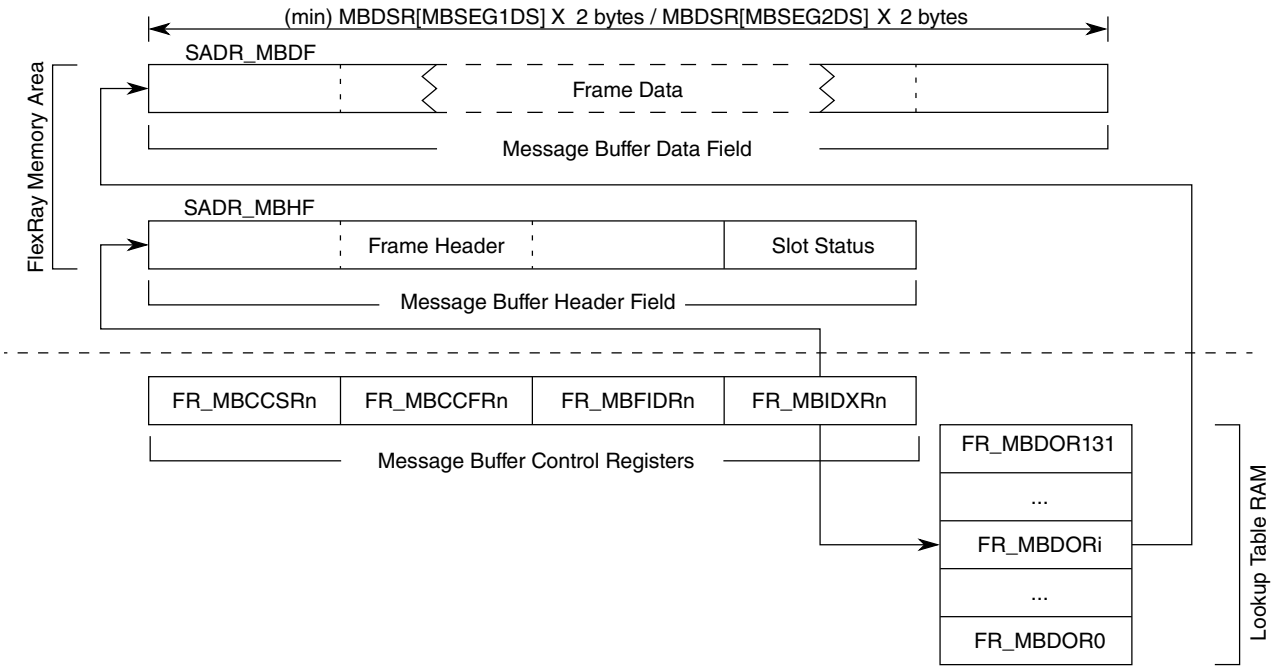

Figure 54-3. Individual Message Buffer Structure

54.7.3.1.1 Individual Message Buffer Segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- *all physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length*
- *the minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes*
- *the minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.*

54.7.3.2 Receive Shadow Buffers

The receive shadow buffers are required for the frame reception process for individual message buffers. The CC provides four receive shadow buffers, one receive shadow buffer per channel and per message buffer segment.

Each receive shadow buffer consists of two parts, the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in the figure below. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR\_MBHF = (FR\_RSBIR[RSBIDX] \times 8) + SMBA$$

Equation 34

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

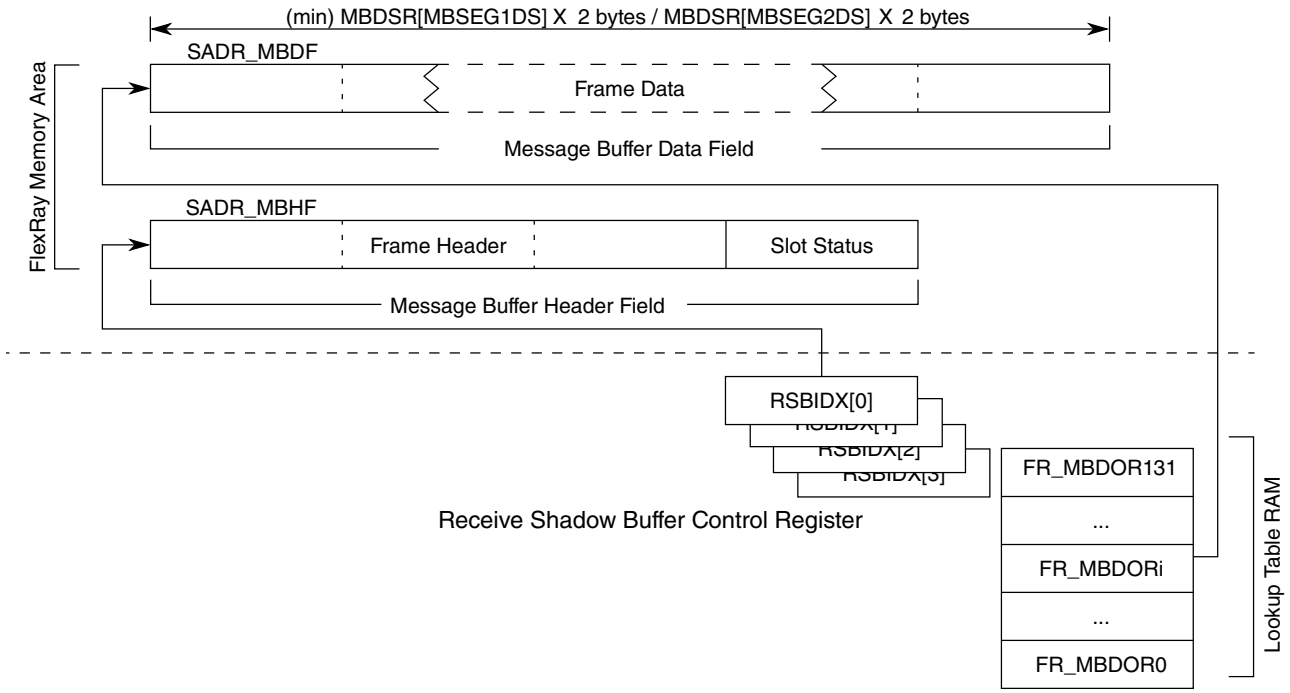

Figure 54-4. Receive Shadow Buffer Structure

54.7.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in the Receive FIFO Structure figure, later in this section.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR) / Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM] in the Module Configuration Register.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to Equation 35 on page 2586.

$$SADR\_MBHF[1] = (8 \times FR\_RFSIR[SIDX]) + SMBA$$

Equation 35

The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according Equation 36 on page 2587 .

$$SADR\_MBHF[n] = (8 \times (FR\_RFSIR[SIDX] + FR\_RFDSR[FIFO\_DEPTH])) + SMBA$$

Equation 36

The required information to access the current entry of the FIFO is given in the following registers:

- *The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.*

  The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

$$RF\_DFO[X] = FR\_RFSDOR[X] + (FR\_RFDSR[X][ENTRY\_SIZE] \times 2) \times i - FR\_RFSIDX[X])$$

Equation 37

Note

The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to FIFO Update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

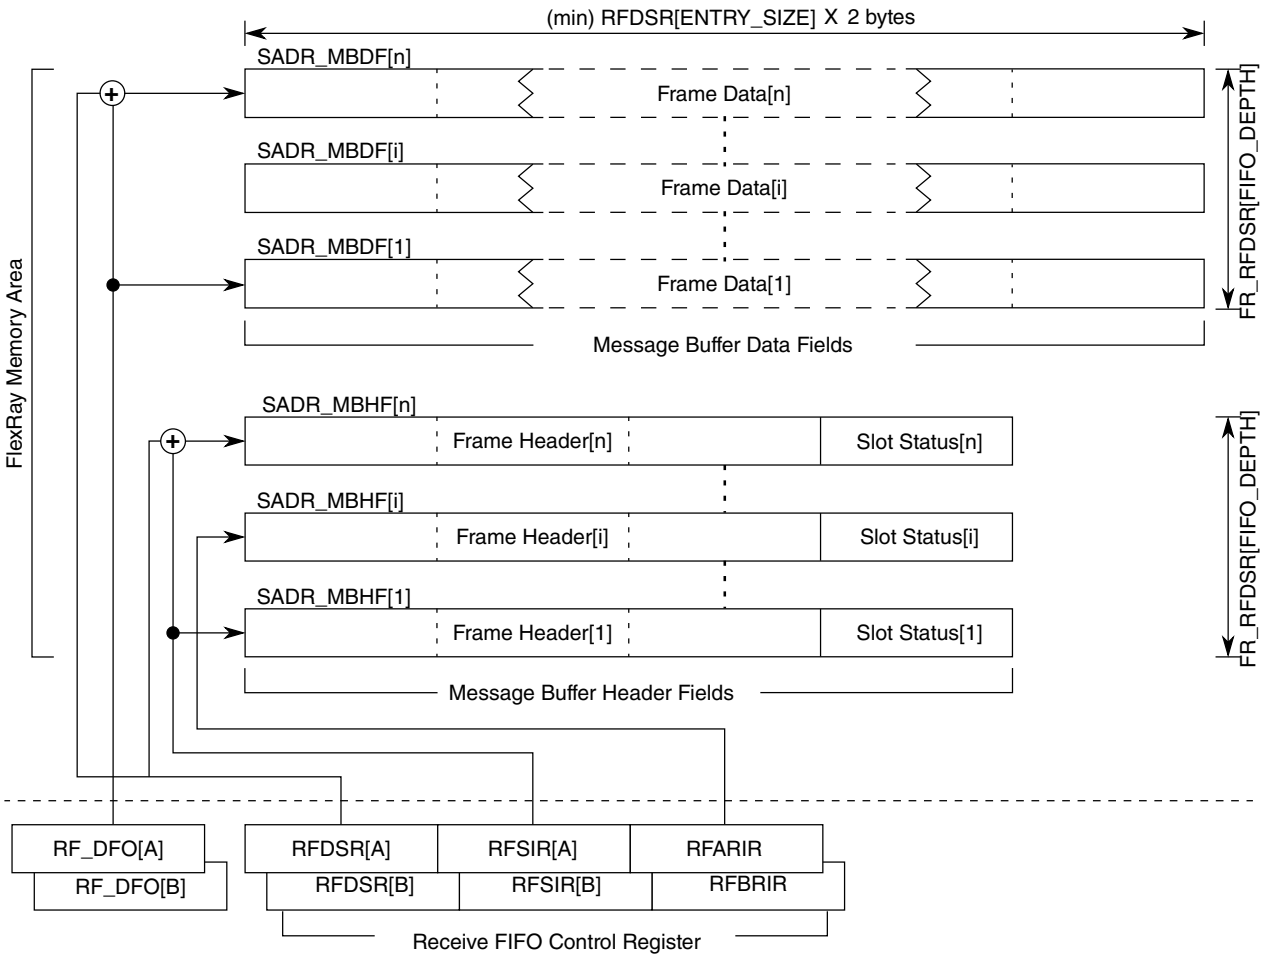

Figure 54-5. Receive FIFO Structure

Note

The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 37 on page 2587. They are not stored in a register.

54.7.3.4 Message Buffer Configuration and Control Data

This section describes the configuration and control data for each message buffer type.

54.7.3.4.1 Individual Message Buffer Configuration Data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

54.7.3.4.1.1 Common Configuration Data

The set of common configuration data for individual message buffers is located in the following registers.

- *Message Buffer Data Size Register (FR_MBDSR)*

  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.

- *Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)*

  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, see Individual Message Buffer Segments.

54.7.3.4.1.2 Specific Configuration Data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- *Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)*

  The MTD bit configures the message buffer type.

- *Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)*

  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.

- *Message Buffer Frame ID Registers (FR_MBFIDRn)*

  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.

- *Message Buffer Index Registers (FR_MBIDXRn)This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.*

54.7.3.5 Individual Message Buffer Control Data

During normal operation, each individual message buffer can be controlled by the control and trigger bits CMT, LCKT, EDT, and MBIE in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn).

54.7.3.6 Receive Shadow Buffer Configuration Data

Before frame reception into the individual message buffers can be performed, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

54.7.3.7 Receive FIFO Control and Configuration Data

This section describes the configuration and control data for the two receive FIFOs.

54.7.3.7.1 Receive FIFO Configuration Data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- *Receive FIFO Periodic Timer Register (FR_RFPTR)*

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- *Receive FIFO Watermark and Selection Register (FR_RFWMSR)*
- *Receive FIFO Start Index Register (FR_RFSIR)*
- *Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *Receive FIFO Depth and Size Register (FR_RFDSR)*
- *Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)*
- *Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)*
- *Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)*

- *Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*

54.7.3.7.2 Receive FIFO Control Data

The application can access the FIFOs at any time using the control bits in the following registers:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

54.7.3.7.3 Receive FIFO Status Data

The current status of the receive fifo is provided in the following register:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO A Read Index Register (FR_RFARIR)*
- *Receive FIFO B Read Index Register (FR_RFBRIR)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

54.7.4 FlexRay Memory Area Layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].

54.7.4.1 FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

In the figure given below, shows an example layout for the FIFO address mode FR_MCR[FAM]=0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is maximum 64 KB.
- The FlexRay memory area starts at a 16 byte boundary

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

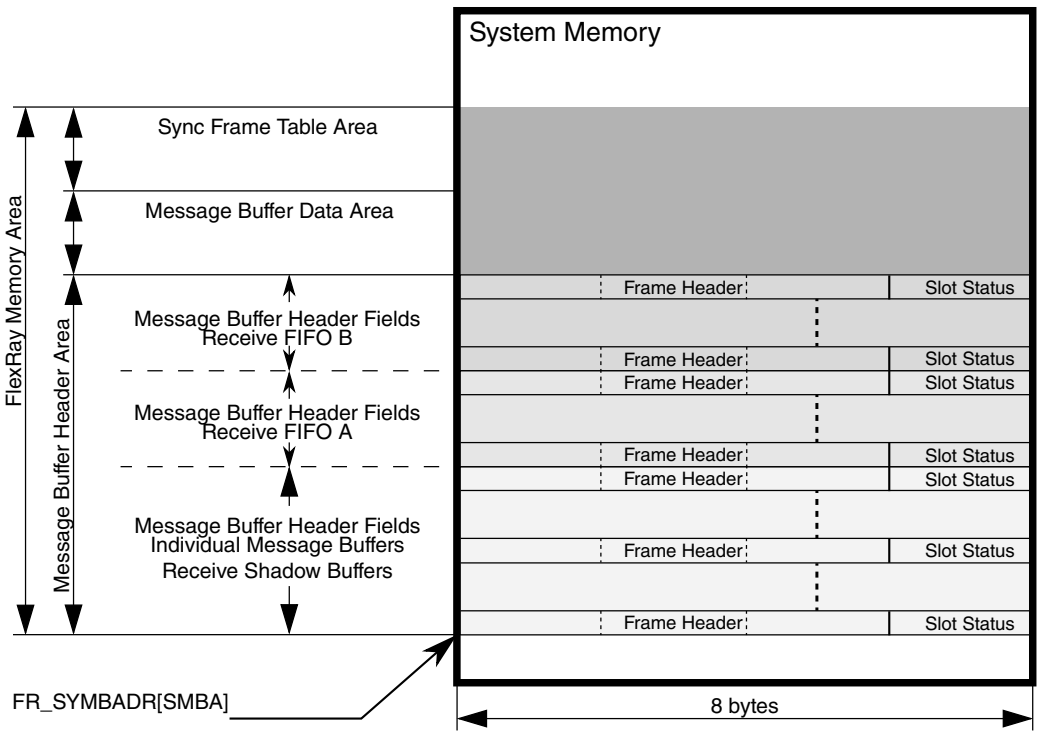

Figure 54-6. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

54.7.4.2 FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

The following figure shows an example layout for the FIFO address mode FR_MCR[FAM]=1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

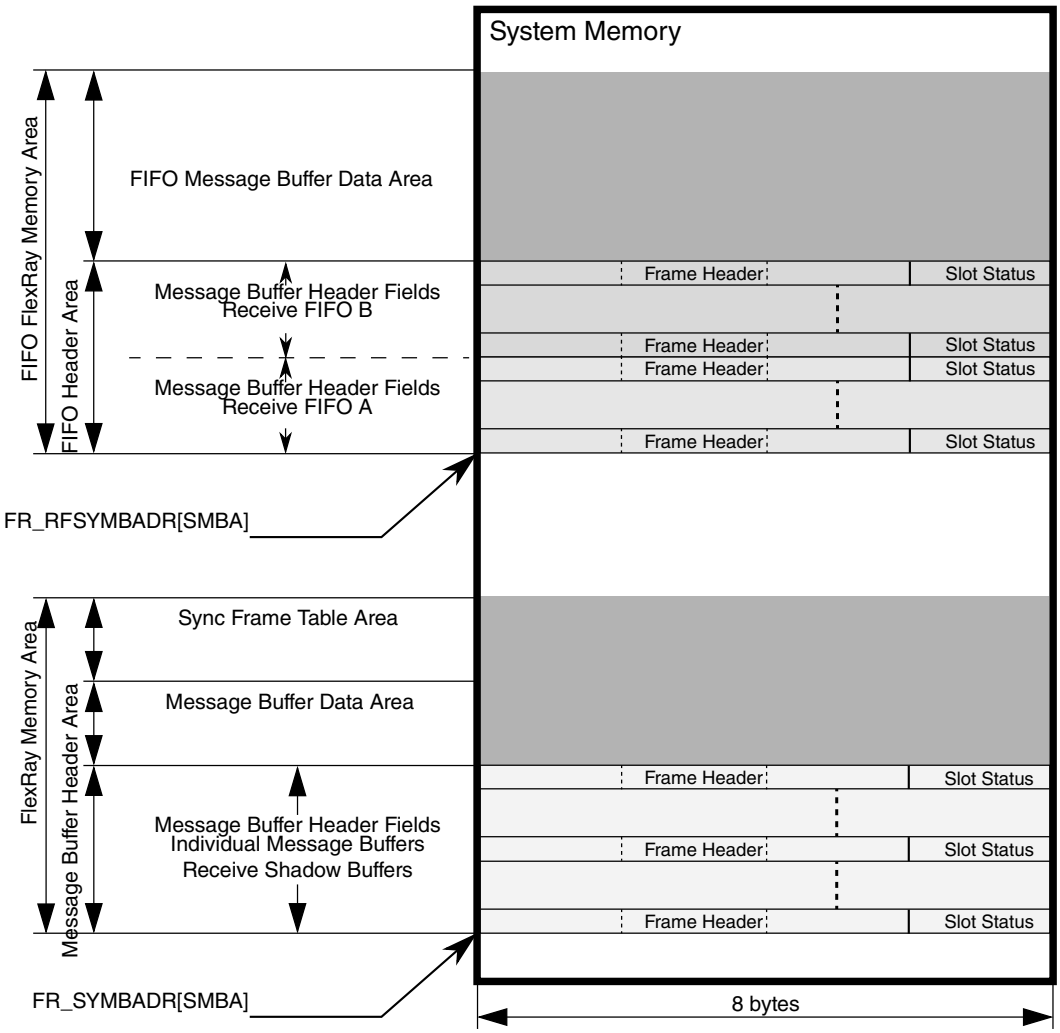

Figure 54-7. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

54.7.4.3 Message Buffer Header Area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rules apply to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for *individual message buffers* and *receive shadow buffers* must fulfill Equation 38 on page 2593.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 38

2. The start byte address SADR_MBHF of each message buffer header field for the *FIFO* must fulfill Equation 38 on page 2593.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 39

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 40

3. The message buffer header fields for each FIFO have to be a contiguous area.

54.7.4.4 Message Buffer Header Area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill Equation 41 on page 2594.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 41

54.7.4.5 FIFO Message Buffer Header Area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill the following equation:Equation 42 on page 2594.

$$SADR\_MBHF = (i\gamma 8) + FR\_RFSYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 42

2. The message buffer header fields for each FIFO have to be a contiguous area.

54.7.4.6 Message Buffer Data Area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

54.7.4.7 Sync Frame Table Area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to Sync Frame ID and Sync Frame Deviation Tables for the description of the sync frame table area.

54.7.5 Physical Message Buffer Description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer, the message buffer header field and the message buffer data field.

54.7.5.1 Message Buffer Protection and Data Consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

54.7.5.2 Message Buffer Header Field Description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in Message Buffer Header Field. Each message buffer header field consists of two sections: the frame header section and the slot status section.

54.7.5.2.1 Frame Header Description

Frame header content, access, and checks are discussed in this section.

54.7.5.2.1.1 Frame Header Content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in the figure below. A detailed description is given in Table 54-22.

Table 54-18. Frame Header Structure (Receive Message Buffer and Receive FIFO)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID										
0x2	0	0	CYCCNT						0	PLDLEN						
0x4	0	0	0	0	0	HDCRC										

The structure of the frame header in the message buffer header field for transmit message buffers is given in the following figure. A detailed description is given in Table 54-23. The checks that will be performed are described in Frame Header Checks.

Table 54-19. Frame Header Structure (Transmit Message Buffer)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID [1]										
0x2			CYCCNT							PLDLEN [2]						
0x4						HDCRC										

= not used

1. checked
2. checked if not static

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in the figure below.

Table 54-20. Frame Header Structure (Transmit Message Buffer for Key Slot)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID										
0x2			CYCCNT							PLDLEN						
0x4						HDCRC										

= not used

54.7.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in the following table. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 54-21. Frame Header Write Access Constraints (Transmit Message Buffer)

Field	Static Segment	Dynamic Segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	MB_LCK

54.7.5.2.1.3 Frame Header Checks

As shown in Table 54-19 and Table 54-20 not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag FID_EF in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDRn).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 54-22. Frame Header Field Descriptions (Receive Message Buffer and Receive FFO)

Field	Description
R	**Reserved Bit** — This is the value of the *Reserved bit* of the received frame stored in the message buffer
PPI	**Payload Preamble Indicator** — This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	**Null Frame Indicator** — This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	**Sync Frame Indicator** — This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	**Startup Frame Indicator** — This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	**Frame ID** — This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	**Cycle Count** — This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	**Payload Length** — This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	**Header CRC** — This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 54-23. Frame Header Field Descriptions (Transmit Message Buffer)

Field	Description
R	**Reserved Bit** — This bit is not used, the value of the *Reserved bit* is generated internally according to *FlexRay Communications System Protocol Specification, Version*2.1 Rev A.
PPI	**Payload Preamble Indicator** — This bit provides the value of the *Payload Preamble Indicator* for the frame transmitted from the message buffer.
NUF	**Null Frame Indicator** — This bit is not used, the value of the *Null Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SYF	**Sync Frame Indicator** — This bit is not used, the value of the *Sync Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SUF	**Startup Frame Indicator** — This bit is not used, the value of the *Startup Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
FID	**Frame ID** — This field is checked as described in Frame Header Checks.
CYCCNT	**Cycle Count** — This field is not used, the value of the transmitted *Cycle Count* field is taken from the internal communication cycle counter.
PLDLEN	**Payload Length** — This field is checked and used as described in Frame Header Checks.

Field	Description
HDCRC	**Header CRC** — This field provides the value of the *Header CRC* field for the frame transmitted from the message buffer.

54.7.5.2.2 Slot Status Description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

54.7.5.2.2.1 Receive Message Buffer and Receive FIFO Slot Status Description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given in the next table.

Table 54-24. Receive Message Buffer Slot Status Content

Receive Message Buffer Type	Slot Status Content
Individual Receive Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 54-25
Individual Receive Message Buffer assigned to channel A FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0	see Table 54-26
Individual Receive Message Buffer assigned to channel B FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1	see Table 54-27
Receive FIFO Channel A Message Buffer	see Table 54-26
Receive FIFO Channel B Message Buffer	see Table 54-27

The meaning of the bits in the slot status structure is explained in the Receive Message Buffer Slot Status Field Description table below.

54.7.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given in the table below.

Table 54-29. Transmit Message Buffer Slot Status Content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 54-30

Table continues on the next page...

54.7.5.3 Message Buffer Data Field Description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in the table below. The structure of the message buffer data field is given in the next figure.

Table 54-34. Message Buffer Data Field Minimum Length

physical message buffer assigned to	minimum length defined by
Individual Message Buffer in Segment 1	FR_MBDSR[MBSEG1DS]
Receive Shadow Buffer in Segment 1	FR_MBDSR[MBSEG1DS]
Individual Message Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive Shadow Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note

The CC will not access any locations outside the message buffer data field boundaries given in the table above.

Table 54-35. Message Buffer Data Field Structure

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	DATA0 / MID0 / NMV0								DATA1 / MID1 / NMV1							
0x2	DATA2 / NMV2								DATA3 / NMV3							
…	…								…							
0xN-2	DATA N-2								DATA N-1							

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

54.7.5.3.1 Message Buffer Data Field Read Access

For transmit message buffers, the CC will not modify the content of the Message Buffer Data Field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXRn). While the message buffer is locked, the CC will not update the Message Buffer Data Field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

54.7.5.3.2 Message Buffer Data Field Write Access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in the Frame Data Write Access Constraints table below.

Table 54-36. Frame Data Write Access Constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 54-37. Frame Data Field Descriptions

Field	Description
DATA 0, DATA 1, … DATA N-1	**Message Data** — Provides the message data received or to be transmitted.For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	**Message Identifier** — If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.

Table continues on the next page...

Table 54-37. Frame Data Field Descriptions (continued)

Field	Description
NMV 0, NMV 1, … NMV 11	**Network Management Vector** — If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

54.7.6 Individual Message Buffer Functional Description

The CC provides these basic types of individual message buffers:

1. Transmit Message Buffers
2. Receive Message Buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in Individual Message Buffer Configuration Data.

54.7.6.1 Individual Message Buffer Configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

54.7.6.1.1 Common Configuration Data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. These data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

54.7.6.1.2 Specific Configuration Data

The second part of the message buffer configuration data is specific for each message buffer.

These data can be changed only when either

- *the protocol is in the POC:config state or*
- *the message buffer is disabled, i.e. FR_MBCCSRn[EDS] = 0*

The individual message buffer type is defined by the MTD and MBT bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) as given in the following table.

Table 54-38. Individual Message Buffer Types

FR_MBCCSRn		Individual Message Buffer Description
MTD	MBT	
0	0	Receive Message Buffer
0	1	Reserved
1	0	Transmit Message Buffer
1	1	Reserved

The message buffer specific configuration data are

1. MTD bits in Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
2. all fields and bits in Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)

3. all fields and bits in Message Buffer Frame ID Registers (FR_MBFIDRn)
4. all fields and bits in Message Buffer Index Registers (FR_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions in the Transmit Message Buffers section and Receive Message Buffers section.

54.7.6.2 Transmit Message Buffers

The section provides a detailed description of the functionality of single buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number n is configured to be a transmit message buffer by the following settings:

- FR__ MBCCSRn[MBT] = 0(singlebufferedmessagebuffer)
- FR_ MBCCSRn[MDT] = 1(transmitmessagebuffer)

54.7.6.2.1 Access Regions

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented, which is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in the figure below. A description of the regions is given in Table 54-40. If an region is active as indicated in Table 54-41, the access scheme given for that region applies to the message buffer.

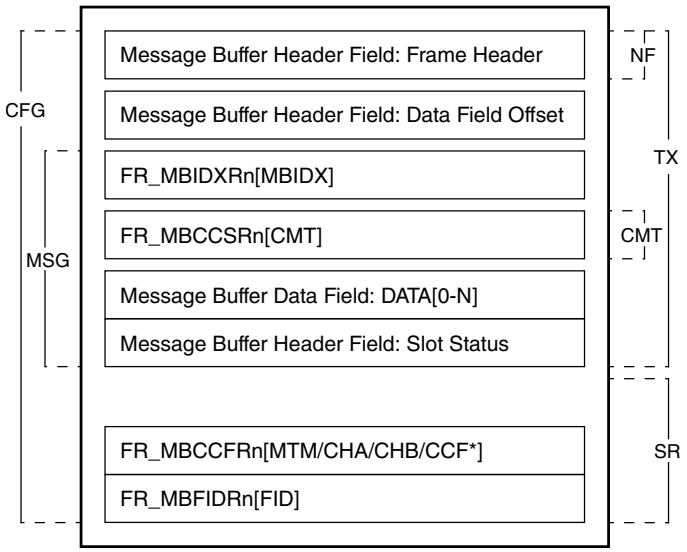

Figure 54-8. Transmit Message Buffer Access Regions

Table 54-39. Transmit Message Buffer Access Regions Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration
MSG	read/write	-	Message Data and Slot Status Access
NF	-	read-only	Message Header Access for Null Frame Transmission
TX	-	read/write	Message Transmission and Slot Status Update
CM	-	read-only	Message Buffer Validation
SR	-	read-only	Message Buffer Search

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT], and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in the next figure. A description of the states is given in Table 54-40, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

54.7.6.2.2 Message Buffer States

This section describes the transmit message buffer states and provides a state diagram.

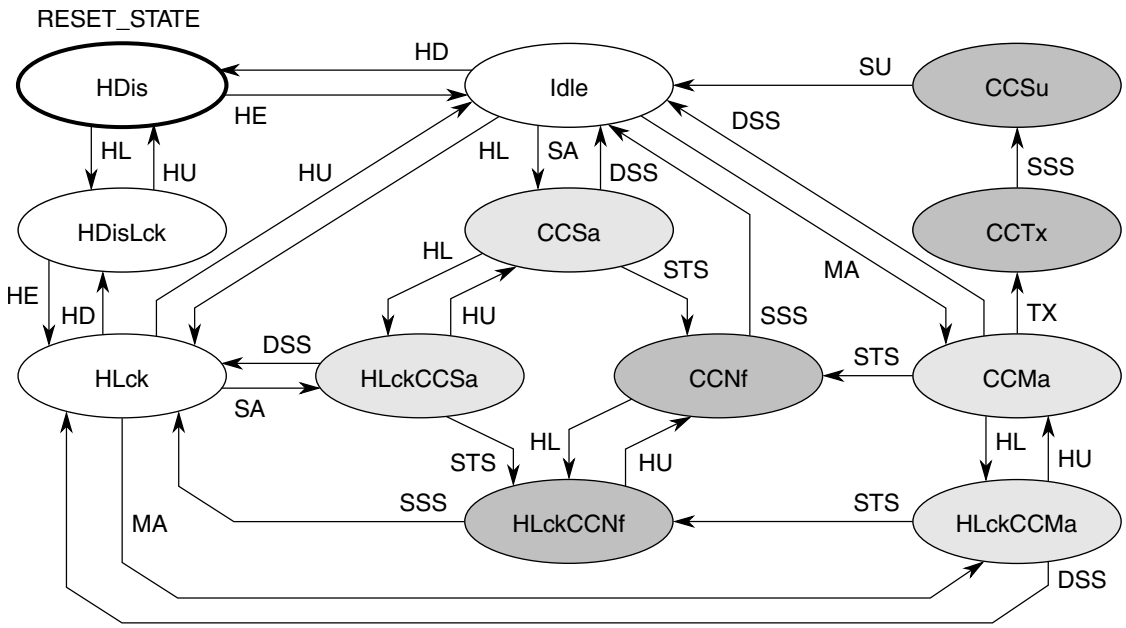

Figure 54-9. Transmit Message Buffer States

Table 54-40. Transmit Message Buffer State Description (Sheet 1 of 2)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	CM,SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	SR	**Locked** - Applications access to data, control, and status.Included in message buffer search.
CCSa	1	0	–	–	**Slot Assigned** - Message buffer assigned to next static slot.Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	–	**Locked and Slot Assigned** - Applications access to data, control, and status.Message buffer assigned to next static slot
CCNf	1	0	–	NF	**Null Frame Transmission** Header is used for null frame transmission.

Table continues on the next page...

Table 54-40. Transmit Message Buffer State Description (Sheet 1 of 2) (continued)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
HLckCCNf	1	1	MSG	NF	**Locked and Null Frame Transmission** - Applications access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	–	CM	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
HLckCCMa	1	1	MSG	–	**Locked and Message Available** - Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	–	TX	**Message Transmission** - Message buffer data transmit. Payload data from buffer transmitted
CCSu	1	0	–	TX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

54.7.6.2.3 Message Buffer Transitions

Application transitions, module transitions, and transition priorities are discussed in this section.

54.7.6.2.3.1 Application Transitions

The application transitions can be triggered by the application using the commands described in the table below. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

54.7.6.2.3.1.1 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

54.7.6.2.3.1.2 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 54-41. Transmit Message Buffer Application Transitions

Transition	Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]:= 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

54.7.6.2.3.2 Module Transitions

The module transitions that can be triggered by the CC are described in the following table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 54-42. Transmit Message Buffer Module Transitions

Transition	Condition	Description
SA	slot match andstatic slot	**Slot Assigned** - Message buffer is assigned to next static slot.
MA	slot match andCycleCounter match	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
TX	slot start and FR_MBCCSRn[CMT] = 1	**Transmission Slot Start** - Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	status updated	**Status Updated** - Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	static slot start	**Static Slot Start** - Start of static slot.
DSS	dynamic slot start orsymbol window start orNIT start	**Dynamic Slot or Segment Start.** - Start of dynamic slot or symbol window or NIT.
SSS	slot start orsymbol window start orNIT start	**Slot or Segment Start** - Start of static slot or dynamic slot or symbol window or NIT.

54.7.6.2.3.3 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of the next table, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and subsequently the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions is given in the second part of the table below.

Table 54-43. Transmit Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle, HLck	SA > HD	Slot Assigned > Message Buffer Disable
	MA > HD	Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS	Transmission Slot Start > Static Slot Start
	TX > DSS	Transmission Slot Start > Dynamic Slot Start

54.7.6.2.4 Transmit Message Setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit CMT in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). The physical access to the message buffer data field is described in Individual Message Buffers.

As indicated by Table 54-33, the application shall write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in Table 54-33. The state change is indicated through the FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa the FR_MBCCSRn[DVAL] flag is negated.

54.7.6.2.5 Message Transmission

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. the message buffer is in the message available state CCMa
2. the message data are still valid, i.e. FR_MBCCSRn[CMT] = 1

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in the "Message Transmission Timing" figure below. In this example, the message buffer with message buffer number n is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid, i.e. FR_MBCCSRn[CMT] = 1.

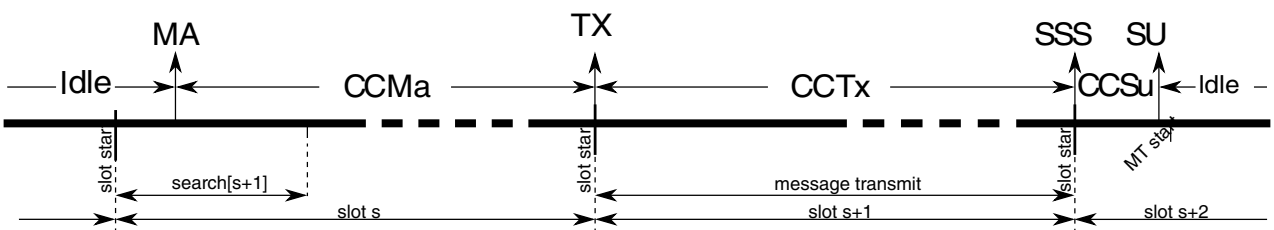

Figure 54-10. Message Transmission Timing

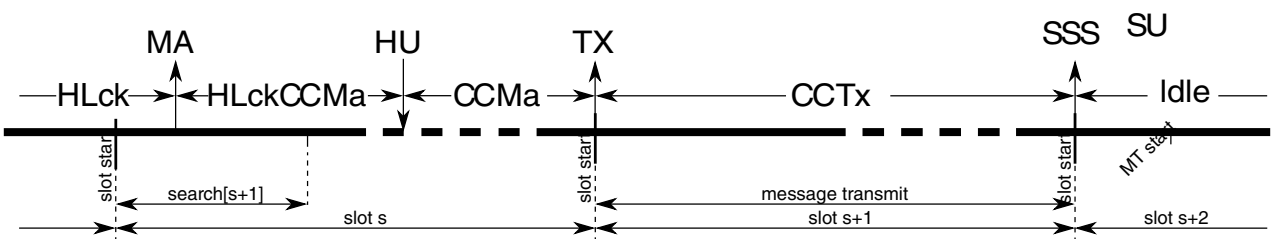

Figure 54-11. Message Transmission from HLck state with unlock

The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)

3. the value of the PLDLEN field in the message buffer header field, as described in Frame Header Description

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN <= MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

54.7.6.2.6 Null Frame Transmission

A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDRn[FID] set to S and FR_MBCCFRn[CHA] set to 1. A Null Frame is transmitted in the static slot S on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDRn[FID] = s and FR_MBCCFRn[CHA] = 1 are either not committed, i.e FR_MBCCSRn[CMT] = 0, or locked by the application, i.e. FR_MBCCSRn[LCKS] = 1, or the cycle counter filter is enabled and does not match.

Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in the figure below.

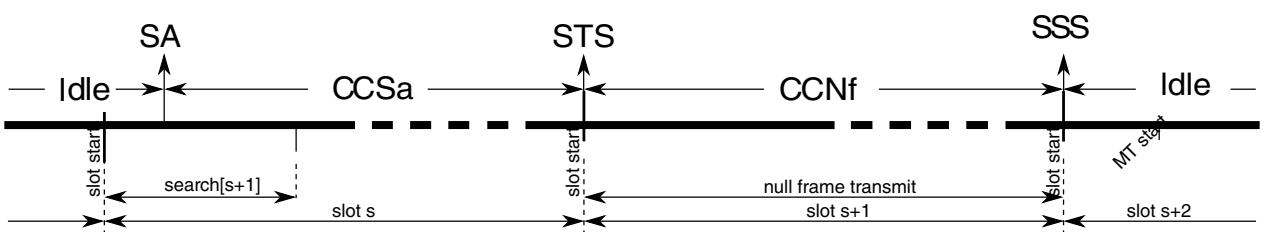

Figure 54-12. Null Frame Transmission from Idle state

A message buffer timing and state change diagram for null frame transmission from HLck state is given in the following figure.

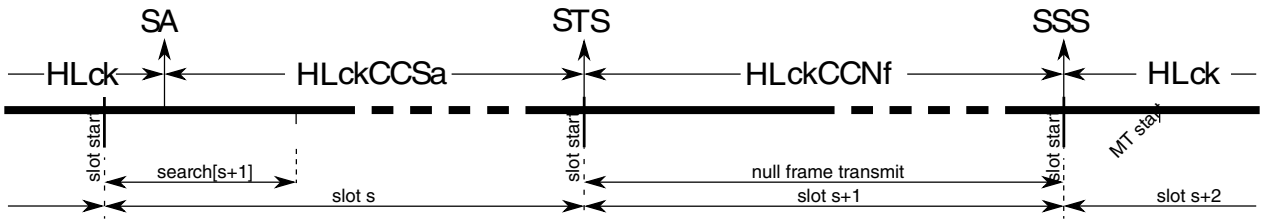

Figure 54-13. Null Frame Transmission from HLck state

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the next figure.

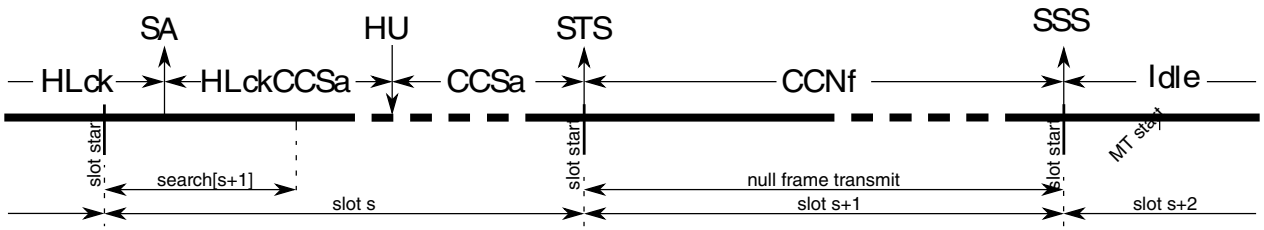

Figure 54-14. Null Frame Transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the figure below.

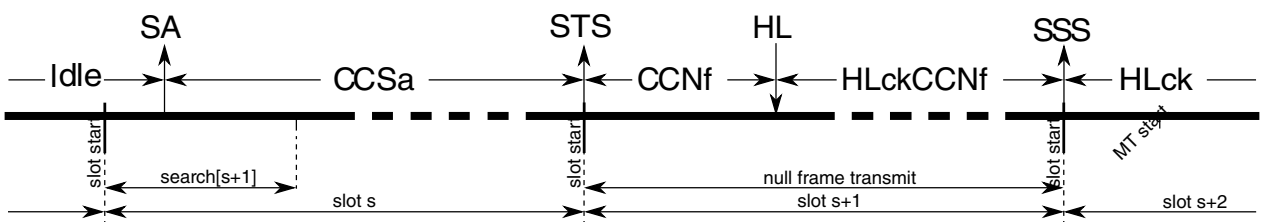

Figure 54-15. Null Frame Transmission from Idle state with locking

54.7.6.2.7 Message Buffer Status Update

After the end of each slot, the PE generates the slot status vector. Depending on the this status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

54.7.6.2.7.1 Message Buffer Status Update after Complete Message Transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer were send to FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSRn[MBIF] to indicate the successful message transmission.

Depending on the transmission mode flag FR_MBCCFRn[MTM], the CC changes the commit flag FR_MBCCSRn[CMT] and the valid flag FR_MBCCSRn[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in the *event transmission mode*. In this case, each committed message is transmitted only once. The commit flag FR_MBCCSRn[CMT] is cleared with the SU transition. If the FR_MBCCFRn[MTM] flag is asserted, the message buffer is in the *state transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSRn[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSRn[DVAL] to indicate that the message will be transmitted again.

54.7.6.2.7.2 Message Buffer Status Update after Incomplete Message Transmission

The term incomplete message transmission refers to the fact that not all payload data that should be transmitted were send to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

In any of these two aforementioned conditions occur, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

54.7.6.2.7.3 Message Buffer Status Update after Null Frame Transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

54.7.6.3 Receive Message Buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used it is required to configure the related receive shadow buffer as described in Receive Shadow Buffers.

A receive message buffer is used to receive a message from the FlexRay Bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application.

1. message data received
2. information about the reception process
3. status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration settings

$$FR\_MBCCSRn[MTD] = 0 (receive message buffer)$$

Equation 43

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented that is used to control the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in the figure below. A description of the regions is given in the following table. If a region is active as indicated in the "Receive Message Buffer States and Access (Sheet 2 of 2)" table below, the access scheme given for that region applies to the message buffer.

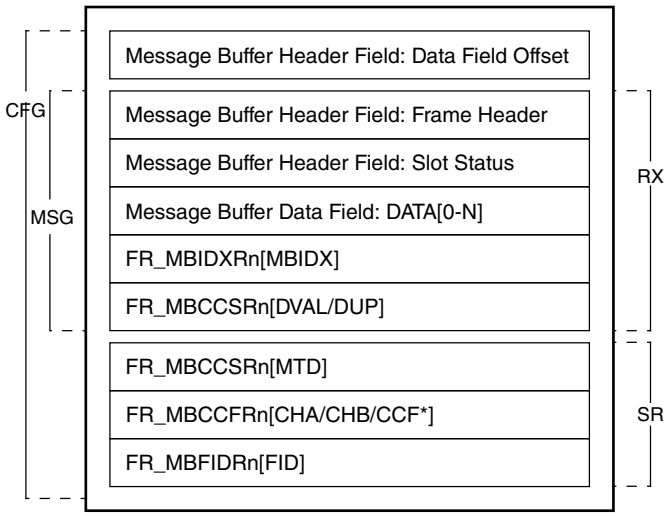

Figure 54-16. Receive Message Buffer Access Regions

Table 54-44. Receive Message Buffer Access Region Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration, Message Data and Status Access
MSG	read/write	-	Message Data, Header, and Status Access
RX	-	write-only	Message Reception and Status Update
SR	-	read-only	Message Buffer Search Data

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT] and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in the figure below. A description of the message buffer states is given in Table 54-40, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

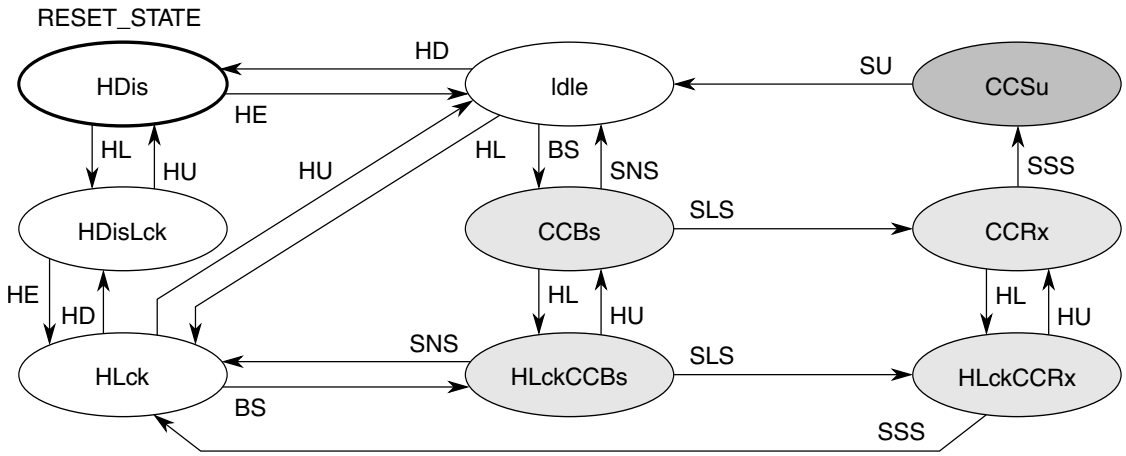

Figure 54-17. Receive Message Buffer States

Table 54-45. Receive Message Buffer States and Access (Sheet 2 of 2)

State	FR_MBCCSRn		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	–	**Locked** - Applications access to data, control, and status.Included in message buffer search.
CCBs	1	0	–	–	**Buffer Subscribed** - Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	–	**Locked and Buffer Subscribed** - Applications access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	–	–	**Message Receive** - Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	–	**Locked and Message Receive** - Applications access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	–	RX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

54.7.6.3.1 Message Buffer Transitions

Application transitions, message buffer enable and disable, message buffer lock and unlock, module transitions, and transition priorities are discussed in this section.

54.7.6.3.1.1 Application Transitions

The application transitions that can be triggered by the application using the commands described in Table 54-41. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

54.7.6.3.1.2 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCBs, HLckCCBs, or CCRx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

54.7.6.3.1.3 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL while the message buffer is in the state CCRx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 54-46. Receive Message Buffer Application Transitions

Transition	Host Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]: = 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

54.7.6.3.1.4 Module Transitions

The module transitions that can be triggered by the CC are described in the next table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 54-47. Receive Message Buffer Module Transitions

Transition	Condition	Description
BS	slot match and CycleCounter match	**Buffer Subscribed** - The message buffer filter matches next slot and cycle.
SLS	slot start	**Slot Start** - Start of either Static Slot or Dynamic Slot.
SNS	symbol window start or NIT start	**Symbol Window or NIT Start** - Start of either Symbol Window or NIT.
SSS	slot start or symbol window start or NIT start	**Slot or Segment Start** - Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	status updated	**Status Updated** - Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

54.7.6.3.1.5 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the table below, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU and can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the buffer subscribed state CCBs and the module triggers the slot start transition SLS at the same time as the application locks the message buffer by the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state HLckCCRx.

Table 54-48. Receive Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle	BS > HD	Buffer Subscribed > Message Buffer Disable
HLck	BS > HD	Buffer Subscribed > Message Buffer Disable
CCRx	SSS > HL	Slot or Segment Start > Message Buffer Lock

54.7.6.3.2 Message Reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to the either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffers assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot the module trigger the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data are written into the shadow buffers. For details on receive shadow buffers, see Receive Shadow Buffers Concept. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

54.7.6.3.3 Message Buffer Update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer was in the locked state HLckCCRx, no update will be performed. The received data are lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state it is now in the CCSu state. After the evaluation of the slot status provided by the PE the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to. This is described in Table 54-51.

Table 54-49. Receive Message Buffer Update (Continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
1	1	**Valid non-null frame received.** - Message Buffer Data Field updated. - Frame Header Field updated. - Slot Status Field updated. - DUP:= 1 - DVAL:= 1 - MBIF:= 1
1	0	**Valid null frame received.**

Table continues on the next page...

Table 54-49. Receive Message Buffer Update (Continued) (continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
		- Message Buffer Data Field *not* updated. - Frame Header Field *not* updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed - MBIF:= 1
0	x	**No valid frame received.** - Message Buffer Data Field not updated. - Frame Header Field not updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed. - MBIF:= 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: *vSS!ValidFrame* = 0 and *vSS!SyntaxError* = 0 and *vSS! ContentError* = 0 and *vSS!BViolation* = 0.

Note

If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > *n* will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in the following figure.

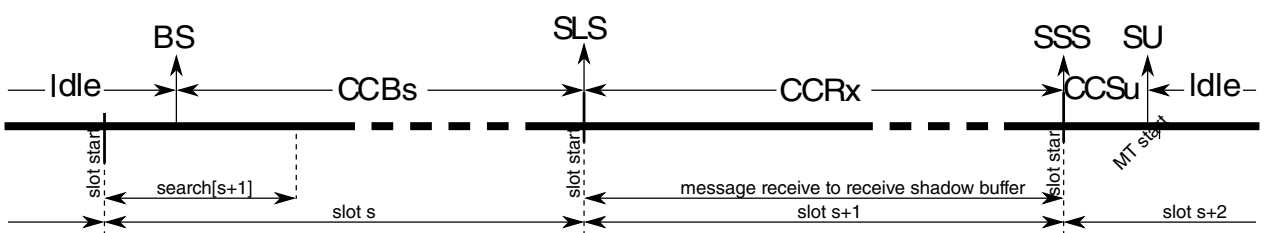

Figure 54-18. Message Reception Timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following two items:

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. the number of bytes received over the FlexRay bus

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

54.7.6.3.4 Received Message Access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in Individual Message Buffers.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

54.7.6.3.5 Receive Shadow Buffers Concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in Receive Shadow Buffers.

The receive shadow buffers temporarily store the received frame header and message data. After the slot boundary the slot status information is generated. If the slot status information indicates the reception of the valid non-null frame (see Table 54-49), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXRn) with the content of the corresponding internal shadow buffer index register. In all other cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXRn).

54.7.7 Individual Message Buffer Search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel if a slot s in a communication cycle c is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm which is invoked at the following protocol related events:

1. NIT start
2. slot start in the static segment
3. minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *n* searches for message buffers assigned or subscribed to slot *n+1*.

In general, the message buffer search for the next slot *n* considers only message buffers which are

1. enabled, i.e. FR_MBCCSRn[EDS] = 1, and
2. matches the next slot *n*, i.e. FR_MBFIDRn[FID] = *n*, and

On top of that, for the static segment only those message buffers are considered, that match the condition of at least one row of the "Message Buffer Search Priority (static segment)" table shown below. For the dynamic segment only those message buffers are considered, that match the condition of at least one row of the next "Message Buffer Search Priority (dynamic segment)" table. These message buffers are called *matching* message buffers.

For each enabled channel the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers the message buffers with highest priority according to the "Message Buffer Search Priority (static segment)" table for the static segment and according to the "Message Buffer Search Priority (dynamic segment)" table for the dynamic segment are selected.

Table 54-50. Message Buffer Search Priority (static segment)

Priority	MTD	LCKS	CMT	CCFM-[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	1	-	0	1	transmit buffer, matches cycle count, not committed	SA
	1	1	-	1	transmit buffer, matches cycle count, locked	SA
2	1	-	-	-	transmit buffer	SA
3	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 4	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.
2. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

Table 54-51. Message Buffer Search Priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM-[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 2	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.
2. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffer which have the highest priority must have a consistent channel assignment as specified in Message Buffer Channel Assignment Consistency.

Depending on the message buffer channel assignment the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in Individual Message Buffers.

54.7.7.1 Message Buffer Cycle Counter Filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled, i.e. CCFE = 0, this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

$$MBCCFRn[CCFE] = 0$$

$$CYCCNT \,\&\, MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \,\&\, MBCCFRn[CCFMSK]$$

54.7.7.2 Message Buffer Channel Assignment Consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFRn[CHA] = 1 and transmits or receives on channel B if FR_MBCCFRn[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined, if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in the figure below.

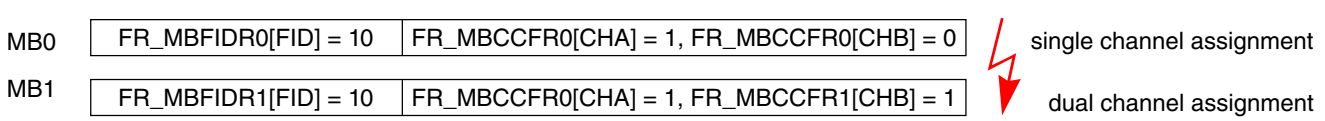

Figure 54-19. Inconsistent Channel Assignment

54.7.7.3 Node Related Slot Multiplexing

The term *Node Related Slot Multiplexing* applies to the dynamic segment only and refers to the functionality if there are transmit as well as receive message buffers are configured for the same slot.

According to Table 54-51 the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

54.7.7.4 Message Buffer Search Error

There are two kinds of errors which may occur during message buffer search[1].

54.7.7.4.1 Message Buffer Search Start while Running

If the message buffer search is running in slot *n-1* and the next message buffer search start event appears due to the start of slot *n*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *n*. Additionally, the search engine will not be started in slot *n*, and consequently no individual message buffer is identified for transmission or reception in slot *n+1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see Number of Usable Message Buffers.

54.7.7.4.2 Illegal Message Buffer Index Found

If the message buffer search has finished the message buffer search in slot *n-1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) is set and no individual message buffer is identified for transmission or reception in slot

1. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

n. The legal message buffer index values for the individual and receive shadow buffers are specified in the Receive Shadow Buffer Index Register section (FR_RSBIR) and the Message Buffer Index Registers sections (FR_MBIDXRn).

54.7.8 Individual Message Buffer Reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data can not be reconfigured when the protocol is out of the *POC:config* state.

54.7.8.1 Reconfiguration Schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

54.7.8.1.1 Basic Type Not Changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSRn[MTD] are not changed. This type of reconfiguration is denoted by RC1 in Figure 54-20. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

54.7.8.1.2 Buffer Type Not Changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in the figure below. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

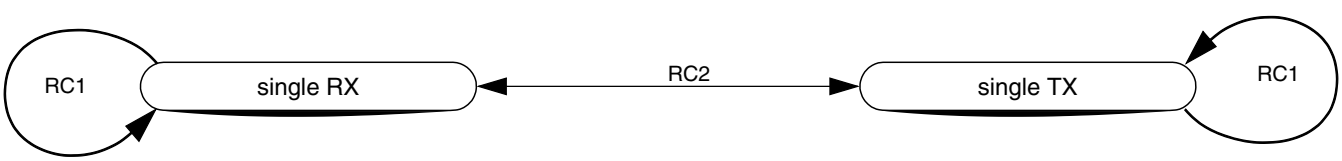

Figure 54-20. Message Buffer Reconfiguration Scheme

54.7.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

54.7.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, the other FIFO is assigned to channel B. Both FIFOs work completely independent from each other.

The message buffer structure of each FIFO is described in Receive FIFO. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- *The FIFO system memory base address*
- *The index of the first FIFO entry given by Receive FIFO Start Index Register (FR_RFSIR)*
- *The data field offset of the data field belonging to the first FIFO entry given by Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *The number of FIFO entries and the length of each FIFO entry as given by Receive FIFO Depth and Size Register (FR_RFDSR)*

54.7.9.2 FIFO Configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO address mode bit FAM in the Module Configuration Register (FR_MCR).

54.7.9.2.1 Single System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is System Memory Base Address Register (FR_SYMBADR).

54.7.9.2.2 Dual System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data are given in Receive FIFO Control and Configuration Data. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details see FlexRay Memory Area Layout.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

- Configure the FIFO update and address modes in Module Configuration Register (FR_MCR)
- Configure the FIFO system memory base address
- Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO
- Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth
- Configure the FIFO Filters

54.7.9.3 FIFO Periodic Timer

The FIFO periodic timer is used to generate an FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached, but the FIFO is not empty. This can be used to prevent frames from get stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

54.7.9.4 FIFO Reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO, if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case the FIFO filter path shown in Figure 54-21 is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

54.7.9.5 FIFO Almost-Full Interrupt Generation

If the fifo fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM, i.e. FLA>WM_A (FLB>WM_B), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

If the periodic timer expires, and FIFOA (FIFOB) is not empty, i.e. FLA>0 (FLB>0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

54.7.9.6 FIFO Overflow Error Generation

If the FIFOA (FIFOB) is full, i.e. FLA=$FIFO\_DEPTH_A$ (FLB=$FIFO\_DEPTH_B$) and the conditions for a FIFO reception as described in FIFO Reception are fulfilled, then the fifo overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

54.7.9.7 FIFO Message Access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the

(Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to Equation 1-125.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, than the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to Equation 1-125. The application can access the message data as described in Receive FIFO. When the application has read the message buffer data and status information, it can update the FIFO as described in FIFO Update.

54.7.9.8 FIFO Update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

54.7.9.8.1 FIFO Interrupt Flag Update

The FIFO Interrupt Flag Update mode is configured, when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode FIFOA (FIFOB) will be updated by 1 entry, when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1, if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

54.7.9.9 FIFO Filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in the figure below.

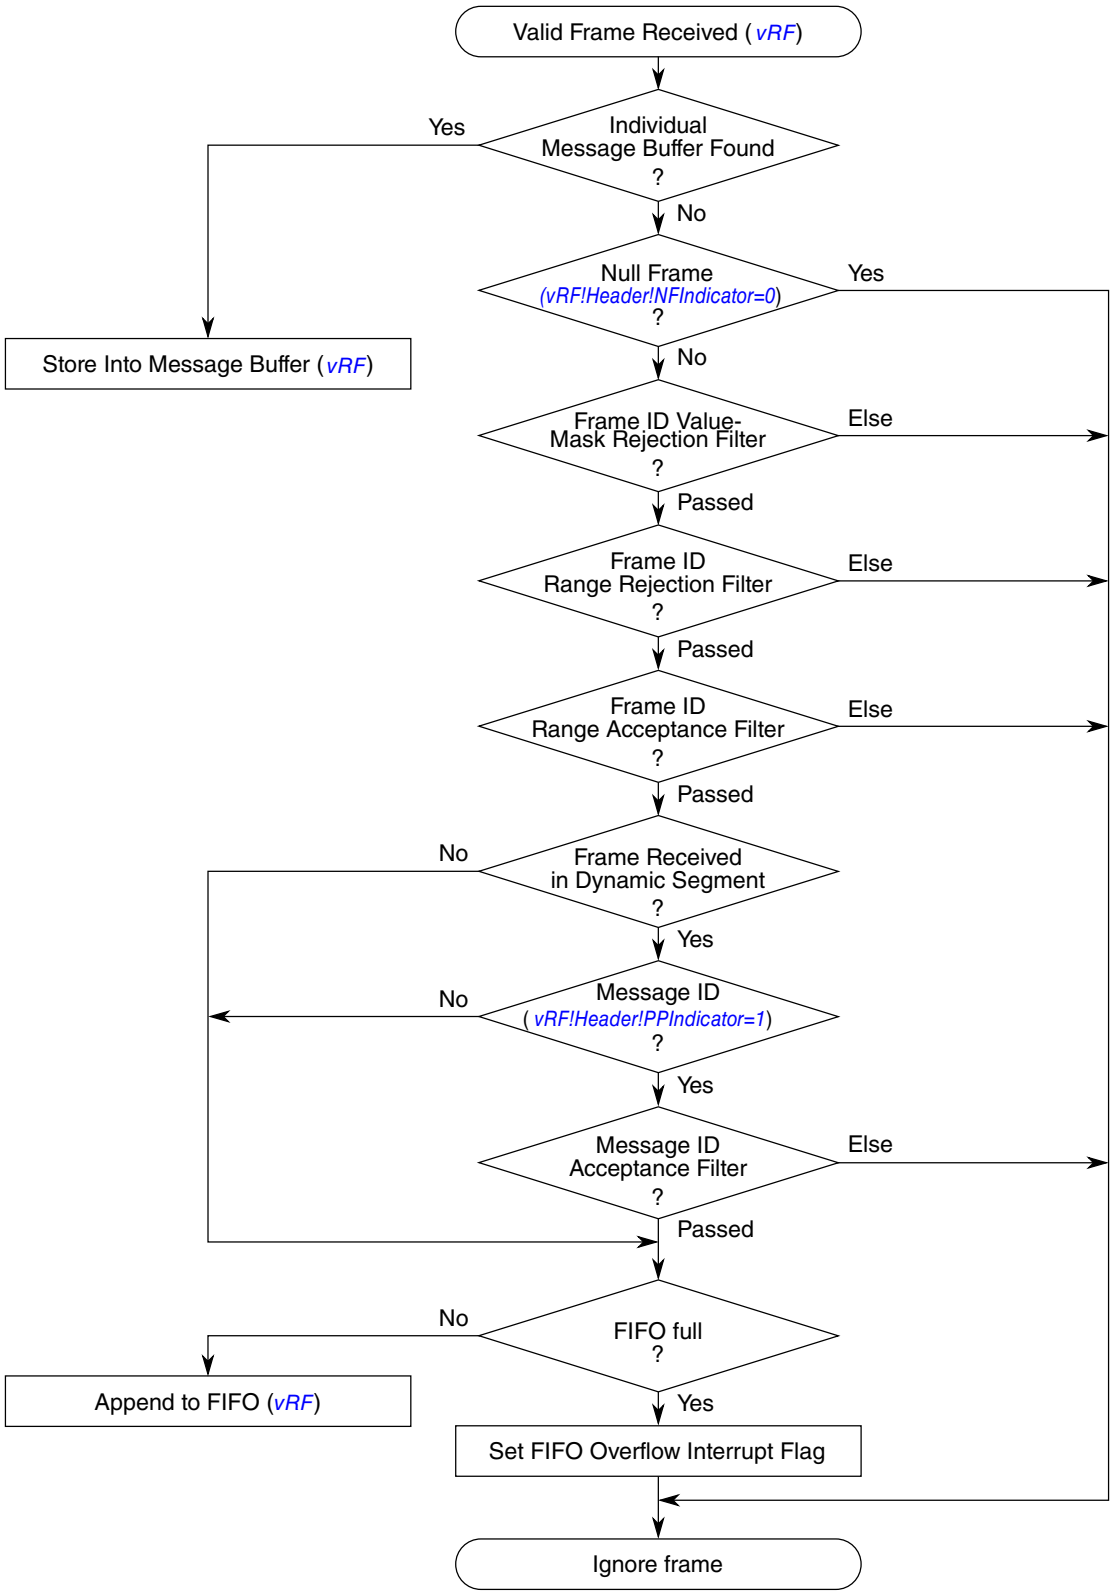

Figure 54-21. Received Frame FIFO Filter Path

A received frame passes the FIFO filtering if it has passed all three type of filter.

54.7.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter

The frame ID value-mask rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter, i.e. is not rejected.

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-Mask Rejection Filter if Equation 44 on page 2637 is fulfilled.

$$FID \,\&\, FR\_RFFIDRFMR[FIDRFMSK] \neq FR\_RFFIDRFVR[FIDRFVAL] \,\&\, FR\_RFFIDRFMR[FIDRFMSK]$$

Equation 44

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to pass all frames by the following settings.

$$FR\_RFFIDRFVR[FIDRFVAL] = 0x000 \text{ and } FR\_RFFIDRFMR[FIDRFMSK] = 0x7FF$$

Equation 45

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to reject all frames by the following settings.

$$FR\_RFFIDRFMR[FIDRFMSK] = 0x000$$

Equation 46

Using these settings, Equation 44 on page 2637 can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

54.7.9.9.2 RX FIFO Frame ID Range Rejection Filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range rejection filters if either no rejection filter is enabled, or, for all of the enabled RX FIFO Frame ID Range rejection filters, i.e. FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1, Equation 47 on page 2638 is fulfilled.

$$FID < FR\_RFRFCFR_{SEL}[SID_{IBD=0}]) or (FR\_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Equation 47

Consequently, all frames with a frame ID that fulfills Equation 48 on page 2638 for at least one of the enabled rejection filters will be rejected and thus not pass.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 48

54.7.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, for at least one of the enabled RX FIFO Frame ID Range acceptance filters, i.e. FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1, Equation 49 on page 2638 is fulfilled.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 49

54.7.9.9.4 RX FIFO Message ID Acceptance Filter

The RX FIFO Message ID Acceptance Filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance Filter if Equation 50 on page 2638 is fulfilled.

$$MID \,\&\, FR\_RFMIDAFMR[MIDAFMSK] = FR\_RFMIDAFMR[MIDAFVAL] \,\&\, FR\_RFMIDAFMR[MIDAFMSK]$$

Equation 50

The RX FIFO Message ID Acceptance Filter can be configured to accept all frames by setting

$$FR\_RFMIDAFMR[MIDAFMSK] := 0x000$$

Equation 51

Using these settings, Equation 50 on page 2638 is always fulfilled and all frames will pass.

54.7.10 Channel Device Modes

This section describes the two FlexRay channel device modes that are supported by the CC.

54.7.10.1 Dual Channel Device Mode

In the dual channel device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and $\overline{\text{FR\_B\_TX\_EN}}$ is connected to the physical bus channel B. The dual channel system is shown in the following figure.

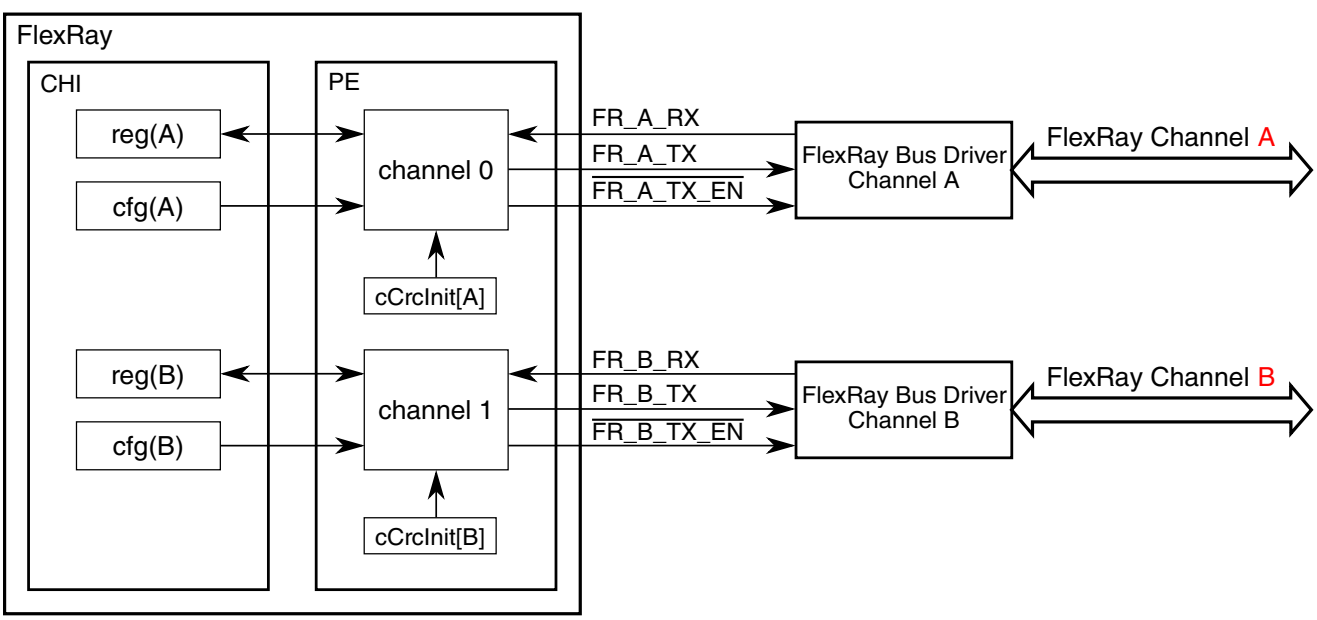

Figure 54-22. Dual Channel Device Mode

54.7.10.2 Single Channel Device Mode

The single channel device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ and can be connected to either the physical bus channel A (shown in the "Single Channel Device Mode (Channel A)" figure below) or the physical bus channel B (shown in the "Single Channel Device Mode (Channel B)" figure below).

If the device is configured as a single channel device by setting FR_MCR[SCM] to 1, only the internal channel A and the FlexRay Port A is used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay Channel A or FlexRay Channel B. The bit FR_MCR[CHA] must be set, if the FlexRay Port A is connected to a FlexRay Channel A. The bit FR_MCR[CHB] must be set if the FlexRay Port A is connected to a FlexRay Channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single channel device, the application can access and configure only the registers related to internal channel A.

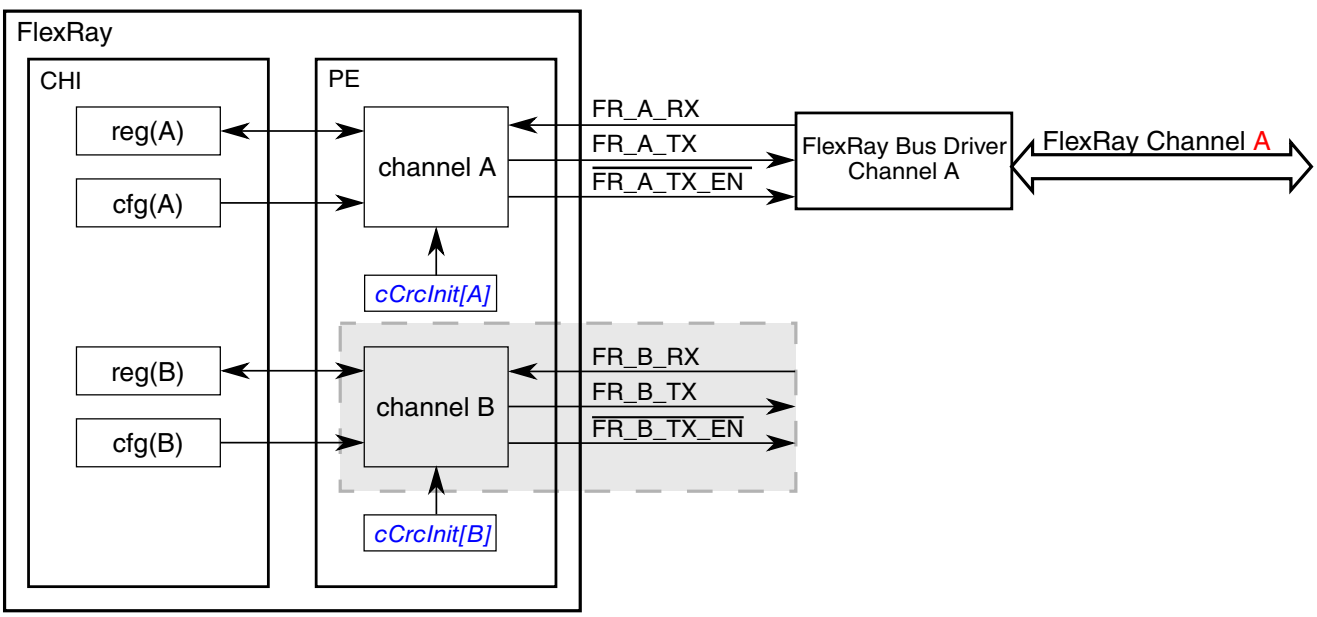

Figure 54-23. Single Channel Device Mode (Channel A)

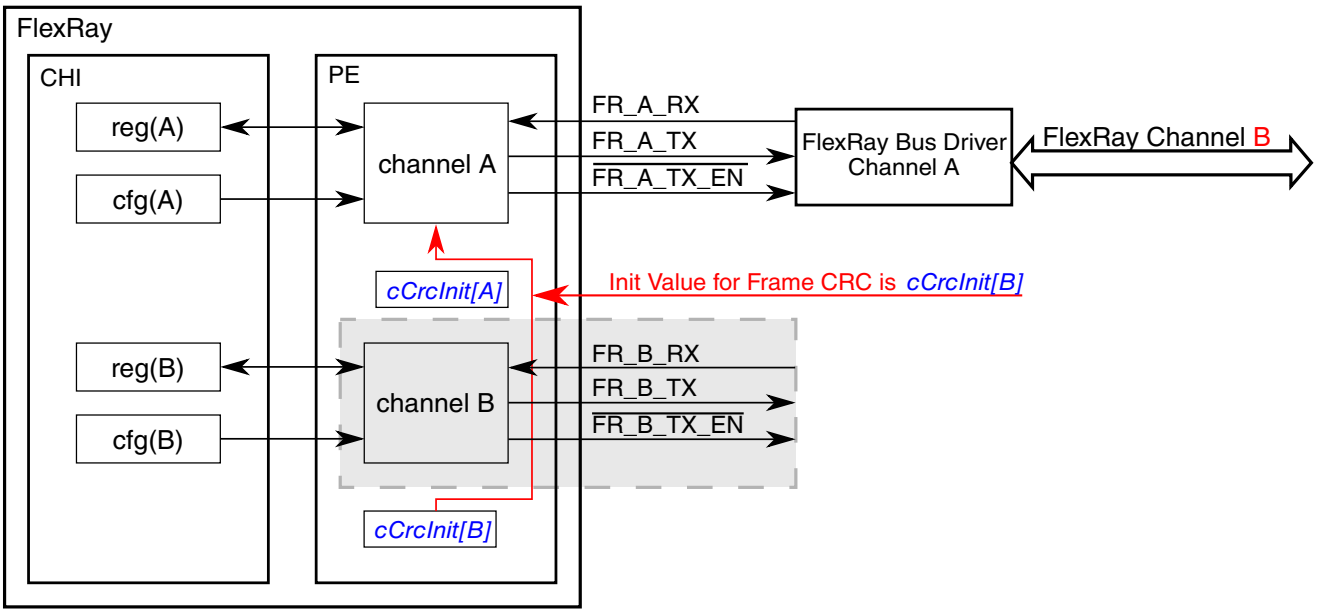

Figure 54-24. Single Channel Device Mode (Channel B)

54.7.11 External Clock Synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in the "External Offset Correction Write and Application Timing" figure and the "External Rate Correction Write and Application Timing" figures below.

Note

The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n+1 shall be affect by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end of the static segment of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle 2n+1. If the value is not applied in cycle 2n+1, then the value will be applied in the cycle 2n+3. Refer to the following for timing details.

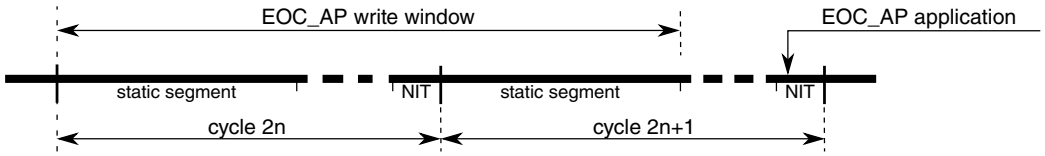

Figure 54-25. External Offset Correction Write and Application Timing

If the rate correction for the cycle pair [2n+2, 2n+3] shall be affect by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle pair [2n+2, 2n+3]. If the value is not applied for cycle pair [2n+2, 2n+3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to the following for details.

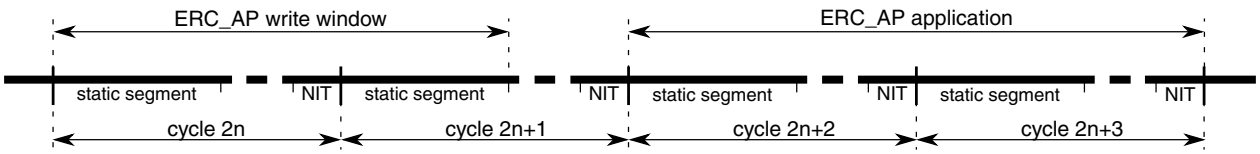

Figure 54-26. External Rate Correction Write and Application Timing

54.7.12 Sync Frame ID and Sync Frame Deviation Tables

The FlexRay protocol requires the provision of a snapshot of the Synchronization Frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note

Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

54.7.12.1 Sync Frame ID Table Content

The Sync Frame ID Table is a snapshot of the protocol related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

54.7.12.2 Sync Frame Deviation Table Content

The Sync Frame Deviation Table is a snapshot of the protocol related variable zsDev(id)(oe)(ch)!Value. Each Sync Frame Deviation Table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the Sync Frame ID Table.

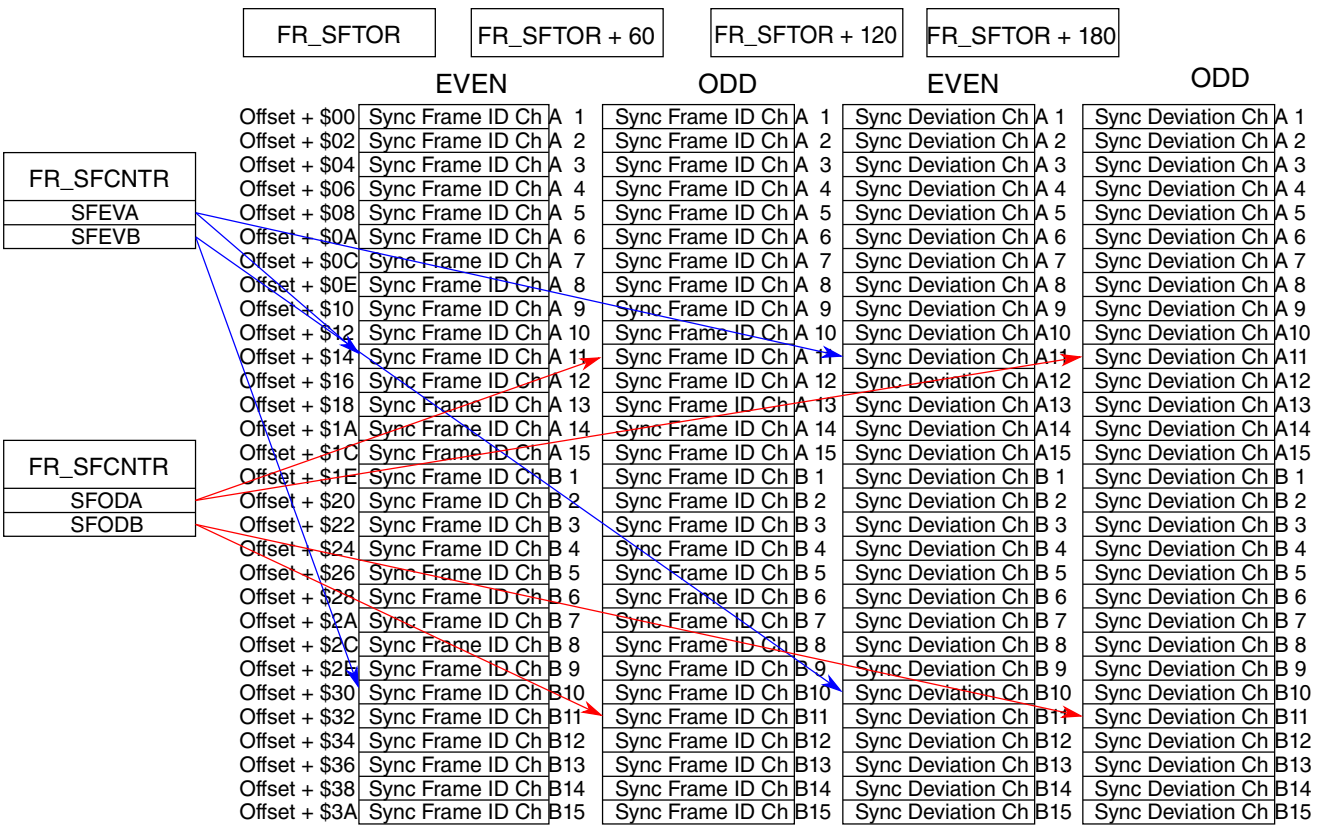

Figure 54-27. Sync Table Memory Layout

54.7.12.3 Sync Frame ID and Sync Frame Deviation Table Setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in Figure 54-27. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

54.7.12.4 Sync Frame ID and Sync Frame Deviation Table Generation

The application controls the generation process of the Sync Frame ID and Sync Frame Deviation Tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in the table below.

Table 54-52. Sync Frame Table Generation Modes

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No Sync Frame Table copy
0	0	1	Sync Frame ID Tables will be copied continuously
0	1	0	Reserved
0	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables will be copied continuously
1	0	0	No Sync Frame Table copy
1	0	1	Sync Frame ID Tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables for next even-odd-cycle pair will be copied

The Sync Frame Table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even cycle related tables after the start of the NIT of the next even cycle. The CC checks if the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. Once all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating these tables. The locking is initiated by writing a 1 to the even table lock trigger FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding

status information fields SFRA, SFRB in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in Figure 54-27.

After reading all the data from the locked tables, the application must unlock the table by writing to the even table lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

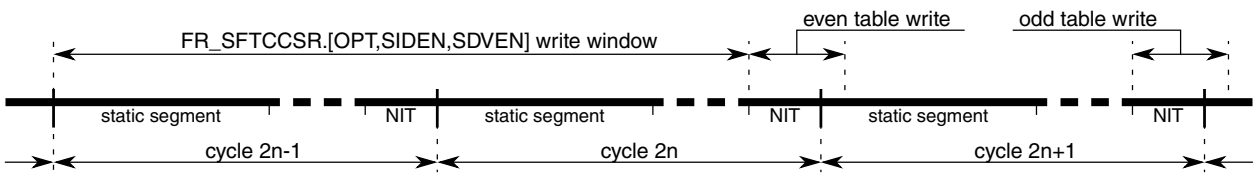

Figure 54-28. Sync Frame Table Trigger and Generation Timing

54.7.12.5 Sync Frame Table Access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in Figure 54-27. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

54.7.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

54.7.13 MTS Generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol MTS in the symbol window on channel A or channel B.

The application can configure the set of communication cycles in which the MTS will be transmitted over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR\_PSR0[PROTSTATE] = POC:\ normalactive$$

Equation 52

$$FR\_MTSACRF[MTE] = 1$$

Equation 53

$$CYCCNT \,\&\, FR\_MTSACFR[CYCCNTMSK] = FR\_MTSACFR[CYCCNTVAL] \,\&\, FR\_MTSACFR[CYCCNTMSK]$$

Equation 54

The MTS is transmitted over channel B in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR\_MTSBCRF[MTE] = 1$$

Equation 55

$$CYCCNT \,\&\, FR\_MTSBCFR[CYCCNTMSK] = FR\_MTSBCFR[CYCCNTVAL] \,\&\, FR\_MTSBCFR[CYCCNTMSK]$$

Equation 56

54.7.14 Key Slot Transmission

Key slot assignment, transmission in POC:startup state, and transmission in POC:normal active state are discussed in this section.

54.7.14.1 Key Slot Assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2), otherwise no key slot is assigned.

54.7.14.2 Key Slot Transmission in POC:startup

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version *2.1 Rev A* .

54.7.14.3 Key Slot Transmission in POC:normal active

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in the following table is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see Message Transmission). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see Null Frame Transmission).

Table 54-53. Key Slot Frame Type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	normal frame
0	1	normal frame1[1]
1	0	sync frame
1	1	startup frame

1. The frame transmitted has an semantically incorrect header and will be detected as an invalid frame at the receiver.

54.7.15 Sync Frame Filtering

Each received synchronization frame must pass the Sync Frame Acceptance Filter and the Sync Frame Rejection Filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled, i.e. the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared, all received synchronization

frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

54.7.15.1 Sync Frame Acceptance Filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if the following equations evaluates to true.

$$FR\_MCR[SFFE] = 0$$

Equation 57

$$FID \,\&\, FR\_SFIDAFMR[FMSK] = FR\_SFIDAFVR[FVAL] \,\&\, FR\_SFIDAFMR[FMSK]$$

Equation 58

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

54.7.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if the following equations evaluates to true.

$$FR\_MCR[SFFE] = 0$$

Equation 59

$$FID \neq FR\_SFIDRFR[SYNFRID]$$

Equation 60

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

54.7.16 Strobe Signal Support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in the Strobe Signal Mapping table, located in the Register Descriptions section.

54.7.16.1 Strobe Signal Assignment

Each of the strobe signals listed in the Strobe Signal Mapping table, located in the Register Descriptions section, can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

To read out the current settings for a strobe signal with number N, the application must execute the following sequence.

1. Write to FR_STBSCR with WMD = 1 and SEL = N. (updates SEL field only)
2. Read STBCSR.

   The SEL field provides N and the ENB and STBPSEL fields provides the settings for signal N.

54.7.16.2 Strobe Signal Timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay Bus. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a negative clock offset. An example waveform is given in the following figure.

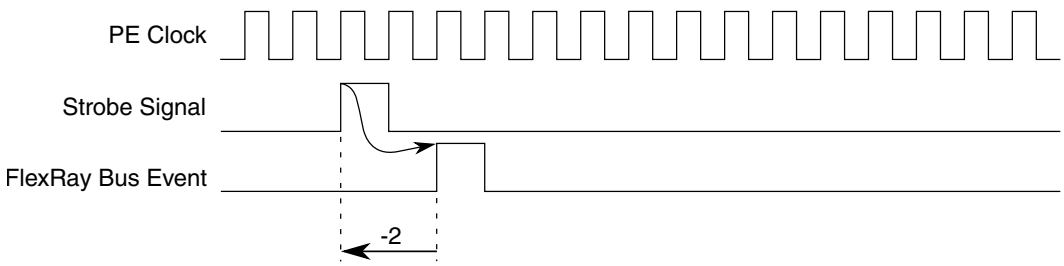

Figure 54-29. Strobe Signal Timing (type = pulse, clk_offset = -2)

Other signals refer to events that occurred on the FlexRay Bus some cycles before the strobe signal is changed. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a positive clock offset. An example waveform is given in the figure below.

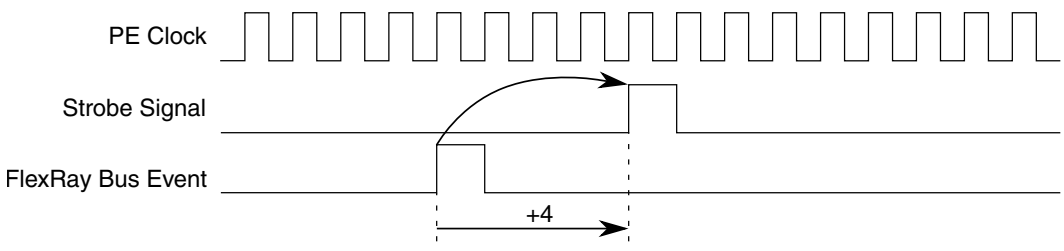

Figure 54-30. Strobe Signal Timing (type = pulse, clk_offset = +4)

54.7.17 Timer Support

The CC provides two timers, which run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In the non-repetitive mode, timer stops if it expires. In repetitive mode, timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

54.7.17.1 Absolute Timer T1

The absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if the following equations are fulfilled.

$$CYCTR[CTCCNT] \& FR\_TI1CYSR[T1\_CYC\_MSK] = FR\_TI1CYSR[T1\_CYC\_VAL] \& FR\_TI1CYSR[T1\_CYC\_MSK]$$

Equation 61

$$FR\_MTCTR[MTCT] = FR\_TI1MTOR[T1\_MTOFFSET]$$

Equation 62

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding Interrupt condition (i.e., when the abovementioned equations are fulfilled) also leads to an event out indication on an output port (*fr_evt_tim1*) based on the [TIM1_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

54.7.17.2 Absolute / Relative Timer T2

The timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

54.7.17.2.1 Absolute Timer T2

If timer T2 is configured as an absolute timer, it has the same functionality timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. On expiration of timer T2, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

54.7.17.2.2 Relative Timer T2

If the timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set, when the programmed amount of macroticks MT[31:0], defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1), has expired since the trigger or restart of timer 2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr_evt_tim2*) based on the [TIM2_EE] bit of the Protocol Event Output Enable Register (FR_PEOER).

54.7.18 Slot Status Monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per channel base. The content of the slot status vector is described in the "Slot Status Content" table below. The PE provides the slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in the below figure.

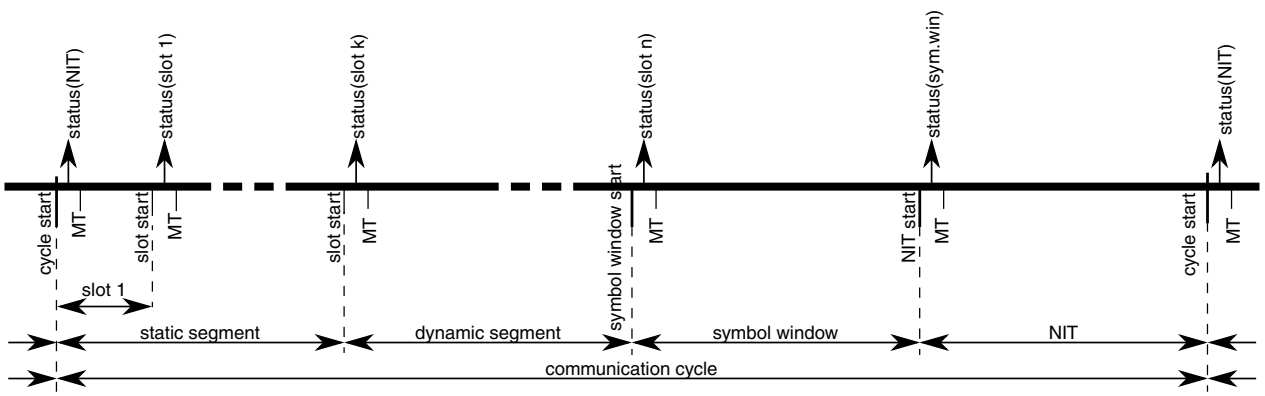

Figure 54-31. Slot Status Vector Update

Note

The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 54-54. Slot Status Content

	Status Content
static /dynamic Slot	**slot related status**

Table continues on the next page...

Table 54-54. Slot Status Content (continued)

	Status Content
	vSS!ValidFrame - valid frame received
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!ContentError - content error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict - reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict - reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	received frame related status
	extracted from
	a)header of valid frame, if vSS!ValidFrame = 1
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator - Null Frame Indicator (0 for null frame)
	vRF!Header!SuFIndicator - Startup Frame Indicator
	vRF!Header!SyFIndicator - Sync Frame Indicator
Symbol Window	**window related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - reception ongoing while transmission starts
	received symbol related status
	vSS!ValidMTS - valid Media Test Access Symbol received
	received frame related status
	see static/dynamic slot
NIT	**NIT related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - always 0
	received frame related status
	see static/dynamic slot

54.7.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR), incremented by one, if at least one of four slot status error bits, *vSS!SyntaxError, vSS! ContentError, vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap round after they have reached the maximum value.

54.7.18.2 Protocol Status Registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the Network Idle Time NIT and the Symbol Window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.

54.7.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status related and received frame / symbol related status information, as given in Table 54-54, except of the *first valid* indicator for non-transmission slots.

54.7.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in the figure below.

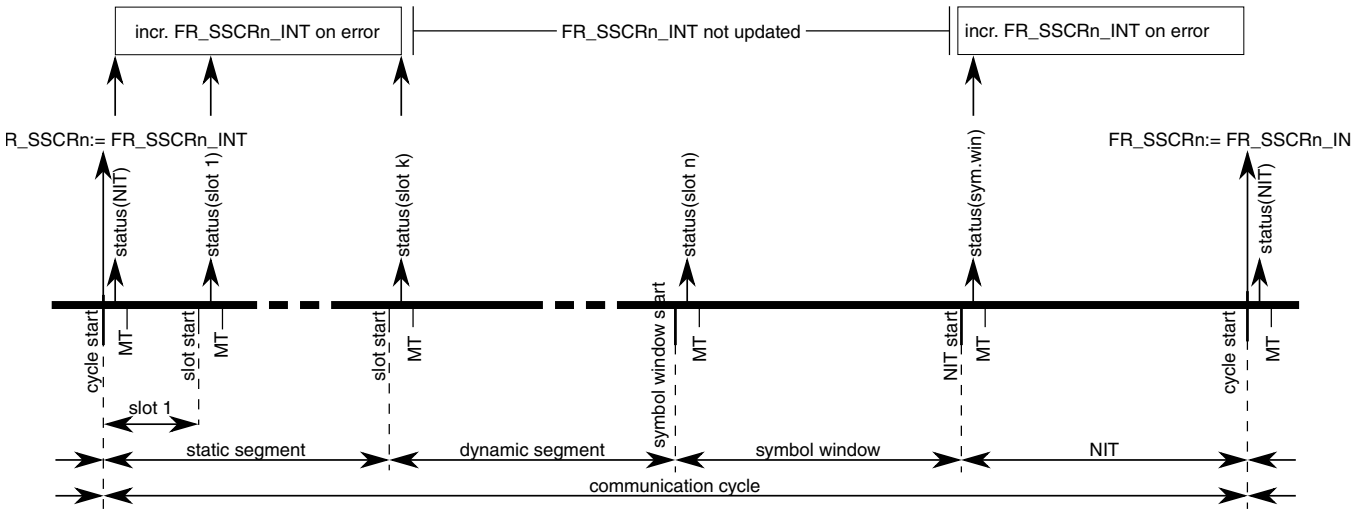

Figure 54-32. Slot Status Counting and FR_SSCRn Update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCRn register reflects, in cycle n, the status of the NIT of cycle n-2, and the status of all static slots and the symbol window of cycle n-1.

The increment condition for each slot status counter consists of two parts, the frame related condition part and the slot related condition part. The internal slot status counter FR_SSCRn_INT is incremented if at least one of the conditions is fulfilled:

1. frame related condition:

   (FR_SSCCRn[VFR] | FR_SSCCRn[SYF] | FR_SSCCRn[NUF] | FR_SSCCRn[SUF]) // count on frame condition

   = 1;

   and

   ((~FR_SSCCRn[VFR] | vSS!ValidFrame) & // valid frame restriction

   (~FR_SSCCRn[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction

   (~FR_SSCCRn[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction

   (~FR_SSCCRn[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction

   = 1;

Note

The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus it is required to set the VFR always, whenever count on frame condition is used.

slot related condition:

((FR_SSCCRn[STATUSMASK[3]] & vSS!ContentError) | // increment on content error

(FR_SSCCRn[STATUSMASK[2]] & vSS!SyntaxError) | // increment on syntax error

(FR_SSCCRn[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation

(FR_SSCCRn[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict

= 1;

If the slot status counter is in single cycle mode, i.e. FR_SSCCRn[MCY] = 0, the internal slot status counter FR_SSCRn_INT is reset at each cycle start. If the slot status counter is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset and incremented, until the maximum value is reached.

54.7.18.5 Message Buffer Slot Status Field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in Table 54-54 for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update Sections in Individual Message Buffer Configuration Data.

54.7.19 System Bus Access

This section provides a description of the system bus accesses failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in System Bus Access Failure Types.

The behavior of the CC after the occurrence of a system bus access failure is described in System Bus Access Failure Response.

54.7.19.1 System Bus Access Failure Types

This section describes the two types of system bus access failures.

54.7.19.1.1 System Bus Illegal Address Access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions which are treated as a system bus illegal address access:

- The system bus subsystem detects an CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see CHI LRAM Error Response after CC Read).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

54.7.19.1.2 System Bus Access Timeout

A system bus access timout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see Configure System Memory Access Time-Out Register (FR_SYMATOR)).

If a system bus access timout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

54.7.19.2 System Bus Access Failure Response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

54.7.19.2.1 Continue after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is 0, the CC will continue its operation after the occurrence of the system bus access failure, but will not generate any system bus accesses until the start of the next communication cycle.Since no

data are read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated with the remaining header and frame data are replaced by all zeros. Depending on the point in time this can affect the PPI bit, the Header CRC, the Payload Length in case of an dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted and received, except for the key slot, where a sync or startup null-frame is transmitted, if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

54.7.19.2.2 Freeze after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is set to 1, the CC will go into the freeze mode immediately after the occurrence of one of the system bus access failures.

54.7.20 Interrupt Support

The CC provides 172 individual interrupt sources and five combined interrupt sources.

54.7.20.1 Individual Interrupt Sources

Message buffer interrupts are discussed in this section.

54.7.20.1.1 Message Buffer Interrupts

The CC provides 128 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSRn[MBIF] and an interrupt enable bit FR_MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

54.7.20.1.2 FIFO Interrupts

The CC provides 2 FIFO interrupt sources.

Each of the 2 FIFO provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding Receive FIFO fill level exceeds the defined watermark.

54.7.20.1.3 Wakeup Interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

54.7.20.1.4 Protocol Interrupts

The CC provides 25 interrupt sources for protocol related events. For details, see Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

54.7.20.1.5 CHI Interrupts

The CC provides 16 interrupt sources for CHI related error events. For details, see CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

54.7.20.2 Combined Interrupt Sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

54.7.20.2.1 Receive Message Buffer Interrupt

The Receive Message Buffer Interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

54.7.20.2.2 Transmit Message Buffer Interrupt

The Transmit Message Buffer Interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

54.7.20.2.3 Protocol Interrupt

The Protocol Interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set..

54.7.20.2.4 CHI Interrupt

The CHI Interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

54.7.20.2.5 Module Interrupt

The Module Interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

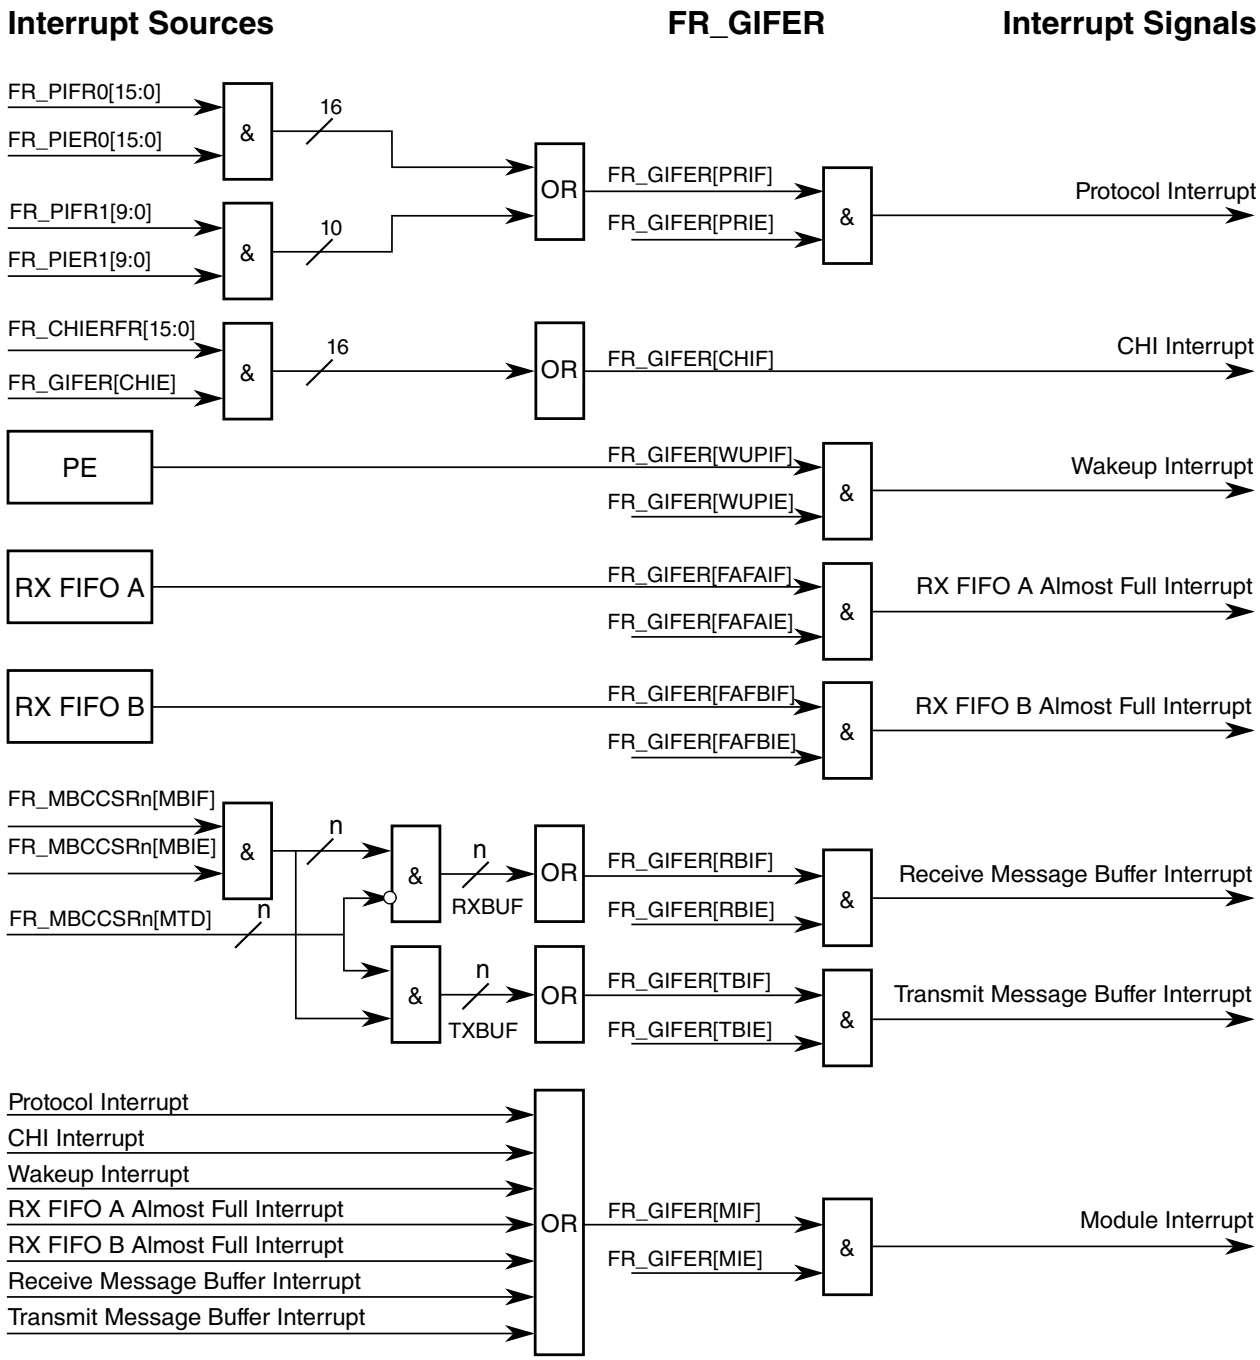

Figure 54-33. Scheme of FR_GIFER interrupt signal generation

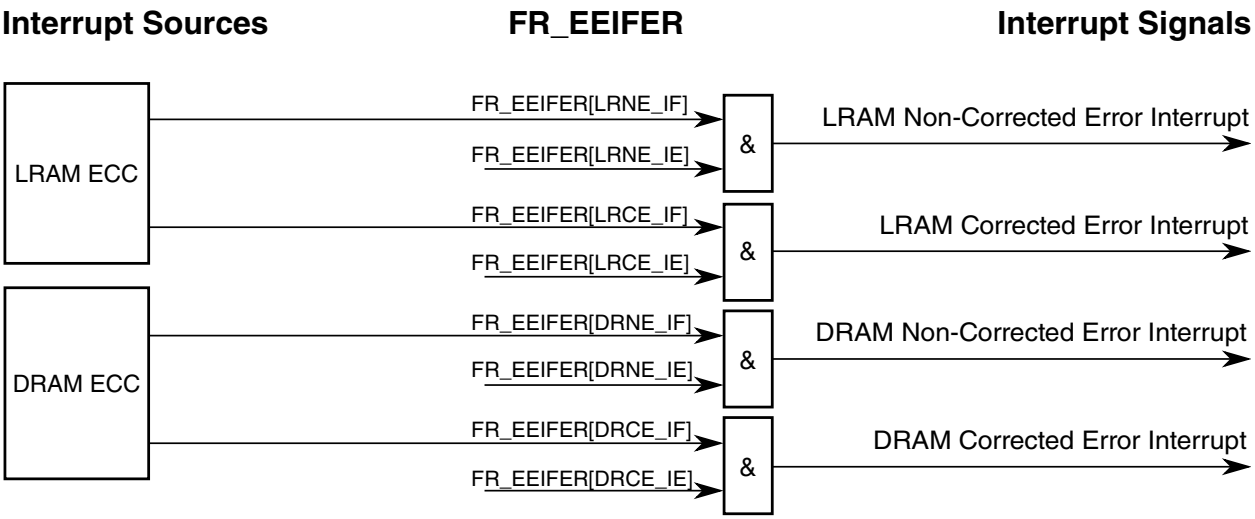

Figure 54-34. Scheme of FR_EEIFER interrupt signal generation

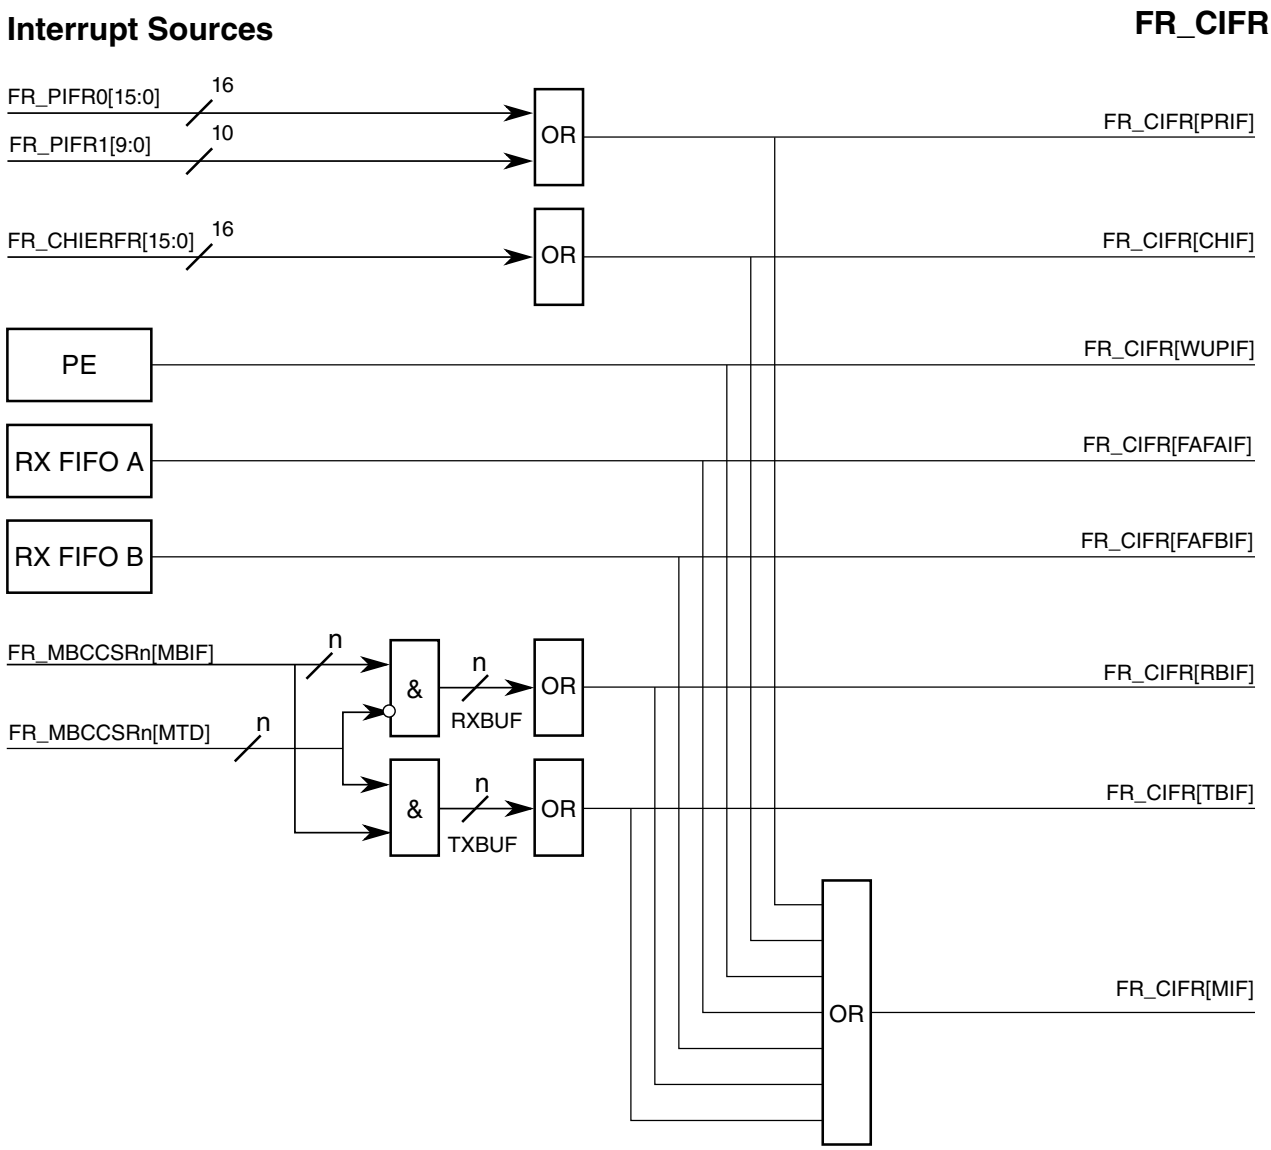

Figure 54-35. Scheme of FR_CIFR flags generation

54.7.21 Lower Bit Rate Support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings and related protocol parameter values are shown in the "FlexRay Channel Bit Rate Control" table below.

Table 54-55. FlexRay Channel Bit Rate Control

FlexRay Channel Bit Rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick [ns]*	*gdSampleClockPeriod [ns]*	*pSamplesPerMicrotick*	*cSamplesPerBit*	*cStrobeOffset*
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note

The bit rate of 8 Mbit/s is not defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

54.7.22 PE Data Memory (PE DRAM)

The PE Data Memory (PE DRAM) is 128 word, 16-bit wide memory with byte access, which contains the program data of the PE internal CPU. The PE DRAM is divided into two banks, 8-bit each. The memory data [7:0] are assigned to BANK0, the memory data [15:8] are assigned to BANK1.

Table 54-56. PE DRAM Layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via PE DRAM Access Register (FR_PEDRAR) and PE DRAM Access Register (FR_PEDRAR). This functionality is used to check the memory error detection.

54.7.22.1 PE DRAM Read Access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;

   // INST=0x5; ADDR=070

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA];

   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25us).

54.7.22.2 PE DRAM Write Access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;

   // write value to be written into data register

2. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

3. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

4. val = FR_PEDRDR[DATA];

   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may causes an response delay with a maximum of 1000 PE clock cycle (25us).

If the conditions given in PE DRAM Write Access Limitations are fulfilled, the data provided in PE DRAM Access Regsiter (FR_PEDRAR) are written into the PE DRAM, read back in the next clock cycle and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data are not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

54.7.22.3 PE DRAM Write Access Limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not *in POC:default config* state, only PE DRAM address 0x70 is writable.

54.7.23 CHI Lookup-Table Memory (CHI LRAM)

The CHI Lookup-Table Memory (CHI LRAM) is an CHI internal memory which contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or 6 data field offsets are contained in one memory row. The CHI LRAM is divided into 6 memory BANKs.

Table 54-57. CHI LRAM Layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x3F	FR_MBIDXR127	FR_MBFIDR127	FR_MBCCFR127	FR_MBIDXR126	FR_MBFIDR126	FR_MBCCFR126
0x40	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0x55	FR_MBDOR131	FR_MBDOR130	FR_MBDOR129	FR_MBDOR128	FR_MBDOR127	FR_MBDOR126
0x56	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

54.7.23.1 CHI LRAM Read and Write Access

The CHI LRAM is accessed by the application via regular register read and write accesses.

54.7.24 Memory Content Fault Detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses an standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED) . The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

54.7.24.1 Memory Error Types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as an special case. The FlexRay module detects and indicates the memory errors as shown in the "Detected Memory Error Types" table below. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row, and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error free bank has been read.

Table 54-58. Detected Memory Error Types

Memory	Priority	Memory Data	Indication
CHI LRAM	0 (highest)	All Zero's	Non-Corrected Error
PE DRAM			Non-Corrected Error
CHI LRAM		All One's	Non-Corrected Error
PE DRAM			
CHI LRAM	1 (lowest)	One Bit Flipped	Non-Corrected Error
PE DRAM			Corrected Error

Table continues on the next page...

Table 54-58. Detected Memory Error Types (continued)

Memory	Priority	Memory Data	Indication
CHI LRAM		Two Bits Flipped	Non-Corrected Error
PE DRAM			
CHI LRAM		Three or more Bits Flipped	one out of {No error, Non-Corrected Error}, defined by coding given in CHI LRAM Checkbits and CHI LRAM Syndrome
PE DRAM			one out of {No error, Corrected Error, Non-Corrected Error}, defined by coding given in PE DRAM Checkbits and PE DRAM Syndrome

54.7.24.2 Memory Error Reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories exists two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- *If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.*
- *If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.*

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to above the Error indications (corrected / non corrected) along with the failing address is sent out from the module for external error logging and corrective actions by the Software.

54.7.24.2.1 PE DRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in Table 54-58. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 54-59. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4[1]	X	X	X	X	X	X	X	X	X	X	X	X
3[2]	-	-	-	-	X	X	X	X	-	-	-	-
2	-	-	-	-	X	-	-	-	X	X	X	-
1	-	-	-	-	-	X	X	-	X	X	-	X
0	-	-	-	-	-	X	-	X	X	-	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is a even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is a odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words and written into the memory.

54.7.24.2.2 PE DRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in the following table.

Table 54-60. FR_EERCR[CODE] PE DRAM Syndrome Coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (Never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected Error (Parity Bit 0)
0x0	0x2	Corrected Error (Parity Bit 1)
0x0	0x3	Corrected Error (Data Bit 0)
0x0	0x4	Corrected Error (Parity Bit 2)
0x0	0x5	Corrected Error (Data Bit 1)
0x0	0x6	Corrected Error (Data Bit 2)
0x0	0x7	Corrected Error (Data Bit 3)
0x0	0x8	Corrected Error (Parity Bit 3)
0x0	0x9	Corrected Error (Data Bit 4)

Table continues on the next page...

Table 54-60. FR_EERCR[CODE] PE DRAM Syndrome Coding (continued)

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x0	0xA	Corrected Error (Data Bit 5)
0x0	0xB	Corrected Error (Data Bit 6)
0x0	0xC	Corrected Error (Data Bit 7)
0x0	0xD-0xF	Non-Corrected Error
0x1	0x1-0xF	Non-Corrected Error

54.7.24.2.3 CHI LRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the table below. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 54-61. CHI LRAM checkbits coding

CODE[1]	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	-	-	-	-	-	-	-	-	-	-	-
3	-	-	-	-	-	X	X	X	X	X	X	X	-	-	-	-
2	X	X	-	-	-	X	X	X	X	-	-	-	X	X	X	-
1	-	-	X	X	-	X	X	-	-	X	X	-	X	X	-	X
0	X	-	X	-	X	X	-	X	-	X	-	X	X	-	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is a odd number of 1's in all columns with X.

54.7.24.2.4 CHI LRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the next table.

Table 54-62. FR_EERCR[CODE] CHI LRAM Syndrome Coding

FR_EERCR[CODE]	Description
0x00	No Error (Never appears in error report registers)
0x01-0x1F	Non Corrected Error

54.7.24.3 Memory Error Response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case of the detection of a *corrected* memory error, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

54.7.24.3.1 CHI LRAM Error Response after CC Read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access the error response of the module depends from LRAM location where the error occurred.

- *If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.*

  If the affected message buffer is a tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is a rx message buffer, no frame will be received to this message buffer in the next slot.

- *If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs w.r.t. payload access is performed for the complete frame.*

54.7.24.3.2 CHI LRAM Error Response after Application Read

The application can read the content of the CHI LRAM via reading the FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn, FR_MBDORn, and FR_LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read and continues its normal operation.

54.7.24.3.3 PE DRAM Error Response after CC Read

If the CC detects an non-corrected memory error during internal read of program data which is contained in PE DRAM, this is considered as an fatal protocol error and the module enters the protocol freeze state immediately.

54.7.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered as an fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

54.7.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address, and the protocol is not in the *POC:default config* state, this error is not considered as an fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

54.7.25 Memory Fault Injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

The error injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).

When the error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

54.7.25.1 CHI LRAM Error Injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in Table 54-57.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see Memory Fault Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality
2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode
3. FR_EEIAR[MID]:= 1;

   // select CHI LRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;

   // select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. FR_EEIAR[ADDR]:= I_ADDR;

   // select address for error injection; I_ADDR <= 0x 56
6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern
8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;

If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;

If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;

If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;

If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;

If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;

// write DATA to the defined injection bank and injection address (see Table 54-57).

54.7.25.2 PE DRAM Error Injection

The following sequence describes an memory error injection sequence for the PE DRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see PE DRAM Error Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality

2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode

3. FR_EEIAR[MID]:= 0;

   // select PE DRAM for error injection

4. FR_EEIAR[BANK]:= I_BANK;

   // define bank for error injection; I_BANK = {0,1}

5. FR_EEIAR[ADDR]:= I_ADDR;

   // define address for error injection; I_ADDR <= 0x7F

6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access (e.g. I_ADDR=0x70):

1. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA]; |

   // get read back PE DRAM data

Note

The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

54.7.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick and are fulfilled.

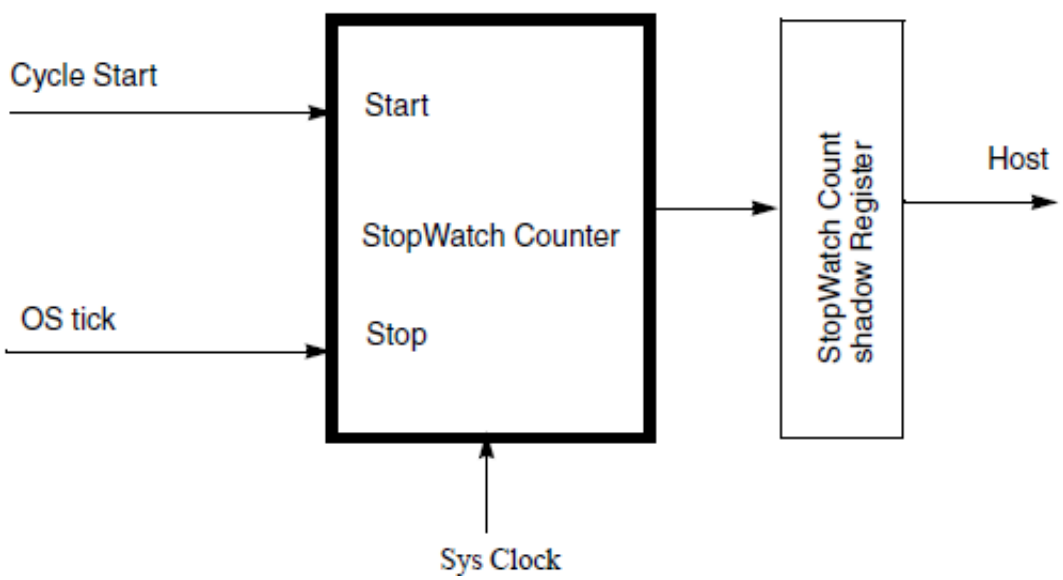

Figure 54-36. StopWatch counter logic

As shown below, there is a 32 bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (Stop Watch Count Register (FR_STPWR)) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared. The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (Protocol Event Output Enable and StopWatch Control Register (FR_PEOER). The counter runs only when this bit is set. The following figure shows the actual timing of the stopwatch counter logic operation.

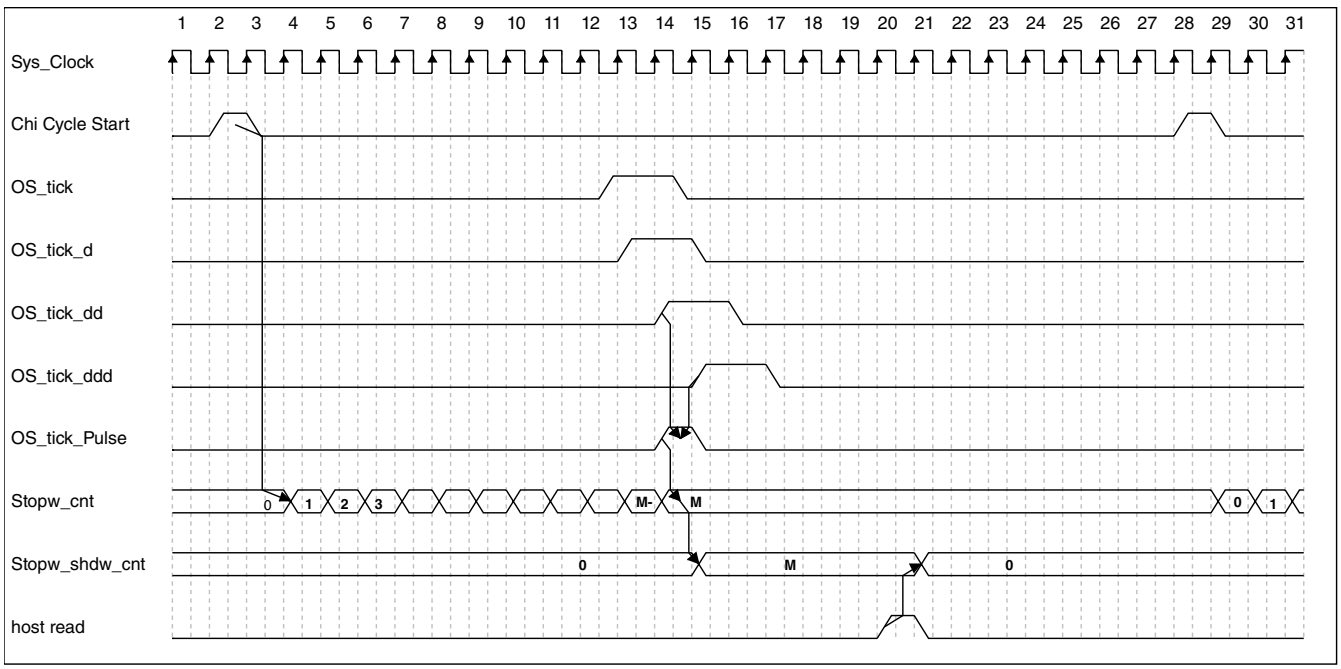

Figure 54-37. StopWatch function timing diagram

NOTE

‘Host read’ implies that all 32 bits have been read out completely. Any partial read (i.e for 8/16 bits access) will not clear the StopWatch count register.

NOTE

If cycle start and OS tick occurs simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and cycle_start has a single stage synchronizer into chi clock domain. So simultaneously here means OS_tick_pulse and chi_cycle_start occurring at the same cycle.

54.8 Application Information

Module operation is discussed in this section.

54.8.1 Module Configuration

This section describes essential parts of the module configuration.

54.8.1.1 Configure System Memory Access Time-Out Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill this equation[1] :

$$0 \le \mathrm{SYMATOR}[\mathrm{TIMEOUT}] \le \lfloor 0.45 \bullet f_{CHI} - 8 \rfloor$$

Equation 63

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in the table below.

Table 54-63. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
>= 18 MHz	0	>= 100 MHz	<= 37
>= 23 MHz	<= 2	>= 120 MHz	<= 46
>= 27 MHz	<= 4	>= 140 MHz	<= 55
>= 32 MHz	<= 6	>= 160 MHz	<= 64
>= 60 MHz	<= 19	>= 180 MHz	<= 73
>= 80 MHz	<= 28	>= 200 MHz	<= 82

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

54.8.1.1.1 System Bus Wait State Constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single channel configurations and if the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0) no timeout will be detected if less than 2 × SYMATOR[TIMEOUT]+1 wait states will be seen on the system bus for each system bus access.

For dual channel configurations, or if the sync frame table generation functionality is used, no timeout will be detected if less than SYMATOR[TIMEOUT]-1 wait states will be seen on the system bus for each system bus access.

54.8.1.2 Configure Data Field Offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDORn) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers which are used.

When the module is enabled, the initilization value of the FR_MBDORn[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (see System Bus Illegal Address Access).

54.8.2 Initialization Sequence

This section describes the required steps to initialize the CC. The first subsection describes the steps required after a module reset, the second section describes the steps required after preceding shutdown of the CC.

54.8.2.1 Module Initialization

This section describes the module related initialization steps after a system reset.

1. Configure CC.
    a. configure the control bits in the Module Configuration Register (FR_MCR)
    b. configure the system memory base address in System Memory Base Address Register (FR_SYMBADR)
2. Enable the CC.

a. write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

The CC now enters the Normal Mode. The application can commence with the protocol initialization described in Protocol Initialization.

54.8.2.2 Protocol Initialization

This section describes the protocol related initialization steps.

1. Configure the Protocol Engine.
   a. issue CONFIG command via Protocol Operation Control Register (FR_POCR)
   b. wait for *POC:config* in Protocol Status Register 0 (FR_PSR0)
   c. configure the FR_PCR0,…, FR_PCR30 registers to set all protocol parameters
2. Configure the Message Buffers and FIFOs.
   a. set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)
   b. define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR)
   c. configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), Message Buffer Index Registers (FR_MBIDXRn)
   d. configure the FIFOs
   e. issue CONFIG_COMPLETE command via Protocol Operation Control Register (FR_POCR)
   f. wait for *POC:ready* in Protocol Status Register 0 (FR_PSR0)

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

54.8.2.3 CHI LRAM Initialization

The initialization of the CHI LRAM is performed by the CC when it leaves the Disabled Mode. The unitization runs for 87 CHI clock cycles. All fields in the FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

54.8.2.4 PE DRAM Initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs, and will delay the state transition from *POC:default config* into *POC:config*.

54.8.3 Memory Fault Injection out of POC:default config

This section provides information for application driven memory fault injection out if *POC:default config*. The CC provides means to inject memory faults from the application without any impacts to the internal protocol operation of the CC.

54.8.3.1 CHI LRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in CHI LRAM Error Injection.

54.8.3.2 PE DRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only one PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM location to inject memory errors into the PE DRAM. The injection sequence is described in PE DRAM Error Injection.

54.8.4 Shut Down Sequence

This section describes a secure shut down sequence to stop the CC gracefully. The main targets of this sequence are

- *finish all ongoing reception and transmission*
- *do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication*

For a graceful shutdown the application shall perform the following tasks:

1. Disable all enabled message buffers.
   a. repeatedly write 1 to FR_MBCCSRn[EDT] until FR_MBCCSRn[EDS] == 0.
2. Stop Protocol Engine.
   a. issue HALT command via Protocol Operation Control Register (FR_POCR)
   b. wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0)

54.8.5 Number of Usable Message Buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[1].

Additional constraints for the minimum CHI clock frequency are given in Controller Host Interface Clocking.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. An corrected empty dynamic slot is a mini-slot and consists of gdMinislot corrected macroticks with a duration of *gdMacrotick*. The minimum duration of an corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of an correct slot

$$\Delta_{slotmin} = 39 \bullet pdMicrotick \bullet gdMinislot$$

Equation 64

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

$$\Delta_{search} = \frac{1}{f_{chi}} \bullet (FR\_MBSSUTR[LAST\_MB\_UTIL] + 27)$$

Equation 65

The message buffer search must be finished within one slot which requires fulfillment of this equation::

$$\Delta_{search} \leq \Delta_{slotmin}$$

Equation 66

This results in the formula given below which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

$$f_{chi} \geq \frac{(FR\_MBSSUTR[LAST\_MB\_UTIL]+27)}{39 \bullet pdMicrotick \bullet gdMinislot}$$

Equation 67

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 127 is given in the following table.

Table 54-64. Minimum fchi [MHz] examples (128 message buffers used)

pdMicrotick [ns]	*gdMinislot*					
	2	**3**	**4**	**5**	**6**	**7**
25.0	79.5	53	39.8	31.8	26.5	22.8
50.0	39.8	26.5	19.9	15.9	13.3	11.4

Note

If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to the CHI Error Flag Register (FR_CHIERFR) for details.

54.8.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of the FR_POCR Field Descriptions table, located in the Register Descriptions section, by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in the next table. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by the table below. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 54-65. Protocol Control Command Priorities

Protocol Command	Priority	Interrupted By	Cleared and Terminated By
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLET, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE,fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE,fatal protocol error

54.8.7 Message Buffer Search On Simple Message Buffer Configuration

This sections describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

54.8.7.1 Simple Message Buffer Configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *S*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has following configuration

Table 54-66. Transmit Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	transmit buffer
FR_MBCCFR*t*	MTM	0	event transition mode
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000011	cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	*S*	assigned to slot S

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number r and has following configuration

Table 54-67. Receive Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	receive buffer
FR_MBCCFR*r*	MTM	-	n/a
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000001	cycle set = {2n} = {0,2,4,6,…}

Table continues on the next page...

Table 54-67. Receive Buffer Configuration (continued)

Register	Field	Value	Description
	CCFVAL	000000	
FR_MBFIDR*r*	FID	*S*	subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSRt[EDS] = 1 and FR_MBCCSRr[EDS] = 1)

Note

The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

54.8.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *S* in the *static* segment.

The configuration of a transmit buffer for a static slot *S* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *S*. In any case, the result of the message buffer search will be the transmit message buffer *t*. The receive message buffer *r* will not be found, no reception is possible.

54.8.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *S* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

54.8.7.3.1 Transmit Data Not Available

If transmit data are *not available*, i.e. the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 and/or locked FR_MBCCSR*t*[LCKS]=1,

1. for the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in the following figure.

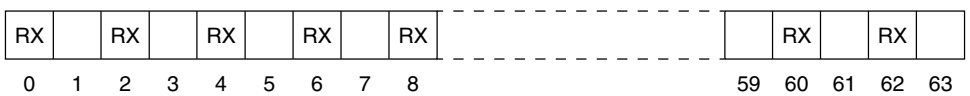

Figure 54-38. Transmit Data Not Available

54.8.7.3.2 Transmit Data Available

If transmit data are *available*, i.e. the transmit buffer is committed FR_MBCCSR*t*[CMT]=1 and not locked FR_MBCCSR*t*[LCKS]=0,

1. for the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in the following figure.

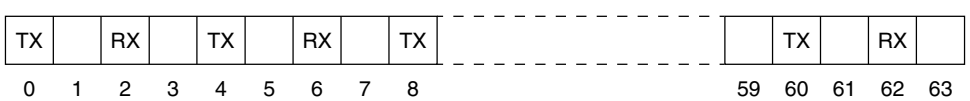

Figure 54-39. Transmit Data Available

Chapter 55
Inter-Integrated Circuit (I2C)

55.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- Introduction to I^2C
- External signal descriptions
- Memory map and register definition
- Functional description
- Initialization/application information

55.2 Introduction to I^2C

This section presents the following topics:

- Definition: I^2C module
- Advantages of the I^2C bus
- Module block diagram
- Features
- Modes of operation
- Definition: I^2C conditions

55.2.1 Definition: I²C module

The I²C module is a functional unit that provides a two-wire— serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

55.2.2 Advantages of the I²C bus

The synchronous, multiple-master two-wire I²C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

55.2.3 Module block diagram

The following figure shows a block diagram of the I²C module.

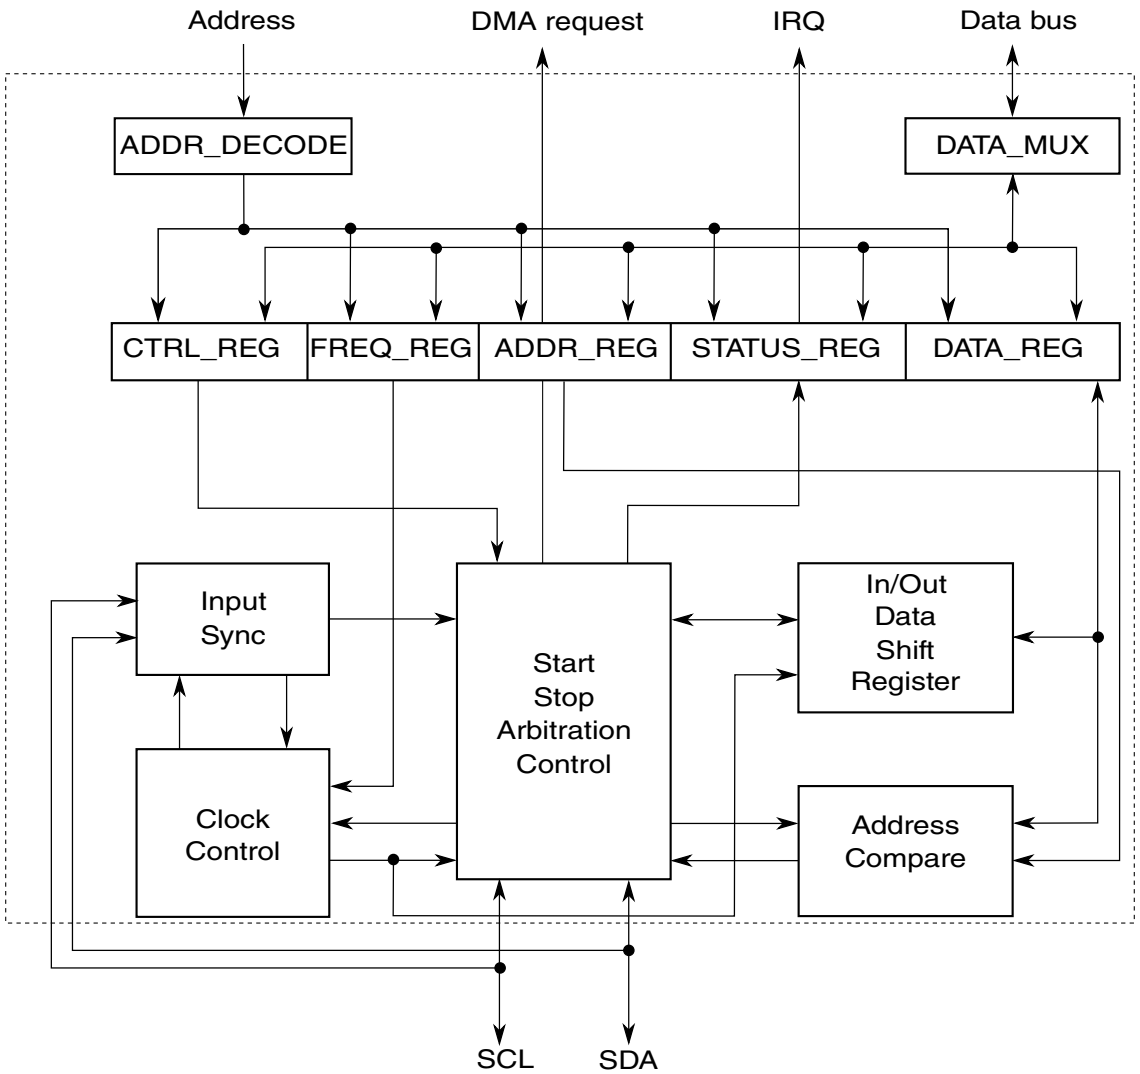

Figure 55-1. I²C block diagram

55.2.4 Features

The I²C module has the following key features:

- Compatible with I²C bus standard[1]
- Operating speeds
  - Up to 100kbps in Standard Mode
  - Up to 400kbps in Fast Mode

1. Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

  - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
  - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400pF

55.2.5 Modes of operation

The I^2C module supports the chip modes described in the following table.

Table 55-1. Chip modes supported by the I^2C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^2C module	The I^2C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. See IPG STOP mode.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See IPG DEBUG mode.

In addition to chip modes, the I^{2}C module has several module-specific modes. These are described in the following table.

Table 55-2. Module-specific modes supported by the I^{2}C module

Module mode	Description	Important notes
Master mode	The I^{2}C module is the driver of the SDA line.	• Do not use the I^{2}C module's slave address as a calling address. • The I^{2}C module cannot be a master and a slave simultaneously.
Slave mode	The I^{2}C module is not the driver of the SDA line.	• Enable the I^{2}C module before a START condition from a non-I^{2}C master is detected. • By default the I^{2}C module performs as a slave receiver.

55.2.6 Definition: I^{2}C conditions

The following table shows the I^{2}C-specific conditions defined for the I^{2}C module.

Table 55-3. I^{2}C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

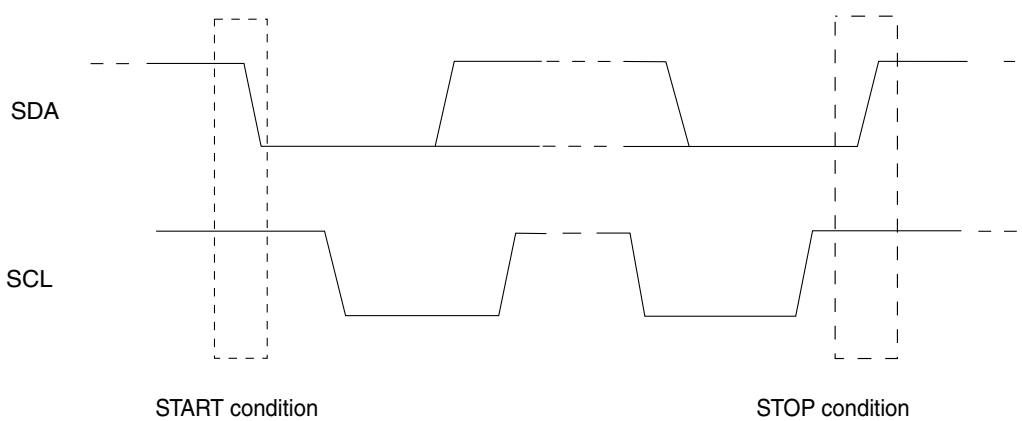

Figure 55-2. START and STOP conditions

55.3 External signal descriptions

This section presents the following topics:

- Signal overview
- Detailed external signal descriptions

55.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

55.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

Table 55-4. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

55.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- Register accessibility
- Register figure conventions

- I2C Bus Address Register (I2C_IBAD)
- I2C Bus Frequency Divider Register (I2C_IBFD)
- I2C Bus Control Register (I2C_IBCR)
- I2C Bus Status Register (I2C_IBSR)
- I2C Bus Data I/O Register (I2C_IBDR)
- I2C Bus Interrupt Config Register (I2C_IBIC)
- I2C Bus Debug Register (I2C_IBDBG)

55.4.1 Register accessibility

Address location 0x0007 is a reserved location, but access to this location will not generate any bus error.

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

55.4.2 Register figure conventions

The register figures show the field structure using the conventions in the following figure.

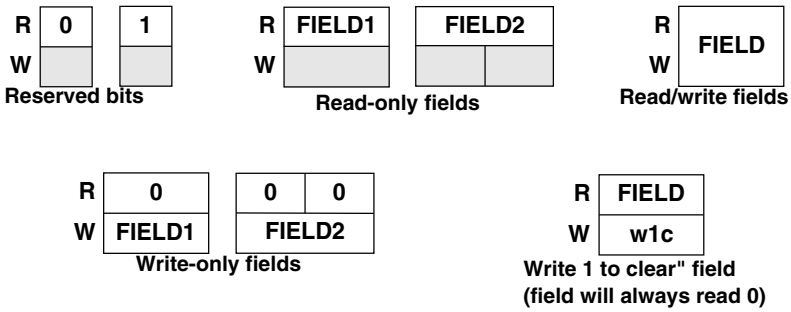

Figure 55-3. Register figure convention

The memory map for the I^{2}C module is given below. The total address for each register is the sum of the base address for the I^{2}C module and the address offset for each register.

I2C memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	I2C Bus Address Register (I2C_IBAD)	8	R/W	00h	55.4.3/2694
1	I2C Bus Frequency Divider Register (I2C_IBFD)	8	R/W	00h	55.4.4/2695
2	I2C Bus Control Register (I2C_IBCR)	8	R/W	80h	55.4.5/2695
3	I2C Bus Status Register (I2C_IBSR)	8	R/W	80h	55.4.6/2697
4	I2C Bus Data I/O Register (I2C_IBDR)	8	R/W	00h	55.4.7/2698
5	I2C Bus Interrupt Config Register (I2C_IBIC)	8	R/W	00h	55.4.8/2699
6	I2C Bus Debug Register (I2C_IBDBG)	8	R/W	00h	55.4.9/2700

55.4.3 I2C Bus Address Register (I2C_IBAD)

This register contains the address the I^{2}C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	ADR							0
Write								
Reset	0	0	0	0	0	0	0	0

I2C_IBAD field descriptions

Field	Description
0–6 ADR	Slave Address. Specific slave address to be used by the I^{2}C Bus module.

Table continues on the next page...

I2C_IBAD field descriptions (continued)

Field	Description
	NOTE: The default mode of I^2C Bus is slave mode for an address match on the bus.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.4 I2C Bus Frequency Divider Register (I2C_IBFD)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 1h offset = 1h

Bit	0	1	2	3	4	5	6	7
Read Write	IBC							
Reset	0	0	0	0	0	0	0	0

I2C_IBFD field descriptions

Field	Description
0–7 IBC	I-Bus Clock Rate. This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 7-6 Selects the prescaled shift register (see Clock rate and IBFD settings) 5-3 Selects the prescaler divider (see Clock rate and IBFD settings) 2-0 Selects the shift register tap point (see Clock rate and IBFD settings)

55.4.5 I2C Bus Control Register (I2C_IBCR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	0
Write						RSTA		
Reset	1	0	0	0	0	0	0	0

I2C_IBCR field descriptions

Field	Description
0 MDIS	Module disable. This bit controls the software reset of the entire I^2C Bus module. **NOTE:** If the I^2C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I^2C Bus module losing arbitration, after which, bus operation would return to normal. 0 The I^2C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled.
1 IBIE	I-Bus Interrupt Enable. 0 Interrupts from the I^2C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I^2C Bus module are enabled. An I^2C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
3 TXRX	Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
4 NOACK	Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I^2C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **NOTE:** Values written to this bit are only used when the I^2C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
5 RSTA	Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect 1 Generate repeat start cycle
6 DMAEN	DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I^2C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I^2C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details.

Table continues on the next page...

I2C_IBCR field descriptions (continued)

Field	Description
	0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.6 I2C Bus Status Register (I2C_IBSR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 3h offset = 3h

Bit	0	1	2	3	4	5	6	7
Read	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
Write				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

I2C_IBSR field descriptions

Field	Description
0 TCF	Transfer complete. While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **NOTE:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave. When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy. This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
3 IBAL	Arbitration Lost.

Table continues on the next page...

I2C_IBSR field descriptions (continued)

Field	Description
	The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: • SDA is sampled low when the master drives a high during an address or data transmit cycle. • SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SRW	Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
6 IBIF	I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs: • Arbitration lost (IBAL bit set) • Byte transfer complete (TCF bit set and DMAEN bit not set) • Addressed as slave (IAAS bit set) • NoAck from Slave (MS & Tx bits set) • I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

55.4.7 I2C Bus Data I/O Register (I2C_IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

NOTE

The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the

transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/ $\overline{W}$ bit (in position D0).

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

I2C_IBDR field descriptions

Field	Description
0–7 DATA	Data transmitted or received

55.4.8 I2C Bus Interrupt Config Register (I2C_IBIC)

To program BIIE = 1, you must ensure that IBCR[MDIS] = 0.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 5h offset = 5h

Bit	0	1	2	3	4	5	6	7
Read Write	BIIE	BYTERXIE	0					
Reset	0	0	0	0	0	0	0	0

I2C_IBIC field descriptions

Field	Description
0 BIIE	Bus Idle Interrupt Enable bit. This config bit can be used to enable the generation of an interrupt once the I^2C bus becomes idle. Once this bit is set, an IBB high-low transition will set the IBIF bit. This feature can be used to signal to the CPU the completion of a STOP on the I^2C bus.

Table continues on the next page...

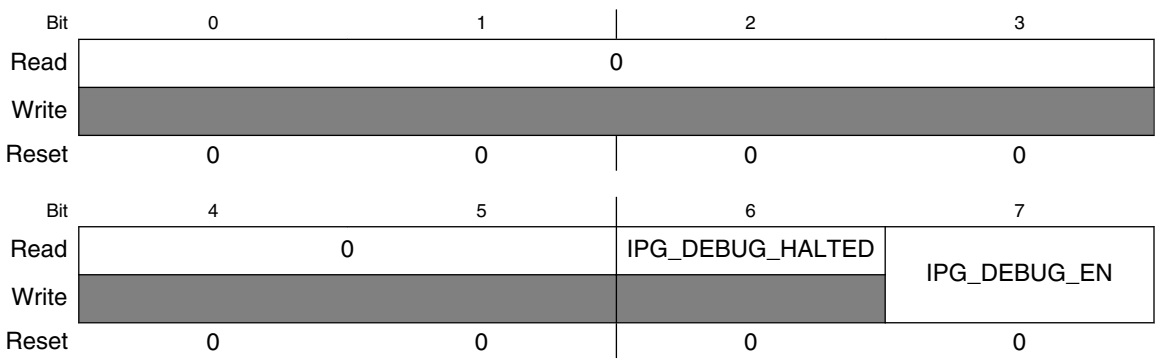
I2C_IBIC field descriptions (continued)

Field	Description
	0 Bus Idle Interrupts disabled 1 Bus Idle Interrupts enabled
1 BYTERXIE	Byte receive interrupt enable This field is used to generate an interrupt every time the I^2C master/slave receives a new byte. This feature can be useful when an I^2C master is receiving data from a slave that is transmitting on an irregular basis.
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.4.9 I2C Bus Debug Register (I2C_IBDBG)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 6h offset = 6h



I2C_IBDBG field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 IPG_DEBUG_ HALTED	Debug Halted Bit: This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
7 IPG_DEBUG_EN	Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. **NOTE:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited.

Table continues on the next page...

I2C_IBDBG field descriptions (continued)

Field	Description
	0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode

55.5 Functional description

This section presents the following topics:

- Notes about module operation
- Transactions
- Arbitration procedure
- Clock behavior
- Interrupts
- IPG DEBUG mode
- DMA interface

55.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

55.5.2 Transactions

This section presents the following topics:

- Protocol overview
- Transaction protocol definitions
- High-level protocol steps
- START condition

- Slave address transmission
- Data transmission
- STOP condition
- Repeated START condition

55.5.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I²C transaction.

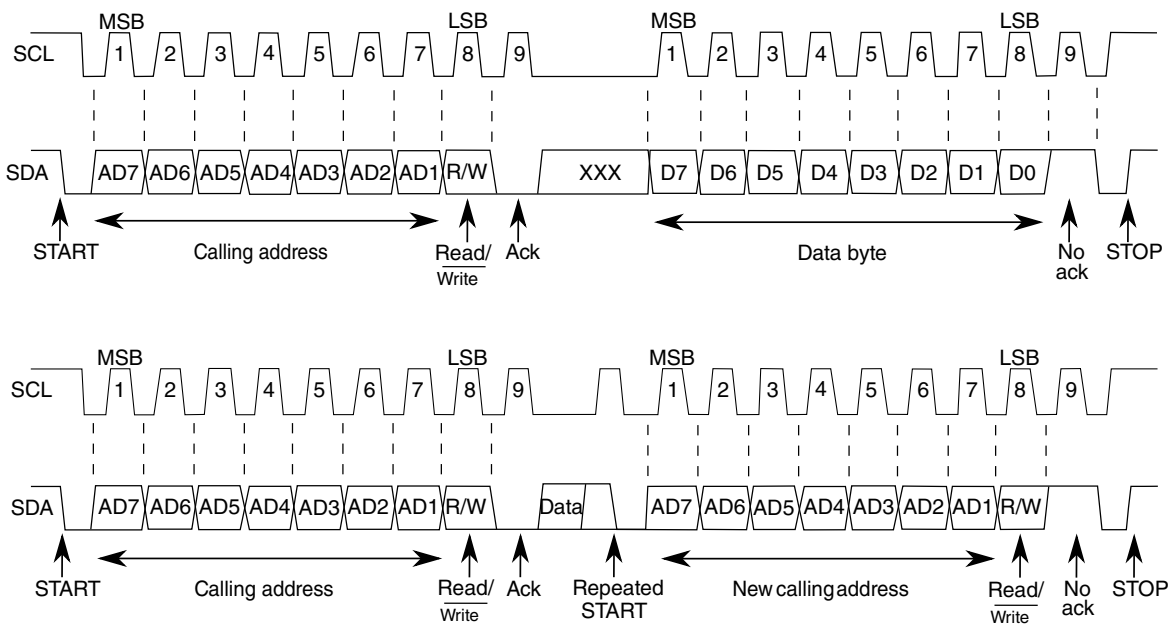


Figure 55-4. I²C transaction protocol

55.5.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 55-4.

Table 55-5. I²C definitions

Term	Definition
START	A START condition, as defined in Section 1.2.6, Definition: I²C conditions"
STOP	A STOP condition, as defined in Section 1.2.6, Definition: I²C conditions"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in Section 1.5.2.3, I²C calling address requirements."

Table continues on the next page...

Table 55-5. I²C definitions (continued)

Term	Definition
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: • 0=The data is being transferred from the master to the slave ("write") • 1=The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

55.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

55.5.2.4 High-level protocol steps

The I²C protocol conceptually supports two types of transfers, which are illustrated in Figure 55-4. The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

Table 55-6. I²C high-level protocol steps

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1–4)	6. (repeat Steps 2–4 as needed)
	7. STOP condition.
	8. (repeat Steps 1–7)

55.5.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see Definition: I^{2}C conditions). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

55.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see START condition). The process of slave address transmission is presented in the following table.

Table 55-7. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

55.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.

- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

55.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see Definition: I^2C conditions). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START condition.

55.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of Figure 55-4.

55.5.3 Arbitration procedure

The I^2C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

55.5.4 Clock behavior

This section presents the following topics:

- Clock synchronization
- Clock stretching
- Handshaking
- Clock rate and IBFD settings

55.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

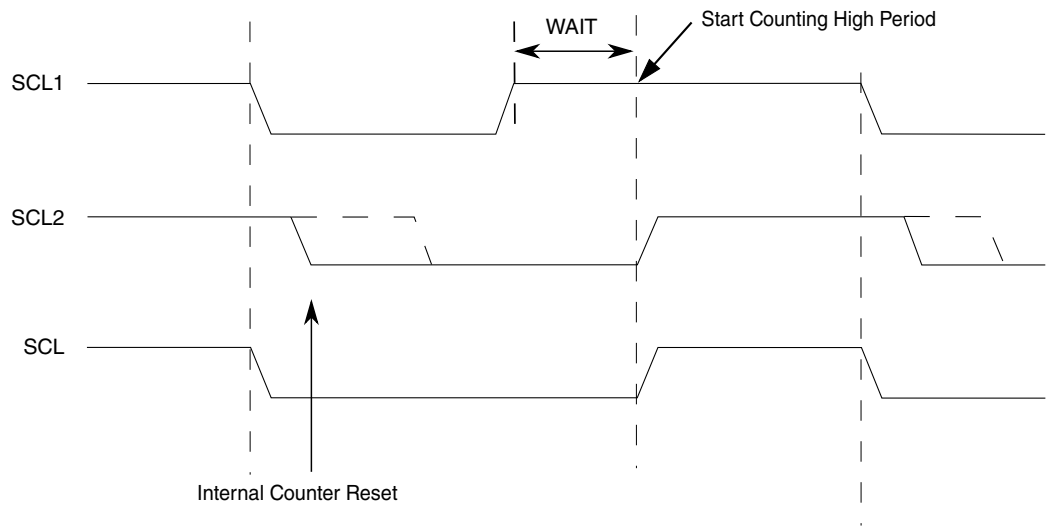

Figure 55-5. I²C bus clock synchronization

55.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

55.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

55.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (see I2C Bus Frequency Divider Register (I2C_IBFD)).

Table 55-8. I-Bus multiplier factor

IBC[0-1]	MUL
00	01
01	02
10	04

Table continues on the next page...

Table 55-8. I-Bus multiplier factor (continued)

IBC[0-1]	MUL
11	Reserved

Table 55-9. I-Bus prescaler divider values

IBC[2-4]	scl2start (clocks)	scl2stop (clocks)	scl2tap (clocks)	tap2tap (clocks)
000	2	7	4	1
001	2	7	4	2
010	2	9	6	4
011	6	9	6	8
100	14	17	14	16
101	30	33	30	32
110	62	65	62	64
111	126	129	126	128

Table 55-10. I-Bus tap and prescale values

IBC[5-7]	SCL Tap (clocks)	SDA Tap (clocks)
000	5	1
001	6	1
010	7	2
011	8	2
100	9	3
101	10	3
110	12	4
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of Table 55-9. All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in Table 55-9. The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

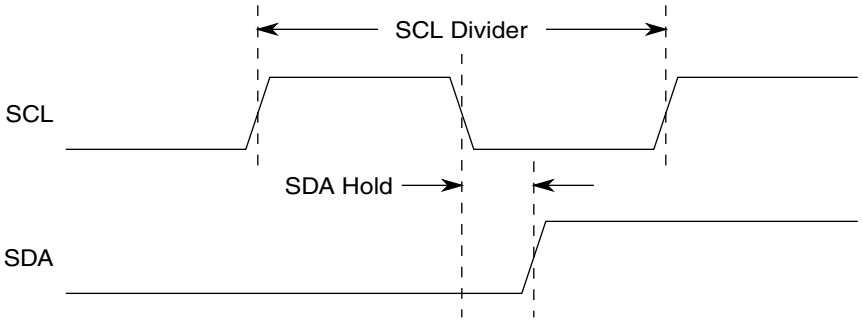

Figure 55-6. SDA Hold time

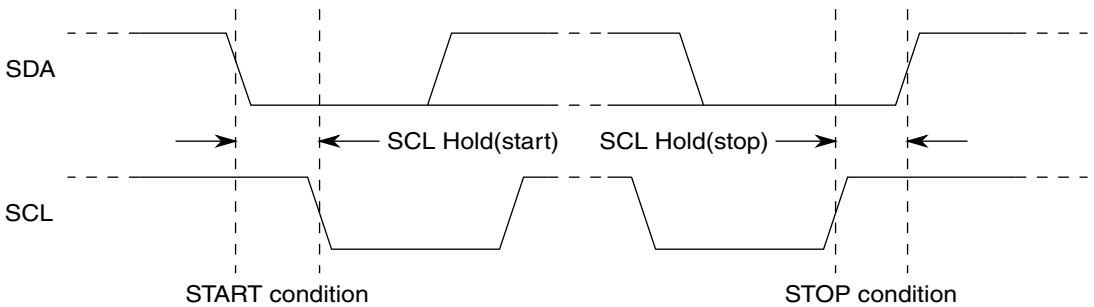

Figure 55-7. SCL Divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

$$\text{SCL Divider} = \text{MUL} \times \{2 \times (\text{scl2tap} + [(\text{SCL\_Tap} - 1) \times \text{tap2tap}] + 2)\}$$

Equation 68. Equation for SCL Divider

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in Table 55-11. The equation used to generate the SDA Hold value from the IBFD bits is:

$$\text{SDA Hold} = \text{MUL} \times \{\text{scl2tap} + [(\text{SDA\_Tap} - 1) \times \text{tap2tap}] + 3\}$$

Equation 69. Equation for SDA Hold

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

$$\text{SCL Hold (start)} = \text{MUL} \times [\text{scl2start} + (\text{SCL\_Tap} - 1) \times \text{tap2tap}]$$

Equation 70. Equation for SCL Hold(start)

$$\text{SCL Hold (end)} = \text{MUL} \times [\text{scl2end} + (\text{SCL\_Tap} - 1) \times \text{tap2tap}]$$

55.5.5 Interrupts

This section presents the following topics:

- Interrupt vector
- Interrupt description

55.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 55-12. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I²C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

55.5.5.2 Interrupt description

There are five types of internal interrupts in the I²C. The interrupt service routine can determine the interrupt type by reading the Status register.

I²C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)

- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I2C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

55.5.6 IPG STOP mode

This mode allows the software to put the I2C module in power-down state. Once the STOP request is asserted, the I2C module comes to a graceful halt after completing all the ongoing transactions.

As soon as the I2C module enters IPG STOP mode:

- The I2C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I2C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. See the figure below for more details.

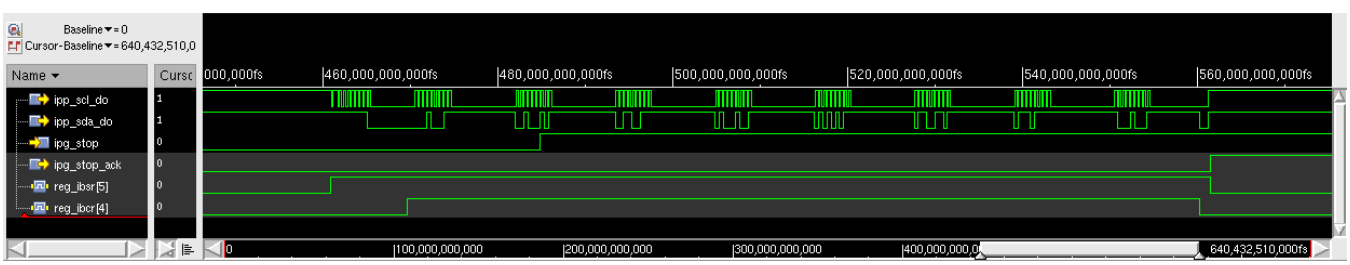

Figure 55-8. I2C stop mode behavior when master is receiving and slave is transmitting

55.5.7 IPG DEBUG mode

This mode allows CPU to debug the I2C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I2C comes to a graceful halt after completing all the ongoing transactions. A Debug halted

signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^2C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I^2C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. See the simulation result in Figure 55-9 for more details.

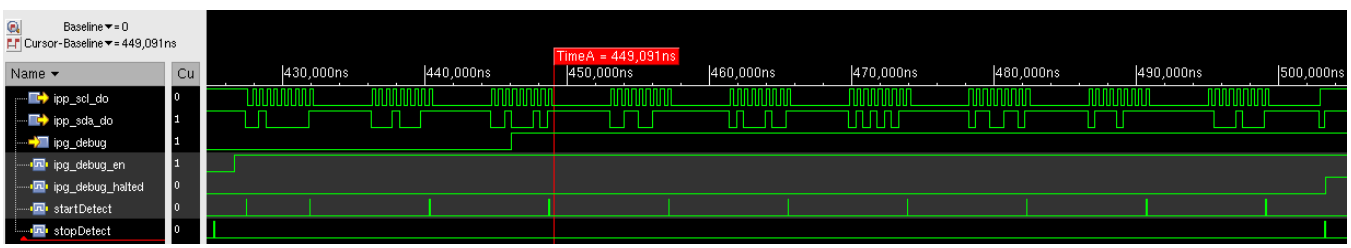

Figure 55-9. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I^2C module enters IPG DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits IPG DEBUG mode, transmission or reception of the remaining bytes resumes. Please see the simulation snapshot shown in Figure 55-10 for details where the I^2C is transmitting 8 bytes using DMA and IPG DEBUG mode is requested while a second byte is being transmitted. IPG DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits IPG DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

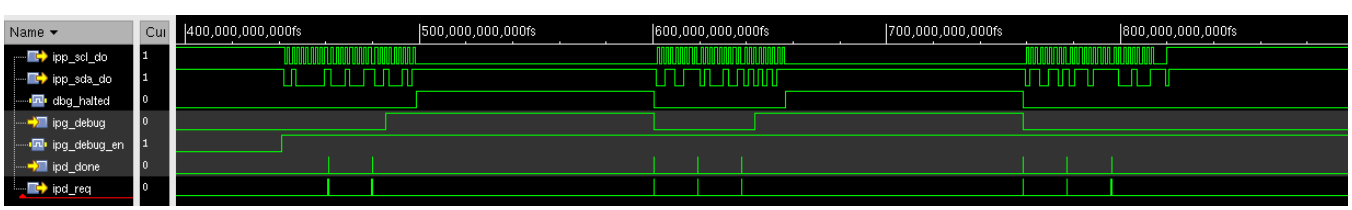

Figure 55-10. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I^2C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I^2C module has entered the IPG DEBUG mode. See the following figure for more details.

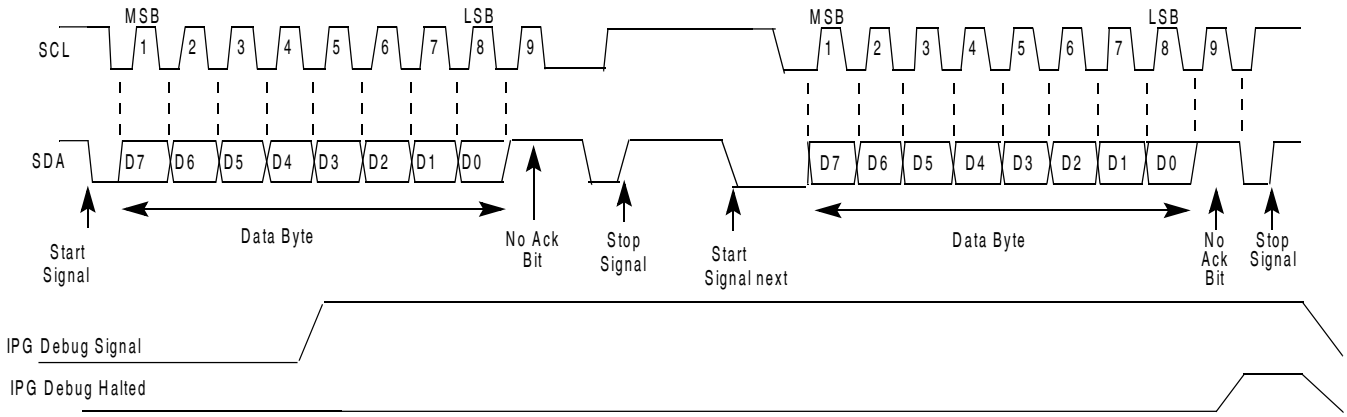

Figure 55-11. IPG DEBUG mode

The following figure shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters IPG DEBUG mode.

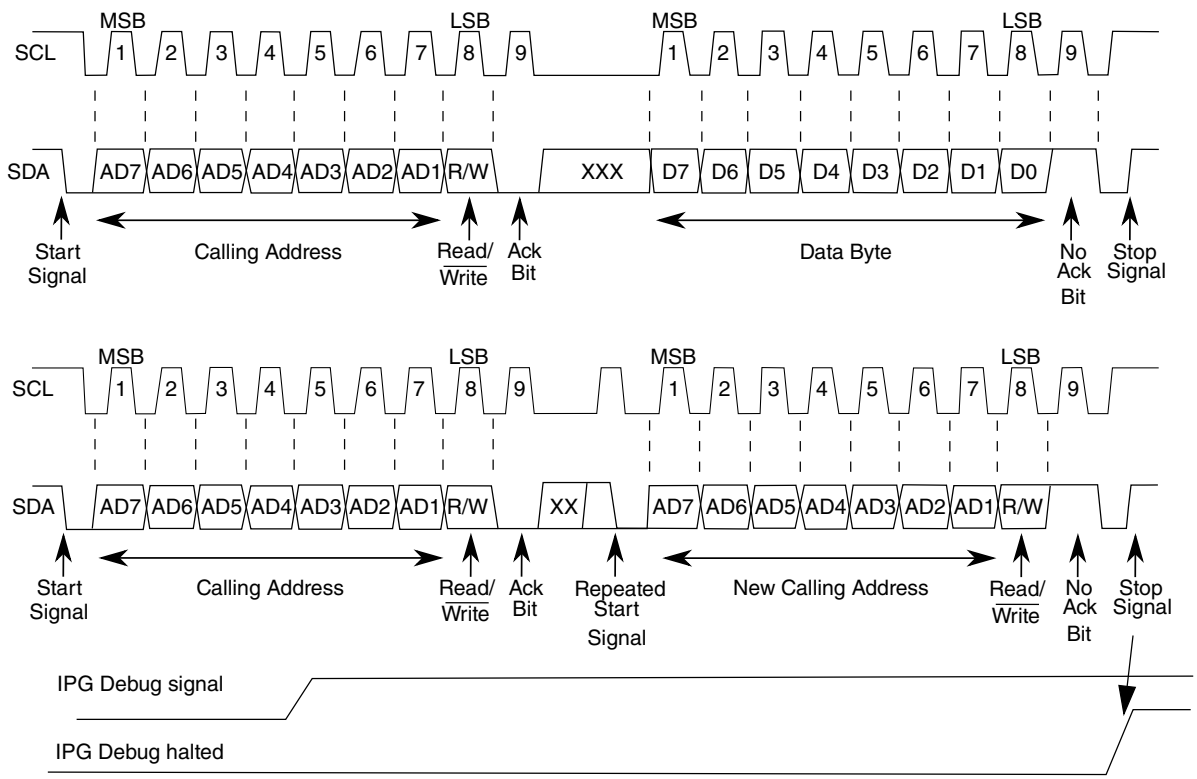

Figure 55-12. IPG debug mode with repeated start

55.5.8 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (see DMA application information). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the Initialization/application information, of this document.

55.6 Initialization/application information

This section presents the following topics:

- Recommended interrupt service flow
- General programming guidelines (for both master and slave mode)
- Programming guidelines specific to master mode
- Programming guidelines specific to slave mode
- DMA application information

55.6.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

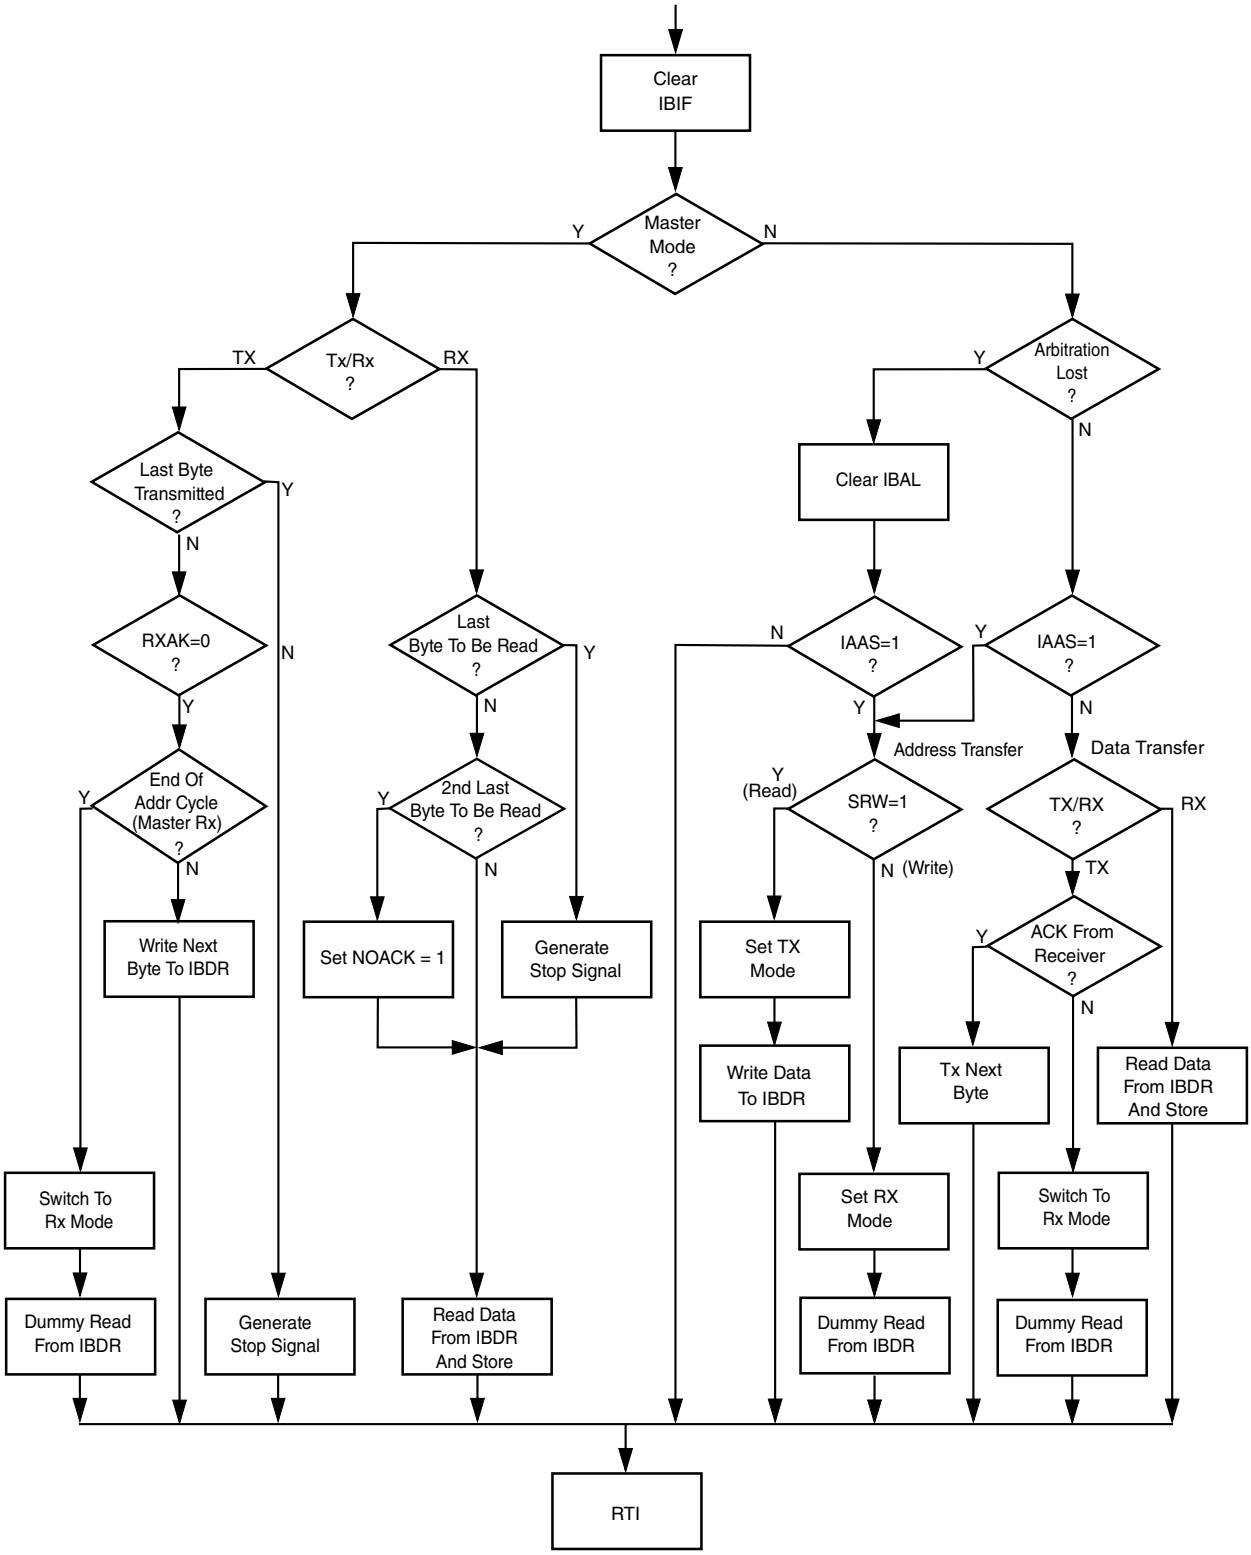

Figure 55-13. Recommended I²C interrupt service routine flowchart

55.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^2C module in both master and slave mode. It presents the following topics:

- Section 1.6.2.1, Initializing the I^2C module
- Software response after a transfer

55.6.2.1 Initializing the I^2C module

The following sequence initializes the I^2C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[MDIS] bit to enable the I^2C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

55.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^2C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^2C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^2C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

55.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- Generating START
- Transmit/receive sequence
- Generating STOP
- Generating repeated START
- Loss of arbitration

55.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1  // master and transmit mode, that is,
                                    // generate start condition
IBDR = calling_address              // send the calling address to the data register
while (bit 5, IBSR ==0)             // wait in loop for IBB flag to be set
```

55.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 55-13. Master transmit sequence

Step	Action
a	Use the IBFD register to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Use the IBCR to select Master mode, Transmit mode and interrupt enable.
d	Write 0 to IBSR[IBIF].
e	Write data to IBDR.
f	Observe changes in IBSR[TCF]: • When IBSR[TCF] becomes 0, the transfer is in progress. • When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until IBSR[IBIF] = 1.
h	Read the fields in the IBSR to determine what happened: • If TCF = 1, the transfer completed. • If RXAK = 1, a No Acknowledge condition occurred. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore Address Detect (IAAS = 1) for master mode (it is valid only for slave mode).
i	Examine IBSR[RXAK] for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 55-14. Master receive sequence

Step	Action
a	Follow steps a through i in Table 55-13 for address dispatch.
b	Write 0 to IBSR[IBIF].
c	Write 0 to IBCR[TXRX] to select Receive mode.
d	Perform a dummy read of the IBDR to initiate the receive operation.
e	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
f	Wait until IBSR[IBIF] = 1.
g	Read the fields in the IBSR to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read the IBDR to determine the data received from the slave.

Table 55-15. Slave transmit sequence

Step	Action
a	Use the IBAD register to define the slave address.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Examine fields in the IBSR as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
d	Write data to IBDR.
e	Wait until IBSR[IBIF] = 1.
f	Wait until IBSR[RXAK] = 0.
g	Write 0 to IBSR[IBIF].
h	Repeat steps d through g for the next consecutive data transfers.

Table 55-16. Slave receive sequence

Step	Action
a	Use the IBAD register to define the slave address.
b	Write 0 to IBCR[IBDIS] to enable the I^2C interface system.
c	Examine fields in the IBSR as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
d	Write 0 to IBSR[IBIF].
e	Perform a dummy read of the IBDR to initiate the receive operation.
f	Wait until IBSR[TCF] becomes 1. (This proves that the transfer is complete.)
g	Wait until IBSR[IBIF] = 1.
h	Read the fields in the IBSR to determine what happened: • If TCF = 1, the reception completed.

Table continues on the next page...

Table 55-16. Slave receive sequence (continued)

Step	Action
	• If IBB = 0, the bus transitioned from Busy to Idle state. • If IBB = 1, you can ignore check of Arbitration Loss (IBAL = 1). **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
i	Read the IBDR to determine the data received from the master.

55.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or     // check to see if all data bytes have been transmitted
  (bit 0, IBSR == 1) {    // or if no ACK generated
    clear bit 5, IBCR     // generate stop condition
  }
else {
 IBDR = data_to_transmit  // write byte of data to DATA register
   tx_count --            // decrement counter
 }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --             // decrease the rx counter
if (rx_count ==1)       // 2nd last byte to be read ?
 bit 3, IBCR = 1        // disable ACK
 if (rx_count == 0)     // last byte to be read ?
 bit 5, IBCR = 0        // generate stop signal
else
data_received = IBDR    // read RX data and store
```

55.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
bit 2, IBCR = 1             // generate another start (restart)
IBDR == calling_address     // transmit the calling address
```

55.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

55.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an "end of data" signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

55.6.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- DMA mode, master transmit
- DMA mode, master reception
- Exiting DMA mode, system requirement considerations

55.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit "n" data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

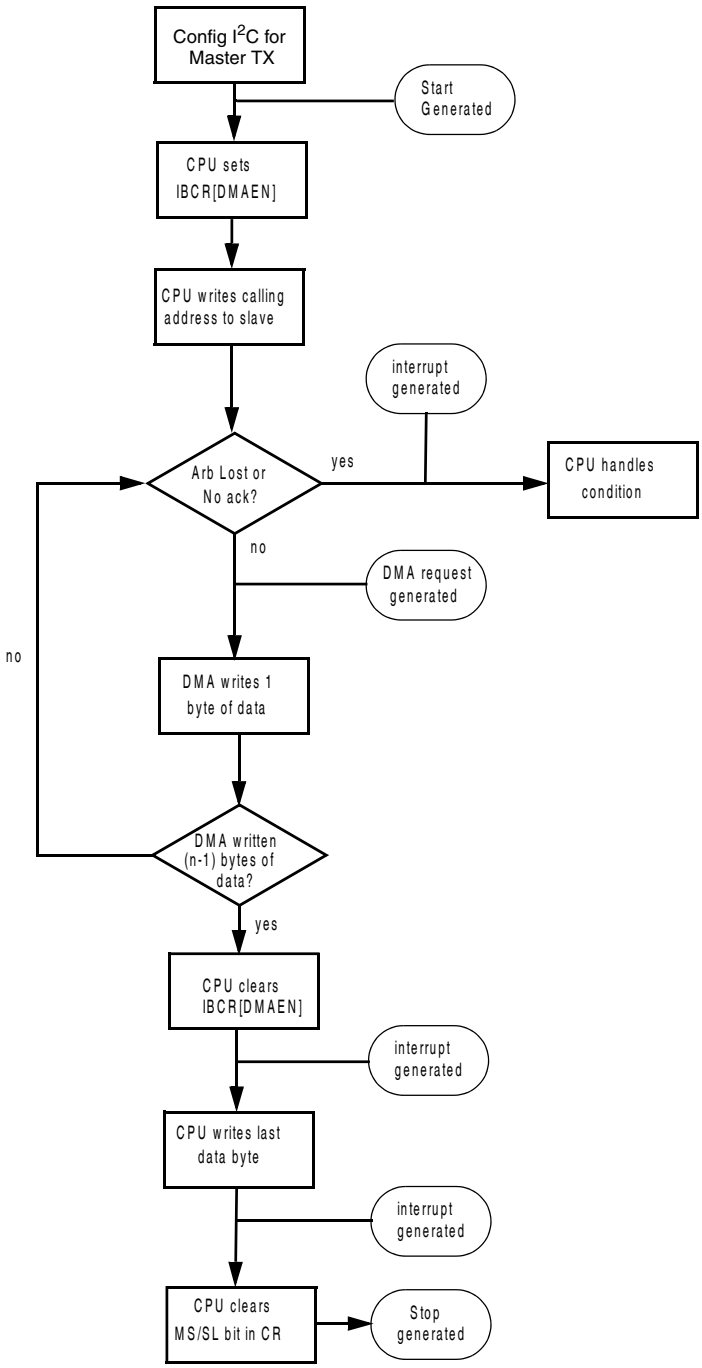

Figure 55-14. Flow-Chart of DMA mode master transmit

55.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive "n" data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

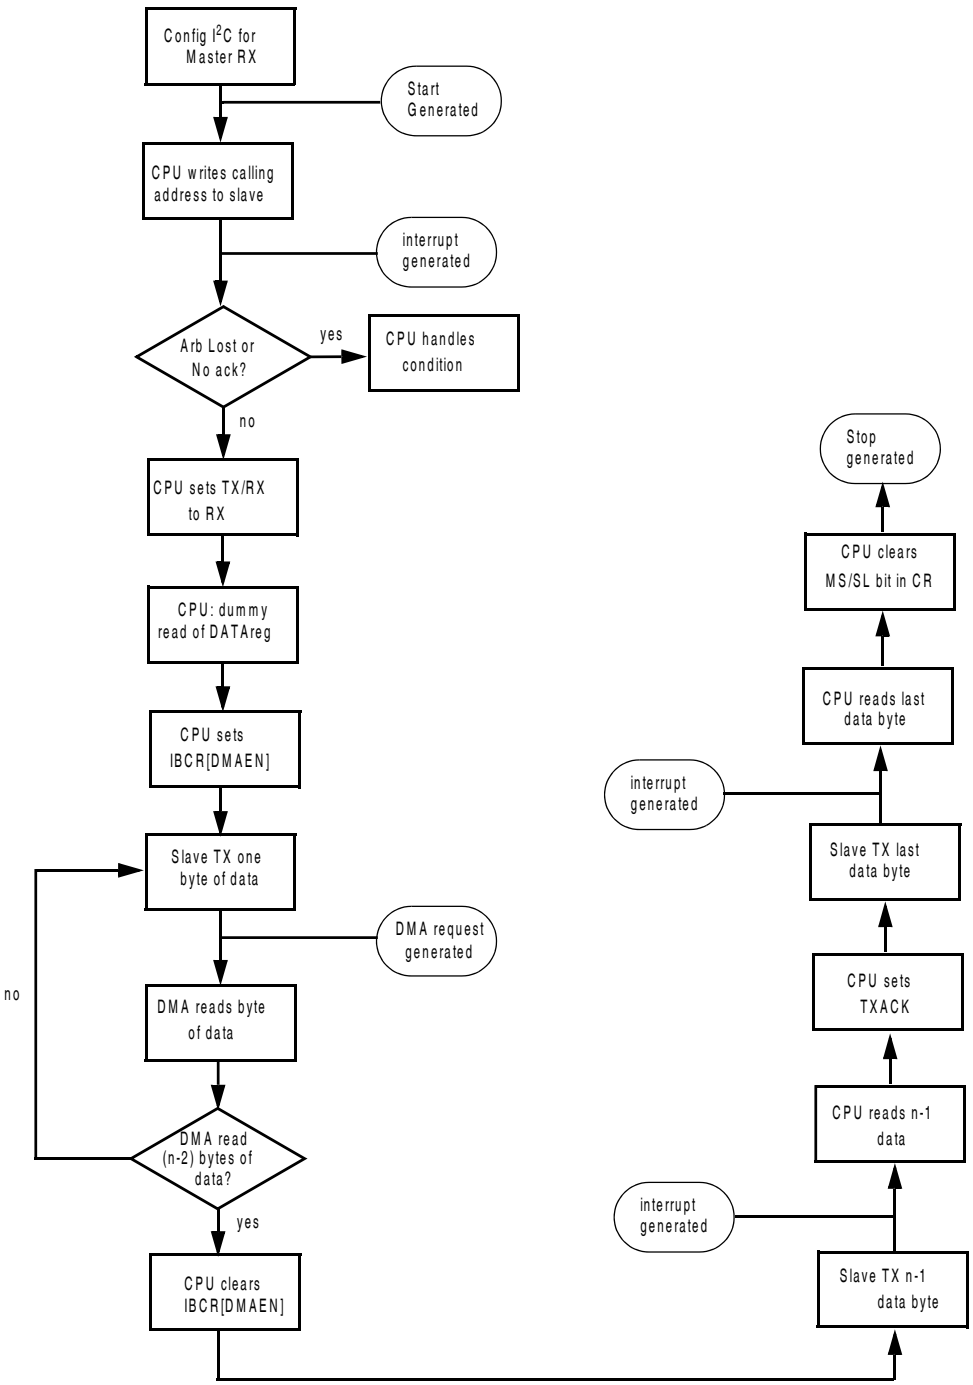

Figure 55-15. Flow-Chart of DMA mode master receive

55.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^2C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For 'fast reaction' the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400kbit/s, T_{SCL} is 2.5µs, so T_R is 20µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority

interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note

The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

   Note

   Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I^2C-transfer" state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note

Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/16 MHz = 250 ns

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

  $8 \times T_{AHD}$ = 8/32 MHz = 250 ns

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/150 MHz = 26.6 ns

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

  $4 \times T_{AHD}$ = 4/150 MHz = 26.6 ns

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

Chapter 56
Peripheral Sensor Interface (PSI5)

56.1 Introduction

The PSI5 interface offers power supply and data transfer between the application and multiple sensors over a two-wire interface. Data transmission from the application to the sensor or sensors is achieved through modulation of the power supply voltage (sync pulse). Data reception from the sensor or sensors to the application is achieved through modulation of the current drawn by a sensor using Manchester encoding.

At the system level, the PSI5 interface consists of mechanisms integrated on the microcontroller and an external physical layer that provides the high-voltage supply and converts the current drawn by the sensor into a digital Manchester-encoded data stream.

56.1.1 Overview

The PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make the PSI5 also suitable for many other automotive sensor applications. The development goal of the PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented free of charge.

The main features of the PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s

- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

In short, PSI5 standardizes the low-level communication between peripheral sensors and electronic control units. Note that the physical layer for the IP (transreceiver) is to be implemented separately outside the IP.

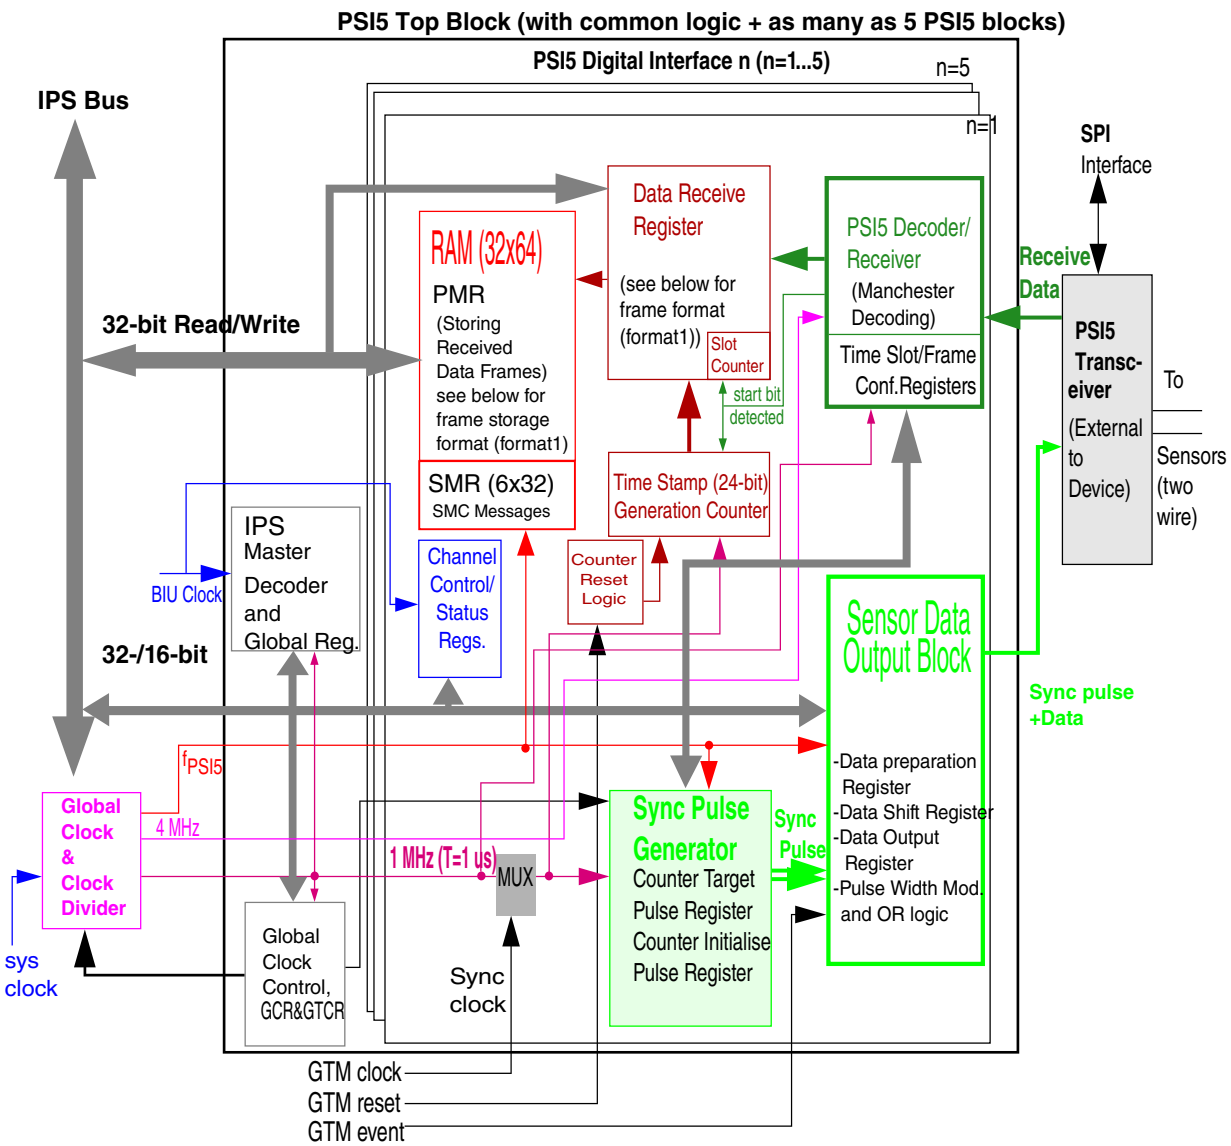

Figure 56-1. PSI5 digital interface block diagram

56.1.2 Features

- IPS interface for register read/write (big endian)
- Supports bidirectional full duplex operations, but with differing baud rate—low, ECU-to-sensor, fast sensor to ECU
- Manchester decoder operating at 125 Kbit/s bit rate with ×32 sample clock rate
- One 64-bit sensor data receive register to which the decoded received sensor data—including header, data, timestamp, frame counter, status bits (E, EM, T, C, F) and CRC, but not including start bits—are written
- A 24-bit time stamp register with a 1 μs (or the GTM clock) resolution. When first rising edge of start bits (S0) of a message or the rising edge of the SYNC pulse is recognized, the value in the time stamp register will be written to the data receive register
- Provision of resetting the Time Stamp Counter through the reset from the GTM module
- Single 32 × 64-bit RAM buffer for storing (moving) content of the data receive register once end of message is recognized
    - Related to each RAM buffer are two diagnostic registers, N and EI. Register N is used to identify the occurence of new messages in the corresponding RAM buffer, while register EI identifies the error status of these messages. The errors that can set the EI register bits are the F (no frame), E (electrical error), EM (electrical error for SMC bits embeddded in PSI5 messages), T (Timing bit error) and C (CRC error). Which of these errors actually set the EI register bits is configurable.
- DMA support for transferring RAM data (including diagnostic data) to system memory
- Support for optional serial messaging channel (SMC) and additional logic to extract SMC frames from PSI5 frames
- Operating modes supported:
    - Asynchronous mode (sensor periodically sends data, no sync pulse, one sensor per interface)
    - Synchronous mode (sync pulse generated, multiple sensor per interface)
- Sync pulse generation for synchronous modes

- The start of each time slot (1 to 6) (see Figure 56-6) on the bus (after the end of the sync pulse) can be defined with a 1 µs resolution
- The end of the last time slot on the bus can be defined with a 1 µs resolution, up to a maximum sync period time of 16 ms
- Trigger logic to generate sync pulses
  - 16-bit Channel Trigger Counter (CTC) used to generate the sync pulses by comparing the values with CIPR and CTPR
  - Counter Initialize Pulse Register (CIPR) to allow configuration of initialization (offset) period
  - Channel Trigger Period (CTP) register to allow configuration of sync period. Value in CTP is the value to which the CTC is updated after each sync pulse generation
  - Possibility to have a common 1 MHz clock source

- An upstream register bit chain consisting of Preparation Register, Buffer Register, Shift register (output data) and pulse width modulation logic, is implemented. Using this, it is possible to send a data word to the sensors through use of data sync pulses: logic 1 with programmable data sync pulse width W1, logic 0 with programmable data sync pulse width W0. The data sync pulse timing can be configured to be dependent on the periodic or event driven timing SYNC pulse. Further, there is no difference between timing sync pulse and data sync pulse during transmission (ECU-to-sensor communication).

56.1.3 Modes of operation

56.1.3.1 Disable mode

Disable mode in the PSI5 reduces power consumption. This mode is entered by setting GCR[GLOBAL_DISABLE_REQ]. All the channels enter Disable mode at once when this bit is set, irrespective of the setting of PCCR[PSI5_CH_EN] and PCCR[PSI5_CH_CONFIG]. In this mode the RX, TX and common time base counters are disabled for any operation. This is the default state after module reset is released. PSI5 can exit Disable mode by clearing the GLOBAL_DISABLE_REQ bit and enabling individual PSI5 channels (setting PCCR[PSI5_CH_EN]). Note that when entering

Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter AND the internal sync pulse generator are, however, reset when entering Disable mode.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter "Configuration/Normal mode" based on the value of PCCR[PSI5_CH_CONFIG].

56.1.3.2 Initialization/Configuration mode

This is the configuration phase, in which, all PSI5 global, channel specific configuration/ control registers can be written. The receiver and transmitter sub-blocks are disabled in this mode. The message receive registers/buffers can be accessed in this mode. This mode can be entered by clearing GCR[GLOBAL_DISABLE_REQ] and setting PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN].

56.1.3.3 Normal mode (NORMAL mode)

In Normal mode, the reciever and the transmitter blocks become active, error handling is enabled and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. Data Preparation Register, Shift Register and data output registers are writable in this mode. Apart from them, there are some register bits that can be written in this mode also. Please refer to the detailed register description. This mode can be entered clearing GCR[GLOBAL_DISABLE_REQ], clearing PCCR[PSI5_CH_CONFIG], and setting PCCR[PSI5_CH_EN].

56.1.3.3.1 PSI5 topology

The different PSI5 user operation modes define topology and parameters of the communication between ECU and sensors such as communication mode, number of data bits, error detection, cycle time, number of time slots per cycle, and bit rate.

These modes as generally denoted as

PSI5-(A / P / U / D)-dd-(P / CRC)-tttt / n(L / H)

The following figure provides a key for these notations.

Table 56-1. Normal operating states

Communication modes		Description
A	Asynchronous mode	PSI5-A describes a point-to-point connection for unidirectional, asynchronous data transmission. Each sensor is connected to the ECU by two wires. After switching on the power supply, the sensor starts transmitting data to the ECU periodically. Timing and repetition rate of the data transmission are controlled by the sensor. No Sync pulse is send from ECU side.
P	Synchronous Parallel Bus mode	The synchronous operation modes work according to the TDMA method (Time Division Multiple Access). Each sensor is connected to the ECU by two wires. The sensor data transmission is synchronized by the ECU using voltage modulation. Synchronization (sync pulses) can be optionally used for point-to-point configurations; it is mandatory for bus modes. The sensors can be arranged as parallel bus, universal bus and daisy chain topology based on sensor addressing and interchangeability of sensors.
U	Synchronous Universal Bus mode	
D	Synchronous Daisy Chain Bus mode	
Data Bits		
dd	No. of data bits	
Error Detection		
P	1 parity bit	
CRC	3-bit Cyclic Redundancy Check (CRC)	
Cycle Time		
tttt	Cycle Time in µs	
n	Number of time slots per cycle	
Bit Rate		
L	125 Kbit/s	

56.1.3.4 Stop mode

When the Stop mode request is asserted, and if there is no active PSI5 transaction ongoing, then the acknowledgement to stop the clocks is given immediately .If start bits of any PSI5 packet have been detected(sucessful detection of both S0 and S1) then the concerned PSI5 packet is sucessfully stored and then the Stop mode acknowledgement is generated by the IP. Note that for generating the acknowledgement, the IP does not wait for the complete reception of any ongoing SMC message, but only waits for the complete reception of any ongoing PSI5 packet transaction.

If the PSI5 transceiver is asynchronous to the PSI5 IP receiver then loss of data can result when the STOP mode is deasserted. Hence, the following guidelines should be followed:

- If the IP is in synchronous mode of operation, then the IP gets resynchronized on the next available sync pulse which occurs after STOP mode de-assertion. Hence, the PSI5 packets occurring between the STOP mode de-assertion event and the subsequent synch pulse would not be reliable and should be ignored by the application.
- If the IP is configured in asynchronous mode, then it should be ensured that the idle time gap between PSI5 packets is greater than or equal to the length of one PSI5 message. In this case, only one PSI5 message will get corrupted, but the IP will sample the subsequent PSI5 messages correctly.

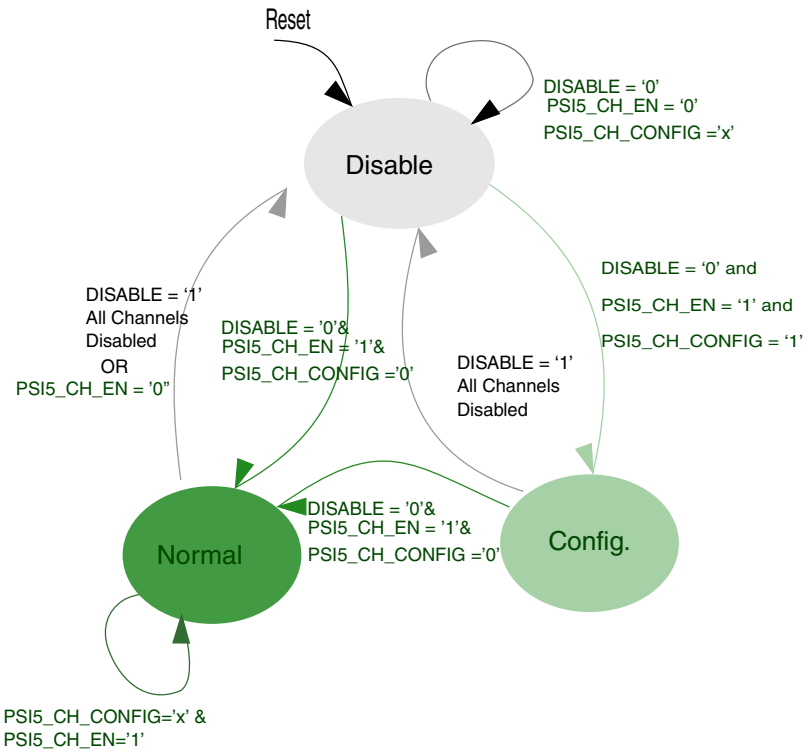
56.1.3.5 Debug mode

In order to enter this mode the debugger has to be connected and it has to encounter a breakpoint. In addition, the DEBUG_EN bit has to be written to 1. The DEBUG_EN bit can be written by either the CPU or by the debugger but only in Configuration mode. Once the above conditions are satisfied the IP enters the Debug Mode. There are two debugging modes available. For simplicity these are being referred to as the “Freeze” and “Open” modes. The IP enters one of the above debugging modes, based on the configuration of a register bit DEBUG_ FREEZE_ CTRL mentioned in the Section 54.3.2.2, PSI5 Channel Control Register (PSI5_PCCR).

In Open mode, the core of the IP keeps on working normally and all the registers are updated from the hardware; just like they were being done in the functional mode (when the IP was out of the debug mode). Thus, even a long term entry to the Debug Mode, wont affect the normal operation of the various registers that are to be updated by the hardware. Down side is that the IP can keep on changing the internal status bits and the registers as the time progresses.

In both the above modes, the various interface registers would be completely visible to the debugger, but debugger action would have no impact on the various status bits and counters that normally get affected by a CPU/DMA read. In this mode, the read pointers of the FIFO do not get incremented, when being read through the Pop-up registers. Thus in Debug mode, reading the DMA PSI5 Message Register (PSI5_DPMR),DMA SMC Frame Register (PSI5_DSFR) or the DMA Diagnostic Status Register (PSI5_DDSR) would keep on returning the same data. Hence the interrupts related to DMA completion operation would not get generated. Further the hardware clearing related to FAST_CLR _SMC and FAST_CLR _PSI5 bits would not have any effect and the hardware clearing would remain disabled. This is also highlighted in the following figure.

56.1.3.6 Operating modes



Note Not possible to reconfigure the PSI5 on the fly. A direct transition from the Normal to Config mode is not there to consider safety aspects.

Figure 56-2. Operating modes

Table 56-2. State transition Table

GCR	PCCR		State	
[GLOBAL_DISABLE_REQ]	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
1	x	x	x	All channel Disable
0	x	0	x	Specific channel Disable
0	1	1	Disable	Config
0	0	1	Config	Normal
0	x	1	Normal	Normal
0	0	1	Disable	Normal

56.2 External signal description

External signal description.

Table 56-3. PSI5 port list

Name	Function	I/O	Reset	Pullup
Signals to/from pads				
SDINn_PSI5_m[1]	Digital sensor data input pin of PSI5 module	I	0	Active
SDOUTn_PSI5_m[1]	Digital sensor data output pin of PSI5 module (sync pulse + data)	O	0	Passive

1. “n” is the Channel Number and “m” is the Module Instance Number.

56.3 Memory map and register description

The module memory map is shown below.

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

Note that , an access(read/write) to any register in the unimplemented register space will result in the generation of transfer error . All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to do a word operation on 16-bit registers will NOT result in the generation of any transfer error. Trying to write to "read only" bits of implemented register space, will be ignored without the generation of any error. Trying to write to any register outside its intended mode of write(Normal/ config) will be ignored without the generation of any transfer error.

For a summary of the register bit accesses in various device modes, please see Device modes and Register bit accesses

PSI5 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Global Control Register (PSI5_GCR)	16	R/W	0001h	56.3.1/2758

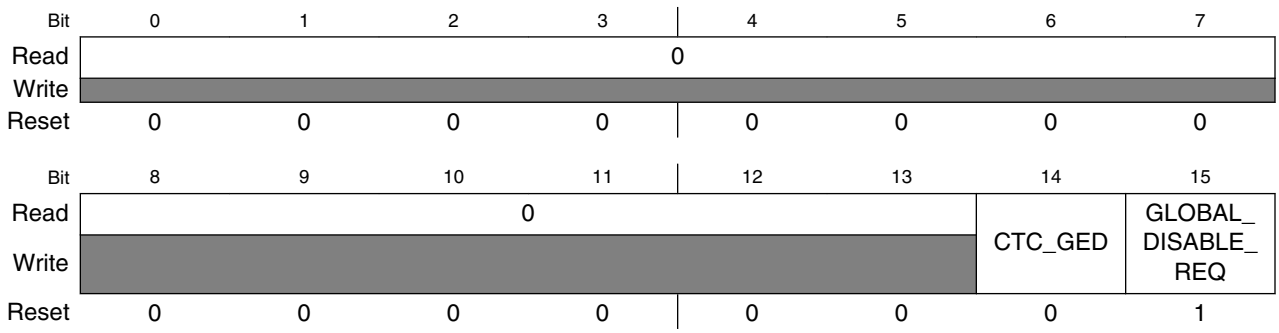
56.3.1 Global Control Register (PSI5_GCR)

The Global Control Register (PSI5_GCR)[1] provides control functions for all the PSI5 channels simultaneously.

Address: 0h base + 0h offset = 0h



PSI5_GCR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTC_GED	Channel Target Counter (CTC) Global Enable/Disable. **NOTE:** This bit is writable in all modes. 0 All the CTC counters having PCCR[CTC_GED_SEL] = 1 are reset. 1 Simultaneously starts the CTC of all the channels that have PCCR[CTC_GED_SEL] = 1.
15 GLOBAL_ DISABLE_REQ	PSI5 Receive Global disable request. When set, all PSI5 channels enter Disable mode (from individual Normal or Config modes) regardless of the settings of the PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN] bits. When cleared, each PSI5 channel enters Config mode or Normal mode based on the setting of the PCCR[PSI5_CH_CONFIG] bit if PCCR[PSI5_CH_CONFIG] is set for that channel; otherwise, that particular channel continues to stay in Disable mode. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 1, then the reset value is "1"(PSI5 module is disabled after reset). Note that when GLOBAL_DISABLE_REQ == 1 then all the clock enables (shown in Figure 1) from the IP go to a 0 (inactive) state. This bit is writable in all the modes.

Table continues on the next page...

1. This register is not present if the specific instance is configured as a slave. Master or slave configuration of the specific PSI5 instance decides if the operating mode (DISABLE/CONFIG/NORMAL) as well as the staggering of the channels can be controlled independently. If the instance is configured as a master, then it controls its own operating mode, staggering of all the channels in that instance and the operating mode and the staggering of any associated slave instance. If the instance is configured as a slave, then its operating mode and stagerring can only be controlled by another master instance. Please refer to the Device Configuration Chapter for instance specific details.

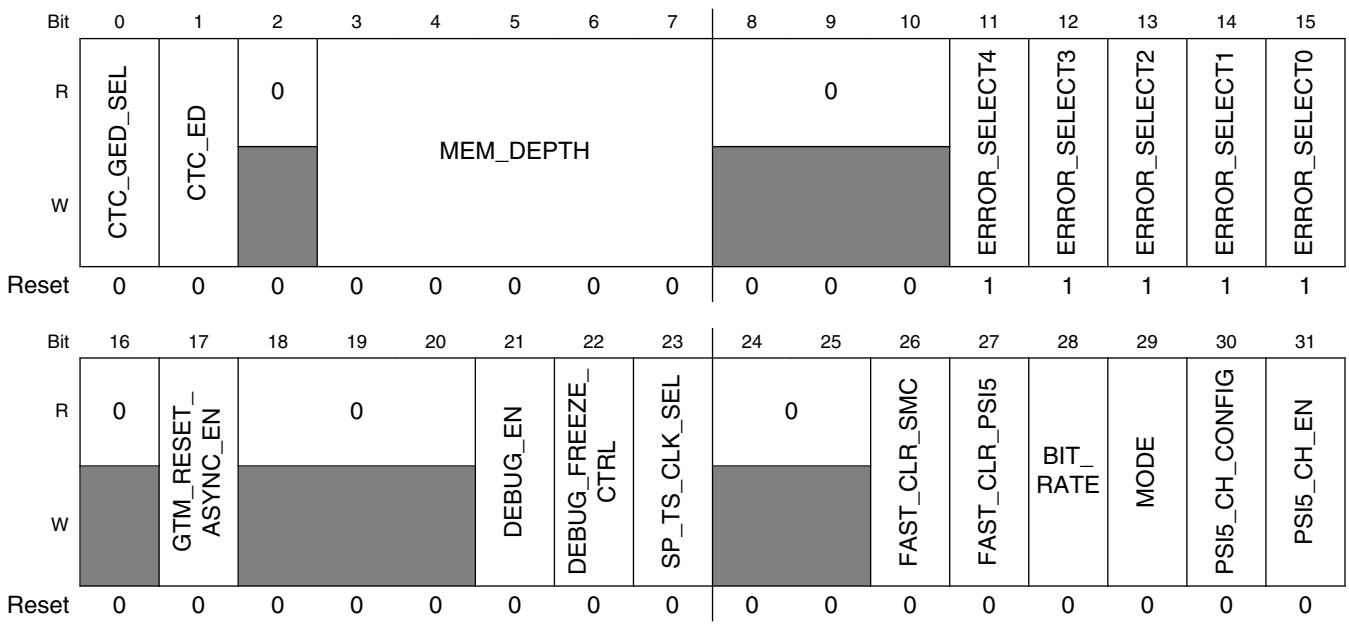
PSI5_GCR field descriptions (continued)

Field	Description
	0 PSI5 channel(s) enters Normal or Config mode, depending on the value of the PCCR[PSI5_CH_CONFIG] bit. 1 All PSI5 Channels are in Disable mode.

56.3.2 PSI5 Channel Control Register (PSI5_CH0_PCCR)

This section shows the PSI5 Channel Control Register.

Address: 0h base + 8h offset = 8h



PSI5_CH0_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select. This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable. This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. **NOTE:** This bit is writable in Normal mode and the Config mode. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access. Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0: it indicates that only 1 location of the memory is available for storage 31: it indicates that all the 32 locations of the memory are available for storage. Notes: • Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). • DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. • DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. • For more details please refer to description of DMA_PM_DS_CONFIG in the DCRs. • The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the manchester decoder. • The memory area above the configured MEM_DEPTH size will always be read as 0. • Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERROR_ SELECT4	The ERROR_SELECT bitfiield indicates which of the C, E, EM, T, or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T,or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_ SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_ SELECT2	Error_Select[2] or EM_INT_SEL

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_ SELECT1	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.
15 ERROR_ SELECT0	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 GTM_RESET_ ASYNC_EN	GTM_RESET_ASYNC_EN 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the gtm reset is synchronized on the SP_TS_CLK. 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the SP_TS_CLK.(For details of SP_TS_CLK, refer to bit 23 of) PSI5 Channel Control Register (PSI5_CH0_PCCR)
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_ FREEZE_CTRL	DEBUG_FREEZE_CTRL 0 When the IP enters the Debug mode then it goes into the “Open” mode, i.e., the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. **NOTE:** In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 As soon as debug mode is asserted, the state of the system registers that are affected by the hardware gets frozen to what ever it was existing at the point at which the Debug mode goes active.This can be useful for reading the state of the system at a particular point of time such that it is NOT affected by the next upcoming events. Note that Manchester decoder/Sync Pulse Generator/ Time Stamp counters keep on working normally but the registers (data/status/timestamp) affected by these are not updated. When the IP enters the “Debug mode” then it goes into the “Freeze Mode”. Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the “freeze mode”, if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the “sdout” line of the IP should be at a low level. Once these two

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. The fact that the freeze mode has been entered, can be checked by reading the GISR[IS_DB_FR] bit. Once the IP comes out of the freeze mode then this bit goes to 0. **NOTE:** In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit. **NOTE:** The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the common clock generator module. **NOTE:** The clock selected using this bit is called SP_TS_CLK. 0 The 1 MHz clock generated from the common clock generator module goes for clocking the Time Stamp Unit and sync pulse generator. 1 The clock generated from the GTM goes for clocking the Time Stamp Unit and Sync Pulse Generator.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. **NOTE:** This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled.
27 FAST_CLR_PSI5	This bit control the clearing mechanism of bits in NDSR(in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR(in conf2 and conf3 modes). **NOTE:** This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: • In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. • In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. • In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresesponding to a specific location are always cleared simultaneoulsy. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing.

Table continues on the next page...

PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	• In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/ PMRL register. Hence the OWSR has to be cleared only by w1c. • In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. • Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c. 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1)
28 BIT_RATE	Bit Rate This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects the 4 MHz driven clock in the common clock generator module. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 Reserved
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_ CONFIG	PSI5 Channel Config mode request. If this bit is set (and PCCR[PSI5_CH_EN] = '1')this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set can not be changed until this bit is set again after entering the Disable mode **NOTE:** This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details please see Figure 56-2 and Table 56-2 . Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 1 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a "0" in the Normal mode will not change the operation mode of the device.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes.

Table continues on the next page...

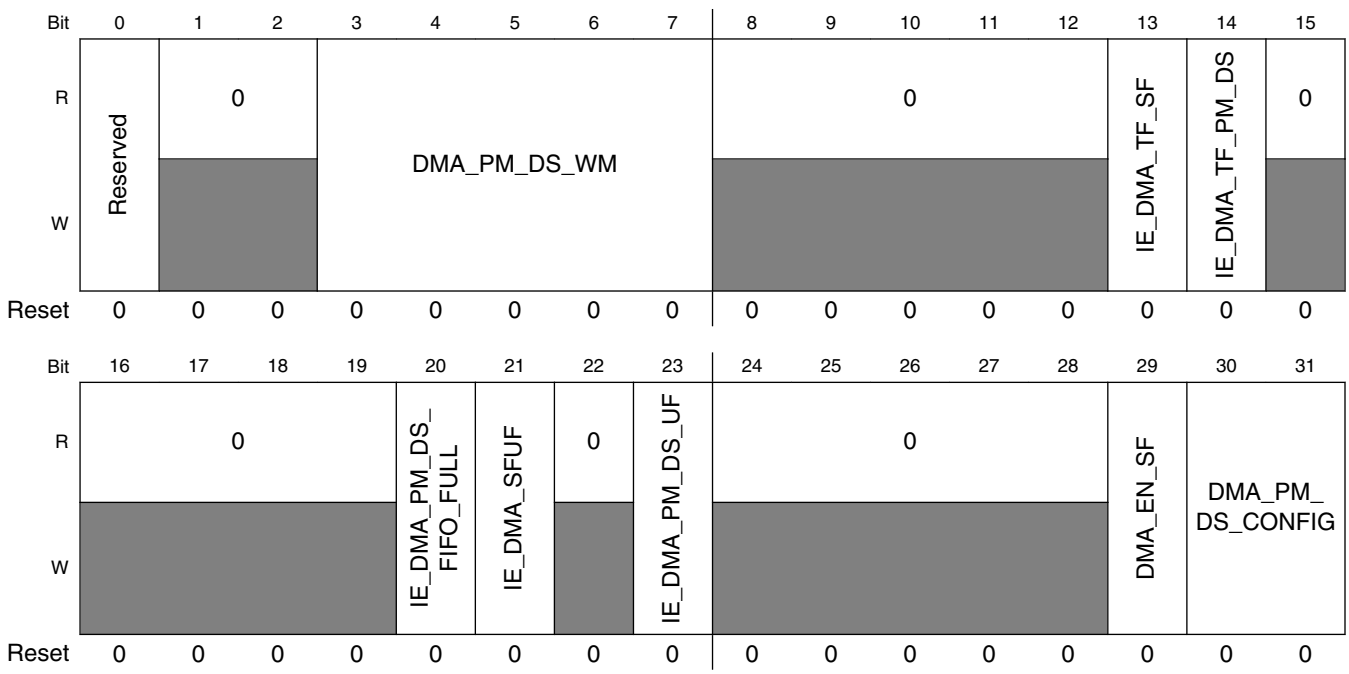
PSI5_CH0_PCCR field descriptions (continued)

Field	Description
	NOTE: When PSI5_CH_EN == 0, then the clock enable for that particular channel that goes from the IP, goes to "0" (inactive state). This also means that the only clock available to the IP in the config mode is the "ipg_clk_s". The enable for the GTM Clock is not controlled by the IP and should be controlled externally. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode.

56.3.3 DMA Control Register (PSI5_CH0_DCR)

This section defines the DMA Control Register.

Address: 0h base + Ch offset = Ch



PSI5_CH0_DCR field descriptions

Field	Description
0 Reserved	This field is reserved. **NOTE:** Only write this field with the reset value.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
3–7 DMA_PM_DS_WM	0 to 31: Valid water mark levels. Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words are present. The default and minimum value of dma_pm_ds_wm is '0', i.e. 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, i.e. the actual watermark = 32 RAM locations. **NOTE:** • These bits are ineffective if DMA_PM_DS_CONFIG = conf1. • These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO, before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. • When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. • In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). • In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. • When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. • In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IE_DMA_TF_SF	**NOTE:** This bit is writeable in Config and Normal modes. Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_DMA_TF_PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IE_DMA_PM_DS_FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases which generate these FIFO FULL conditions please refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. **NOTE:** This bit is writable in Config and Normal modes.
21 IE_DMA_SFUF	

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, i.e. it is empty. Default value is 0. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IE_DMA_PM_DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, please refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30–31 DMA_PM_DS_CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. **NOTE:** For more details please see the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message which was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA. **NOTE:** These bits are writable only in config mode. 00 **conf1** The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 **conf2**

Table continues on the next page...

PSI5_CH0_DCR field descriptions (continued)

Field	Description
	After transferring the "dma_pm_ds_wm" number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 **conf3** "dma_pm_ds_wm" number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 **conf4** Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers.

56.3.4 DMA Status Register (PSI5_CH0_DSR)

This section defines the DMA Status Register.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													IS_DMA_TF_SF	IS_DMA_TF_PM_DS	0
W														w1c	w1c	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				IS_DMA_PM_DS_FIFO_FULL	IS_DMA_SFUF	0	IS_DMA_PM_DS_UF	0							
W					w1c	w1c		w1c								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DSR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes . For the various configurations of this request please refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to DMA request. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. **conf1:** FIFO FULL disabled **conf2 and conf3:** FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. **conf4:** FIFO FULL occurs when there is a "REGISTER FULL" in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. **conf1:** underflow disabled **conf2 and conf3:** Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). **conf4:** Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. The bits are cleared by a w1c.

Table continues on the next page...

PSI5_CH0_DSR field descriptions (continued)

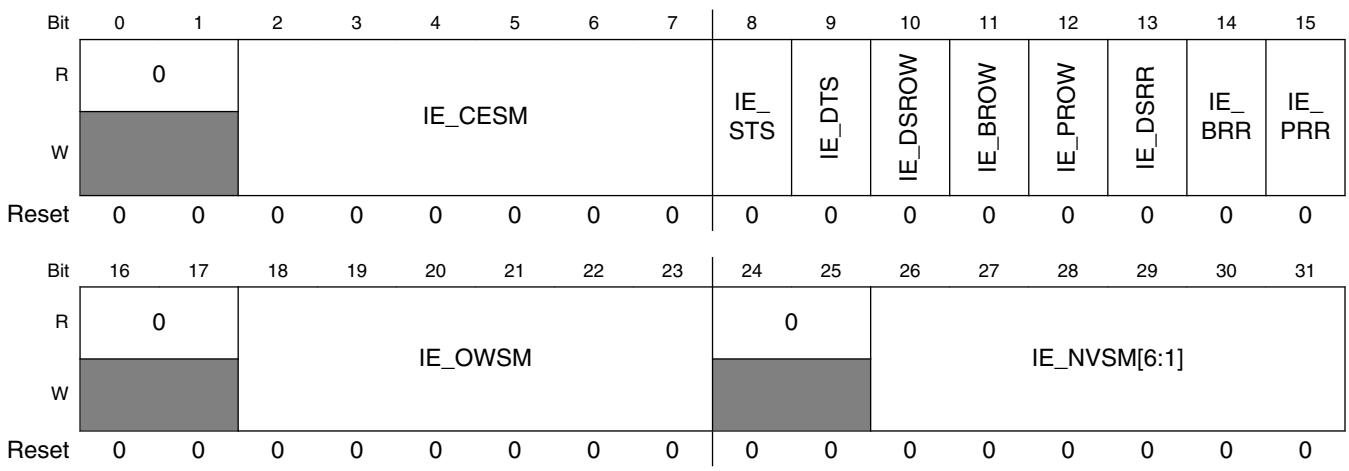
Field	Description
	0 No underflow has occurred. 1 Underflow has occurred.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.3.5 General Interrupt Control Register (PSI5_CH0_GICR)

The GICR contains the bits for controlling interrupts related to:

- SMC messages
- ECU-to-sensor communication
- the Time Stamp

Address: 0h base + 14h offset = 14h



PSI5_CH0_GICR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IE_CESM	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. **NOTE:** This bit is writable in Config and Normal modes.

Table continues on the next page...

PSI5_CH0_GICR field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IE_OWSM	Interrupt request enable for the SMC message Overwrite bits.

Table continues on the next page...

PSI5_CH0_GICR field descriptions (continued)

Field	Description
	The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5} i.e. during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. **NOTE:** These bits are writable in Config and Normal modes. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.6 New Data Interrupt Control Register (PSI5_CH0_NDICR)

The NDICR contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IE_ND

PSI5_CH0_NDICR field descriptions

Field	Description
0–31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.7 Overwrite Interrupt Control Register (PSI5_CH0_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

R	0		IS_OWSM						0		IS_NVSM					
W			w1c								w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_GISR field descriptions

Field	Description
0 IS_DB_FR	This flag is set to “1” when the IP enters the Debug freeze mode. Please see Debug mode for details about the Debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode. 1 IP in debug freeze mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IS_CESM	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.
13 DSR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When "0" it indicates that there is a ongoing command transmission of the data in DSR , or the CPU has done a "w1c" to this bit leading to the new command transmission . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, and PSI5_DOBCR[SW_READY] == 1 , then it indicates to the IP that the data in DSR is valid and is to be used for command shifting . This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, Individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
14 DBR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When "0" it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR . This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used.

Table continues on the next page...

PSI5_CH0_GISR field descriptions (continued)

Field	Description
	NOTE: In configuration mode, writes to this bit are ignored.
15 DPR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Preparation register is ready to receive new data from the system bus side . When "0" it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == "7" then this bit remains at value "0". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR . For detailed action of this bit please refer to Data transmission . **NOTE:** For these register bits individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IS_OWSM	Status for the SMC message overwrite bits. Each of the 6 locations correspond to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are automatically cleared upon message read when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IS_NVSM	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.

56.3.10 DMA PSI5 Message Register (PSI5_CH0_DPMR)

This section defines the DMA PSI5 Message Register.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DPMR field descriptions

Field	Description
0–31 PSI5_RXDATA	PSI5_RXDATA[31:0]

PSI5_CH0_DPMR field descriptions (continued)

Field	Description
	This popup register contain the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations the DATA is pushed sequentially till all the data corresponding to the programmed watermark is complete after which the DMA request goes down. The depth of the FIFO is 32x64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG=conf2 then it pops the PSI5 message followed by NDSR followed by EISR. When DMA_PM_DS_CONFIG= conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG=conf4 then it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH0_PCCR) , DMA Control Register (PSI5_CH0_DCR) and DMA Status Register (PSI5_CH0_DSR) .

56.3.11 DMA SMC Frame Register (PSI5_CH0_DSFR)

This section shows the DMA SMC Frame Register.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SMC_RXDATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DSFR field descriptions

Field	Description
0–31 SMC_RXDATA	When the DMA_EN_SF = 1 then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted till all the registers which have a complete data ready have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location, pointed to by the DMA read pointer.

56.3.12 DMA Diagnostic Status Register (PSI5_CH0_DDSR)

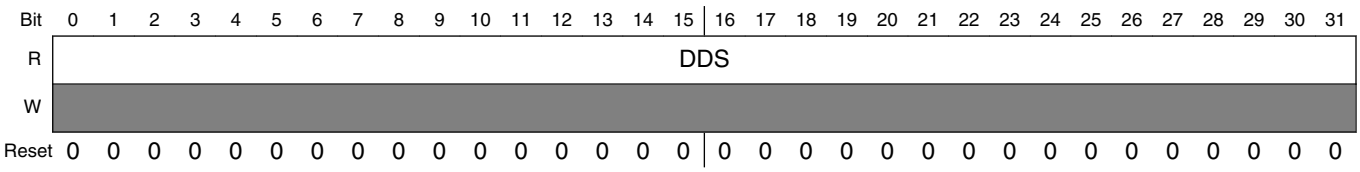
This section defines the DMA Diagnostic Status Register.

NOTE

No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR

or EISR directly) or the DMA (reading the DDSR successively).

Address: 0h base + 30h offset = 30h



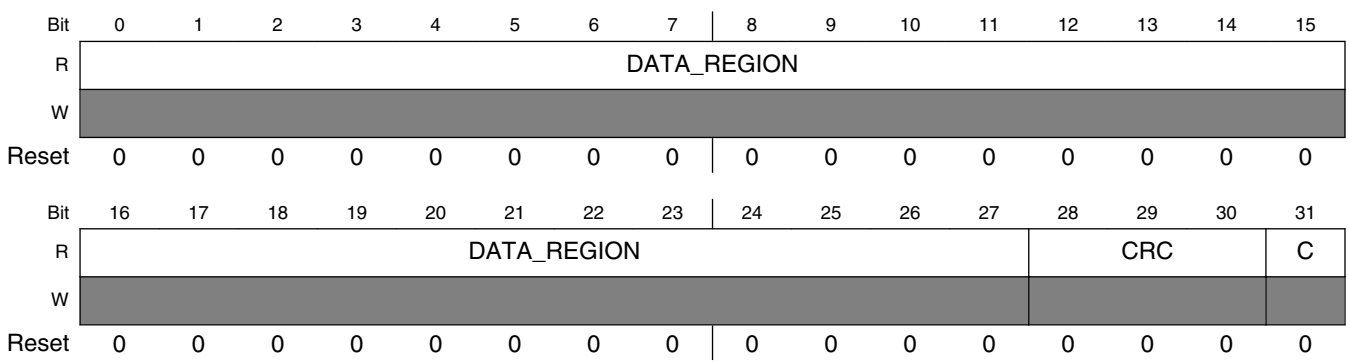
PSI5_CH0_DDSR field descriptions

Field	Description
0–31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH0_PCCR) , DMA Control Register (PSI5_CH0_DCR) and DMA Status Register (PSI5_CH0_DSR) .

56.3.13 PSI5 Message Receive Register Low (PSI5_CH0_PMRRL)

This section defines the PSI5 Message Receive Register Low.

Address: 0h base + 34h offset = 34h



PSI5_CH0_PMRRL field descriptions

Field	Description
0–27 DATA_REGION	These are application-specific optional bits + data payload of received message. See Reception of data frames for more details. The data is left-aligned i.e. Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 ? n ? 28). If n < 28 remaining bit positions are filled with '0's i.e. between last received bit and CRC field.

Table continues on the next page...

PSI5_CH0_PMRRL field descriptions (continued)

Field	Description
28–30 CRC	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

56.3.14 PSI5 Message Receive Register High (PSI5_CH0_PMRRH)

This section defines the PSI5 Message Receive Register High.

NOTE

Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occured.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PSI5_CH0_PMRRH field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH0_PMRRH field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6.
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH0_S*n*FCR) . In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0" . It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM.

56.3.15 PSI5 Message Register Low i (PSI5_CH0_PMRL*n*)

The following figure shows the PSI5 Message Register Low i.

Address: 0h base + 3Ch offset + (8d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	DATA_REGION															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATA_REGION												CRCP			C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_PMRL*n* field descriptions

Field	Description
0–27 DATA_REGION	These are application-specific optional bits + data payload of received message. See Reception of data frames for more details. The data is left-aligned i.e. Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 ? n ? 28). If n < 28 remaining bit positions are filled with '0's i.e. between last received bit and CRC field. This bit is writeable in Config mode.
28–30 CRCP	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity. This bit is writeable in Config mode.
31 C	This bit will be set if CRC/P recalculation return an Error. This bit is writeable in Config mode.

56.3.16 PSI5 Message Register High i (PSI5_CH0_PMRH*n*)

The following figure shows the PSI5 Message Register High i.

Address: 0h base + 40h offset + (8d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	O	F	EM	E	T	Slot_Counter			TimeStampValue							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TimeStampValue															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_PMRH*n* field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. This bit is writable in Config mode (for Test purposes). 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH0_PMRH*n* field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel(M0, M1) i.e. at least one bit is absent during the Tbit period. This bit is writable in Config mode (for Test purposes). 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This Bit Indicates Electrical Error i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). This bit is writable in Config mode (for Test purposes). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. This bit is writable in Config mode (for Test purposes). 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 Slot_Counter	This value indicates the slot number in which this frame was recieved. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6. This bit is writable in Config mode (for Test purposes).
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH0_S*n*FCR) . In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0". It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM. This bit is writable in Config mode (for Test purposes).

56.3.17 SMC Frame Register n (PSI5_CH0_SFR*n*)

The following figure shows the SMC Frame Register n.

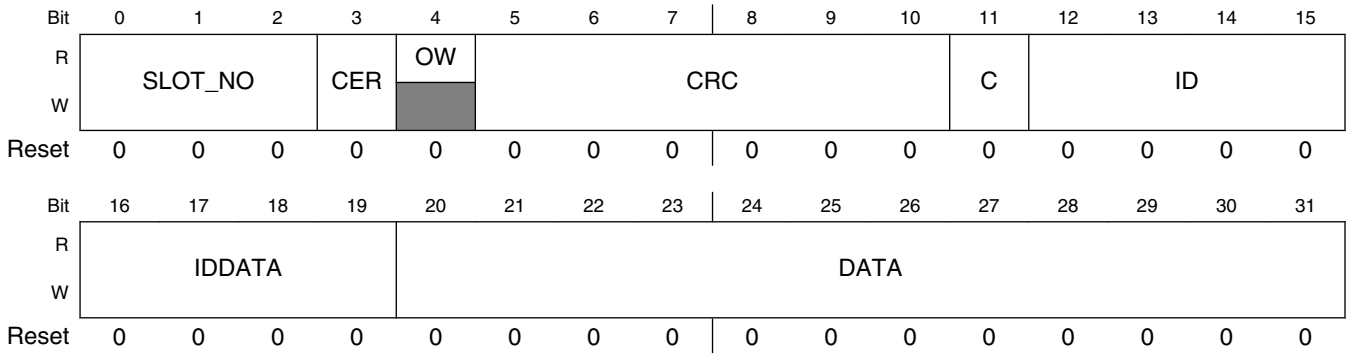
NOTE

Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

NOTE

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

Address: 0h base + 13Ch offset + (4d × i), where i=0d to 5d



PSI5_CH0_SFR*n* field descriptions

Field	Description
0–2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; This field is writable in Config mode (for Test purposes).
3 CER	CRC Error This field is writable in Config mode (for Test purposes). 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status **NOTE:** If the corresponding SOWSM bits in the SSESR have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set. 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message.
5–10 CRC	6-bit CRC for slow serial message

Table continues on the next page...

PSI5_CH0_SFR*n* field descriptions (continued)

Field	Description
	This field is writable in Config mode (for Test purposes).
11 C	Configuration bit This bit is writable in Config mode (for Test purposes). 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID.
12–15 ID	Message ID: If C = '0' indicates ID[7:4], if C = '1' indicates ID[3:0]. This field is writable in Config mode (for Test purposes).
16–19 IDDATA	Message ID/DATA: If C = '0' indicates ID[3:0], if C = '1' indicates DATA[15:12]. This field is writable in Config mode (for Test purposes).
20–31 DATA	DATA payload This field is writable in Config mode (for Test purposes).

56.3.18 New Data Status Register (PSI5_CH0_NDSR)

The following figure shows the New Data Status Register.

Address: 0h base + 154h offset = 154h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_NDSR field descriptions

Field	Description
0–31 NDS	New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when a new Message arrives i.e. faulty or non faulty in corresponding PSI5 MB location. Bit 0 reflects the MB0 location. These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SNDR.

56.3.19 Overwrite Status Register (PSI5_CH0_OWSR)

Address: 0h base + 158h offset = 158h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_OWSR field descriptions

Field	Description
0–31 OWS	Over Write Status flags for PSI5 Messages corresponding to each PSI5 location in the RAM registers. These bits are set when any unread receive PSI5 message is overwritten by a newly arrived message). These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SOWSR.

56.3.20 Error Indication Status Register (PSI5_CH0_EISR)

The following figure shows the Error Indication Status Register.

Address: 0h base + 15Ch offset = 15Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_EISR field descriptions

Field	Description
0–31 ERROR	Error Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when any of the five selectable (by ERROR_SELECT) bits (C, E, EM, T or F) is set for the corresponding PSI5 Message. These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independently by writing in SEISR.

56.3.21 Set New Data Status Register (PSI5_CH0_SNDSR)

The following figure shows the Set New Data Status Register.

Address: 0h base + 160h offset = 160h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_SNDSR field descriptions

Field	Description
0–31 SNDS	Sets New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. The corresponding NDS Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** This bit is writable in config and Normal modes.

56.3.22 Set Overwrite Status Register (PSI5_CH0_SOWSR)

The following figure shows the Set Overwrite Status Register.

Address: 0h base + 164h offset = 164h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

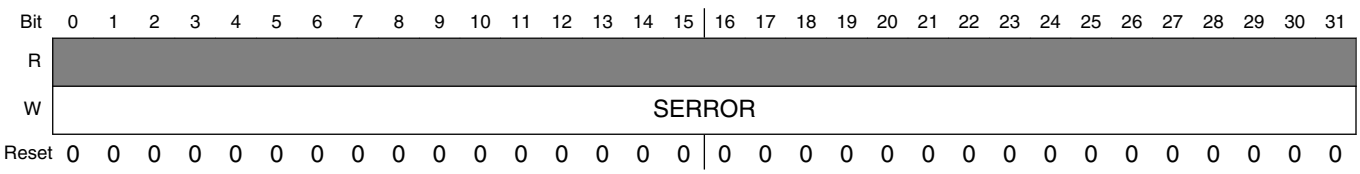
PSI5_CH0_SOWSR field descriptions

Field	Description
0–31 SOWS	Sets overwrite status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding OWS flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.23 Set Error Status Register (PSI5_CH0_SEISR)

The following figure shows the Set Error Status Register.

Address: 0h base + 168h offset = 168h



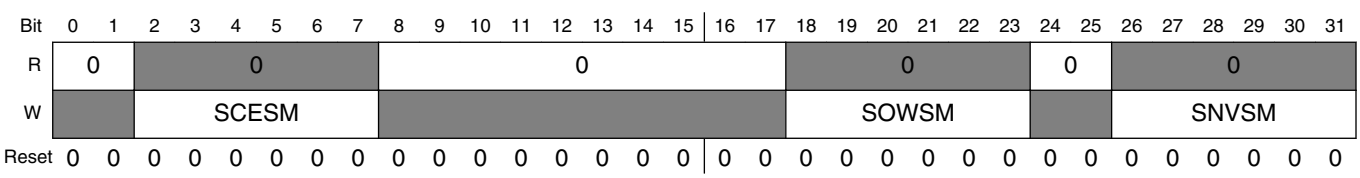
PSI5_CH0_SEISR field descriptions

Field	Description
0–31 SERROR	Sets Error Status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding ERROR flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.24 Set SMC Error Status Register (PSI5_CH0_SSESR)

The following figure shows the Set SMC Error Status Register.

Address: 0h base + 16Ch offset = 16Ch



PSI5_CH0_SSESR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 SCESM	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations.

Table continues on the next page...

PSI5_CH0_SSESR field descriptions (continued)

Field	Description
	The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
8–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 SOWSM	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 SNVSM	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** This bit is writable in Config and Normal modes.

56.3.25 Sync Time Stamp Read Register (PSI5_CH0_STSRR)

The following figure shows the Sync Time Stamp Read Register.

Address: 0h base + 170h offset = 170h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH0_STSRR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 STSV	Sync Time Stamp Value[23:0] This bitfield provides the value of the free-running 24-bit time stamp counter triggered (captured) at last sync pulse.

56.3.26 Data Time Stamp Read Register (PSI5_CH0_DTSRR)

The following figure shows the Data Time Stamp Read Register.

NOTE

If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter , both will correspond to the first slot(S0)

Address: 0h base + 174h offset = 174h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0					SLOT_COUNTER			DTSV							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	DTSV															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DTSRR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 SLOT_ COUNTER	3bit Slot Counter which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode the slot counter has a fixed value of "1".
8–31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected then the value of the Time Stamp counter captured at the rising edge of the S0, is stored in this register at the rising edge of S1.

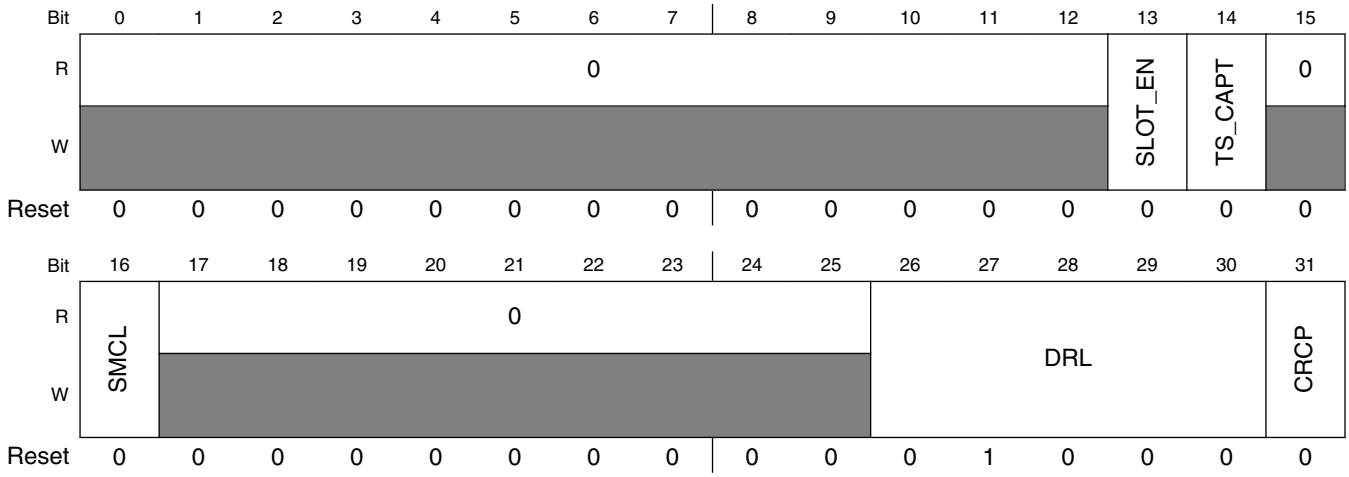
56.3.27 Slot n Frame Configuration Register (PSI5_CH0_S*n*FCR)

The following figure shows the Slot n Frame Configuration Register.

NOTE

In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

Address: 0h base + 178h offset + (4d × i), where i=0d to 5d



PSI5_CH0_S*n*FCR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLOT_EN	SLOT_EN 0 This particular slot is disabled i.e not in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) have no effect. 1 This particular slot is enabled i.e is in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) are applicable.
14 TS_CAPT	TS_CAPT 0 Time stamp value captured at rising edge of S0 and stored Start sequence first edge. 1 Time stamp value captured at corresponding Tsync pulse (posedge) and stored with corresponding slot PSI5 message.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SMCL	Serial Messaging Channel field This field is used to enable the detection of start sequence of SMC frame on particular slot. Detection is not done if this field is '0'. 0 Serial Messaging Channel (optional) not present on Rx Message during Time Slot 'n' 1 2-bit{M1,M0} Serial Messaging Channel present on Rx Message during Time Slot 'n'
17–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–30 DRL	Data Region Length[4:0] This field represents Length of Data region (including Frame Control, Status , Data payload1&2 regions and optional messaging bits M0,M1) in Rx Message during Time Slot 'n' 00000-00111: Invalid 01000: 8 bit long data region 01001: 9 bit long data region 01010: 10 bit long data region ....

Table continues on the next page...

PSI5_CH0_S*n*FCR field descriptions (continued)

Field	Description
	11011: 27 bit long data region 11100: 28 bit long data region 11101-11111: Invalid
31 CRCP	CRCP 0 3 bit CRC[2:0] present on Rx Message during Time Slot 'n' 1 1 bit Parity field present on Rx Message during Time Slot 'n'

56.3.28 Slot 1 Start Boundary Register (PSI5_CH0_S1SBR)

The following figure shows the Slot 1 Start Boundary Register.

Address: 0h base + 190h offset = 190h

1–15 S6SBT	Slot 6 Start Boundary Time This field specifies the time in intervals of 1 µs, occurring after the rising edge of the timing sync pulse, at which the slot 6 should start.

56.3.34 Slot n End Boundary Register (PSI5_CH0_SnEBR)

The following figure shows the Slot *n* Start Boundary Register (PSI5_S *n* SBR).

Slot n End Boundary register is a single register which can be programmed to define the "end" of the nth slot. The n can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SnEBR (Slot n End Boundary register) defines the end of the nth slot. The n is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SnEBR. The SnEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the SnFCR. When the start slot boundaries are properly defined in the SnSBR (Slot n Start Boundary Register) register but the slot_en bit = 0 in the corresponding SnFCR (Slot n Frame Configuration register) register, then the corresponding slot is treated as "available" but "unconfigured." For such a slot the data/diagnostic bits all remain 0. The "T" bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots. Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if "S0" and "S1" are detected in different slots then a T-bit error is set .

NOTE

The start slot boundaries in the S *n* SBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SnEBR are treated as being unavailable (that is, the data

in all the slots occurring after the SnEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the S *n* EBR and define the end boundary of the third slot in S *n* EBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the S *n* EBR by putting slot_no = 6 and define the end boundary of the sixth slot in S *n* EBR.

Address: 0h base + 19Ch offset = 19Ch

PSI5_CH0_SnEBR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 SLOT_NO	The field indicates the Slot number{1-6} for which Slot End Boundary Time is defined. Any value other than 1-6 is defaulted to 0. A value 0 here would mean that the manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 SnEBT	Slot *n* End Boundary Time. This field specifies the time in intervals of 1µs, occurring after the rising edge of timing sync pulse, at which the slot 'n" should end.

56.3.35 Data Output Block Configuration Register (PSI5_CH0_DOBCR)

The following figure shows the Data Output Block Configuration Register.

Table 56-4. CMD_TYPE details

CMD_TYPE	PSI5 Frame [1]	Effect on registers	Writeable Register lengths
"000" - 0	Short Frame(V1.3) with 31 "1s" as the start condition	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15bits[2] in DBR/DSR.
"001" - 1	Short Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"010" - 2	Long Frame(V1.3) with 31 "1s" as the start condition	-do-	16bits in DPR. 29bits[2] in DBR/DSR.
"011" - 3	Long Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"100" - 4	X-Long Frame(V1.3) with 31 "1s" as the start condition	-do-	22bits in DPR. 37bits[2] in DBR/DSR
"101" - 5	X-Long Frame(V1.3) with 5 "0s" as the start condition.	-do-	-do-
"110" - 6	XX-Long (V2.0) -	-do-	24 bits in DPR. 43bits[2] in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCR[DATA_LENGTH] field.

1. The start condition(31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command.
2. This is also the length of the command that will be shifted out during the ECU to Sensor communication, regardless of how many "actual" bits are written to DBR/DSR.

Table 56-5. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1	0	1	1
State2[1]	0	0	1
State3[1]	1	1	1
State4[1]	1	0	1
State5[1]	1	x	0

1. These states are shown in Valid states for integrated sync pulse generator. In State5, the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

NOTE

Please refer to Figure 56-26 for the details about the above bits. Figure 56-26 is the actual implementation of Figure 56-25 such

that various contentions between the switches (S1, S2, and so on) do not happen.

Address: 0h base + 1A0h offset = 1A0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA_LENGTH[5:0]						DBR_RST	DSR_RST	CMD_TYPE			DEFAULT_SYNC	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL	SW_READY
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DOBCR field descriptions

Field	Description
0–5 DATA_LENGTH[5:0]	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard) , then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0, then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH = 1, then the length of the command that can be written to DSR and the DBR is 2 and so on, until a maximum of 64 bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits that shift out of DSR register once the DSR_RDY goes low . After these many shifts have happened , then the value corresponding to "DEFAULT_SYNC" starts getting shifted out and DSR_RDY goes as "1".
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as "1" then the contents of the DBR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register.When this bit is written as "1" then the contents of the DSR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data.Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
8–10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. Table 56-4 is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to "0" then the default value of DSR and DBR registers are all "0s"; when this bit is set to 1 then the default value of DBR and DSR registers are all "1s". This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 0 Internal sync pulse generator shift triggered 1 GTM event shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 0 SP module gets the data from the DSR 1 SP module directly gets input from the GTM_event/internal sync pulse generator

Table continues on the next page...

PSI5_CH0_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects as to which would be driving source of the "ipp_do_psi5_sdout" port. 0 The sync pulse generator select as per the Bit3 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending . Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1 , will the transfer happen. This bit can be written in CONFIG and the Normal modes.

56.3.36 Manchestor Decoder Disable Offset (PSI5_CH0_MDDIS_OFF)

The Manchester Decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 µs, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 µs to 128 µs. This works on the 1 µs clock from the common clock generator module.

Address: 0h base + 1A2h offset = 1A2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0									MDDIS_OFF						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_MDDIS_OFF field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester Decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse . Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester Decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester Decoder BEYOND the Sync Pulse High Time as well. Figure 1032 shows the "MDDIS_OFF" definition.

56.3.37 Pulse Width for Data Bit Value 0 (PSI5_CH0_PW0D)

The following figure shows the Pulse Width for Data Bit 0 Register.

Address: 0h base + 1A4h offset = 1A4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width0							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_PW0D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 Pulse_Width0	This defines the width (in µs) of data value '0' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width0", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. When using PSI5 version 1.3 ECU-to-sensor Communication Pulse_Width0 should be configured to 0. Figure 1032 shows the definition of "Pulse_Width0".

56.3.38 Pulse Width for Data Bit Value 1 (PSI5_CH0_PW1D)

The following figure shows the Pulse Width for Data Bit 1 Register.

NOTE

When using the Version 1.3 format for ECU-to-sensor communication, the pulse width is NOT disabled. In this case, PW0D has to be programmed as 0. PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

Address: 0h base + 1A6h offset = 1A6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width1							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_PW1D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH0_PW1D field descriptions (continued)

Field	Description
9–15 Pulse_Width1	This defines the width (in µs) of data value '1' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width1", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. Figure 1032 shows the definition of "Pulse_Width1".

56.3.39 Counter Target Pulse Register (PSI5_CH0_CTPR)

The following figure shows the Counter Target Pulse Register.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 1A8h offset = 1A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CTPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_CTPR field descriptions

Field	Description
0–15 CTPR	Counter Target Pulse Register. This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16 bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the Time Period of the internally generated sync pulses. The un modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles i.e. the duty cycle of the un modulated internally generated sync pulses is (4/|CTPR| *100). The 4 sp_ts_clk cycles is just the nascent value of the Pulse which actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in Valid states for integrated sync pulse generator . This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

56.3.40 Counter Initialize Pulse Register (PSI5_CH0_CIPR)

The following figure shows the Counter Initialize Pulse Register.

NOTE

Due to internal Flop synchronisation there can be a jitter of +/- 20 ns between the offset times that are programmed in the CIPR of different channels and the ones actually being observed. Similarly there can be a jitter of +/- 20 ns in the programmed CTPR and the measured CTPR.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 1AAh offset = 1AAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CIPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_CIPR field descriptions

Field	Description
0–15 CIPR	Counter initialize pulse register. This is the value using which the CTC gets reset, the first time after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be |CIPR_channel1 - CIPR_channel2| sp_ts_clk cycles. This if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

56.3.41 Data Preparation Register Low (PSI5_CH0_DPRL)

The following figure shows the Data Preparation Register Low.

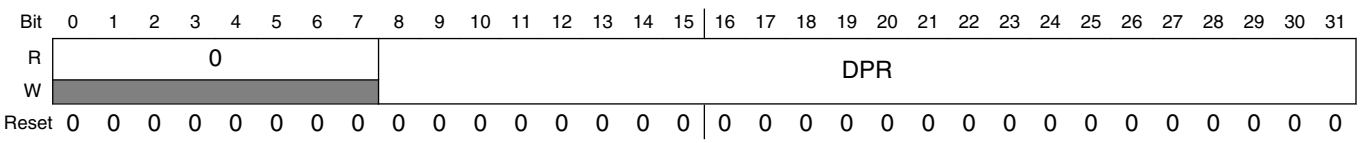
This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when PSI5_GISR[DPR_RDY] == 1. Whenever PSI5_GISR[DPR_RDY] == 1 , then each bit of

this register defaults to 0 . Writing to this register when PSI5_GISR[DPR_RDY] == 0 will cause the PSI5_GISR[IS_PROW] status bit to be set and the generation of an error interrupt, if it is enabled. Further , trying to write to this register when PSI5_DOBCR[CMD_TYPE] = "7" results in the setting of the PSI5_GISR[IS_PROW] bit and the resulting write is rejected.

Table 56-6. DPR details

PSI5_DOBCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL
"0" or "1"	Short Frame(PSI5 V1.3)	6(DPR[5:0])
"2" or "3"	Long Frame(PSI5 V1.3)	16(DPR[15:0])
"4" or "5"	X-Long Frame(PSI5 V1.3)	22(DPR[21:0])
"6"	XX-Long Frame(PSI5 V2.0)	24(DPR[23:0])
"7"	Not Available for write	Not Available for write

Address: 0h base + 1ACh offset = 1ACh

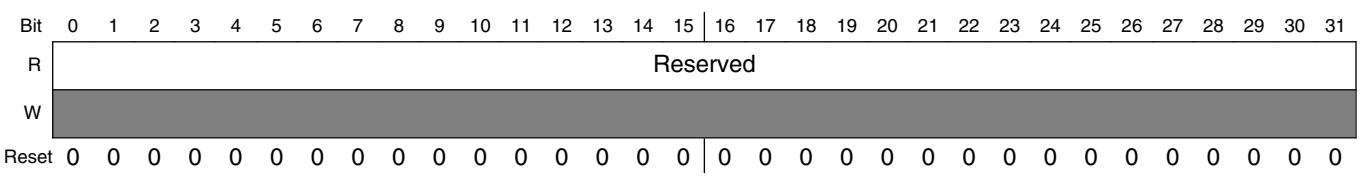


PSI5_CH0_DPRL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 DPR	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length , standard ECU-to-Sensor commands , comprising of the address , data and other fields . Note that the IP is transparent to the arrangement of the address,data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writeable only when using the standard length PSI5 frames . For details about CRC calculation please refer to Data transmission . The writeable bits in this register are governed by the PSI5_DOBCR[CMD_TYPE] bit fields as per Table 56-6 . Note that the unwriteable bits in this register field are always read as "0s" . This register has to be written by the CPU. These bits can be written only in the Normal mode.

56.3.42 Data Preparation Register High (PSI5_CH0_DPRH)

Address: 0h base + 1B0h offset = 1B0h



PSI5_CH0_DPRH field descriptions

Field	Description
0–31 Reserved	This field is reserved. This register is always read as 0s. Writing to this register does not have any effect.

56.3.43 Data Buffer Register Low (PSI5_CH0_DBRL)

The following figure shows the Data Buffer Register Low.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode.

NOTE

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1, then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-7. DBRL[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment

PSI5_CH0_DBRL field descriptions

Field	Description
0–31 DBR	This register contains the Lower 32 bits(DBR[31:0]) of the max-64 bit length command (DBR[63:0]). The higher bits, DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-7 . The table (except when PSI5_DOBCR[CMD_TYPE] = "7") show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == "7"), then only the CPU can write to these registers.

56.3.44 Data Buffer Register High (PSI5_CH0_DBRH)

The following figure shows the Data Buffer Register High.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY]== 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit

PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-8. DBRH[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
"7" - Non Standard Frame lengths	DBR[63:32]]	Variable length of writeable bits , as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]
"6" - XX Long	DBR[63:43]	All 0s
	DBR[42:37]	{CRC[5],CRC[4],CRC[3],CRC[2],CRC[1], CRC[0]}
	DBR[36]	1'b0(stuff)
	DBR[32:35]	DPR[23:20]
"4" or "5" -X Long	DBR[63:37]	All 0s
	DBR[36]	CRC[0]
	DBR[35]	1'b1((stuff)
	DBR[34:32]	{CRC[1],CRC[2],DPR[21]}
"3" or "2"(Long) OR "1" or "0" (Short)	DBR[63:32]	All 0s

Address: 0h base + 1B8h offset = 1B8h

PSI5_CH0_DBRH field descriptions

Field	Description
0–31 DBR	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-8 . Note that when PSI5_DOBCR[CMD_TYPE] == "7") , then only the CPU can write to these registers.

56.3.45 Data Shift Register Low (PSI5_CH0_DSRL)

The following figure shows the Data Shift Register Low.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 1BCh offset = 1BCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DSR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH0_DSRL field descriptions

Field	Description
0–31 DSR	This register contains the lower 32 bits, (DSR[31:0]), of the max-64 bit length command (DSR[63:0]). The higher bits, DSR[63:32], are contained in the DSRH register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRL. Thus, when updated by the hardware, then DSR[31:0] = DBR[31:0]. Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0, then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1. These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1.

56.3.46 Data Shift Register High (PSI5_CH0_DSRH)

The following figure shows the Data Shift Register High.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 1C0h offset = 1C0h

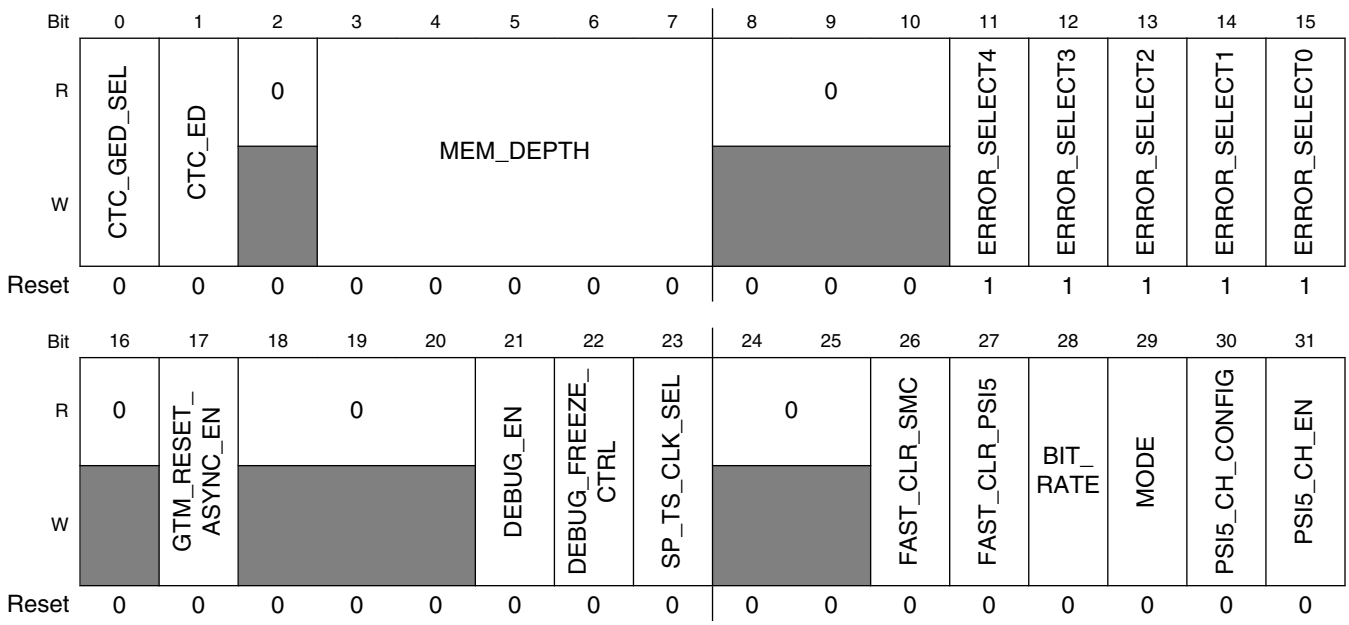
PSI5_CH0_DSRH field descriptions

Field	Description
0–31 DSR	This register contains the higher 32 bits (DSR[63:32) of the max-64 bit length command (DSR[63:0]). The lower bits, DSR[31:0], are contained in the DSRL register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRH. Thus when updated by the hardware, then DSR[63:32]] = DBR[63:32]. Hardware updation occurs when PSI5_GISR[DSR_RDY] == 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0, then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1 . These bits can be written by the CPU in the Normal mode when PSI5_GISR[DSR_RDY] == 1'b1 .

56.3.47 PSI5 Channel Control Register (PSI5_CH1_PCCR)

This section shows the PSI5 Channel Control Register.

Address: 0h base + 1C8h offset = 1C8h



PSI5_CH1_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select. This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable. This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. **NOTE:** This bit is writable in Normal mode and the Config mode. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access.

Table continues on the next page...

PSI5_CH1_PCCR field descriptions (continued)

Field	Description
	Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0: it indicates that only 1 location of the memory is available for storage 31: it indicates that all the 32 locations of the memory are available for storage. Notes: • Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). • DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. • DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. • For more details please refer to description of DMA_PM_DS_CONFIG in the DCRs. • The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the manchester decoder. • The memory area above the configured MEM_DEPTH size will always be read as 0. • Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERROR_ SELECT4	The ERROR_SELECT bitfiield indicates which of the C, E, EM, T, or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T,or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_ SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_ SELECT2	Error_Select[2] or EM_INT_SEL 0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_ SELECT1	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.

Table continues on the next page...

PSI5_CH1_PCCR field descriptions (continued)

Field	Description
15 ERROR_ SELECT0	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 GTM_RESET_ ASYNC_EN	GTM_RESET_ASYNC_EN 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the gtm reset is synchronized on the SP_TS_CLK. 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the SP_TS_CLK.(For details of SP_TS_CLK, refer to bit 23 of) PSI5 Channel Control Register (PSI5_CH1_PCCR)
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_ FREEZE_CTRL	DEBUG_FREEZE_CTRL 0 When the IP enters the Debug mode then it goes into the “Open” mode, i.e., the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. **NOTE:** In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 As soon as debug mode is asserted, the state of the system registers that are affected by the hardware gets frozen to what ever it was existing at the point at which the Debug mode goes active.This can be useful for reading the state of the system at a particular point of time such that it is NOT affected by the next upcoming events. Note that Manchester decoder/Sync Pulse Generator/ Time Stamp counters keep on working normally but the registers (data/status/timestamp) affected by these are not updated. When the IP enters the “Debug mode” then it goes into the “Freeze Mode”. Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the “freeze mode”, if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the “sdout” line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. The fact that the freeze mode has been entered, can be checked by reading the GISR[IS_DB_FR] bit. Once the IP comes out of the freeze mode then this bit goes to 0. **NOTE:** In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_ SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit.

Table continues on the next page...

PSI5_CH1_PCCR field descriptions (continued)

Field	Description
	NOTE: The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the common clock generator module. **NOTE:** The clock selected using this bit is called SP_TS_CLK. 0 The 1 MHz clock generated from the common clock generator module goes for clocking the Time Stamp Unit and sync pulse generator. 1 The clock generated from the GTM goes for clocking the Time Stamp Unit and Sync Pulse Generator.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. **NOTE:** This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled.
27 FAST_CLR_PSI5	This bit control the clearing mechanism of bits in NDSR(in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR(in conf2 and conf3 modes). Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: • In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. • In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. • In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresesponding to a specific location are always cleared simultaneoulsy. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. • In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/ PMRL register. Hence the OWSR has to be cleared only by w1c. • In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. • Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c.

Table continues on the next page...

PSI5_CH1_PCCR field descriptions (continued)

Field	Description
	NOTE: This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1)
28 BIT_RATE	This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects one of the two driven clocks (4 MHz or 6.048 MHz) in the common clock generator module. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 189 Kbit/s bit rate selected (6.048 MHz clock).
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_ CONFIG	PSI5 Channel Config mode request. If this bit is set (and PCCR[PSI5_CH_EN] = '1')this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set can not be changed until this bit is set again after entering the Disable mode **NOTE:** This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details please see Figure 56-2 and Table 56-2 . Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 1 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a "0" in the Normal mode will not change the operation mode of the device.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. **NOTE:** When PSI5_CH_EN == 0 then the clock enable for that particular channel that goes from the IP, goes to "0" (inactive state). This also means that the only clock available to the IP in the config mode is the "ipg_clk_s".The enable for the GTM Clock is not controlled by the IP and should be controlled externally. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.

Table continues on the next page...

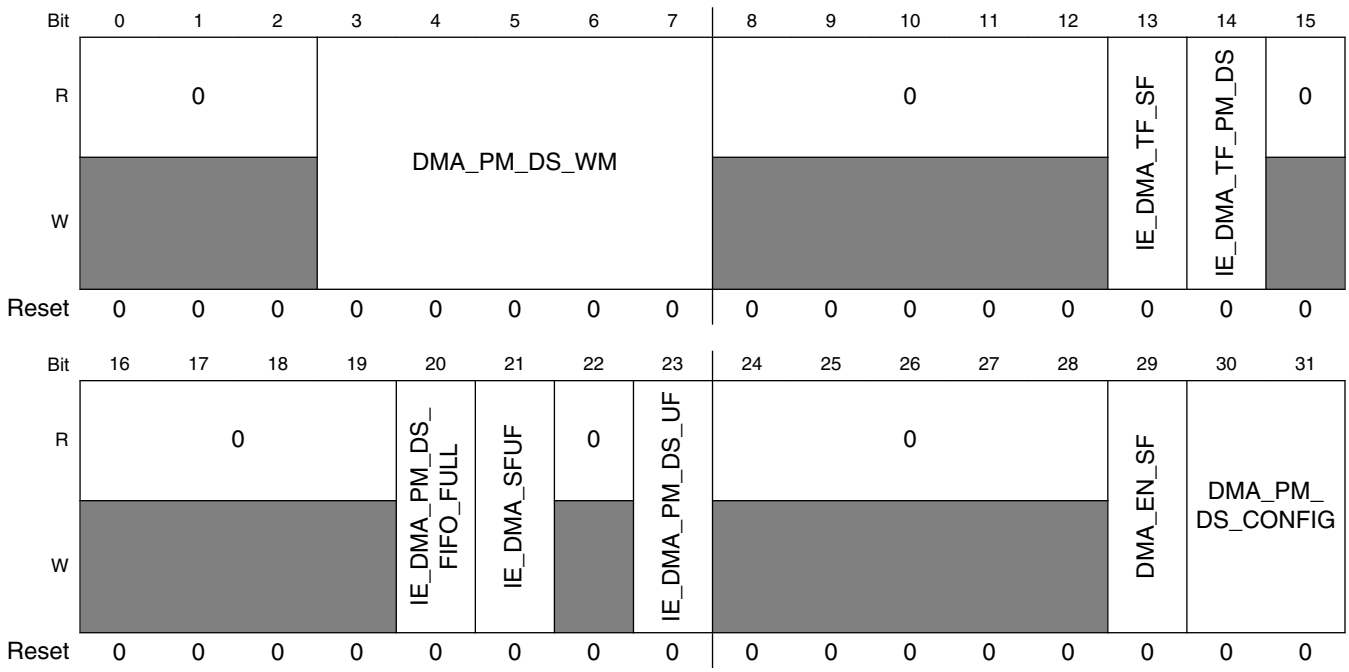
PSI5_CH1_PCCR field descriptions (continued)

Field	Description
	0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode.

56.3.48 DMA Control Register (PSI5_CH1_DCR)

This section defines the DMA Control Register.

Address: 0h base + 1CCh offset = 1CCh



PSI5_CH1_DCR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 DMA_PM_DS_ WM	0 to 31: Valid water mark levels. Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words are present. The default and minimum value of dma_pm_ds_wm is '0', i.e. 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, i.e. the actual watermark = 32 RAM locations. **NOTE:** • These bits are ineffective if DMA_PM_DS_CONFIG = conf1. • These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO,

Table continues on the next page...

PSI5_CH1_DCR field descriptions (continued)

Field	Description
	before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. • When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. • In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). • In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. • When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. • In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IE_DMA_TF_SF	**NOTE:** This bit is writeable in Config and Normal modes. Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_DMA_TF_ PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IE_DMA_PM_ DS_FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases which generate these FIFO FULL conditions please refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. **NOTE:** This bit is writable in Config and Normal modes.
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, i.e. it is empty. Default value is 0. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH1_DCR field descriptions (continued)

Field	Description
23 IE_DMA_PM_DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, please refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30–31 DMA_PM_DS_CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. **NOTE:** For more details please see the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message which was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA. **NOTE:** These bits are writable only in config mode. 00 **conf1** The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 **conf2** After transferring the "dma_pm_ds_wm" number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 **conf3** "dma_pm_ds_wm" number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 **conf4** Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers.

56.3.49 DMA Status Register (PSI5_CH1_DSR)

This section defines the DMA Status Register.

Address: 0h base + 1D0h offset = 1D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													IS_DMA_TF_SF	IS_DMA_TF_PM_DS	0

PSI5_CH1_DSR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes . For the various configurations of this request please refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to DMA request. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. **conf1:** FIFO FULL disabled **conf2 and conf3:** FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. **conf4:** FIFO FULL occurs when there is a "REGISTER FULL" in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. **conf1:** underflow disabled **conf2 and conf3:** Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). **conf4:** Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. The bits are cleared by a w1c.

Table continues on the next page...

PSI5_CH1_DSR field descriptions (continued)

Field	Description
	0 No underflow has occurred. 1 Underflow has occurred.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.3.50 General Interrupt Control Register (PSI5_CH1_GICR)

The GICR contains the bits for controlling interrupts related to:

- SMC messages
- ECU-to-sensor communication
- the Time Stamp

Address: 0h base + 1D4h offset = 1D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PSI5_CH1_GICR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IE_CESM	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. **NOTE:** This bit is writable in Config and Normal modes.

Table continues on the next page...

PSI5_CH1_GICR field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IE_OWSM	Interrupt request enable for the SMC message Overwrite bits.

Table continues on the next page...

PSI5_CH1_GICR field descriptions (continued)

Field	Description
	The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5} i.e. during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. **NOTE:** These bits are writable in Config and Normal modes. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.51 New Data Interrupt Control Register (PSI5_CH1_NDICR)

The NDICR contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 1D8h offset = 1D8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IE_ND																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_NDICR field descriptions

Field	Description
0–31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.52 Overwrite Interrupt Control Register (PSI5_CH1_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 1DCh offset = 1DCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH1_OWICR field descriptions

Field	Description
0–31 IE_OW	Interrupt request enabled when any new message overwrites the old unread PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt generated only when corresponding RAM buffer Ready with new data. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.53 Error Interrupt Control Register (PSI5_CH1_EICR)

The following figure shows the Error Interrupt Control Register.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 1E0h offset = 1E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH1_EICR field descriptions

Field	Description
0–31 IE_ERROR	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when

PSI5_CH1_EICR field descriptions (continued)

Field	Description
	corresponding RAM buffer Ready with new data. Which of the error condition (any of C, E, EM, T, or F) would generate the interrupt is selectable by PCCR[ERROR_SELECT] field. If all are selected then which out of C,E,EM,T,F is set can be isolated by reading corresponding received message. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.54 General Interrupt Status Register (PSI5_CH1_GISR)

The GISR contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Address: 0h base + 1E4h offset = 1E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	IS_DB_FR	0	IS_CESM						IS_STS	IS_DTS	IS_DSROW	IS_BROW	IS_PROW	DSR_RDY	DBR_RDY	DPR_RDY

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0		IS_OWSM						0		IS_NVSM					
W			w1c								w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_GISR field descriptions

Field	Description
0 IS_DB_FR	This flag is set to “1” when the IP enters the Debug freeze mode. Please see Debug mode for details about the Debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode. 1 IP in debug freeze mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IS_CESM	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.
13 DSR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When "0" it indicates that there is a ongoing command transmission of the data in DSR , or the CPU has done a "w1c" to this bit leading to the new command transmission . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, and PSI5_DOBCR[SW_READY] == 1 , then it indicates to the IP that the data in DSR is valid and is to be used for command shifting . This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, Individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
14 DBR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When "0" it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR . This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used.

Table continues on the next page...

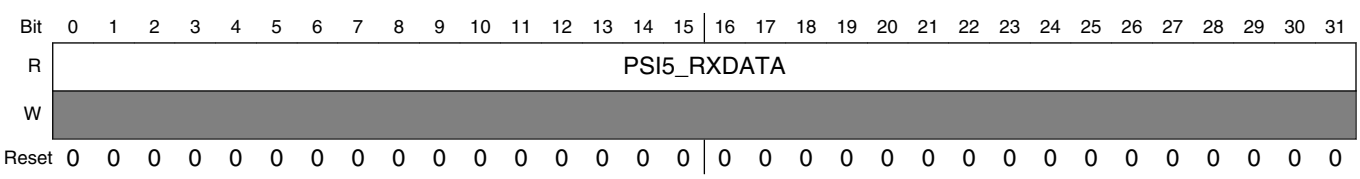
PSI5_CH1_GISR field descriptions (continued)

Field	Description
	NOTE: In configuration mode, writes to this bit are ignored.
15 DPR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Preparation register is ready to receive new data from the system bus side . When "0" it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == "7" then this bit remains at value "0". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR . For detailed action of this bit please refer to Data transmission . **NOTE:** For these register bits individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IS_OWSM	Status for the SMC message overwrite bits. Each of the 6 locations correspond to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are automatically cleared upon message read when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IS_NVSM	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.

56.3.55 DMA PSI5 Message Register (PSI5_CH1_DPMR)

This section defines the DMA PSI5 Message Register.

Address: 0h base + 1E8h offset = 1E8h



PSI5_CH1_DPMR field descriptions

Field	Description
0–31 PSI5_RXDATA	PSI5_RXDATA[31:0]

PSI5_CH1_DPMR field descriptions (continued)

Field	Description
	This popup register contain the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations the DATA is pushed sequentially till all the data corresponding to the programmed watermark is complete after which the DMA request goes down. The depth of the FIFO is 32x64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG=conf2 then it pops the PSI5 message followed by NDSR followed by EISR. When DMA_PM_DS_CONFIG= conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG=conf4 then it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH1_PCCR) , DMA Control Register (PSI5_CH1_DCR) and DMA Status Register (PSI5_CH1_DSR) .

56.3.56 DMA SMC Frame Register (PSI5_CH1_DSFR)

This section shows the DMA SMC Frame Register.

Address: 0h base + 1ECh offset = 1ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SMC_RXDATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_DSFR field descriptions

Field	Description
0–31 SMC_RXDATA	When the DMA_EN_SF = 1 then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted till all the registers which have a complete data ready have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location, pointed to by the DMA read pointer.

56.3.57 DMA Diagnostic Status Register (PSI5_CH1_DDSR)

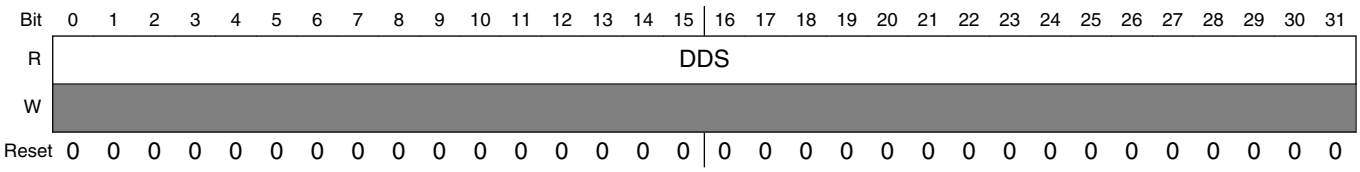
This section defines the DMA Diagnostic Status Register.

NOTE

No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR

or EISR directly) or the DMA (reading the DDSR successively).

Address: 0h base + 1F0h offset = 1F0h



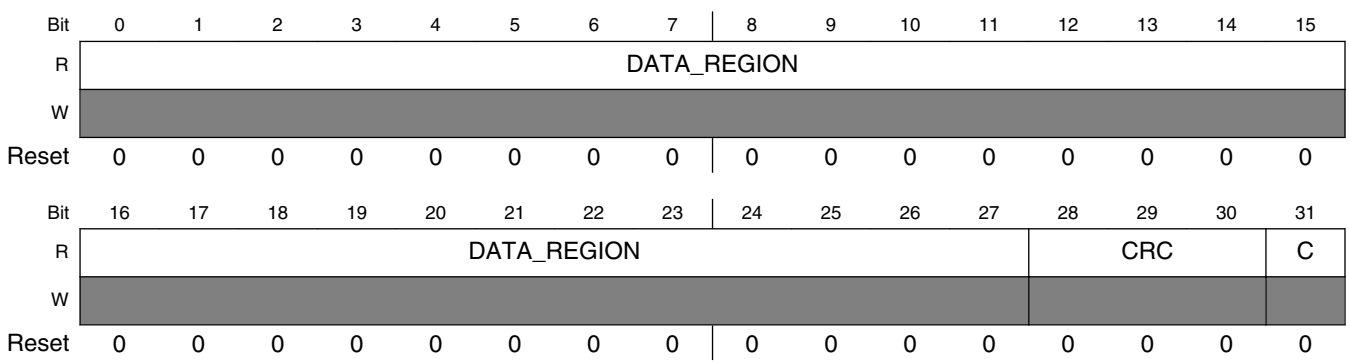
PSI5_CH1_DDSR field descriptions

Field	Description
0–31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH1_PCCR) , DMA Control Register (PSI5_CH1_DCR) and DMA Status Register (PSI5_CH1_DSR) .

56.3.58 PSI5 Message Receive Register Low (PSI5_CH1_PMRRL)

This section defines the PSI5 Message Receive Register Low.

Address: 0h base + 1F4h offset = 1F4h



PSI5_CH1_PMRRL field descriptions

Field	Description
0–27 DATA_REGION	These are application-specific optional bits + data payload of received message. See Reception of data frames for more details. The data is left-aligned i.e. Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 ? n ? 28). If n < 28 remaining bit positions are filled with '0's i.e. between last received bit and CRC field.

Table continues on the next page...

PSI5_CH1_PMRRL field descriptions (continued)

Field	Description
28–30 CRC	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

56.3.59 PSI5 Message Receive Register High (PSI5_CH1_PMRRH)

This section defines the PSI5 Message Receive Register High.

NOTE

Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occured.

Address: 0h base + 1F8h offset = 1F8h

PSI5_CH1_PMRRH field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH1_PMRRH field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6.
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH1_S*n*FCR) . In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0" . It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM.

56.3.60 PSI5 Message Register Low i (PSI5_CH1_PMRL*n*)

The following figure shows the PSI5 Message Register Low i.

Address: 0h base + 1FCh offset + (8d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TimeStampValue															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_PMRH*n* field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. This bit is writable in Config mode (for Test purposes). 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH1_PMRH*n* field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel(M0, M1) i.e. at least one bit is absent during the Tbit period. This bit is writable in Config mode (for Test purposes). 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This Bit Indicates Electrical Error i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). This bit is writable in Config mode (for Test purposes). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. This bit is writable in Config mode (for Test purposes). 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 Slot_Counter	This value indicates the slot number in which this frame was recieved. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6. This bit is writable in Config mode (for Test purposes).
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH1_S*n*FCR) . In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0". It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM. This bit is writable in Config mode (for Test purposes).

56.3.62 SMC Frame Register n (PSI5_CH1_SFR*n*)

The following figure shows the SMC Frame Register n.

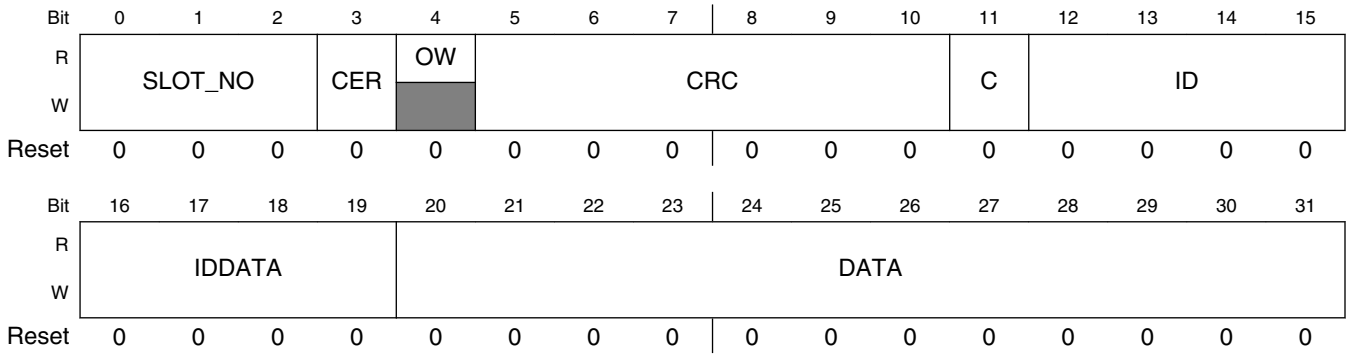
NOTE

Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

NOTE

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

Address: 0h base + 2FCh offset + (4d × i), where i=0d to 5d



PSI5_CH1_SFR*n* field descriptions

Field	Description
0–2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; This field is writable in Config mode (for Test purposes).
3 CER	CRC Error This field is writable in Config mode (for Test purposes). 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status **NOTE:** If the corresponding SOWSM bits in the SSESR have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set. 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message.
5–10 CRC	6-bit CRC for slow serial message

Table continues on the next page...

PSI5_CH1_SFR*n* field descriptions (continued)

Field	Description
	This field is writable in Config mode (for Test purposes).
11 C	Configuration bit This bit is writable in Config mode (for Test purposes). 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID.
12–15 ID	Message ID: If C = '0' indicates ID[7:4], if C = '1' indicates ID[3:0]. This field is writable in Config mode (for Test purposes).
16–19 IDDATA	Message ID/DATA: If C = '0' indicates ID[3:0], if C = '1' indicates DATA[15:12]. This field is writable in Config mode (for Test purposes).
20–31 DATA	DATA payload This field is writable in Config mode (for Test purposes).

56.3.63 New Data Status Register (PSI5_CH1_NDSR)

The following figure shows the New Data Status Register.

Address: 0h base + 314h offset = 314h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NDS																															
W	w1c

PSI5_CH1_NDSR field descriptions

Field	Description
0–31 NDS	New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when a new Message arrives i.e. faulty or non faulty in corresponding PSI5 MB location. Bit 0 reflects the MB0 location.These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SNDR.

56.3.64 Overwrite Status Register (PSI5_CH1_OWSR)

Address: 0h base + 318h offset = 318h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH1_OWSR field descriptions

Field	Description
0–31 OWS	Over Write Status flags for PSI5 Messages corresponding to each PSI5 location in the RAM registers. These bits are set when any unread receive PSI5 message is overwritten by a newly arrived message). These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SOWSR.

56.3.65 Error Indication Status Register (PSI5_CH1_EISR)

The following figure shows the Error Indication Status Register.

Address: 0h base + 31Ch offset = 31Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH1_EISR field descriptions

Field	Description
0–31 ERROR	Error Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when any of the five selectable (by ERROR_SELECT) bits (C, E, EM, T or F) is set for the corresponding PSI5 Message. These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independently by writing in SEISR.

56.3.66 Set New Data Status Register (PSI5_CH1_SNDSR)

The following figure shows the Set New Data Status Register.

Address: 0h base + 320h offset = 320h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH1_SNDSR field descriptions

Field	Description
0–31 SNDS	Sets New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. The corresponding NDS Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** This bit is writable in config and Normal modes.

56.3.67 Set Overwrite Status Register (PSI5_CH1_SOWSR)

The following figure shows the Set Overwrite Status Register.

Address: 0h base + 324h offset = 324h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

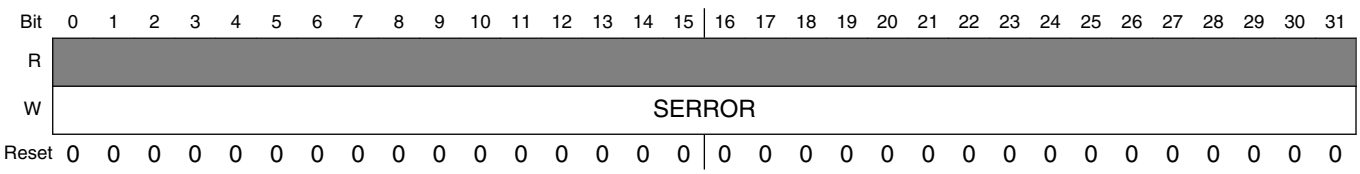
PSI5_CH1_SOWSR field descriptions

Field	Description
0–31 SOWS	Sets overwrite status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding OWS flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.68 Set Error Status Register (PSI5_CH1_SEISR)

The following figure shows the Set Error Status Register.

Address: 0h base + 328h offset = 328h



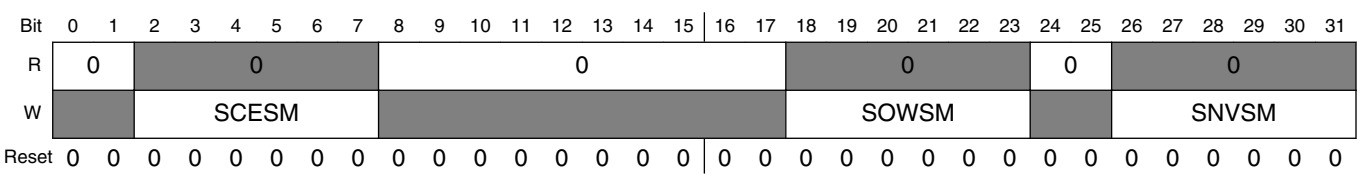
PSI5_CH1_SEISR field descriptions

Field	Description
0–31 SERROR	Sets Error Status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding ERROR flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.69 Set SMC Error Status Register (PSI5_CH1_SSESR)

The following figure shows the Set SMC Error Status Register.

Address: 0h base + 32Ch offset = 32Ch



PSI5_CH1_SSESR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 SCESM	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations.

Table continues on the next page...

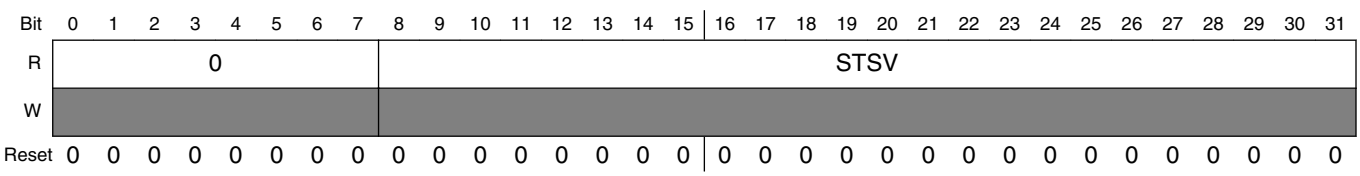
PSI5_CH1_SSESR field descriptions (continued)

Field	Description
	The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
8–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 SOWSM	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 SNVSM	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** This bit is writable in Config and Normal modes.

56.3.70 Sync Time Stamp Read Register (PSI5_CH1_STSRR)

The following figure shows the Sync Time Stamp Read Register.

Address: 0h base + 330h offset = 330h



PSI5_CH1_STSRR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 STSV	Sync Time Stamp Value[23:0] This bitfield provides the value of the free-running 24-bit time stamp counter triggered (captured) at last sync pulse.

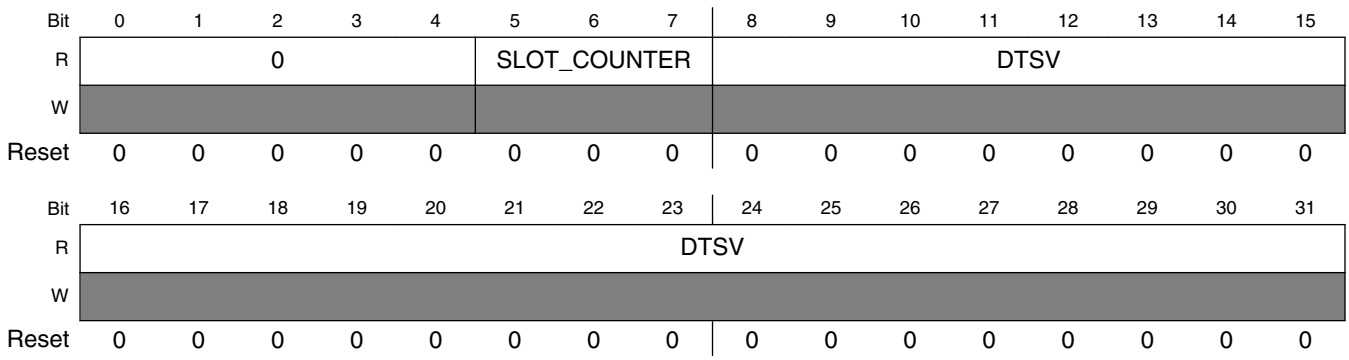
56.3.71 Data Time Stamp Read Register (PSI5_CH1_DTSRR)

The following figure shows the Data Time Stamp Read Register.

NOTE

If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter , both will correspond to the first slot(S0)

Address: 0h base + 334h offset = 334h



PSI5_CH1_DTSRR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 SLOT_ COUNTER	3bit Slot Counter which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode the slot counter has a fixed value of "1".
8–31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected then the value of the Time Stamp counter captured at the rising edge of the S0, is stored in this register at the rising edge of S1.

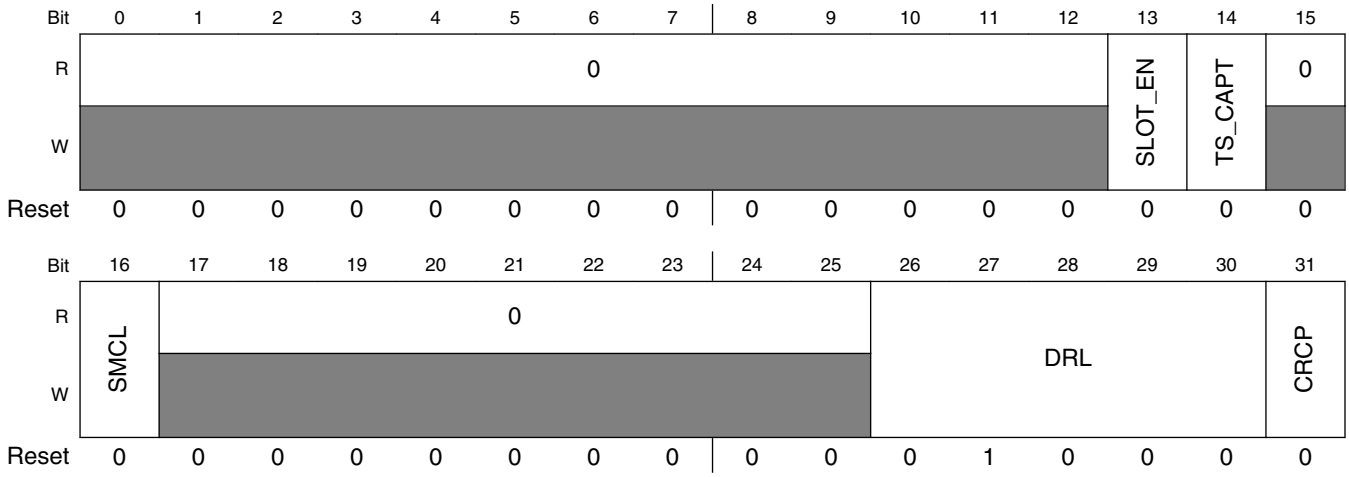
56.3.72 Slot n Frame Configuration Register (PSI5_CH1_S*n*FCR)

The following figure shows the Slot n Frame Configuration Register.

NOTE

In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

Address: 0h base + 338h offset + (4d × i), where i=0d to 5d



PSI5_CH1_S*n*FCR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLOT_EN	SLOT_EN 0 This particular slot is disabled i.e not in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) have no effect. 1 This particular slot is enabled i.e is in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) are applicable.
14 TS_CAPT	TS_CAPT 0 Time stamp value captured at rising edge of S0 and stored Start sequence first edge. 1 Time stamp value captured at corresponding Tsync pulse (posedge) and stored with corresponding slot PSI5 message.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SMCL	Serial Messaging Channel field This field is used to enable the detection of start sequence of SMC frame on particular slot. Detection is not done if this field is '0'. 0 Serial Messaging Channel (optional) not present on Rx Message during Time Slot 'n' 1 2-bit{M1,M0} Serial Messaging Channel present on Rx Message during Time Slot 'n'
17–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–30 DRL	Data Region Length[4:0] This field represents Length of Data region (including Frame Control, Status , Data payload1&2 regions and optional messaging bits M0,M1) in Rx Message during Time Slot 'n' 00000-00111: Invalid 01000: 8 bit long data region 01001: 9 bit long data region 01010: 10 bit long data region ....

Table continues on the next page...

PSI5_CH1_S*n*FCR field descriptions (continued)

Field	Description
	11011: 27 bit long data region 11100: 28 bit long data region 11101-11111: Invalid
31 CRCP	CRCP 0 3 bit CRC[2:0] present on Rx Message during Time Slot 'n' 1 1 bit Parity field present on Rx Message during Time Slot 'n'

56.3.73 Slot 1 Start Boundary Register (PSI5_CH1_S1SBR)

The following figure shows the Slot 1 Start Boundary Register.

Address: 0h base + 350h offset = 350h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PSI5_CH1_S6SBR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 S6SBT	Slot 6 Start Boundary Time This field specifies the time in intervals of 1 µs, occurring after the rising edge of the timing sync pulse, at which the slot 6 should start.

56.3.79 Slot n End Boundary Register (PSI5_CH1_SnEBR)

The following figure shows the Slot *n* Start Boundary Register (PSI5_S *n* SBR).

Slot n End Boundary register is a single register which can be programmed to define the "end" of the nth slot. The n can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SnEBR (Slot n End Boundary register) defines the end of the nth slot. The n is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SnEBR. The SnEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the SnFCR. When the start slot boundaries are properly defined in the SnSBR (Slot n Start Boundary Register) register but the slot_en bit = 0 in the corresponding SnFCR (Slot n Frame Configuration register) register, then the corresponding slot is treated as "available" but "unconfigured." For such a slot the data/diagnostic bits all remain 0. The "T" bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots. Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if "S0" and "S1" are detected in different slots then a T-bit error is set .

NOTE

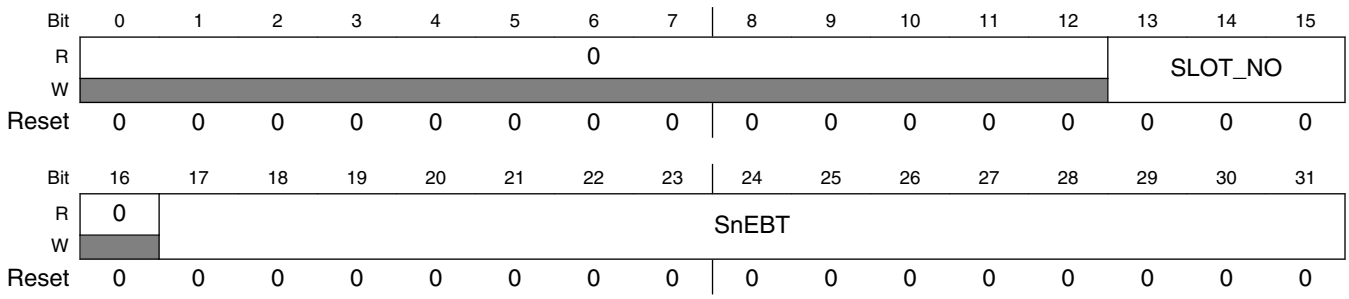
The start slot boundaries in the S *n* SBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SnEBR are treated as being unavailable (that is, the data

in all the slots occurring after the SnEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the S *n* EBR and define the end boundary of the third slot in S *n* EBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the S *n* EBR by putting slot_no = 6 and define the end boundary of the sixth slot in S *n* EBR.

Address: 0h base + 35Ch offset = 35Ch



PSI5_CH1_SnEBR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 SLOT_NO	The field indicates the Slot number{1-6} for which Slot End Boundary Time is defined. Any value other than 1-6 is defaulted to 0. A value 0 here would mean that the manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 SnEBT	Slot *n* End Boundary Time. This field specifies the time in intervals of 1µs, occurring after the rising edge of timing sync pulse, at which the slot 'n" should end.

56.3.80 Data Output Block Configuration Register (PSI5_CH1_DOBCR)

The following figure shows the Data Output Block Configuration Register.

Table 56-9. CMD_TYPE details

CMD_TYPE	PSI5 Frame [1]	Effect on registers	Writeable Register lengths
"000" - 0	Short Frame(V1.3) with 31 "1s" as the start condition	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15bits[2] in DBR/DSR.
"001" - 1	Short Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"010" - 2	Long Frame(V1.3) with 31 "1s" as the start condition	-do-	16bits in DPR. 29bits[2] in DBR/DSR.
"011" - 3	Long Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"100" - 4	X-Long Frame(V1.3) with 31 "1s" as the start condition	-do-	22bits in DPR. 37bits[2] in DBR/DSR
"101" - 5	X-Long Frame(V1.3) with 5 "0s" as the start condition.	-do-	-do-
"110" - 6	XX-Long (V2.0) -	-do-	24bits in DPR. 43bits[2] in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCR[DATA_LENGTH] field.

1. The start condition(31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command.
2. This is also the length of the command that will be shifted out during the ECU to Sensor communication, regardless of how many "actual" bits are written to DBR/DSR.

Table 56-10. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1	0	1	1
State2[1]	0	0	1
State3[1]	1	1	1
State4[1]	1	0	1
State5[1]	1	x	0

1. These states are shown in Valid states for integrated sync pulse generator. In State5, the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

NOTE

Please refer to Figure 56-26 for the details about the above bits. Figure 56-26 is the actual implementation of Figure 56-25 such

that various contentions between the switches (S1, S2, and so on) do not happen.

Address: 0h base + 360h offset = 360h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	DATA_LENGTH[5:0]						DBR_RST	DSR_RST	CMD_TYPE			DEFAULT_SYNC	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL	SW_READY
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_DOBCR field descriptions

Field	Description
0–5 DATA_LENGTH[5:0]	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard) , then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0, then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH = 1, then the length of the command that can be written to DSR and the DBR is 2 and so on, until a maximum of 64 bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits that shift out of DSR register once the DSR_RDY goes low . After these many shifts have happened , then the value corresponding to "DEFAULT_SYNC" starts getting shifted out and DSR_RDY goes as "1".
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as "1" then the contents of the DBR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register.When this bit is written as "1" then the contents of the DSR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data.Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
8–10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. Table 56-4 is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to "0" then the default value of DSR and DBR registers are all "0s"; when this bit is set to 1 then the default value of DBR and DSR registers are all "1s". This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 0 Internal sync pulse generator shift triggered 1 GTM event shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 0 SP module gets the data from the DSR 1 SP module directly gets input from the GTM_event/internal sync pulse generator

Table continues on the next page...

PSI5_CH1_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects as to which would be driving source of the "ipp_do_psi5_sdout" port. 0 The sync pulse generator select as per the Bit3 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending . Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1 , will the transfer happen. This bit can be written in CONFIG and the Normal modes.

56.3.81 Manchestor Decoder Disable Offset (PSI5_CH1_MDDIS_OFF)

The Manchester Decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 µs, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 µs to 128 µs. This works on the 1 µs clock from the common clock generator module.

Address: 0h base + 362h offset = 362h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								MDDIS_OFF							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_MDDIS_OFF field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester Decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse . Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester Decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester Decoder BEYOND the Sync Pulse High Time as well. Figure 1032 shows the "MDDIS_OFF" definition.

56.3.82 Pulse Width for Data Bit Value 0 (PSI5_CH1_PW0D)

The following figure shows the Pulse Width for Data Bit 0 Register.

Address: 0h base + 364h offset = 364h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width0							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_PW0D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 Pulse_Width0	This defines the width (in µs) of data value '0' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width0", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. When using PSI5 version 1.3 ECU-to-sensor Communication Pulse_Width0 should be configured to 0. Figure 1032 shows the definition of "Pulse_Width0".

56.3.83 Pulse Width for Data Bit Value 1 (PSI5_CH1_PW1D)

The following figure shows the Pulse Width for Data Bit 1 Register.

NOTE

When using the Version 1.3 format for ECU-to-sensor communication, the pulse width is NOT disabled. In this case, PW0D has to be programmed as 0. PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

Address: 0h base + 366h offset = 366h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width1							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_PW1D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH1_PW1D field descriptions (continued)

Field	Description
9–15 Pulse_Width1	This defines the width (in µs) of data value '1' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width1", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. Figure 1032 shows the definition of "Pulse_Width1".

56.3.84 Counter Target Pulse Register (PSI5_CH1_CTPR)

The following figure shows the Counter Target Pulse Register.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 368h offset = 368h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CTPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_CTPR field descriptions

Field	Description
0–15 CTPR	Counter Target Pulse Register. This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16 bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the Time Period of the internally generated sync pulses. The un modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles i.e. the duty cycle of the un modulated internally generated sync pulses is (4/|CTPR| *100). The 4 sp_ts_clk cycles is just the nascent value of the Pulse which actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in Valid states for integrated sync pulse generator . This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

56.3.85 Counter Initialize Pulse Register (PSI5_CH1_CIPR)

The following figure shows the Counter Initialize Pulse Register.

NOTE

Due to internal Flop synchronisation there can be a jitter of +/- 20 ns between the offset times that are programmed in the CIPR of different channels and the ones actually being observed. Similarly there can be a jitter of +/- 20 ns in the programmed CTPR and the measured CTPR.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 36Ah offset = 36Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CIPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH1_CIPR field descriptions

Field	Description
0–15 CIPR	Counter initialize pulse register. This is the value using which the CTC gets reset, the first time after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be |CIPR_channel1 - CIPR_channel2| sp_ts_clk cycles. This if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

56.3.86 Data Preparation Register Low (PSI5_CH1_DPRL)

The following figure shows the Data Preparation Register Low.

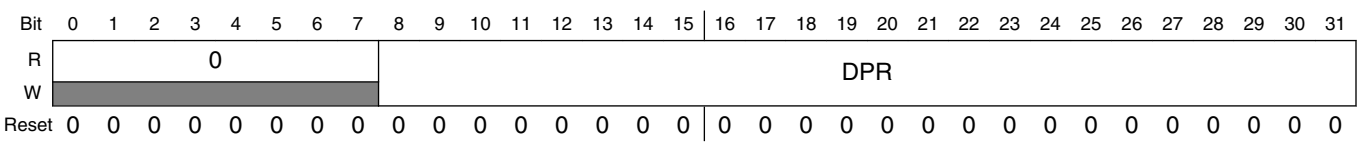
This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when PSI5_GISR[DPR_RDY] == 1. Whenever PSI5_GISR[DPR_RDY] == 1 , then each bit of

this register defaults to 0 . Writing to this register when PSI5_GISR[DPR_RDY] == 0 will cause the PSI5_GISR[IS_PROW] status bit to be set and the generation of an error interrupt, if it is enabled. Further , trying to write to this register when PSI5_DOBCR[CMD_TYPE] = "7" results in the setting of the PSI5_GISR[IS_PROW] bit and the resulting write is rejected.

Table 56-11. DPR details

PSI5_DOBCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL
"0" or "1"	Short Frame(PSI5 V1.3)	6(DPR[5:0])
"2" or "3"	Long Frame(PSI5 V1.3)	16(DPR[15:0])
"4" or "5"	X-Long Frame(PSI5 V1.3)	22(DPR[21:0])
"6"	XX-Long Frame(PSI5 V2.0)	24(DPR[23:0])
"7"	Not Available for write	Not Available for write

Address: 0h base + 36Ch offset = 36Ch

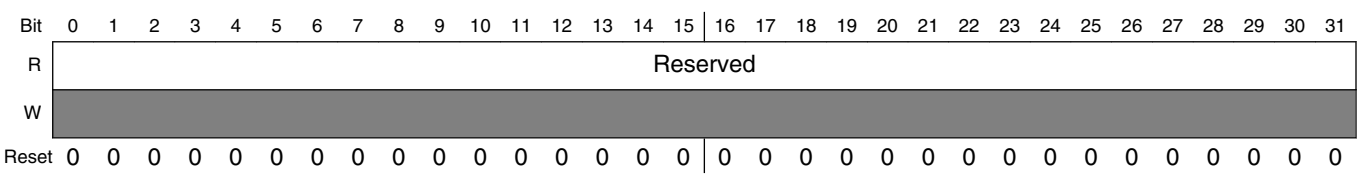


PSI5_CH1_DPRL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 DPR	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length , standard ECU-to-Sensor commands , comprising of the address , data and other fields . Note that the IP is transparent to the arrangement of the address,data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writeable only when using the standard length PSI5 frames . For details about CRC calculation please refer to Data transmission . The writeable bits in this register are governed by the PSI5_DOBCR[CMD_TYPE] bit fields as per Table 56-6 . Note that the unwriteable bits in this register field are always read as "0s" . This register has to be written by the CPU. These bits can be written only in the Normal mode.

56.3.87 Data Preparation Register High (PSI5_CH1_DPRH)

Address: 0h base + 370h offset = 370h



PSI5_CH1_DPRH field descriptions

Field	Description
0–31 Reserved	This field is reserved. This register is always read as 0s. Writing to this register does not have any effect.

56.3.88 Data Buffer Register Low (PSI5_CH1_DBRL)

The following figure shows the Data Buffer Register Low.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode.

NOTE

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1, then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-12. DBRL[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment

PSI5_CH1_DBRL field descriptions

Field	Description
0–31 DBR	This register contains the Lower 32 bits, (DBR[31:0]), of the max-64 bit length command (DBR[63:0]). The higher bits, DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-7 . The table (except when PSI5_DOBCR[CMD_TYPE] = "7") show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == "7"), then only the CPU can write to these registers.

56.3.89 Data Buffer Register High (PSI5_CH1_DBRH)

The following figure shows the Data Buffer Register High.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY]== 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit

PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-13. DBRH[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
"7" - Non Standard Frame lengths	DBR[63:32]]	Variable length of writeable bits , as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]
"6" - XX Long	DBR[63:43]	All 0s

PSI5_CH1_DBRH field descriptions

Field	Description
0–31 DBR	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-8 . Note that when PSI5_DOBCR[CMD_TYPE] == "7") , then only the CPU can write to these registers.

56.3.90 Data Shift Register Low (PSI5_CH1_DSRL)

The following figure shows the Data Shift Register Low.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 37Ch offset = 37Ch

PSI5_CH1_DSRL field descriptions

Field	Description
0–31 DSR	This register contains the lower 32 bits, (DSR[31:0]), of the max-64 bit length command (DSR[63:0]). The higher bits, DSR[63:32], are contained in the DSRH register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits.When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRL . Thus when updated by the hardware, then DSR[31:0] = DBR[31:0] . Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1 . These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1 .

56.3.91 Data Shift Register High (PSI5_CH1_DSRH)

The following figure shows the Data Shift Register High.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 380h offset = 380h

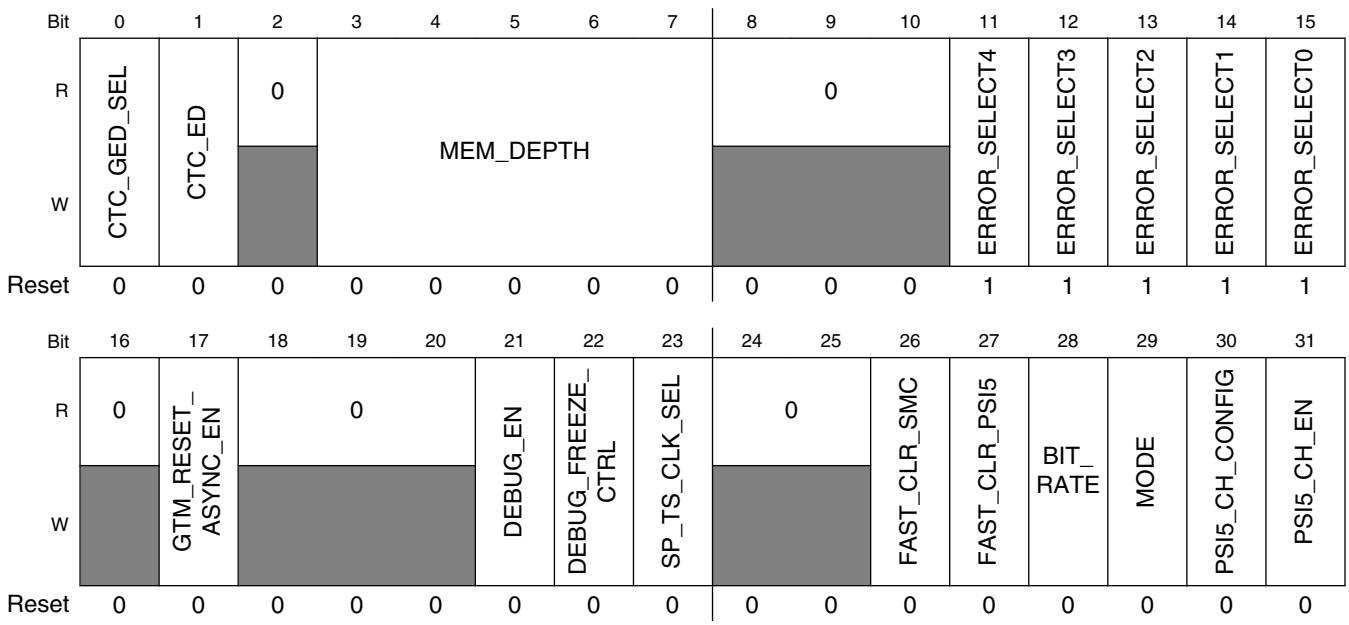
PSI5_CH1_DSRH field descriptions

Field	Description
0–31 DSR	This register contains the higher 32 bits (DSR[63:32) of the max-64 bit length command (DSR[63:0]). The lower bits, DSR[31:0], are contained in the DSRL register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRH . Thus when updated by the hardware, then DSR[63:32]] = DBR[63:32] . Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1 . These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1 .

56.3.92 PSI5 Channel Control Register (PSI5_CH2_PCCR)

This section shows the PSI5 Channel Control Register.

Address: 0h base + 388h offset = 388h



PSI5_CH2_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select. This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable. This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. **NOTE:** This bit is writable in Normal mode and the Config mode. 0 The CTC counters is disabled and reset. 1 The CTC counter is enabled and start counting.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access.

Table continues on the next page...

PSI5_CH2_PCCR field descriptions (continued)

Field	Description
	Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0: it indicates that only 1 location of the memory is available for storage 31: it indicates that all the 32 locations of the memory are available for storage. Notes: • Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). • DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. • DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. • For more details please refer to description of DMA_PM_DS_CONFIG in the DCRs. • The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the manchester decoder. • The memory area above the configured MEM_DEPTH size will always be read as 0. • Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERROR_ SELECT4	The ERROR_SELECT bitfiield indicates which of the C, E, EM, T, or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T,or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.
12 ERROR_ SELECT3	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_ SELECT2	Error_Select[2] or EM_INT_SEL 0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_ SELECT1	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.

Table continues on the next page...

PSI5_CH2_PCCR field descriptions (continued)

Field	Description
15 ERROR_ SELECT0	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 GTM_RESET_ ASYNC_EN	GTM_RESET_ASYNC_EN 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the gtm reset is synchronized on the SP_TS_CLK. 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the SP_TS_CLK.(For details of SP_TS_CLK, refer to bit 23 of) PSI5 Channel Control Register (PSI5_CH0_PCCR)
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_ FREEZE_CTRL	DEBUG_FREEZE_CTRL 0 When the IP enters the Debug mode then it goes into the “Open” mode, i.e., the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. **NOTE:** In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time. 1 As soon as debug mode is asserted, the state of the system registers that are affected by the hardware gets frozen to what ever it was existing at the point at which the Debug mode goes active.This can be useful for reading the state of the system at a particular point of time such that it is NOT affected by the next upcoming events. Note that Manchester decoder/Sync Pulse Generator/ Time Stamp counters keep on working normally but the registers (data/status/timestamp) affected by these are not updated. When the IP enters the “Debug mode” then it goes into the “Freeze Mode”. Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the “freeze mode”, if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the “sdout” line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. The fact that the freeze mode has been entered, can be checked by reading the GISR[IS_DB_FR] bit. Once the IP comes out of the freeze mode then this bit goes to 0. **NOTE:** In the above configuration, incoming packets could get lost while the Debug mode is active.
23 SP_TS_CLK_ SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit.

Table continues on the next page...

PSI5_CH2_PCCR field descriptions (continued)

Field	Description
	NOTE: The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the common clock generator module. **NOTE:** The clock selected using this bit is called SP_TS_CLK. 0 The 1 MHz clock generated from the common clock generator module goes for clocking the Time Stamp Unit and sync pulse generator. 1 The clock generated from the GTM goes for clocking the Time Stamp Unit and Sync Pulse Generator.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FAST_CLR_SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. **NOTE:** This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing. If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled.
27 FAST_CLR_PSI5	This bit control the clearing mechanism of bits in NDSR(in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR(in conf2 and conf3 modes). Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: • In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. • In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. • In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresesponding to a specific location are always cleared simultaneoulsy. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. • In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/PMRL register. Hence the OWSR has to be cleared only by w1c. • In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. • Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c.

Table continues on the next page...

PSI5_CH2_PCCR field descriptions (continued)

Field	Description
	NOTE: This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below. 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1)
28 BIT_RATE	This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects one of the two driven clocks (4 MHz or 6.048 MHz) in the common clock generator module. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 189 Kbit/s bit rate selected (6.048 MHz clock).
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).
30 PSI5_CH_ CONFIG	PSI5 Channel Config mode request. If this bit is set (and PCCR[PSI5_CH_EN] = '1')this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set can not be changed until this bit is set again after entering the Disable mode **NOTE:** This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details please see Figure 56-2 and Table 56-2 . Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written. 1 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a "0" in the Normal mode will not change the operation mode of the device.
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. **NOTE:** When PSI5_CH_EN == 0 then the clock enable for that particular channel that goes from the IP, goes to "0" (inactive state). This also means that the only clock available to the IP in the config mode is the "ipg_clk_s".The enable for the GTM Clock is not controlled by the IP and should be controlled externally. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.

Table continues on the next page...

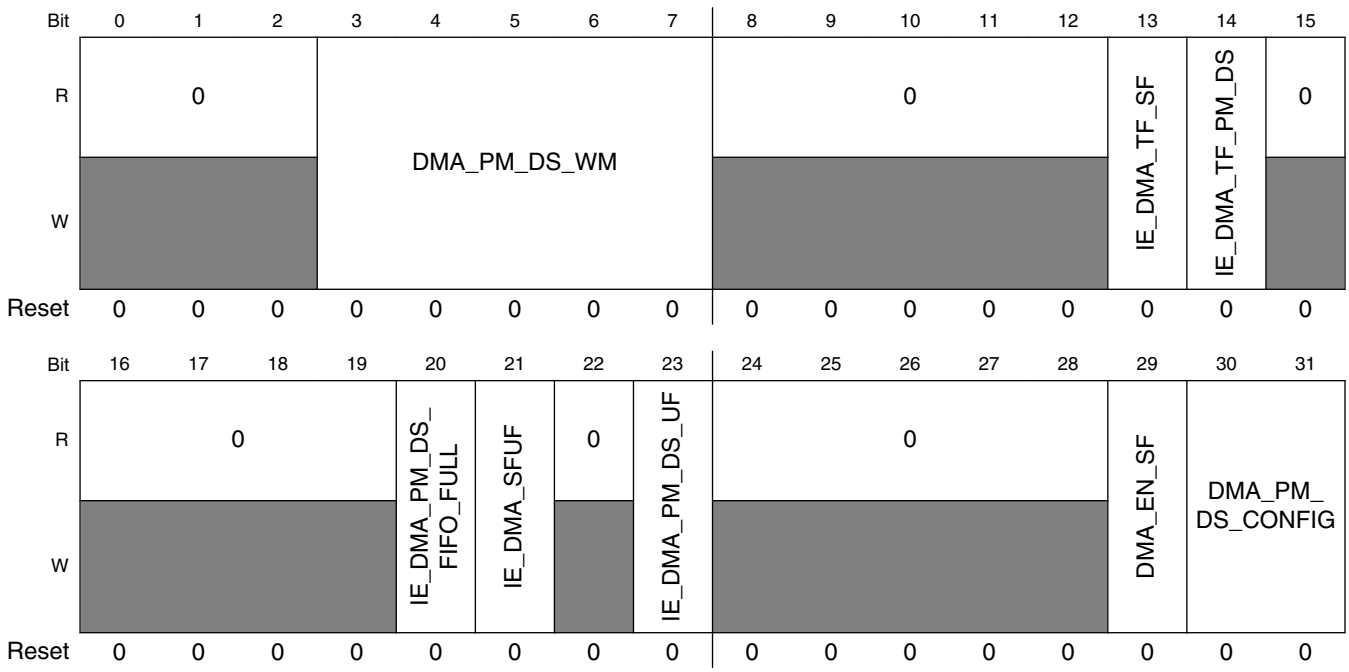
PSI5_CH2_PCCR field descriptions (continued)

Field	Description
	0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode.

56.3.93 DMA Control Register (PSI5_CH2_DCR)

This section defines the DMA Control Register.

Address: 0h base + 38Ch offset = 38Ch



PSI5_CH2_DCR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 DMA_PM_DS_WM	0 to 31: Valid water mark levels. Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words are present. The default and minimum value of dma_pm_ds_wm is '0', i.e. 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, i.e. the actual watermark = 32 RAM locations. **NOTE:** • These bits are ineffective if DMA_PM_DS_CONFIG = conf1. • These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO,

Table continues on the next page...

PSI5_CH2_DCR field descriptions (continued)

Field	Description
	before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. • When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. • In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). • In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. • When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. • In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IE_DMA_TF_SF	**NOTE:** This bit is writeable in Config and Normal modes. Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_DMA_TF_ PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IE_DMA_PM_ DS_FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases which generate these FIFO FULL conditions please refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. **NOTE:** This bit is writable in Config and Normal modes.
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, i.e. it is empty. Default value is 0. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH2_DCR field descriptions (continued)

Field	Description
23 IE_DMA_PM_DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, please refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30–31 DMA_PM_DS_CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. **NOTE:** For more details please see the description of the DCR[DMA_PM_DS_WM] bits. When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message which was scheduled to be read by the DMA. Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA. **NOTE:** These bits are writable only in config mode. 00 **conf1** The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 **conf2** After transferring the "dma_pm_ds_wm" number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 **conf3** "dma_pm_ds_wm" number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 **conf4** Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers.

56.3.94 DMA Status Register (PSI5_CH2_DSR)

This section defines the DMA Status Register.

Address: 0h base + 390h offset = 390h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0													IS_DMA_TF_SF	IS_DMA_TF_PM_DS	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_DSR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes . For the various configurations of this request please refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.
15–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to DMA request. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. **conf1:** FIFO FULL disabled **conf2 and conf3:** FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. **conf4:** FIFO FULL occurs when there is a "REGISTER FULL" in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. **conf1:** underflow disabled **conf2 and conf3:** Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). **conf4:** Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. The bits are cleared by a w1c.

Table continues on the next page...

PSI5_CH2_DSR field descriptions (continued)

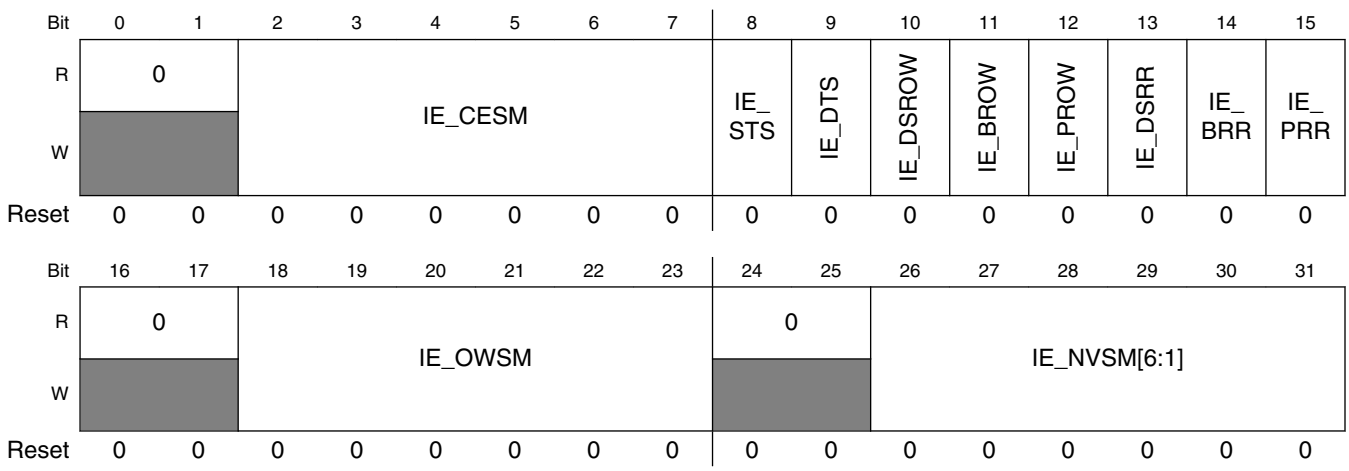
Field	Description
	0 No underflow has occurred. 1 Underflow has occurred.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.3.95 General Interrupt Control Register (PSI5_CH2_GICR)

The GICR contains the bits for controlling interrupts related to:

- SMC messages
- ECU-to-sensor communication
- the Time Stamp

Address: 0h base + 394h offset = 394h



PSI5_CH2_GICR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IE_CESM	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. **NOTE:** This bit is writable in Config and Normal modes.

Table continues on the next page...

PSI5_CH2_GICR field descriptions (continued)

Field	Description
	0 Interrupt is disabled. 1 Interrupt is enabled.
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. **NOTE:** This bit is writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IE_OWSM	Interrupt request enable for the SMC message Overwrite bits.

Table continues on the next page...

PSI5_CH2_GICR field descriptions (continued)

Field	Description
	The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5} i.e. during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. **NOTE:** These bits are writable in Config and Normal modes. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.96 New Data Interrupt Control Register (PSI5_CH2_NDICR)

The NDICR contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 398h offset = 398h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IE_ND																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_NDICR field descriptions

Field	Description
0–31 IE_ND	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.97 Overwrite Interrupt Control Register (PSI5_CH2_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

NOTE

Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

Address: 0h base + 39Ch offset = 39Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH2_EICR field descriptions

Field	Description
0–31 IE_ERROR	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when

PSI5_CH2_EICR field descriptions (continued)

Field	Description
	corresponding RAM buffer Ready with new data. Which of the error condition (any of C, E, EM, T, or F) would generate the interrupt is selectable by PCCR[ERROR_SELECT] field. If all are selected then which out of C,E,EM,T,F is set can be isolated by reading corresponding received message. **NOTE:** These bits are writable in Config and Normal modes. 0 Interrupt is disabled. 1 Interrupt is enabled.

56.3.99 General Interrupt Status Register (PSI5_CH2_GISR)

The GISR contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Address: 0h base + 3A4h offset = 3A4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	IS_DB_FR	0	IS_CESM						IS_STS	IS_DTS	IS_DSROW	IS_BROW	IS_PROW	DSR_RDY	DBR_RDY	DPR_RDY

PSI5_CH2_GISR field descriptions

Field	Description
0 IS_DB_FR	This flag is set to “1” when the IP enters the Debug freeze mode. Please see Debug mode for details about the Debug mode. This bit is auto cleared by the hardware when the IP exits the debug freeze mode. 0 IP not in debug freeze mode. 1 IP in debug freeze mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 IS_CESM	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.
13 DSR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When "0" it indicates that there is a ongoing command transmission of the data in DSR , or the CPU has done a "w1c" to this bit leading to the new command transmission . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, and PSI5_DOBCR[SW_READY] == 1 , then it indicates to the IP that the data in DSR is valid and is to be used for command shifting . This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, Individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
14 DBR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When "0" it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as "1". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR . This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit please refer to Data transmission . **NOTE:** For this field, individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used.

Table continues on the next page...

PSI5_CH2_GISR field descriptions (continued)

Field	Description
	NOTE: In configuration mode, writes to this bit are ignored.
15 DPR_RDY	This bit acts both as a status and a control bit. Status bit Action : When "1" it indicates that the Data Preparation register is ready to receive new data from the system bus side . When "0" it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a "w1c" to this bit . In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCR[CMD_TYPE] == "7" then this bit remains at value "0". Control Bit Action : When a "w1c" is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR . For detailed action of this bit please refer to Data transmission . **NOTE:** For these register bits individual "bit setting" commands should not be used. Rather, the normal register read/write commands should be used. **NOTE:** In configuration mode, writes to this bit are ignored.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 IS_OWSM	Status for the SMC message overwrite bits. Each of the 6 locations correspond to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are automatically cleared upon message read when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 IS_NVSM	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are automatically cleared upon message read, when the FAST_CLR_SMC =1 and the DMA_EN_SF = 1.

56.3.100 DMA PSI5 Message Register (PSI5_CH2_DPMR)

This section defines the DMA PSI5 Message Register.

Address: 0h base + 3A8h offset = 3A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH2_DPMR field descriptions

Field	Description
0–31 PSI5_RXDATA	PSI5_RXDATA[31:0]

PSI5_CH2_DPMR field descriptions (continued)

Field	Description
	This popup register contain the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations the DATA is pushed sequentially till all the data corresponding to the programmed watermark is complete after which the DMA request goes down. The depth of the FIFO is 32x64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG=conf2 then it pops the PSI5 message followed by NDSR followed by EISR. When DMA_PM_DS_CONFIG= conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG=conf4 then it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH2_PCCR) , DMA Control Register (PSI5_CH2_DCR) and DMA Status Register (PSI5_CH2_DSR) .

56.3.101 DMA SMC Frame Register (PSI5_CH2_DSFR)

This section shows the DMA SMC Frame Register.

Address: 0h base + 3ACh offset = 3ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SMC_RXDATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_DSFR field descriptions

Field	Description
0–31 SMC_RXDATA	When the DMA_EN_SF = 1 then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted till all the registers which have a complete data ready have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location, pointed to by the DMA read pointer.

56.3.102 DMA Diagnostic Status Register (PSI5_CH2_DDSR)

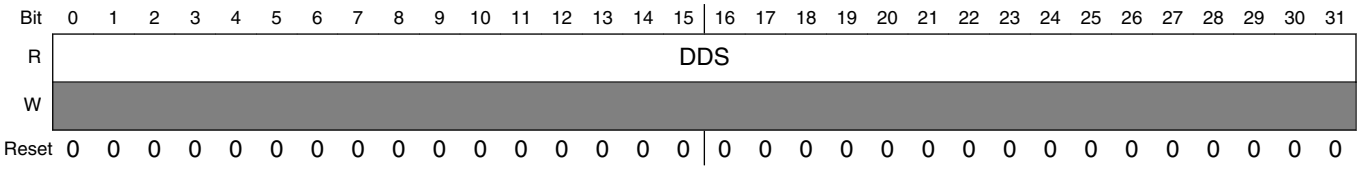
This section defines the DMA Diagnostic Status Register.

NOTE

No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR

or EISR directly) or the DMA (reading the DDSR successively).

Address: 0h base + 3B0h offset = 3B0h



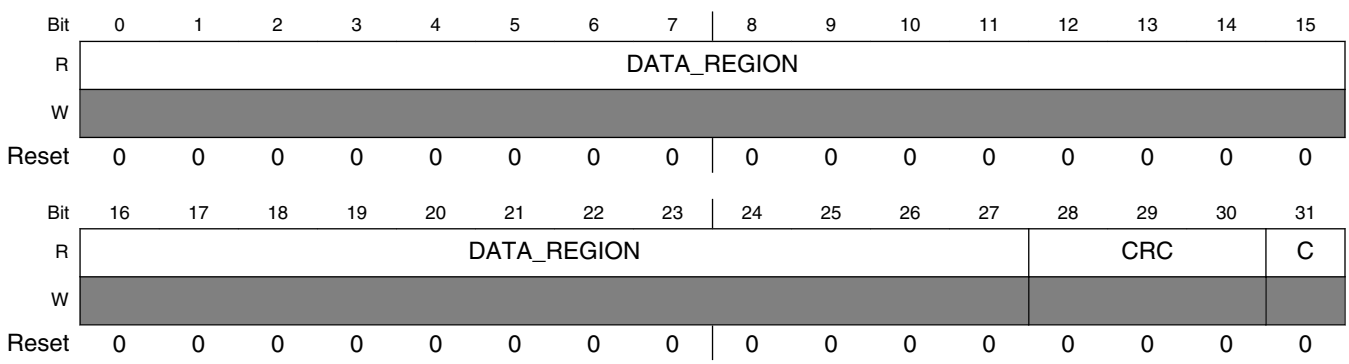
PSI5_CH2_DDSR field descriptions

Field	Description
0–31 DDS	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the PSI5 Channel Control Register (PSI5_CH2_PCCR) , DMA Control Register (PSI5_CH2_DCR) and DMA Status Register (PSI5_CH2_DSR) .

56.3.103 PSI5 Message Receive Register Low (PSI5_CH2_PMRRL)

This section defines the PSI5 Message Receive Register Low.

Address: 0h base + 3B4h offset = 3B4h



PSI5_CH2_PMRRL field descriptions

Field	Description
0–27 DATA_REGION	These are application-specific optional bits + data payload of received message. See Reception of data frames for more details. The data is left-aligned i.e. Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: 8 ? n ? 28). If n < 28 remaining bit positions are filled with '0's i.e. between last received bit and CRC field.

Table continues on the next page...

PSI5_CH2_PMRRL field descriptions (continued)

Field	Description
28–30 CRC	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

56.3.104 PSI5 Message Receive Register High (PSI5_CH2_PMRRH)

This section defines the PSI5 Message Receive Register High.

NOTE

Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occured.

Address: 0h base + 3B8h offset = 3B8h

PSI5_CH2_PMRRH field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH2_PMRRH field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 SlotCounter	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6.
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH2_S*n*FCR) . In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0" . It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM.

56.3.105 PSI5 Message Register Low i (PSI5_CH2_PMRL*n*)

The following figure shows the PSI5 Message Register Low i.

Address: 0h base + 3BCh offset + (8d × i), where i=0d to 31d

PSI5_CH2_PMRH*n* field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. This bit is writable in Config mode (for Test purposes). 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table continues on the next page...

PSI5_CH2_PMRH*n* field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel(M0, M1) i.e. at least one bit is absent during the Tbit period. This bit is writable in Config mode (for Test purposes). 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This Bit Indicates Electrical Error i.e. at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). This bit is writable in Config mode (for Test purposes). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields.
4 T	This bit indicates timing error i.e. frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. This bit is writable in Config mode (for Test purposes). 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 Slot_Counter	This value indicates the slot number in which this frame was recieved. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of "1". The six slots are numbered as Slot1, Slot2,....Slot6. This bit is writable in Config mode (for Test purposes).
8–31 TimeStampValue	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_CH2_S*n*FCR) . In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where "F" bit has been set ; the value of the Time Stamp appendded to the message is "0". It is possible to reset the time stamp counter by asserting to "1" the "gtm_reset" signal from the GTM. This bit is writable in Config mode (for Test purposes).

56.3.107 SMC Frame Register n (PSI5_CH2_SFR*n*)

The following figure shows the SMC Frame Register n.

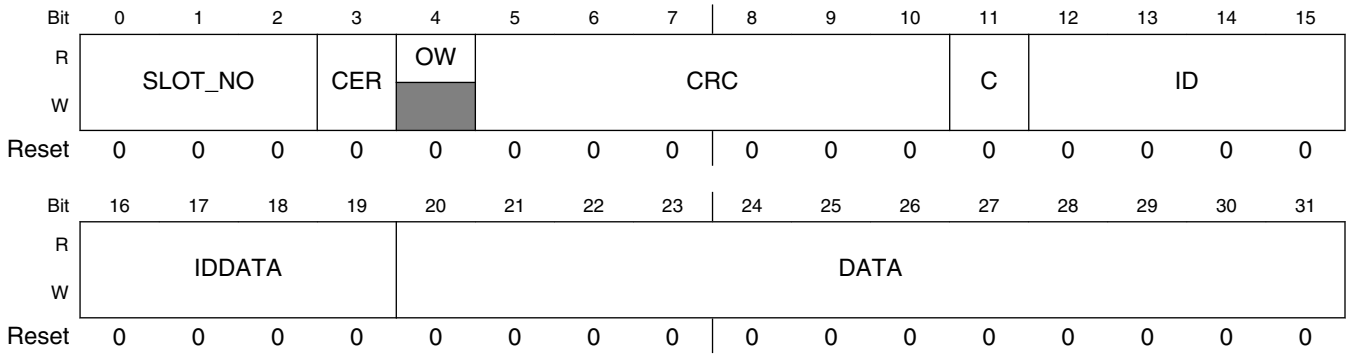
NOTE

Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

NOTE

No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

Address: 0h base + 4BCh offset + (4d × i), where i=0d to 5d



PSI5_CH2_SFR*n* field descriptions

Field	Description
0–2 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6; This field is writable in Config mode (for Test purposes).
3 CER	CRC Error This field is writable in Config mode (for Test purposes). 0 The present data has no CRC error. 1 The present data has a CRC error.
4 OW	Overwrite status **NOTE:** If the corresponding SOWSM bits in the SSESR have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set. 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message.
5–10 CRC	6-bit CRC for slow serial message

Table continues on the next page...

PSI5_CH2_SFR*n* field descriptions (continued)

Field	Description
	This field is writable in Config mode (for Test purposes).
11 C	Configuration bit This bit is writable in Config mode (for Test purposes). 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID.
12–15 ID	Message ID: If C = '0' indicates ID[7:4], if C = '1' indicates ID[3:0]. This field is writable in Config mode (for Test purposes).
16–19 IDDATA	Message ID/DATA: If C = '0' indicates ID[3:0], if C = '1' indicates DATA[15:12]. This field is writable in Config mode (for Test purposes).
20–31 DATA	DATA payload This field is writable in Config mode (for Test purposes).

56.3.108 New Data Status Register (PSI5_CH2_NDSR)

The following figure shows the New Data Status Register.

Address: 0h base + 4D4h offset = 4D4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

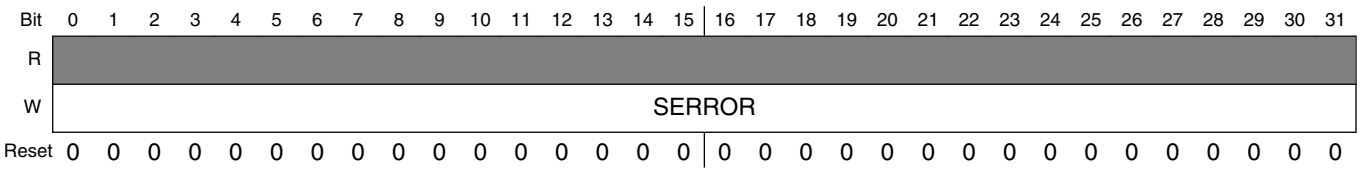
PSI5_CH2_SOWSR field descriptions

Field	Description
0–31 SOWS	Sets overwrite status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding OWS flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.113 Set Error Status Register (PSI5_CH2_SEISR)

The following figure shows the Set Error Status Register.

Address: 0h base + 4E8h offset = 4E8h



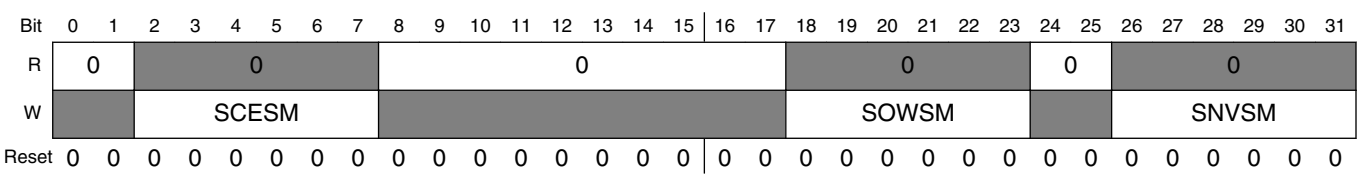
PSI5_CH2_SEISR field descriptions

Field	Description
0–31 SERROR	Sets Error Status flags for PSI5 messages corresponding to each PSI5 MB locations. The corresponding ERROR flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can set the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as 0. **NOTE:** These bits are writable in Config and Normal modes.

56.3.114 Set SMC Error Status Register (PSI5_CH2_SSESR)

The following figure shows the Set SMC Error Status Register.

Address: 0h base + 4ECh offset = 4ECh



PSI5_CH2_SSESR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 SCESM	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations.

Table continues on the next page...

PSI5_CH2_SSESR field descriptions (continued)

Field	Description
	The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
8–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 SOWSM	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** These bits are writable in Config and Normal modes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 SNVSM	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. **NOTE:** This bit is writable in Config and Normal modes.

56.3.115 Sync Time Stamp Read Register (PSI5_CH2_STSRR)

The following figure shows the Sync Time Stamp Read Register.

Address: 0h base + 4F0h offset = 4F0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5_CH2_STSRR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 STSV	Sync Time Stamp Value[23:0] This bitfield provides the value of the free-running 24-bit time stamp counter triggered (captured) at last sync pulse.

56.3.116 Data Time Stamp Read Register (PSI5_CH2_DTSRR)

The following figure shows the Data Time Stamp Read Register.

NOTE

If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter , both will correspond to the first slot(S0)

Address: 0h base + 4F4h offset = 4F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0					SLOT_COUNTER			DTSV							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	DTSV															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_DTSRR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 SLOT_ COUNTER	3bit Slot Counter which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of "0". The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode the slot counter has a fixed value of "1".
8–31 DTSV	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected then the value of the Time Stamp counter captured at the rising edge of the S0, is stored in this register at the rising edge of S1.

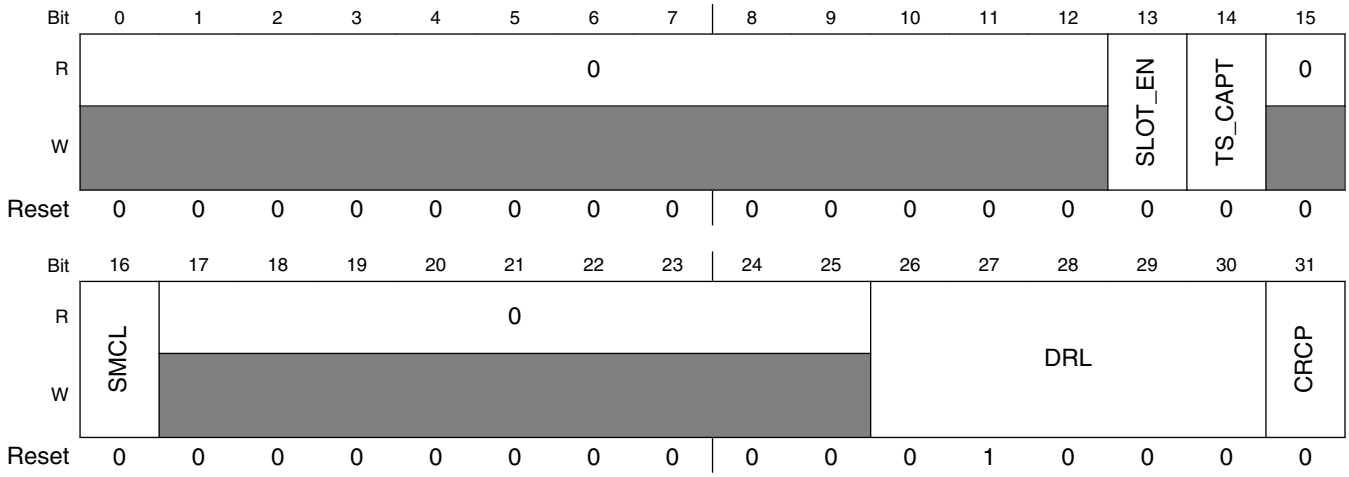
56.3.117 Slot n Frame Configuration Register (PSI5_CH2_S*n*FCR)

The following figure shows the Slot n Frame Configuration Register.

NOTE

In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

Address: 0h base + 4F8h offset + (4d × i), where i=0d to 5d



PSI5_CH2_S*n*FCR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLOT_EN	SLOT_EN 0 This particular slot is disabled i.e not in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) have no effect. 1 This particular slot is enabled i.e is in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) are applicable.
14 TS_CAPT	TS_CAPT 0 Time stamp value captured at rising edge of S0 and stored Start sequence first edge. 1 Time stamp value captured at corresponding Tsync pulse (posedge) and stored with corresponding slot PSI5 message.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SMCL	Serial Messaging Channel field This field is used to enable the detection of start sequence of SMC frame on particular slot. Detection is not done if this field is '0'. 0 Serial Messaging Channel (optional) not present on Rx Message during Time Slot 'n' 1 2-bit{M1,M0} Serial Messaging Channel present on Rx Message during Time Slot 'n'
17–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–30 DRL	Data Region Length[4:0] This field represents Length of Data region (including Frame Control, Status , Data payload1&2 regions and optional messaging bits M0,M1) in Rx Message during Time Slot 'n' 00000-00111: Invalid 01000: 8 bit long data region 01001: 9 bit long data region 01010: 10 bit long data region ....

Table continues on the next page...

PSI5_CH2_S*n*FCR field descriptions (continued)

Field	Description
	11011: 27 bit long data region 11100: 28 bit long data region 11101-11111: Invalid

0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 S6SBT	Slot 6 Start Boundary Time This field specifies the time in intervals of 1 µs, occurring after the rising edge of the timing sync pulse, at which the slot 6 should start.

56.3.124 Slot n End Boundary Register (PSI5_CH2_SnEBR)

The following figure shows the Slot *n* Start Boundary Register (PSI5_S *n* SBR).

Slot n End Boundary register is a single register which can be programmed to define the "end" of the nth slot. The n can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots. The seventh register SnEBR (Slot n End Boundary register) defines the end of the nth slot. The n is programmed in the slot_no field of this register.

The number of slots would automatically be available from the SnEBR. The SnEBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the SnFCR. When the start slot boundaries are properly defined in the SnSBR (Slot n Start Boundary Register) register but the slot_en bit = 0 in the corresponding SnFCR (Slot n Frame Configuration register) register, then the corresponding slot is treated as "available" but "unconfigured." For such a slot the data/diagnostic bits all remain 0. The "T" bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots. Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if "S0" and "S1" are detected in different slots then a T-bit error is set .

NOTE

The start slot boundaries in the S *n* SBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SnEBR are treated as being unavailable (that is, the data

in all the slots occurring after the SnEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the S *n* EBR and define the end boundary of the third slot in S *n* EBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the S *n* EBR by putting slot_no = 6 and define the end boundary of the sixth slot in S *n* EBR.

Address: 0h base + 51Ch offset = 51Ch

PSI5_CH2_SnEBR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 SLOT_NO	The field indicates the Slot number{1-6} for which Slot End Boundary Time is defined. Any value other than 1-6 is defaulted to 0. A value 0 here would mean that the manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 SnEBT	Slot *n* End Boundary Time. This field specifies the time in intervals of 1µs, occurring after the rising edge of timing sync pulse, at which the slot 'n" should end.

56.3.125 Data Output Block Configuration Register (PSI5_CH2_DOBCR)

The following figure shows the Data Output Block Configuration Register.

Table 56-14. CMD_TYPE details

CMD_TYPE	PSI5 Frame [1]	Effect on registers	Writeable Register lengths
"000" - 0	Short Frame(V1.3) with 31 "1s" as the start condition	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15bits[2] in DBR/DSR.
"001" - 1	Short Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"010" - 2	Long Frame(V1.3) with 31 "1s" as the start condition	-do-	16bits in DPR. 29bits[2] in DBR/DSR.
"011" - 3	Long Frame(V1.3) with 5 "0s" as the start condition	-do-	-do-
"100" - 4	X-Long Frame(V1.3) with 31 "1s" as the start condition	-do-	22bits in DPR. 37bits[2] in DBR/DSR
"101" - 5	X-Long Frame(V1.3) with 5 "0s" as the start condition.	-do-	-do-
"110" - 6	XX-Long (V2.0) -	-do-	24bits in DPR. 43bits[2] in DBR/DSR
"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCR[DATA_LENGTH] field.

1. The start condition(31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command.
2. This is also the length of the command that will be shifted out during the ECU to Sensor communication, regardless of how many "actual" bits are written to DBR/DSR.

Table 56-15. DOBCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1	0	1	1
State2[1]	0	0	1
State3[1]	1	1	1
State4[1]	1	0	1
State5[1]	1	x	0

1. These states are shown in Valid states for integrated sync pulse generator. In State5, the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the "sdout" pin.

NOTE

Please refer to Figure 56-26 for the details about the above bits. Figure 56-26 is the actual implementation of Figure 56-25 such

that various contentions between the switches (S1, S2, and so on) do not happen.

Address: 0h base + 520h offset = 520h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	DATA_LENGTH[5:0]						DBR_RST	DSR_RST	CMD_TYPE			DEFAULT_SYNC	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL	SW_READY
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_DOBCR field descriptions

Field	Description
0–5 DATA_LENGTH[5:0]	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCR[CMD_TYPE] == 7(Non Standard) , then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0, then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH = 1, then the length of the command that can be written to DSR and the DBR is 2 and so on, until a maximum of 64 bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits that shift out of DSR register once the DSR_RDY goes low . After these many shifts have happened , then the value corresponding to "DEFAULT_SYNC" starts getting shifted out and DSR_RDY goes as "1".
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as "1" then the contents of the DBR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register.When this bit is written as "1" then the contents of the DSR are reset to all "0s" (if DEFAULT_SYNC = = 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data.Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
8–10 CMD_TYPE	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. Table 56-4 is a brief description of the same.
11 DEFAULT_SYNC	When this bit is set to "0" then the default value of DSR and DBR registers are all "0s"; when this bit is set to 1 then the default value of DBR and DSR registers are all "1s". This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 0 Internal sync pulse generator shift triggered 1 GTM event shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 0 SP module gets the data from the DSR 1 SP module directly gets input from the GTM_event/internal sync pulse generator

Table continues on the next page...

PSI5_CH2_DOBCR field descriptions (continued)

Field	Description
14 OP_SEL	This bit selects as to which would be driving source of the "ipp_do_psi5_sdout" port. 0 The sync pulse generator select as per the Bit3 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending . Once the software makes this bit as "1" and DSR_RDY also goes as "1" the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1 , will the transfer happen. This bit can be written in CONFIG and the Normal modes.

56.3.126 Manchestor Decoder Disable Offset (PSI5_CH2_MDDIS_OFF)

The Manchester Decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 µs, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 µs to 128 µs. This works on the 1 µs clock from the common clock generator module.

Address: 0h base + 522h offset = 522h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								MDDIS_OFF							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_MDDIS_OFF field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester Decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the manchester decoder remains disabled = TsyncH + MDDIS_OFF where TsyncH is the high time for the sync pulse . Thus TsyncH = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a "0" is being pulse modulated or a "1". Note that the Manchester Decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester Decoder BEYOND the Sync Pulse High Time as well. Figure 1032 shows the "MDDIS_OFF" definition.

56.3.127 Pulse Width for Data Bit Value 0 (PSI5_CH2_PW0D)

The following figure shows the Pulse Width for Data Bit 0 Register.

Address: 0h base + 524h offset = 524h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width0							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_PW0D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 Pulse_Width0	This defines the width (in µs) of data value '0' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width0", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. When using PSI5 version 1.3 ECU-to-sensor Communication Pulse_Width0 should be configured to 0. Figure 1032 shows the definition of "Pulse_Width0".

56.3.128 Pulse Width for Data Bit Value 1 (PSI5_CH2_PW1D)

The following figure shows the Pulse Width for Data Bit 1 Register.

NOTE

When using the Version 1.3 format for ECU-to-sensor communication, the pulse width is NOT disabled. In this case, PW0D has to be programmed as 0. PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

Address: 0h base + 526h offset = 526h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								Pulse_Width1							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_PW1D field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5_CH2_PW1D field descriptions (continued)

Field	Description
9–15 Pulse_Width1	This defines the width (in µs) of data value '1' to be send from Data Output Register. It is the number of clock cycles(1µs clock) counted upto width "Pulse_Width1", as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM . Can take max value of 127. Figure 1032 shows the definition of "Pulse_Width1".

56.3.129 Counter Target Pulse Register (PSI5_CH2_CTPR)

The following figure shows the Counter Target Pulse Register.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 528h offset = 528h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CTPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_CTPR field descriptions

Field	Description
0–15 CTPR	Counter Target Pulse Register. This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16 bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the Time Period of the internally generated sync pulses. The un modulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles i.e. the duty cycle of the un modulated internally generated sync pulses is (4/|CTPR| *100). The 4 sp_ts_clk cycles is just the nascent value of the Pulse which actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in Valid states for integrated sync pulse generator . This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

56.3.130 Counter Initialize Pulse Register (PSI5_CH2_CIPR)

The following figure shows the Counter Initialize Pulse Register.

NOTE

Due to internal Flop synchronisation there can be a jitter of +/- 20 ns between the offset times that are programmed in the CIPR of different channels and the ones actually being observed. Similarly there can be a jitter of +/- 20 ns in the programmed CTPR and the measured CTPR.

NOTE

Please see Internal SYNC Pulse generation and coordination across PSI5 channels for details about the Sync Pulse generation and coordination.

Address: 0h base + 52Ah offset = 52Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CIPR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_CIPR field descriptions

Field	Description
0–15 CIPR	Counter initialize pulse register. This is the value using which the CTC gets reset, the first time after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be |CIPR_channel1 - CIPR_channel2| sp_ts_clk cycles. This if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

56.3.131 Data Preparation Register Low (PSI5_CH2_DPRL)

The following figure shows the Data Preparation Register Low.

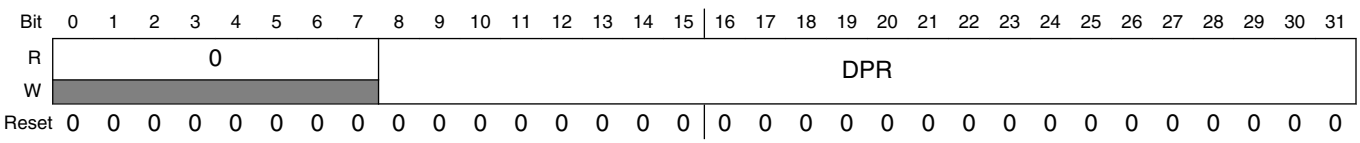
This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when PSI5_GISR[DPR_RDY] == 1. Whenever PSI5_GISR[DPR_RDY] == 1 , then each bit of

this register defaults to 0 . Writing to this register when PSI5_GISR[DPR_RDY] == 0 will cause the PSI5_GISR[IS_PROW] status bit to be set and the generation of an error interrupt, if it is enabled. Further , trying to write to this register when PSI5_DOBCR[CMD_TYPE] = "7" results in the setting of the PSI5_GISR[IS_PROW] bit and the resulting write is rejected.

Table 56-16. DPR details

PSI5_DOBCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL
"0" or "1"	Short Frame(PSI5 V1.3)	6(DPR[5:0])
"2" or "3"	Long Frame(PSI5 V1.3)	16(DPR[15:0])
"4" or "5"	X-Long Frame(PSI5 V1.3)	22(DPR[21:0])
"6"	XX-Long Frame(PSI5 V2.0)	24(DPR[23:0])
"7"	Not Available for write	Not Available for write

Address: 0h base + 52Ch offset = 52Ch

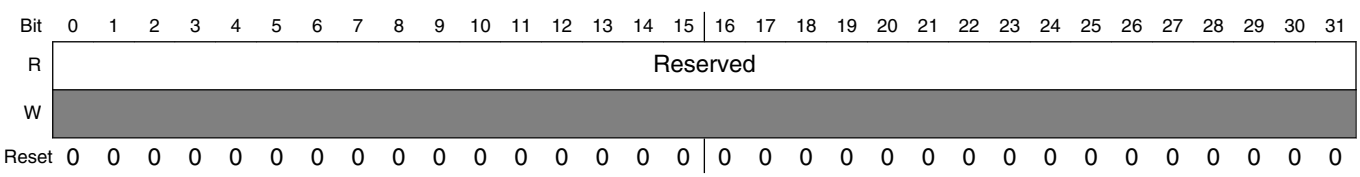


PSI5_CH2_DPRL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 DPR	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length , standard ECU-to-Sensor commands , comprising of the address , data and other fields . Note that the IP is transparent to the arrangement of the address,data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writeable only when using the standard length PSI5 frames . For details about CRC calculation please refer to Data transmission . The writeable bits in this register are governed by the PSI5_DOBCR[CMD_TYPE] bit fields as per Table 56-6 . Note that the unwriteable bits in this register field are always read as "0s" . This register has to be written by the CPU. These bits can be written only in the Normal mode.

56.3.132 Data Preparation Register High (PSI5_CH2_DPRH)

Address: 0h base + 530h offset = 530h



PSI5_CH2_DPRH field descriptions

Field	Description
0–31 Reserved	This field is reserved. This register is always read as 0s. Writing to this register does not have any effect.

56.3.133 Data Buffer Register Low (PSI5_CH2_DBRL)

The following figure shows the Data Buffer Register Low.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode.

NOTE

Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1, then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-17. DBRL[DBR] details

PSI5_CH2_DBRL field descriptions

Field	Description
0–31 DBR	This register contains the Lower 32 bits(DBR[31:0]) of the max-64 bit length command (DBR[63:0]). The higher bits , DBR[63:32] are contained in the DBRH register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-7 . The table (except when PSI5_DOBCR[CMD_TYPE] = "7") show the bit assignment of the DBR[31:0] when these bits are automatically updated by the hardware. When PSI5_DOBCR[CMD_TYPE] == "7"), then only the CPU can write to these registers.

56.3.134 Data Buffer Register High (PSI5_CH2_DBRH)

The following figure shows the Data Buffer Register High.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DBR_RDY]== 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DBR_RDY] == 0 will set the status bit

PSI5_GISR[IS_BROW] and generate an error interrupt, if it is enabled.

Table 56-18. DBRH[DBR] details

PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment
"7" - Non Standard Frame lengths	DBR[63:32]]	Variable length of writeable bits , as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]

PSI5_CH2_DBRH field descriptions

Field	Description
0–31 DBR	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU(when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware updation occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in Table 56-8 . Note that when PSI5_DOBCR[CMD_TYPE] == "7") , then only the CPU can write to these registers.

56.3.135 Data Shift Register Low (PSI5_CH2_DSRL)

The following figure shows the Data Shift Register Low.

This register is CPU writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0, then default value of this register is 00000000. When DEFAULT_SYNC == 1, then the default value of this register is FFFFFFFF. Note that the default value is different from the reset value. The reset value of the register is always "00000000". The default value is loaded once the IP enters the Normal mode. Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 53Ch offset = 53Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DSR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5_CH2_DSRL field descriptions

Field	Description
0–31 DSR	This register contains the lower 32 bits, (DSR[31:0]), of the max-64 bit length command (DSR[63:0]). The higher bits, DSR[63:32], are contained in the DSRH register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits.When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRL . Thus when updated by the hardware, then DSR[31:0] = DBR[31:0] . Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1 . These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1 .

56.3.136 Data Shift Register High (PSI5_CH2_DSRH)

The following figure shows the Data Shift Register High.

This register is writable only in Normal mode.

NOTE

When DEFAULT_SYNC == 0 then the default value of this register is 00000000 . When DEFAULT_SYNC == 1 then the default value of this register is FFFFFFFF . Further, the commands to this register are accepted ONLY when PSI5_GISR[DSR_RDY] == 1. Whenever PSI5_GISR[DBR_RDY] == 1 then each bit of this register defaults to DEFAULT_SYNC value. Writing to this register when PSI5_GISR[DSR_RDY] == 0 will set the status bit GISR[IS_DSROW] and generate an error interrupt, if it is enabled. Note that for the hardware updation of DSR with DBR contents, additional condition PSI5_DOBCR[SW_READY] == 1, should also be satisfied in addtion to PSI5_GISR[DSR_RDY] == 1 .

Address: 0h base + 540h offset = 540h

PSI5_CH2_DSRH field descriptions

Field	Description
0–31 DSR	This register contains the higher 32 bits (DSR[63:32) of the max-64 bit length command (DSR[63:0]). The lower bits, DSR[31:0], are contained in the DSRL register. These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of PSI5_DOBCR[CMD_TYPE] register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit postions in this register and the bit positions in the DBRH . Thus when updated by the hardware, then DSR[63:32]] = DBR[63:32] . Hardware updation occurs when PSI5_GISR[DSR_RDY]== 1 and PSI5_GISR[DBR_RDY] == 0 and PSI5_DOBCR[SW_READY] == 1. Note that if PSI5_DOBCR[SW_READY] == 0 then the updation of the data from the DBR to DSR will NOT happen even though PSI5_GISR[DSR_RDY] == 1 . These bits can be written by the CPU in the Normal mode , when PSI5_GISR[DSR_RDY] == 1'b1 .

56.3.137 Device modes and Register bit accesses

1. The following bits are writable in all modes (Normal, Config, and Disable).
   - GCR[GLOBAL_DISABLE_REQ]
   - PCCR[PSI5_CH_CONFIG]
   - PCCR[PSI5_CH_EN]
   - Global Counter Enable/Disable (GCR[CTC_GED]). This is to allow the Sync Pulse Generator to be enabled/disabled independently among those channels that are used for staggering, irrespective of the state of the channels NOT being used for staggering.

2. The following register is writeable only in Normal mode and is initialized to all 0s.
   - DPRL
3. The following registers are writable ONLY in Normal mode. Initialization in Config mode depends on the value of PSI5_DOBCR[DEFAULT_SYNC] bit. When PSI5_DOBCR[DEFAULT_SYNC] == 1 in Config mode, then the below registers are initialized to all 1s in Normal mode. When PSI5_DOBCR[DEFAULT_SYNC] = 0 in Config mode, then the below registers are initialized to all 0s in Normal mode. Once in Normal mode, these registers can then be programmed for any command that needs to be sent. x
   - DBRH/DBRL
   - DSRH/DSRL
4. The following registers are writable in Config and Normal modes only:
   - All interrupt control registers
   - All SET registers (the one shot registers which are used to set the error flags for software drivers)
   - DMA Control register
   - Channel Enable/Disable (PCCR[CTC_ED]). Using this it is possible to allow the Sync Pulse Generator to be enabled/disabled in Normal mode. The counter is reset when CTC_ED == 0
   - All w1c bits
5. Apart from these, all other register bits can be written only in Config mode , including the Data registers(PMRH/PMRL/SFRn), that, in Normal mode, are updated by the hardware only.
6. Debug mode: If the device is in Normal mode and the debug mode is enabled, then ONLY the registers mentioned in pts. 1, 2, 3, and 4 above can be written by the debugger. Register bits mentioned in pt. 5 above, will not be available for write through the debugger. In case the debugger has to change any register, then the device has to be brought in the Disable -> Config mode. The debugger can, however, read any register in any mode.

56.4 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. The following figure shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

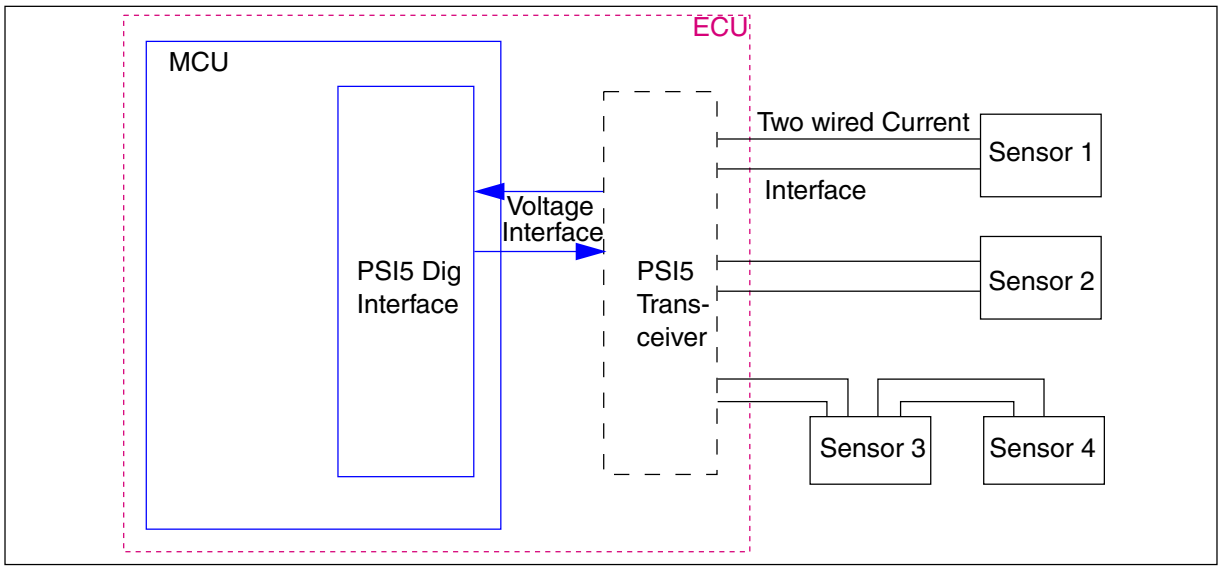

Figure 56-3. System setup (peripheral sensor connected to device)

The ECU (Electronic Control Unit) comprises PSI5 digital interface and the PSI5 transceiver (present externally).

56.4.1 Sensor-to-ECU communication

56.4.1.1 Physical layer

The PSI5 uses two wires to provide both power supply and data transmission to the sensors. The ECU provides a pre-regulated voltage to the sensors. Data transmission from the sensor to the ECU is done by current modulation on the power supply lines. Current oscillations are damped by the ECU.

56.4.1.2 Bit encoding

A "low" level ($I_{S,Low}$) is represented by the Normal (quiescent) current consumption of the sensor(s). A "high" level ($I_{S,High}$) is generated by an increased current sink of the sensor ($I_{S,Low}$ + …I_S). The current modulation is detected within the PSI5 transceiver.

Manchester coding is used for data transmission. A logic 0 is represented by a rising slope and a logic 1 by a falling slope of the current in the middle of T bit.

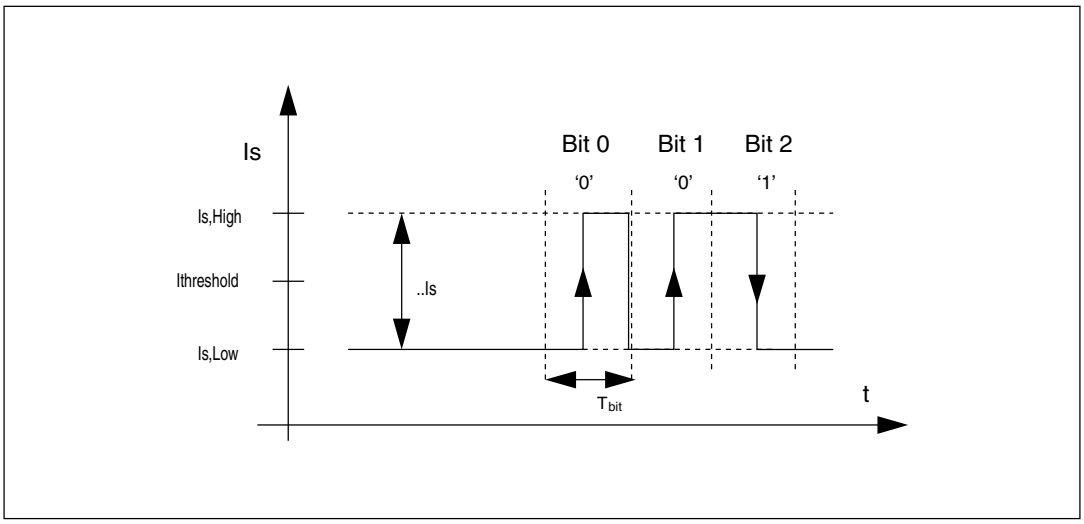

Figure 56-4. Bit encoding of data from sensor

56.4.1.3 Synchronization

For synchronized operation and bus mode, a sync pulse is generated by the PSI5 receiver. The sync pulse is output from the integrated PSI5 receiver to an external PSI5 transceiver that processes these pulses to a pre-regulated voltage level on supply lines to sensors. The voltage change is detected within the sensors.

56.4.2 Data Link Layer

The PSI5 message is received as serial Manchester-coded bits. The bit stream is passed through a Manchester decoder stage that converts it to normal NRZ format bit by bit and stores it serially in the receive register (64 bits). This block clearly identifies start (00) and end of receive frame using preprogrammed frame configuration registers.

- The Manchester-coded bits can be received at the rate of 125 Kbit/s.
- The Manchester decoder is designed to consider data with duty cycle of 30–70%.
- The bit decoding is done using an oversampling and counting algorithm with majority voting and edge recognition. Clocks of (125 kHz) × 32 (4 MHz also referred to as 32× clock) are supplied from a common clock generator module. This clock is used for oversampling of the receive bit and thereby decoding it as normal 1 or 0 (NRZ).

- The Manchester decoder is masked (switched off) for the duration when the sync pulse is transmitted. In addition to this, it can be configured to be off for an additional time, after the falling edge of the sync pulse. The duration of this time is configurable in the MDDIS_OFF register.
- It uses a 2oo3 voter to recognize the encoded half bits.
- There is a 3oo5 majority voting glitch filter at the data input of the Manchester decoder.

56.4.2.1 Reception of data frames

The extended PSI5 (Power Train Applications) receive data frame consists of *p* bits containing:

- Two start bits (S1 and S2) {S1=0, S2=0}
- One parity bit (P) with even parity (or 3 CRC bits C0, C1, and C2).
- A data region (D0…..D[*k* – 1]) with *k* = 8 to 28 bits with 1-bit granularity.
- The total length of a PSI5 frame is p = *k* + 3 data bits (in case of frames with parity bit) or p = *k* + 5 data bits (in case of frames with CRC).
- Data bits are received LSB first. The parity or CRC check bits cover the bits of the entire data region.

The length of the data region can vary between *k* = 8 to 28 bits (with 1-bit granularity). The data region can be split into the following fields and regions:

- The bits D0 and D1 can optionally represent Serial Messaging Channel M0, M1.
  - This Serial Messaging Channel (SMC) is used to receive initialization data during fast startup phase or slow acknowledgement/response messages (to command transmitted from ECU requesting data or diagnostic information from the sensor).

Note, that the maximum length of the entire data region is 28 bits. Thus the signal payload region and the optional data fields cannot concurrently be used at their maximum length in some cases.

As the PSI5 module is targeted for powertrain applications, the data frame format differs from standard PSI5 frames for safety applications specified in version 1.3 of the PSI5 specifications. More specifically for supporting the version 2.0 powertrain substandard. The Powertrain data frame format and optional Serial Messaging Channel (SMC) frame format are shown in the following figure.

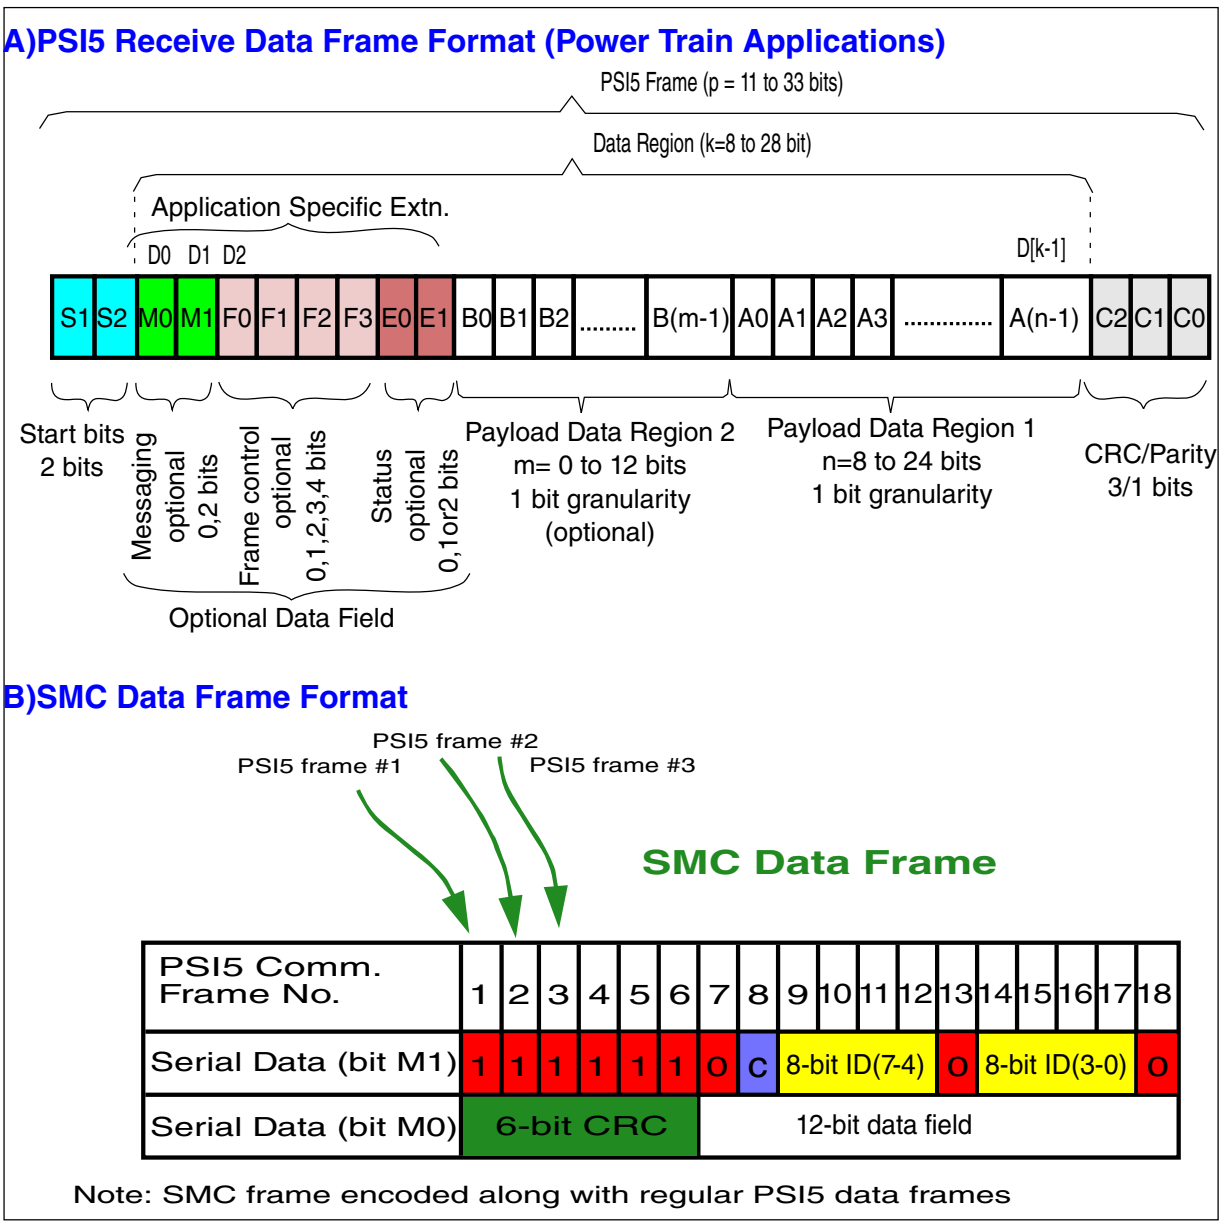

Figure 56-5. Receive data frame format

56.4.2.2 Data Frame Configuration Control

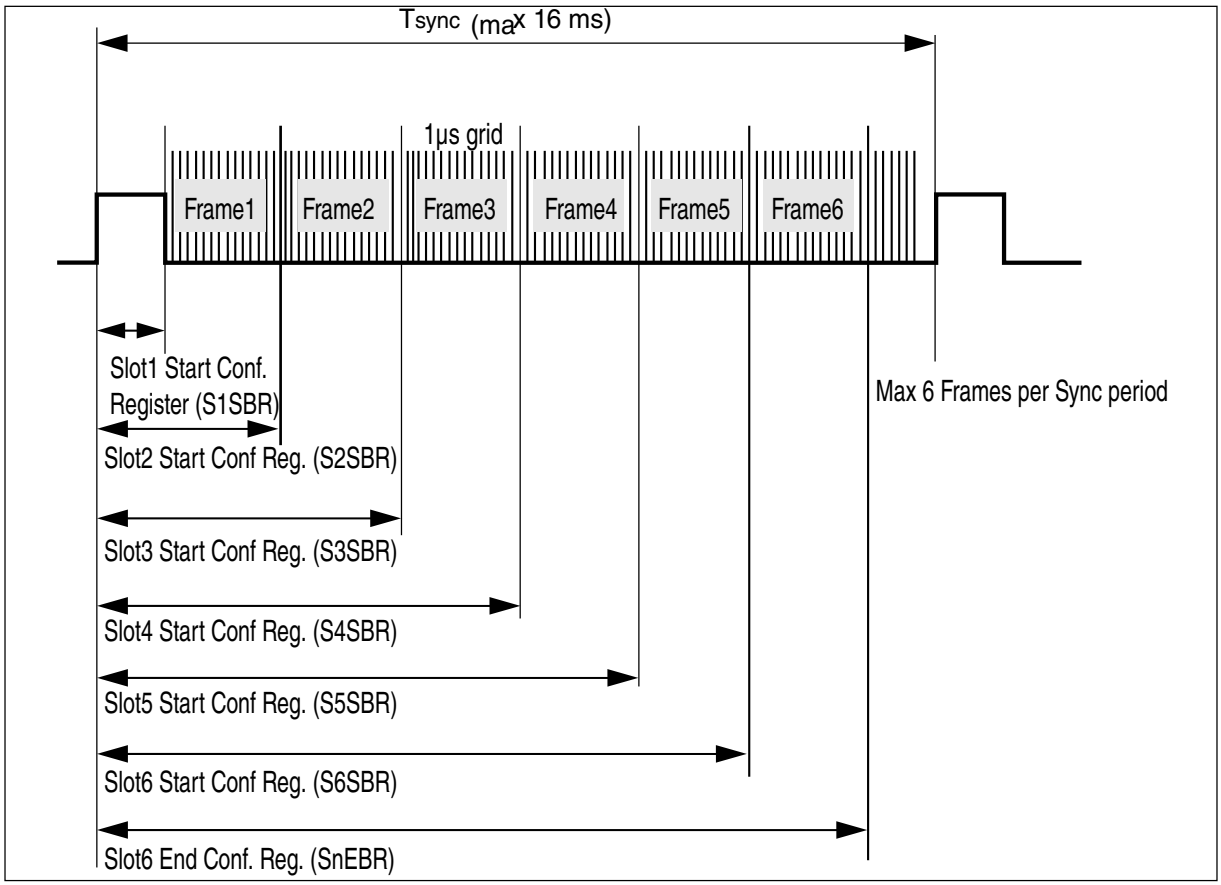

Figure 56-6. Data frame configuration and sampling

At the receive path, as many as six frame slots (reception windows) can be programmed with a start time of consecutive slots (slot1 to slot6) and end time or last slot which can be configured through the Slot *n* Start/End Configuration Registers (Slot 1 Start Boundary Register (PSI5_CH0_S1SBR)-Slot 6 Start Boundary Register (PSI5_CH0_S6SBR) and Slot n End Boundary Register (PSI5_CH0_SnEBR)) there are seven registers for six slots. The slot time value is with respect to timing sync pulse.

The following range is always maintained for T_{sync} (during programming of the GCR and CTPR registers) when timing (sync) pulses are generated through the Sync Pulse Generator.

$$T_{sync} < 16\text{ms}$$

For the maximum defined six frame slots, six frame configuration registers (S1FCR, S2FCR, S3FCR, S4FCR, S5FCR, and S6FCR) are also available. In these registers it is possible to configure the payload region of the expected frames, in addition to other channel-specific parameters.

56.4.2.3 Data frame handling

The following figure shows the detection of the start bits and the various parameters for the same.

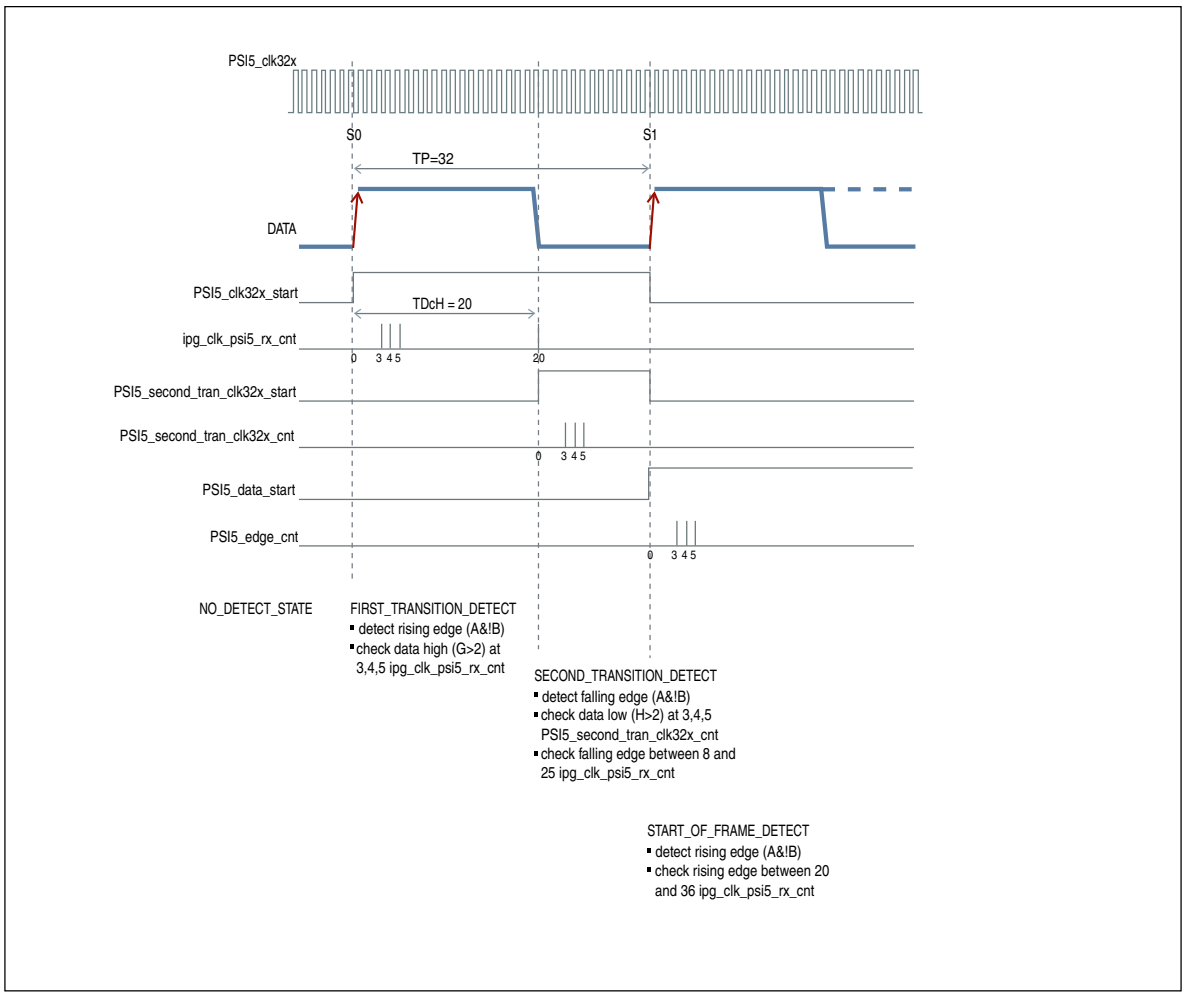

Figure 56-7. Start detection

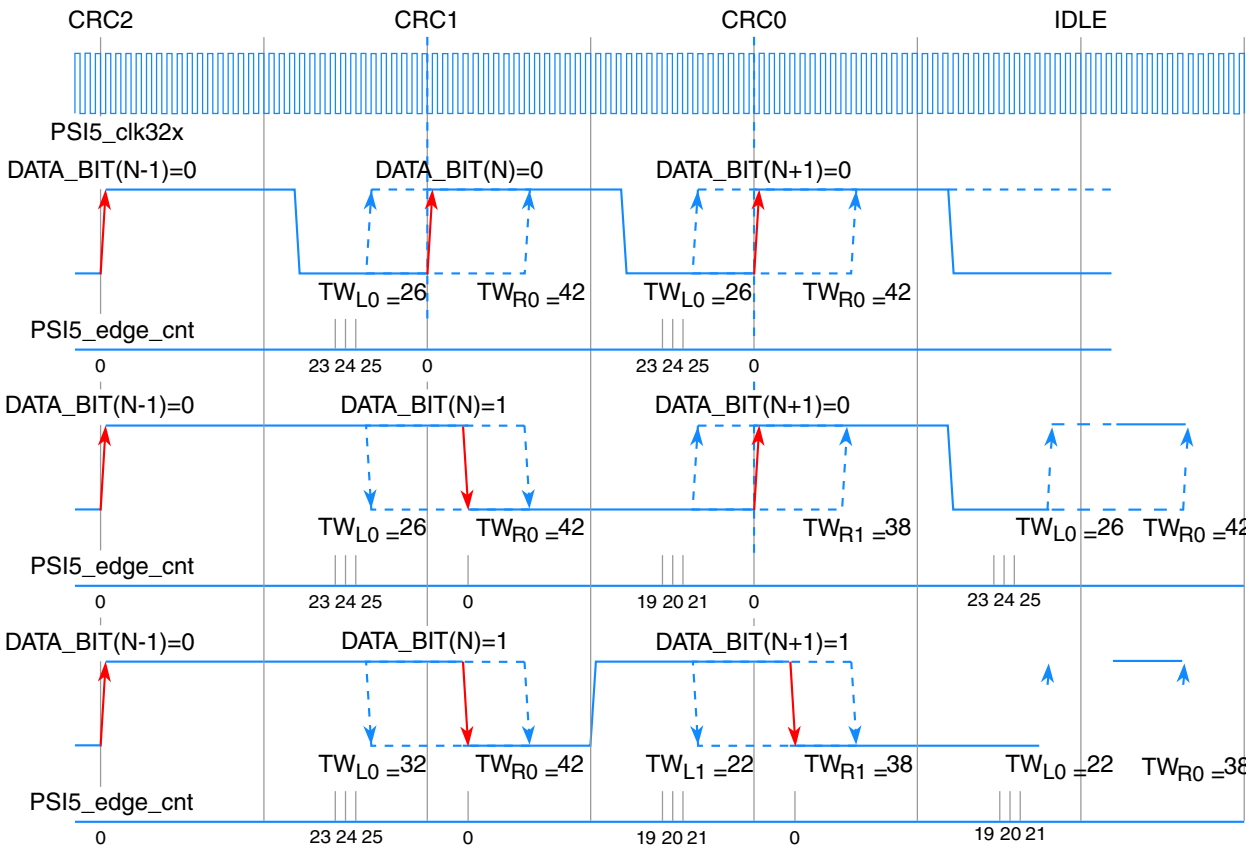
Figure 56-8. Start Bit Detection

The following figure shows how the bits are differentiated into a “1” or a “0” based on the various margins and sample points.



Start Sequence Measured: Tp = 32 and TDcH = 20
Calculations:
TDcL = Tp–TDcH=12, DeltaDc = TDcH–Tp/2 = 4; TMarginL = TDcL/2=6; TMarginH = TDcH/2 = 10
If DATA_BIT(N) = 0, TWI = TDcH+TMarginL=26; signal sampled at TWI-3, -2 and -1

- If signal low, expect rising edge between TWL0 and TWR0 then DATA_BIT(N+1) = 0.
  TW_{L0} = TDcH+TMarginL and TWR0 = Tp+TMarginH
- If signal high, expect falling edge between TWL0 and TWR0 then DATA_BIT(N+1) = 1.
  TW_{L0} = TDcH+TMarginL and TWR0 = Tp+DeltaDc+TMarginL

If DATA_BIT(N) = 1, TWI = TDcL+TMarginH = 22; signal sampled at TWI-3, -2 and -1

- If signal low, expect rising edge between TWL1 and TWR1 then DATA_BIT(N+1) = 0.
  TW_{L1} = TDcL+TMarginH and TW_{R1} = Tp–DeltaDc+TMarginH
- If signal high, expect falling edge between TWL1 and TWR1 then DATA_BIT(N+1) = 1.
  TW_{L1} = TDcL+TMarginH and TW_{R1} = Tp+TMarginL

IDLE state can be reached in two ways:

1. Idle can be detected after zero(last data bit) .In this the edge is searched in the same window as for data zero i.e. TWLO-26 to TWRO = 42
2. Idle is detected after one(last data bit).In this the edge is searched in the same window as for data one i.e. TWLO = 22 to TWRO = 38

Figure 56-9. Bit Extraction

56.4.2.3.1 Start of frame recognition

56.4.2.3.2 Data state

In the data state, the Manchester decoder samples the number of data bits corresponding to the configured length of the data payload region and 3-bit CRC or 1-bit parity.

56.4.2.3.3 Message diagnostic checks

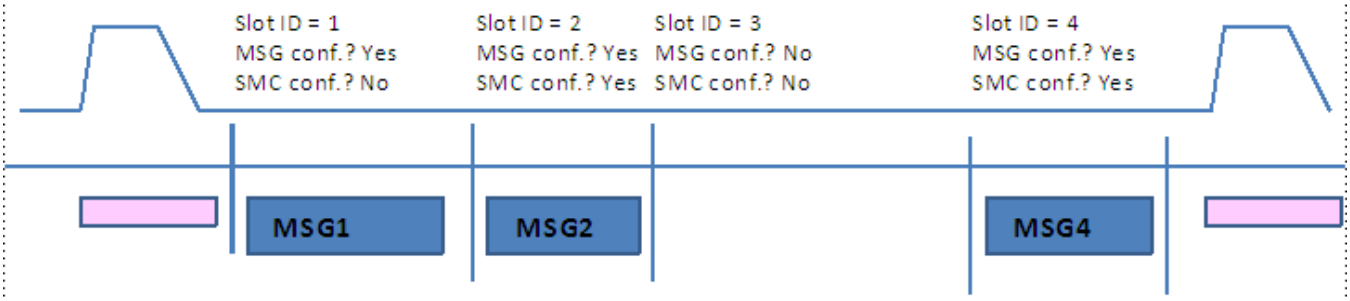
During the data state, electrical correctness of each bit in regard of Manchester encoding is checked. If an incorrect bit is detected, a 0 is written into the data payload region. Following completion of reception, correctness of the entire message is checked with the CRC and timing of the message reception.

- CRC is recalculated for the data and compared with received CRC bits. The CRC comparison result is stored as a status bit, denoted as the C field in the receive register and the RAM register. Irrespective of the value of the “C” bit the, the frame is always stored in the RAM register and is never discarded.
- If at least one bit is electrically faulty (apart from M0M1), then the bit field E is set to 1 and stored as status bit in the receive register and the RAM register.
- The EM bit is set to 1 if any of M0 or M1 bits are electrically faulty. Note that the E and the EM bits can be set only when a valid start sequence has been detected.
- Set status bit field T in the receive register to 1 if the frame received is in the wrong slot (boundary violations). This bit is NOT set for asynchronous modes.
- Set status bit F if no frame is received in defined frame slot. This bit is NOT set for asynchronous modes.
- The incoming frames after the sync pulse are to be numbered from 1 to 6 (max). This is done by a 3-bit slot counter, which is incremented automatically after the end of each slot irrespective of whether a valid message is received or not. This 3-bit value is stored in the receive register and the RAM registers as the "slot_counter" field.

56.4.2.3.4 T-bit handling

The following paragraphs describe how the IP handles error cases that generate T bit errors. A number of examples are shown, including the error free case, which is used to explain the reception process.

56.4.2.3.4.1 Error free case



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

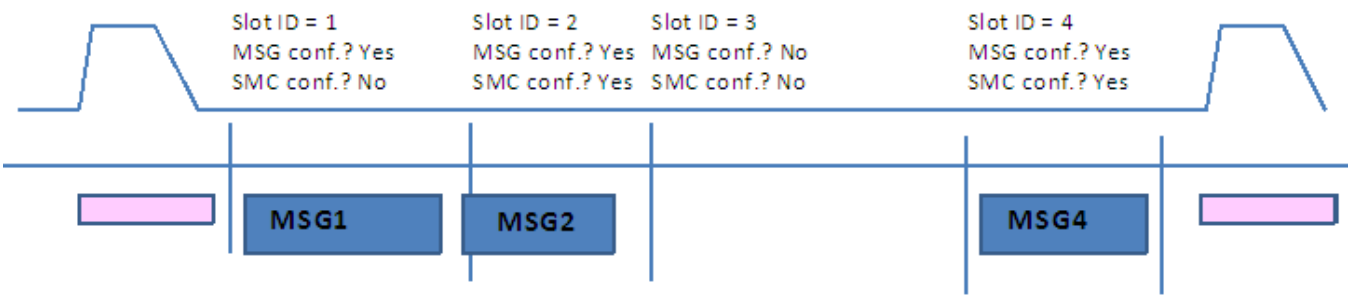
Figure 56-10. Error free case

In this case, all messages are received in the correct slots.

- As soon as the Manchester decoder block is enabled (after the SYNC pulse has finished and any configured disable offset has expired, pink region) the IP checks for the first configured message and starts monitoring the output of the PSI5 transceiver.
- The IP identifies a correct start of message sequence (S0, S1)== ’00’, and captures the slot counter when the first rising edge of the start sequence is detected. This first rising edge detected is the mid-point transition of the Manchester encoded S0 bit of the message start sequence.
- The expected number of bits configured in the message is received and decoded. Any error in the Manchester encoded bits of the message E bit is set - unless the error is in one of the first two bits and SMC message is configured, in which case the EM bit is set.
- After the final bit is received, a check is made that the message CRC or parity is correct. If the CRC or parity check is not correct, C bit is set for the message.
- Once the CRC checks have been made, the received message — along with the status bits, slot counter in which the start sequence was received, the timestamp of the message, the message data and CRC or parity is saved to the channel message FIFO.

- As soon as the received message has been stored,the idle state of the bus is verified and monitoring of the transceiver output restarts to check for the next configured message.
- If the serial message channel (SMC) is configured, the first two data bits are extracted from a sequence of 7 PSI5 messages as long as no electrical error is detected in those bits (EM error). If the correct start sequence for the SMC message is detected on M1 (6 logical 1s and a logical 0) in those 7 messages, M0 and M1 from the following 11 messages are also extracted and saved in the SMC buffer allocated to the slot in which the PSI5 message is received (in total, 18 PSI5 messages are needed to build one SMC message). When the SMC has been received, the CRC is checked and the status of the check is saved in the SMC buffer. If an EM error occurs after a start sequence has been detected and before the end of the message is reached, M0 and M1 are both saved as 0 and the rest of the message is received, at which point the CRC is checked as normal.

56.4.2.3.4.2 Message Too Early



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	1	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

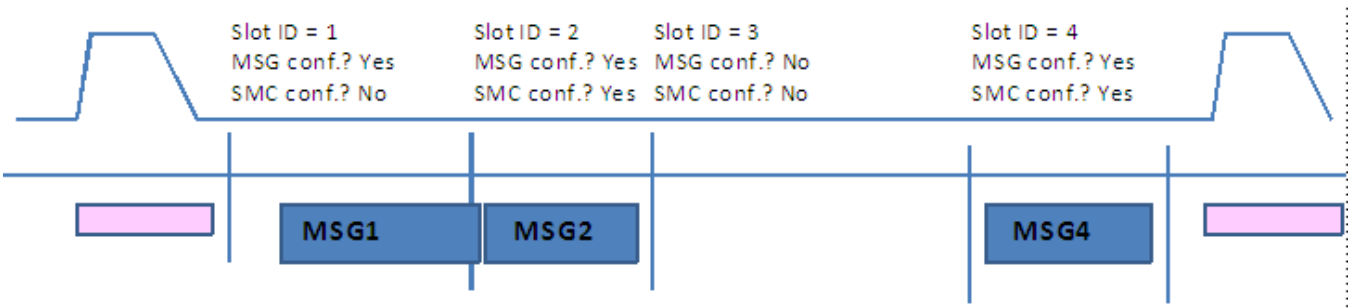
Figure 56-11. Message Too Early

In this scenario, MSG2 reception starts early, before slot 2 boundary is crossed, and so the slot counter is captured as “1” and because the message starts in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the

correct MSG2 has been received but not entirely in it's correct slot. The status of the message will include the T bit set and slot counter will be 1, so software can interpret that MSG2 was too early.

The SMC message is received correctly.

56.4.2.3.4.3 Message Too Late



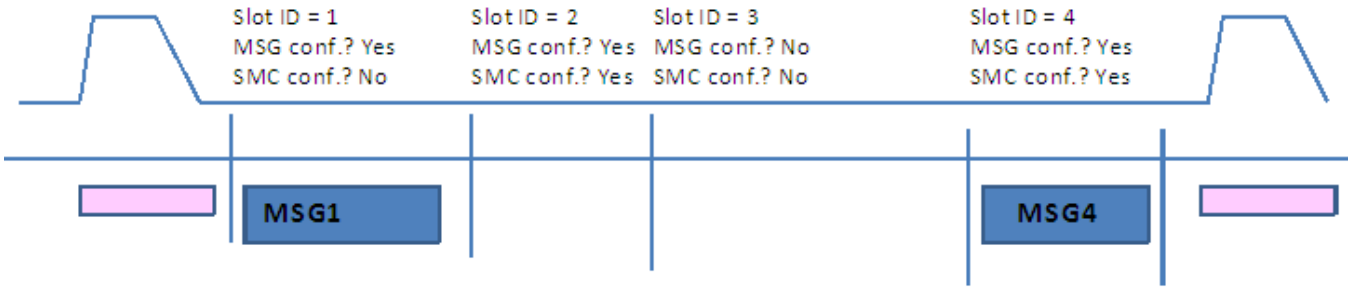
Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

Figure 56-12. Message Too Late

In this scenario, MSG1 reception starts later than expected and ends after slot 2 boundary is crossed. The slot counter is captured as "1" and because the message ends in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG1 has been received but not entirely in it's correct slot. The status of the message will include the T bit set and slot counter will be "1", so software can interpret that MSG1 was late.

The SMC message is received correctly.

56.4.2.3.4.4 Message Missing



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	Yes	No	No	2	0/0
MSG4	4	No	No	No	No	4	M0/M1

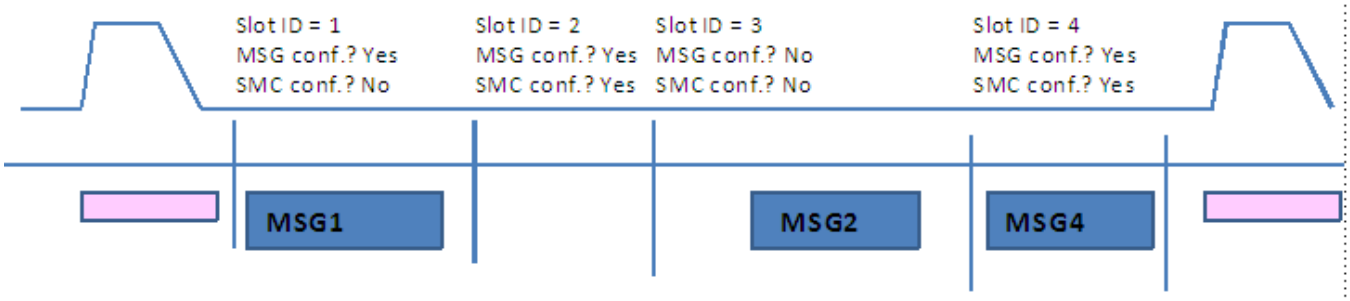
Figure 56-13. Message Missing

In this scenario, MSG2 is missing.

At the end of slot 2, the IP writes message buffer location 2 (MSG2 location) with slot counter 2 and the F bit set. The data and timestamp regions are filled with 0s.

The IP waits until the start of the next configured slot (slot 4) to update the SMC buffer 2 with “00”. If slot 4 was not configured, the SMC for the missing MSG2 would be updated at the end of the final slot.

56.4.2.3.4.5 Message Too Much Late (in unconfigured slot)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2a	2	No	Yes	No	No	2	No update
MSG2b	3	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

Figure 56-14. Message Much Too Late (in unconfigured slot)

In this scenario, MSG2 reception doesn't start in it's own slot, and the F bit is set for message buffer location 2 (MSG2a).

Because slot 3 is not configured, the IP continues to wait for MSG2 in slot 3 and does not update the SMC message buffer 2. The IP recognizes the MSG2 start condition in the normal way and updates PSI5 message buffer 3 (MSG2b), capturing slot 3 as the start slot counter and setting T bit, so that the software can recognize that MSG2 has come in slot 3.

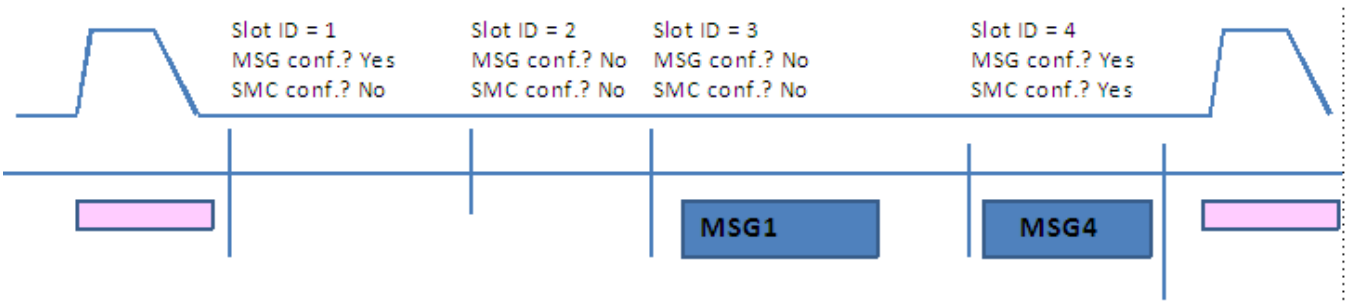
When MSG2 has been received, SMC message buffer 2 is updated at the end of slot 3. MSG4 is received normally.

NOTE

Any scenario where an expected message arrives in an unconfigured slot, leads to an issue when DMA access is used to read the PSI5 message buffer. This is because instead of the expected three entries in the PSI5 message buffer, there will be four, and assuming the DMA watermark is set for the expected three messages, the DMA request will be activated before MSG4 has been received.

In order to overcome this, if DMA access is required, no slots can be left unconfigured and the DMA watermark must be set to the number of slots in the SYNC period. In that way, the DMA will always be syncronised, but depending on how the 'empty' slot is configured, when a message is too late as described here, the result can be that the late message and its associated SMC content is lost.

56.4.2.3.4.6 Message Much Too Late (in unconfigured slot)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1a	1	No	Yes	No	No	No	No
MSG1b	3	Yes	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

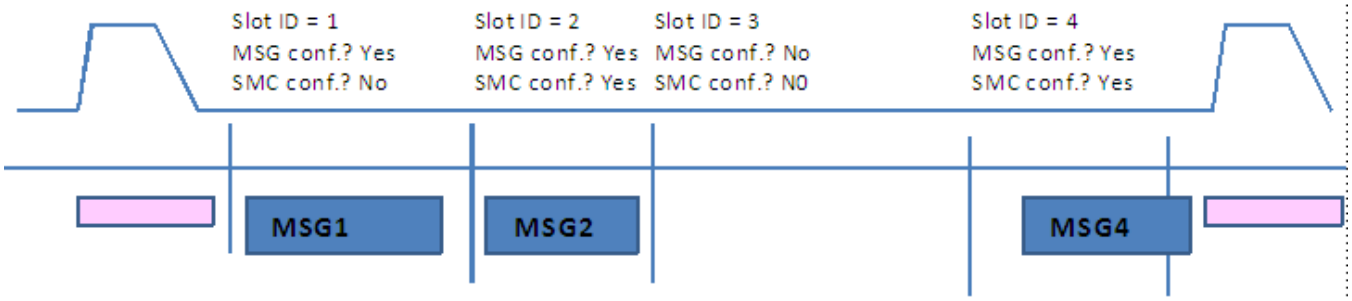
Figure 56-15. Message Much Too Late (in unconfigured slot)

In this scenario, MSG1 is received much too late, in the second of two unconfigured slots.

When MSG1 does not arrive in slot 1, MSG1a is saved in the message buffer with F bit set. The IP waits throughout the two unconfigured slots and is received in slot 3 with slot counter 3. Because MSG1b is received completely in slot 3 it is saved in the message buffer with T bit set.

MSG4 is received normally.

56.4.2.3.4.7 Message Too Late (in last slot)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	No	No	4	M0/M1

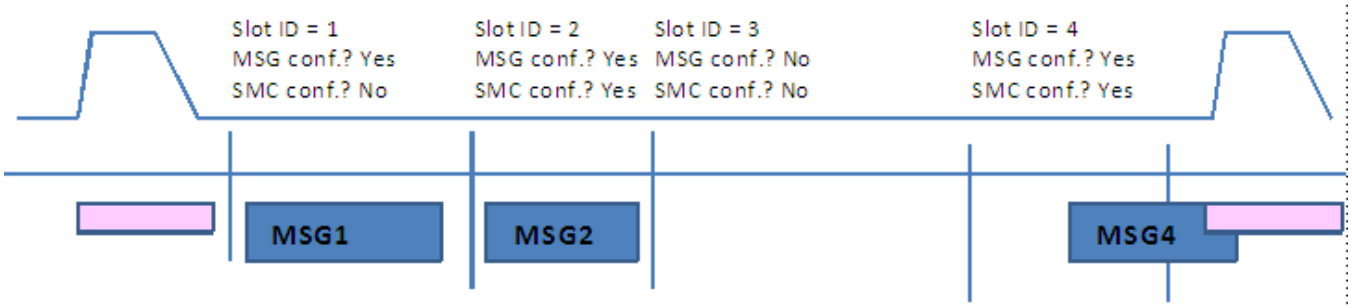
Figure 56-16. Message Much Too Late (in last slot)

In this scenario, the last message is received late.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the end of the final slot, but before the Manchester decoder is disabled by the SYNC pulse on the bus. The message is received correctly with the T bit set.

56.4.2.3.4.8 Message Too Late (in last slot)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	Yes	Yes	4	M0/M1 or 0/0

Figure 56-17. Message Much Too Late (in last slot)

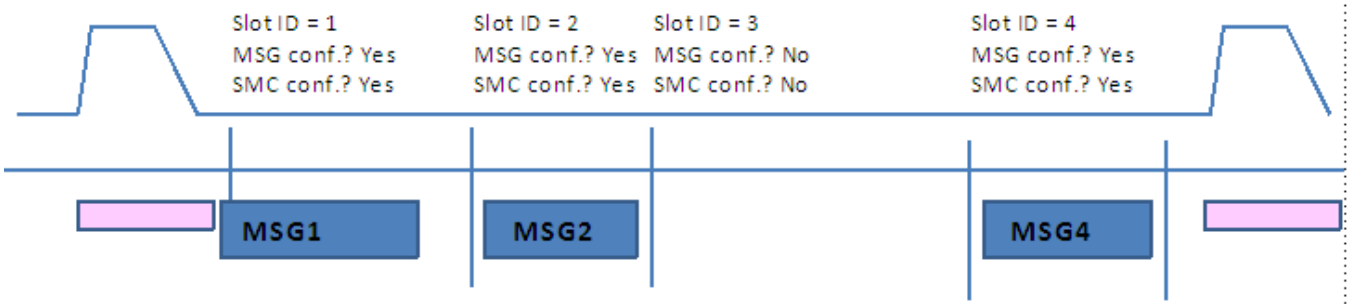
In this scenario, the last message is received late in the last slot.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the Manchester decoder is disabled by the SYNC pulse on the bus, so the last part of the message cannot be received correctly. Nevertheless, the message reception is completed and the message is stored in the message buffer with the T bit set and 0 written in the buffer for all bits received while the Manchester decoder is disabled. This leads to E and C bit errors.

In an extreme case, it could also lead to EM bit errors, in which case the SMC buffer will also be written with (0,0) otherwise, the correct bits are written to the SMC buffer.

56.4.2.3.4.9 Message Too Early (in first slot)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	0	Yes	No	No	No	1	M0/M1
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

Figure 56-18. Message Much Too Early (in first slot)

In this scenario, the first message is received early.

As soon as the Manchester decoder disable phase has ended, the IP verifies the idle condition on the signal line and then looks for the first message start sequence. MSG1 start sequence is received before the start of slot 1 with slot counter 0 captured. MSG1 is then received normally and saved with slot counter 0 and T bit set.

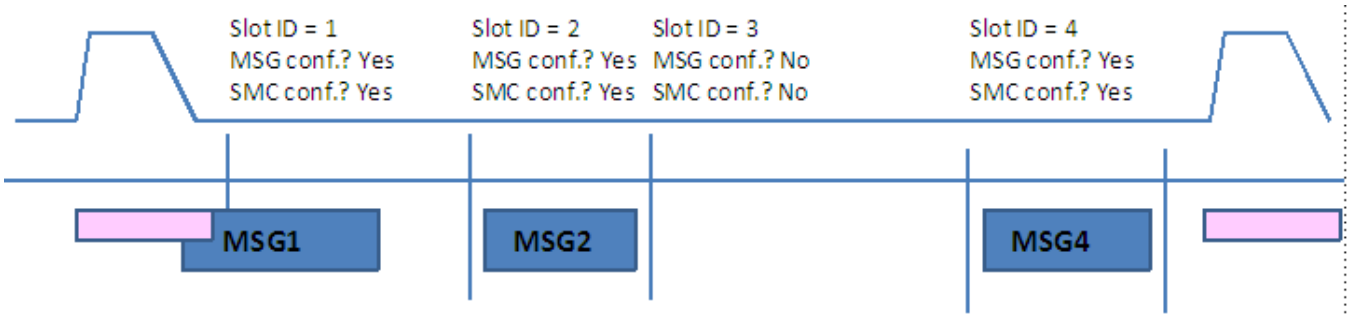
SMC bits M0/M1 are saved to SMC buffer 1.

MSG2 and MSG4 are received normally.

NOTE

This scenario can be avoided if the start of slot 1 is configured to coincide with the end of the Manchester decoder disable phase.

56.4.2.3.4.10 Message Too Early (in first slot and overlaps Manchester Decoder disable)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	Yes	No	No	1	0/0
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

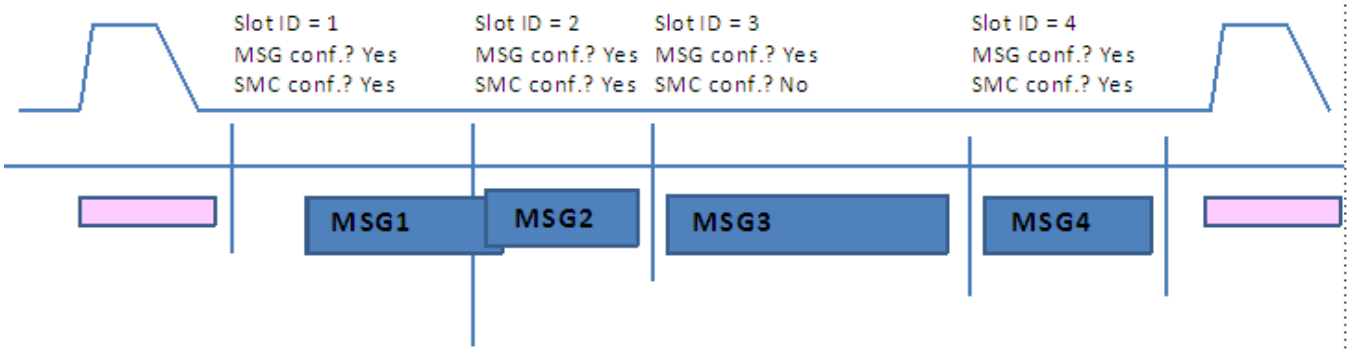
Figure 56-19. Message Too Early (in first slot)

In this scenario, the first message is received early and overlaps with the Manchester decoder disable phase.

As soon as the Manchester decoder disable phase has ended, the IP starts looking for “idle condition” on the signal line by monitoring it for 42 counts of the sample clock. If the signal line is found to be initially high or if a valid transition occurs in the time frame of 42 samples of the sample clock, the Manchester decoder stops decoding until the end of slot 1. Decoding will restart at the beginning of slot 2.

MSG1 is assumed to be lost and the “F” bit is set for that message with the Slot Counter as “1”. If MSG1 SMC is configured then SMC is saved with “00” appended for the M0/M1 bits.

56.4.2.3.4.11 Message Too Late (overlaps next message)



Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	Yes	Yes	1	M0/M1
MSG2	2	No	Yes	No	No	2	0/0
MSG3	3	No	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

Figure 56-20. Message Too Late (overlaps next message)

In this scenario, MSG1 is received too late and overlaps with MSG2.

MSG1 start is recognized in slot 1. The last bits of MSG1 are disrupted by the start of MSG2 leading to likely E and C bit errors.

At the end of MSG1, idle time is found to be violated by either the signal line being high as soon as NO_DETECT_STATE is entered or FIRST_TRANSITION_DETECT occurs within 42 counts of the idle detect sample clock. The Manchester decoder stops decoding until the end of slot 2. Decoding is restarted at the start of slot3. MSG2 is not received and MSG2 location in the memory will be saved with the F-bit set. The SMC buffer 2 will be updated with 00.

MSG3 and MSG4 are received correctly in their own slots.

56.4.2.3.5 Data Frame Storage

Once the data frame is received and all required status fields updated (for example, Time stamp, C, E, EM, T, F and Frame Counter), this 64-bit value in the data receive register is moved to the RAM Register (PMB).

- This RAM buffer is a 32 (depth) × 64 (frame size) register array with DMA transfer capability (both single or burst).
- Also, the individual RAM locations can be accessed directly by the microcontroller core any time.
- Care needs to be taken that receive data is assigned to the sensor and frame slot unambiguously.

56.4.2.3.6 Message diagnostics

Apart from the regular status bits (mentioned above), a few more diagnostic checks are done and stored as status bits along with each data frame location in RAM. These are:

- Diagnosis registers are associated with each sensor data RAM buffer to indicate
  - RAM buffer has been filled with data.
  - RAM buffer has been overwritten before data previously stored was read.
  - Data written to buffer includes an error bit (E, EM, C, T, or F, configurable).
- The diagnosis registers are able to be read with a single DMA access.
- After successfully completing a read access, these registers are reset by hardware. This is done by mapping these diagnosis bits byte-wise so that one byte access clears a single bit without affecting other bits.

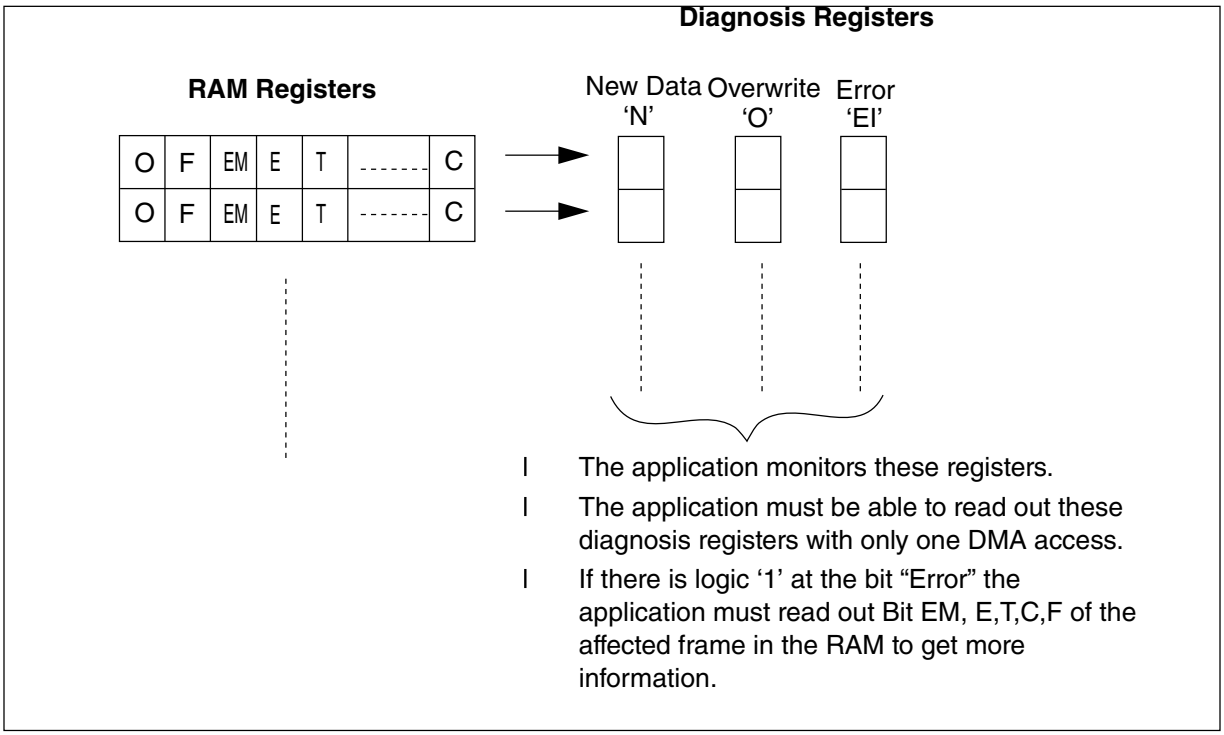


Figure 56-21. Diagnosis Information attached to every frame

Note

See Implementation of EI Diagnostic Register for more detail.

56.4.2.3.7 SMC message extraction

The optional messaging channel M0, M1 (shown in Figure 56-5) is used by sensors to send an SMC frame along with the normal PSI5 frame. It takes 18 PSI5 frames to send one SMC frame.

The extraction of SMC bits is done for each slot separately and stored separately into the SMC frame receive buffers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (depth of SMC frame, as defined below)

The extraction logic works as follows:

- Search for SMC start sequence 111111 followed by 0 on M1 and keep storing last 6 bits {CRC} on M0.
- If the start sequence is detected it continues with further extraction and storage of M1 and M0.
    - Store the extracted frame on the corresponding slot buffer.

- Move the SMC frame to corresponding SFR[i] register period. Once complete, the SMC frame is extracted and generates an interrupt, so that it can be read by the CPU.
- If the start sequence is not detected, it continues with the search.

The SMC frame is extracted in hardware and stored separately as memory-mapped registers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (depth of SMC frame).

56.4.2.4 Message Read Logic

PSI5 supports two kinds of read access to received sensor data.

- Read access through memory-mapped RAM registers. These registers can be read by the CPU any time or, specifically, when the concerned interrupts are raised. Applicable for both the SMC and the PSI5 messages.
- Read access through DMA request. Here the DMA sequencer treats the memory-mapped registers as a block and reads them sequentially. Note that even if the DMA is used, the CPU can read the RAM registers any time by addressing them. This is applicable for both the SMC and the PSI5 messages. When reading the PSI5 messages, it is possible to read only the PSI5 messages or PSI5 + diagnostic registers.

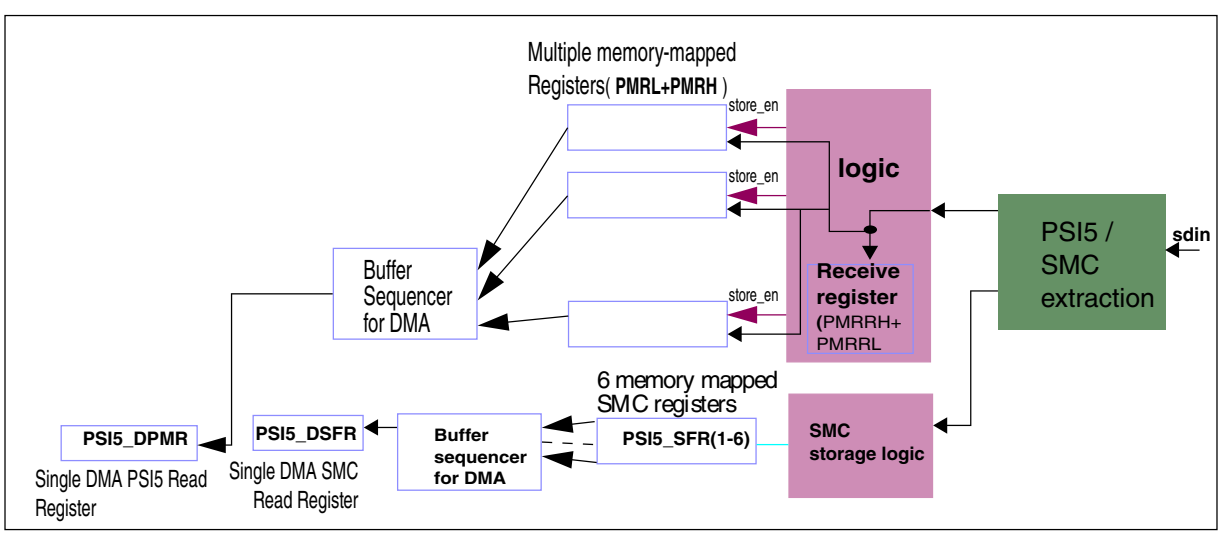

Figure 56-22. PSI5 and SMC Message Read Logic Block

56.4.2.5 CRC Recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

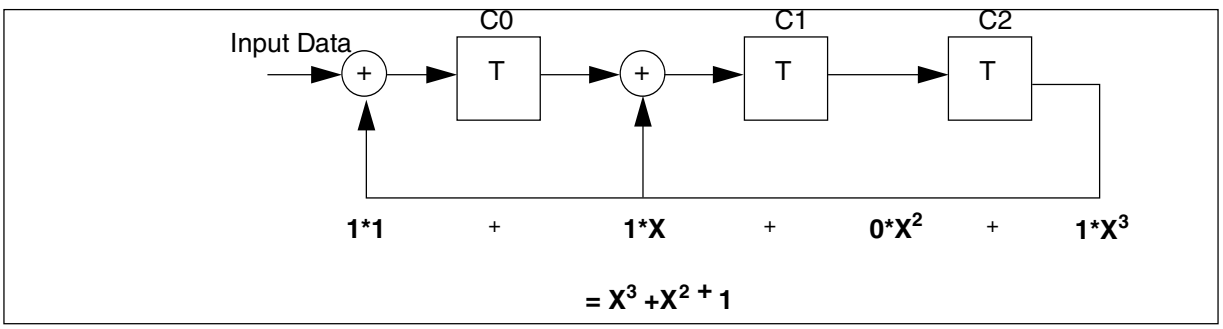

Figure 56-23. CRC calculation scheme

Table 56-19. CRC Calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 56-20. Transmitted and Received Sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 56-21. CRC Re-Calculation (At Receiver Side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

56.4.3 ECU-to-sensor communication

Whereas the sensor-to-ECU communication is realized by current modulation, voltage modulation on the supply lines is used to transmit commands to the sensors. A predefined start sequence allows the sensors to recognize that a command is being transmitted during all synchronous operation modes.

56.4.3.1 Physical Layer

A logical 1/0 is represented by data sync pulse of variable length, a logical 1 by the sync pulse of width W1(programmable from 0 to 127 µs) and logical '0' by sync pulse with W0{programmable from 0 to 127 µs}.

56.4.3.2 Data Link Layer

56.4.3.3 Bit coding

The bit period is the cycle time as specified for the operation mode, for example, 500 µs in the PSI5-P10P-500/3L mode. (For details about this topology, please refer Section PSI5 topology) The lower limit depends on the filter characteristics of the hardware circuitry used for the sync signal detection (subsequent sync signals might vary the internal $V_{ss,\ base}$ reference).

56.4.3.4 Data transmission

The IP supports the standard and the Non-Standard ECU to Sensor communication Formats . In the Non-Standard mode of communication it can be used to send any frame size programmable from 1-64 bits. In the Standard Formats it supports both the V1.3 and the V2.0 of the PSI5 ECU to Sensor Communication as briefed below in Figure 56-24 and the text that follows it.

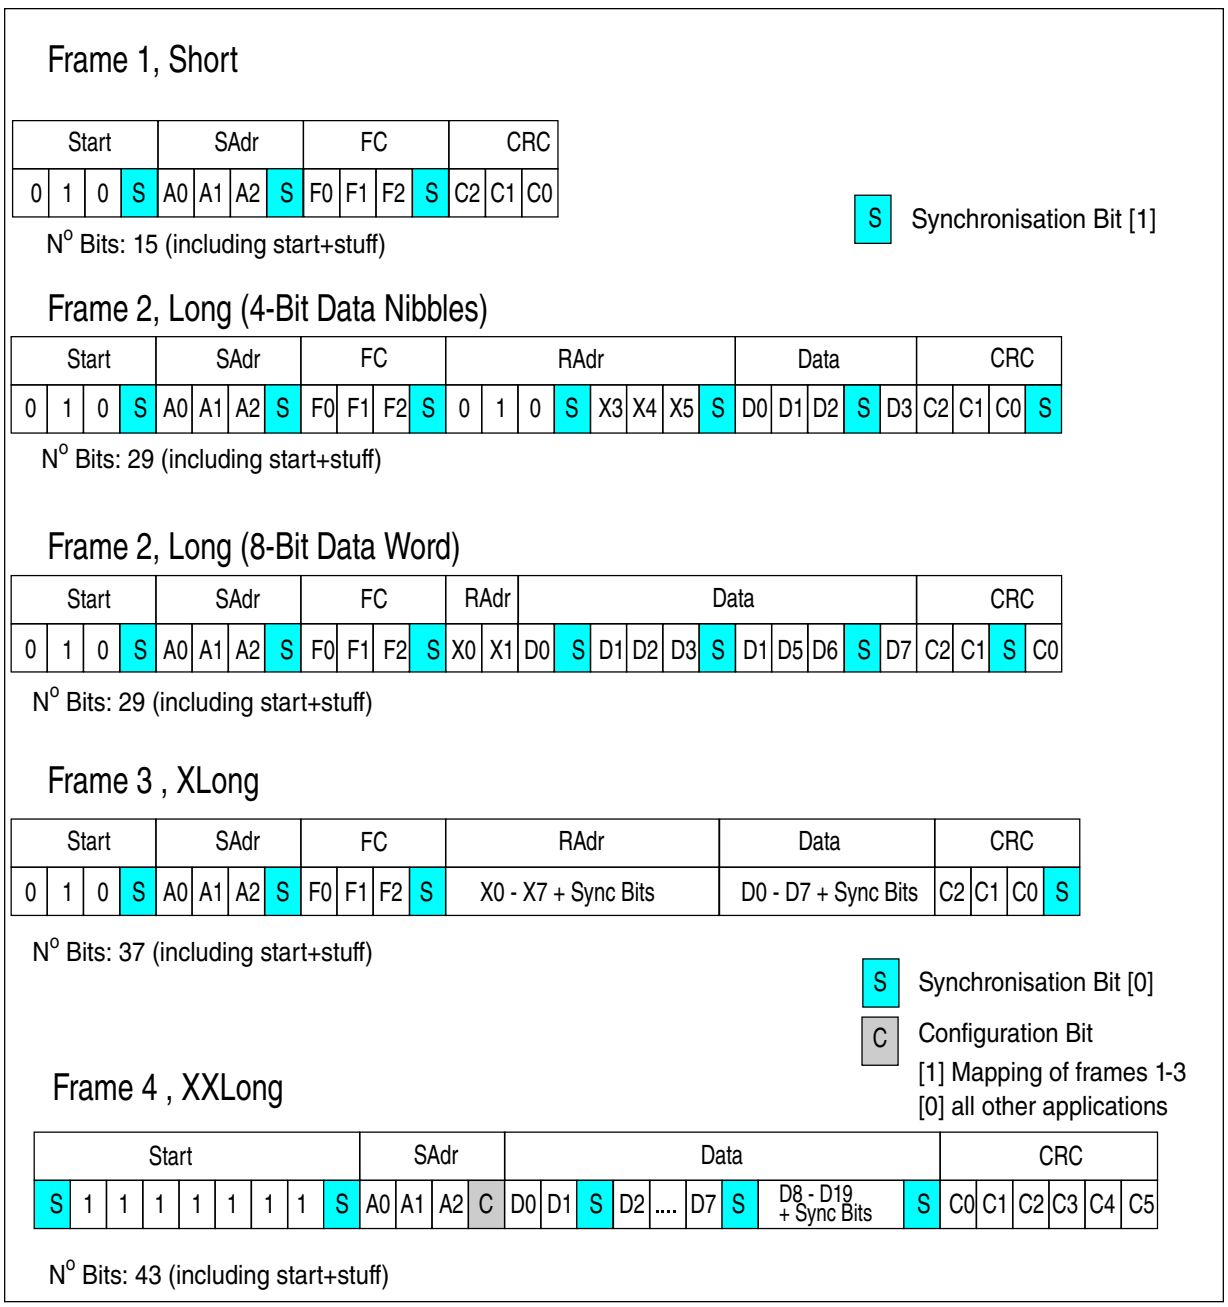

Figure 56-24. Standard Frame Fomats Supported

- **Short(V1.3)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- **"010", S, "A0, A1, A2", S, "F0, F1, F2", S, "C2, C1, C0"** where "010" is the start sequence "S" is the stuff bit(1) ,A0-A2 is the sensor address ,F0-F2 are the functional codes and "C2-C0" is the CRC. Please refer Figure 56-24 for the frame structure.
  - The CRC polynomial used is $x3 + x2 + 1$ with a binary initialisation value of "111(C2:C0)".
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]….DPR[5],000) with DPR[0] being fed first in the CRC calculator.
- **Long(V1.3 - 4bit Data Nibble)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- **"010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5, S, "D0, D1, D2", S,"D3, C2, C1", S, "C0"** where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,"X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer Figure 56-24 for the frame structure.
  - The CRC polynomial used is $x3 + x2 + 1$ with a binary initialisation value of "111(C2:C0)".
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0..X5,D0…D3,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]….DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- **Long(V1.3 - 8bit Data Word)** : It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - **"010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, D0", S, "D1, D2, D3, S, "D4, D4, D6", S,"D7, C2, C1", S, "C0"** where "010" is the start sequence "S" is the stuff

bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,"X0-X1" is the Range Address, "D0-D7" is the data and "C2-C0" is the CRC .Please refer Figure 56-24 for the frame structure.

- The CRC polynomial used is $x3 + x2 + 1$ with a binary initialisation value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0..X1,D0…D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
- When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]….DPR[15],000) with DPR[0] being fed first in the CRC calculator.

- **X-Long(V1.3) :** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - **"010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5", S, "X6, X7, D0", S, "D1, D2, D3", S, "D4, D5, D6", S, "D7, C2, C1", S, "C0"** where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes,"X0-X5" is the Range Address , "D0-D3" is the data and "C2-C0" is the CRC . Please refer Figure 56-24 for the frame structure.
  - The CRC polynomial used is $x3 + x2 + 1$ with a binary initialisation value of "111(C2:C0)".
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0…X7,D0…D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
  - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]….DPR[21],000) with DPR[0] being fed first in the CRC calculator.
- **XX-Long(V2.0) :** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - **"011111110", "A0, A1, A2", "C", "D0, D1", S, "D2, D3, D4" D5, D6, D7, S, "D8, D9, D10, D11, D12, D13", S, "D14, D15, D16, D17, D18, D19", S, "C0, C1, C2, C3, C4, C5"**

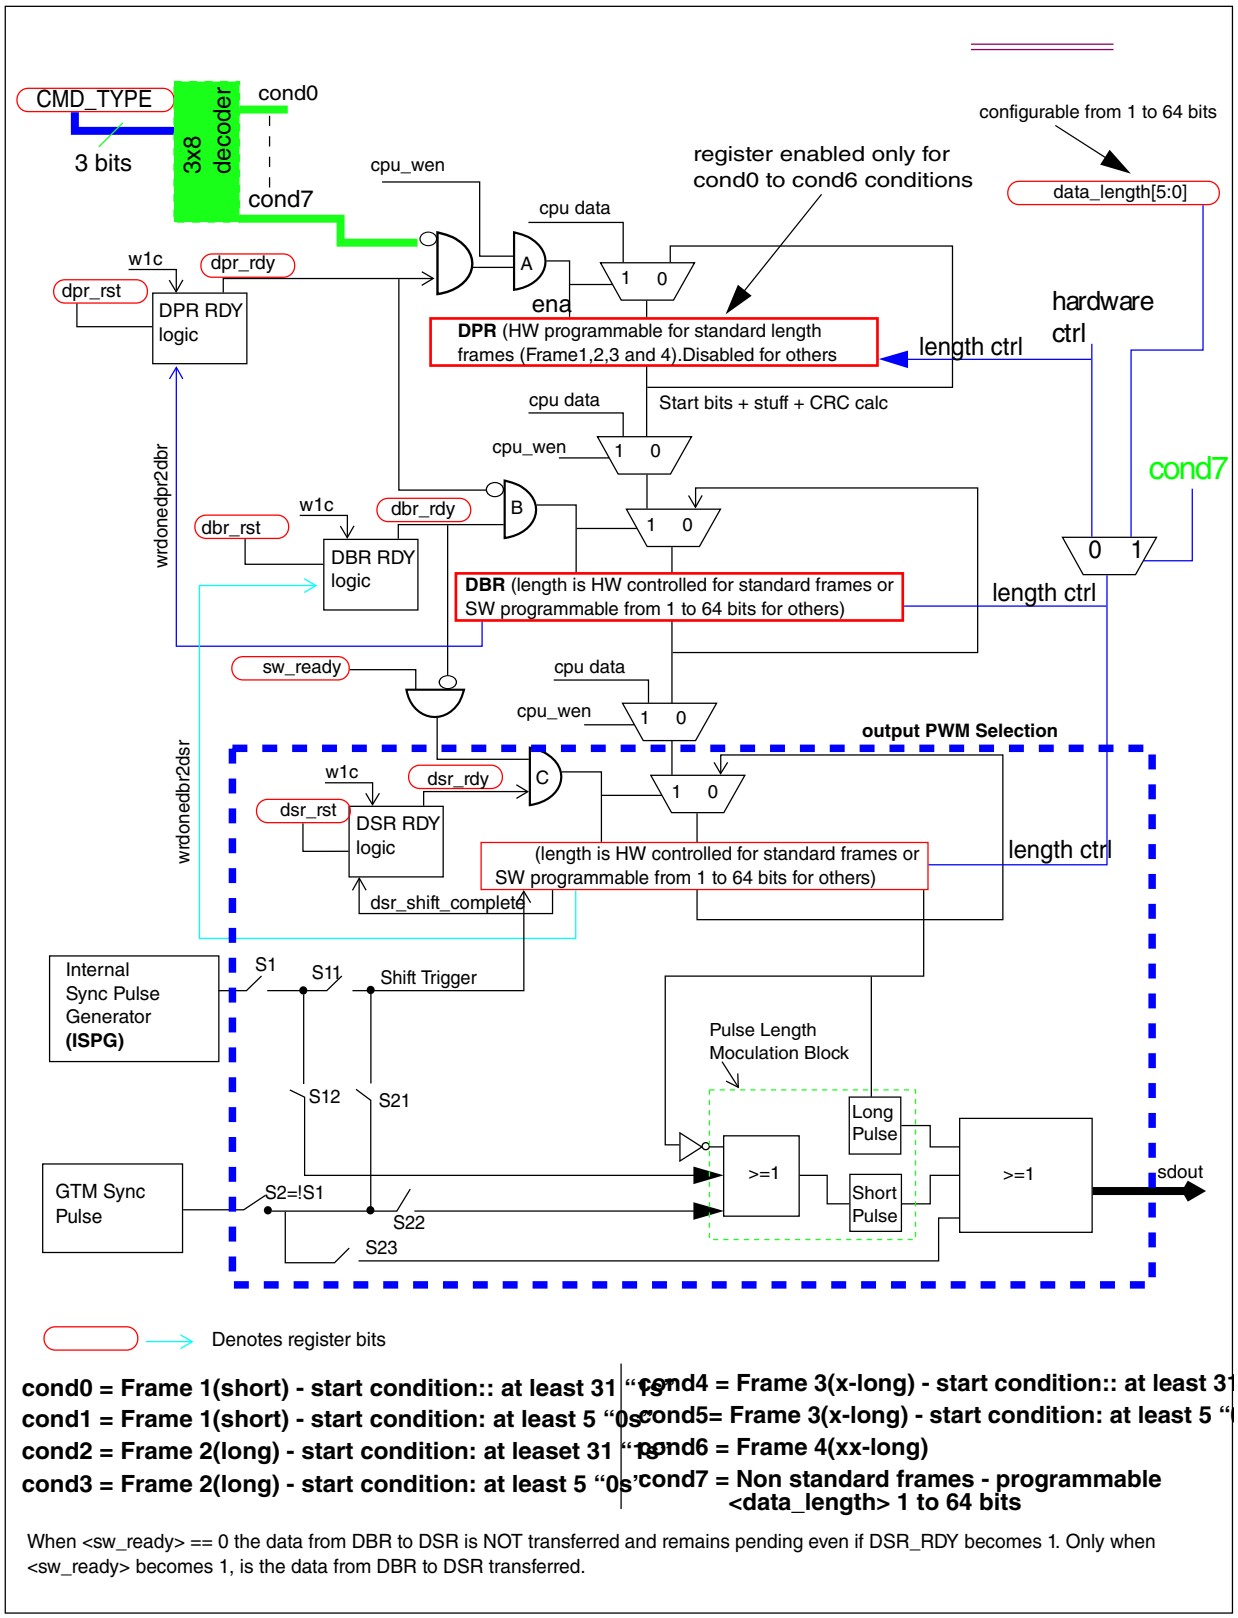
where "011111110" is the start sequence, "S" is the stuff bit(0), A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Please refer Figure 56-24 for the frame structure.

- The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0) .
- The transmitter extends the data bits by six zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,D0..D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved .
- When mapping this sequence to the DPR register bits for calculating the CRC ; then it becomes (DPR[0],DPR[1]….DPR[23],000000) with DPR[0] being fed first in the CRC calculator.

56.4.3.4.1 Transmission Data Framing

The output data transmission block is constructed of seven sub-blocks:

- Data preparation register
- Buffer register
- Data shift register
- Periodic Sync Pulse Trigger Generator
- "GTM driven" sync pulse trigger input (GTM external to PSI5)
- Pulse length modulation block
- OR gate



cond0 = Frame 1(short) - start condition:: at least 31 “1s”
cond1 = Frame 1(short) - start condition: at least 5 “0s”
cond2 = Frame 2(long) - start condition: at leaset 31 “1s”
cond3 = Frame 2(long) - start condition: at least 5 “0s”
cond4 = Frame 3(x-long) - start condition:: at least 31
cond5= Frame 3(x-long) - start condition: at least 5 “
cond6 = Frame 4(xx-long)
cond7 = Non standard frames - programmable <data_length> 1 to 64 bits

When <sw_ready> == 0 the data from DBR to DSR is NOT transferred and remains pending even if DSR_RDY becomes 1. Only when <sw_ready> becomes 1, is the data from DBR to DSR transferred.

Figure 56-25. Data Transmission Block

56.4.3.4.2 Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0)

Upto 24 bits of this register can be written by the CPU. These register bits contain the ECU to sensor command that needs to be transmitted after being appended with the CRC, start bits and stuff bits. The hardware automatically calculates the CRC and adds the start and the stuff bits, before transferring the command to DBR.

- When DPR_RDY == 1, the data to be transmitted to sensors is written to this register via system bus with an order data bit to be transmitted first at LSB and furthest on MSB. The data length to be written is 24 bits in the DPRL. DPRH is always = 0.
- Having written the data to the DPR, the DPR_RDY bit has be cleared with a w1c. This indicates to the internal logic that the data in the DPR is valid and is to be processed.
- If DPR_RDY = 0 and a new command is written to the DPR then the command is rejected and GISR[IS_PROW] is set.
- If the CRC or parity bit calculation is finished, then the data is shifted to the Buffer register with the start bits and the sync bits appended as well. This transfer is done to the Buffer register only if the Buffer register is ready for new data, which is indicated by GISR[DBR_RDY] == 1.
- As mentioned above, once this tranfer is done, the DPR_RDY becomes 1 and a new command can be written to it.

56.4.3.4.3 Data Buffer Register (64-bit register)

- This register has two subregisters DBRH (higher register) and DBRL (lower register). Both of them are collectively referred to as DBR.DBR is of length 64 bits DBR[63:0]
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writeable bits corrresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field please refer bit description in CMD_TYPE[2:0]
- When DPR_RDY == 0 and DBR_RDY goes to 1 then internal logic automatically transfers the data from the DPR (with CRC + stuff bits + sync bits) to the DBR. DBR_RDY goes low and DPR_RDY goes 1.
- If DBR_RDY == 1 AND DPR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping preparation register in case application includes the start and sync bits and calculates the CRC/Parity itself.

If the CPU writes to the DBR when DBR_RDY == 1 but DPR_RDY == 0 and PSI5_DOBCR[CMD_TYPE] != 7, then the results can be unpredictable since the DPR has a pending data that needs to be transferred to DBR.

- If the CPU is writing to the DBR as mentioned above, then the DBR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DBR is valid and is to be used for the shift operation.
- If while DBR_RDY == 0, and a new command is directly written to the DBR then the command is rejected and GISR[IS_BROW] bit is set.
- If while DBR_RDY == 0 a new command HAS to be written in the DBR then DOBCR[DBR_RST] has to be written to 1. Writing a 1 to DBR_RST will reject the current command in the DBR and generate DBR_RDY = 1.
- If the Data Shift Register signals that it is ready for new data (PSI5_GISR[DSR_RDY] == 1), the data of the Buffer register is shifted into the data shift register provided PSI5_DOBCR[SW_READY] is 1.
- If PSI5_DOBCR[SW_READY] == 0 then the data from the DBR is NOT transferred to the DSR automatically even if the DSR_RDY goes as 1. In such a case the IP waits for the software to make the PSI5_DOBCR[SW_READY] bit as 1; only then does it transfer the contents to the DSR.

56.4.3.4.4 Data Shift Register (64-bit register)

- This register has two subregisters DSRH (higher register) and DSRL (lower register). Both of them are collectively referred to as DSR.DSR is of length 64 bits DSR[63:0] . This register has a 1-1 correspondence with the bits in the DBR register when this register is updated automatically by the hardware.
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writeable bits corrresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field please refer bit description in CMD_TYPE[2:0].
- When DBR_RDY == 0 and DSR_RDY goes to 1 then internal logic automatically transfers the data from the DBR to the DSR provided PSI5_DOBCR[SW_READY] == 1'b1, else this transfer remains pending till PSI5_DOBCR[SW_READY] is '0'. Once the transfer is complete, DSR_RDY goes low and DBR_RDY goes 1. DSR contents that would finally get transferred, can be read at this stage, i.e., when DBR_RDY becomes “1”.
- Making PSI5_DOBCR[SW_READY] now as '0' will not interrupt the ongoing transfer in the DSR.

- If DPR_RDY == 1 AND DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY == 1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- When PSI5_DOBCR[CMD_TYPE] == 7 and If DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY == 1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- If the CPU is writing to the DSR as mentioned above then the DSR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DSR is valid and is to be used for the shift operation.
- If while DSR_RDY == 0, and a new command is directly written to t he DSR then the command is rejected and GISR[IS_DSROW] is set.
- If while DSR_RDY == 0 a new command HAS to be written in the DSR then DOBCR[DSR_RST] has to be written to 1. Writing a 1 to DSR_RST will reject the current command in the DSR and generate DSR_RDY = 1.
- This register is clocked by the ISPG pulses or the GTM pulses, as described in Sync Pulse Trigger Generation.
- Once the shift operation is complete in the DSR then DSR_RDY becomes 1.

56.4.3.4.5 Sync Pulse Trigger Generation

The sync pulse trigger can be used to generate the timing pulses or the data pulses.

The sync pulse can be generated based on triggers from two different sources:

- **ISPG (Internal Sync Pulse Generator):** Composed of CTPR, CIPR and Channel Target Counter (per channel). The internal sync pulse generator is clocked by either the GTM clock (max frequency is 3.9 MHz) or the internal 1 MHz clock. The Channel Target Counter operates with a 1 µs resolution (when using the 1 MHz clock) or GTM clock resolution (when using the GTM clock). The ISPG is implemented to allow generation of internal periodic trigger. Please Refer Figure 56-30 for the ISPG structure and Figure 56-29 for the CTPR and CIPR explanation. The ISPG uses the Channel Target Counters (CTCs) for generating the sync pulse. The CTCs can be triggered globally (simultaneous for all channels) or locally (individual to each channel). The CTC_GED bit in the Global Control Register (GCR) ensures that all the CTCs start/stop simultaneously. The individual target

values when the trigger pulse is generated are set in the Counter Target Pulse Register (CTPR) and the Channel Initial Pulse Register (CIPR). These registers are present for each channel. When staggering the channels, the CTC_GED bit should be used for providing a simultaneous trigger to the staggered channels. It is also possible for a subset of channels to work on the above arrangement while the remaining channels independently generate trigger pulses for which start/stop is controlled locally to the channels.

- For each channel, it is possible to configure the trigger period by software using sync pulse generator control/configuration register and setting compare values in Counter Target Pulse Register(s). The Counter Initial Pulse Register (CIPR) can be used to provide the initial offset between various channels.
- It is possible to deactivate each channel separately for the purpose of Sync Pulse generation.
- The periodic pulses can be used to synchronize sensor-to-ECU communication (synchronization timing pulses) [State 1 of Valid states for integrated sync pulse generator]or can be used as data pulse during ECU-to-sensor communication (through the DOBCR) [State 2 of Valid states for integrated sync pulse generator].
- When programming the CTPR, the Tsync period should be programmed >= 6 SP_TS_CLK cycles (For details of SP_TS_CLK, refer to Bit 23 of Section 54.3.2.2, PSI5 Channel Control Register (PSI5_PCCR))

- **GTM event controlled:** Generation of sync Trigger/Pulse can be done based on events (e.g., crank angle or software) through **general timer module (GTM)** output to the PSI5 interface.
  - Here the sync trigger pulses come from external GTM module routed through a full XBAR programmable through SIUL[GTM to PSI5 Connections (in SIUL)]
  - The sync pulse programming (period, etc.) is done inside GTM.
  - In Figure 56-25, if switches S2 and S21 are closed and S22 and S23 are open, the GTM trigger is used for data pulse generation (data pulses for ECU-to-sensor communication). [State 4 of Valid states for integrated sync pulse generator]

- In Figure 56-25, if switches S2 and S22 are closed and S21 and S23 are open, the GTM trigger is used for timing pulse generation (synchronization pulse for sensor-to-ECU communication). [State 3 of Valid states for integrated sync pulse generator]
- In Figure 56-25, if switches S2 and S23 are closed and S21 and S22 are open, the GTM trigger is passed directly to data sync port without pulse length modulation. In this case the sync pulse length is defined by the GTM pulse length. [State 5 of Valid states for integrated sync pulse generator]

- **Programming and control :** For achieving the various states of ISPG control or the GTM control, the switches S1, S2, S11, S12, S21, S22, and S23, shown in Figure 56-25 can be set (closed) or cleared (open) by writing to the three equivalent bits (GTM_TRIG_SEL, SPULSE_SEL and OP_SEL) belonging to the DOBCR, as shown inFigure 56-26. The programming of various states mentioned above, with reference to the Valid states for integrated sync pulse generator can be seen in Table 56-2 and also shown in Figure 56-32. The sending of the ECU to sensor commands, can be controlled by PSI5_GISR[DPR_RDY, DBR_RDY, DSR_RDY] bits and the PSI5_DOBCR register bits.

56.4.3.4.5.1 Timing Pulses

Timing pulses can also be produced without pulse width modulation also . These timing pulses can be generated through two sources:

- Periodic sync pulse from ISPG . In this case the synchro pulse from the internal sync pulse generator can be made available without any modulation. Referring Figure 56-26, in synchronous mode , if DOBCR[GTM_TRIG_SEL] == 0 and DOBCR[OP_SEL] == 0 then the internal sync pulse generator output can be made available without any modulation . The high time of this pulse is fixed at 4 µs.
- Referring Figure 56-26, in synchronous mode , if DOBCR[GTM_TRIG_SEL] == 1 and DOBCR[OP_SEL] == 0 , then the GTM trigger can be used for timing pulse generation without any Pulse Width Modulation.

56.4.3.4.5.2 Data pulse generation

Data pulses are produced through Pulse Length modulation block based on triggers from one of the two selectable sources **ISPG** or the **GTM**, during ECU-to-sensor communication. The selection between the above two sync sources can be done by software programming Pulse length control/configuration register.

- A logical '1' in Data Output Register LSB is coded as data sync pulse of width W1 {up to 127 µs}.
- A logical '0' in Data Output Register LSB is coded as data sync pulse of width W0 {up to 127 µs}.
- The two widths are programmable in Pulse Length Control/Config Register.
- The Data Shift Register is shifted Right by everytime as bit is transmitted.

Figure 56-25 shows the data transmission block.

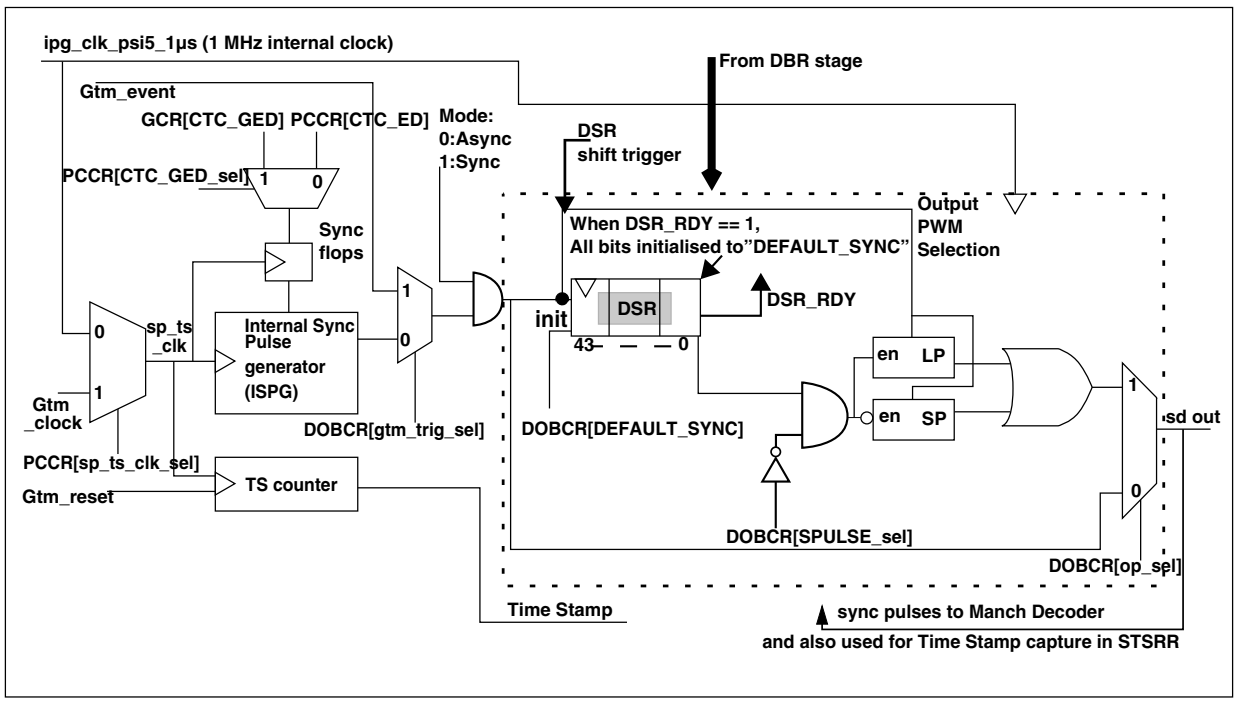


Figure 56-26. ECU-to-sensor communication registers (implementation of the Data Transmission Block figure)

The above figure details the implementation of Figure 56-25 and shows how the various bits mentioned in Section 54.3.2.30, Data Output Block Configuration Register (PSI5_DOBCR) control the behavior of the Output Command path. The above figure also shows the various clock sources to the Internal Sync Pulse Generator and the Time Stamp counter.

56.4.3.5 Response to ECU-to-sensor frames

The response to an ECU-to-sensor frame can be optionally transmitted in two ways:

- Out-of range values of data frame (as fast response coded as normal PSI5 payload region)
- Serial messaging channel (verification of the response frames must be handled by the software)

56.4.4 Tx/Rx scenario

The diagram below shows the communication scenario in synchronous modes. For asynchronous mode, sync pulses are not generated and sensor transmits data asynchronously.

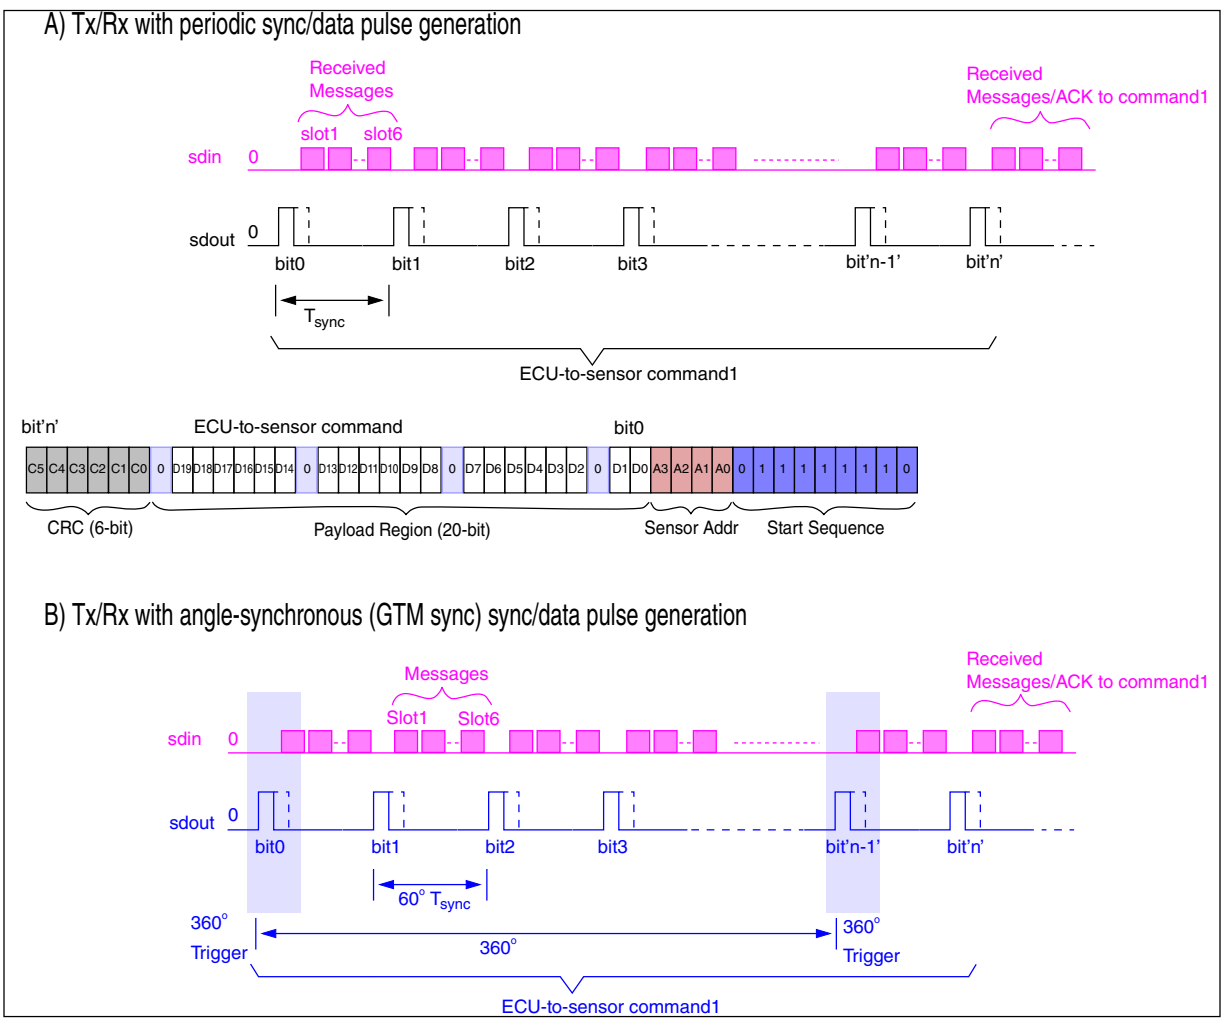

Figure 56-27. Synchronous mode communication scenarios

56.4.5 Interrupt handling

Configurable interrupts based on events (for example, reception of valid message), errors, DMA transfers, and so on are implemented. The following types of events can generate an interrupt:

- Reception of a new PSI5 message
- Reception of a new SMC message
- Unread SMC message overwritten in the SMC buffer area (PSI5_SFR)
- Unread PSI5 message overwritten in the PSI5 buffer area (PSI5_PMRH, PSI5_PMRL)
- Dedicated interrupts for selectable errors, mentioned below:
  - Bit C is set
  - Bit E and/or EM is set
  - Bit T is set
  - No PSI5 frame was received in a defined frame slot (Bit F is set)
- ECU-to-sensor communication-related interrupts
  - The application tries to load new data into the data preparation register before the register has signalized that it is ready for new data. (Note that the new command will be ignored in this case.)
  - The application loads new data into the data buffer register before the register has signalized that it is ready for new data. (Note that the new command will be ignored in this case.)
  - The application loads new data into the data shift register before the register has signalized that it is ready for new data. (Note that the new command will be ignored in this case.)
- DMA related interrupts (transfer finished/FIFO_FULL/underflow)
- Apart from this, a single one sum interrupt OR-ing all the above events.

Various interrupt signals that represent the above events are:

- PSI5 new message arrival interrupt **(Status flags in PSI5_NDSR)** This is asserted when any of the programmed storage PSI5 locations (max 32) receive a new PSI5 message (error/error free). This interrupt also indicates that the PSI5 receive register (PMRRL/PMRRH) has been updated with a new PSI5 message.

- SMC message, ECU-to-sensor communication, and Time Stamp related interrupts **(All Status flags in PSI5_GISR)** : This is asserted during following events:
  - When a new SMC message is received in its corresponding slot OR
  - When there is a CRC error in any SMC message OR
  - When an unread message in some corresponding SMC location (in PSI5_SFR) gets overwritten by a new SMC message OR
  - When DPR is ready for receiving a new data OR
  - When DBR is ready for receiving a new data OR
  - When DSR is ready for receiving a new data OR
  - When there is an attempt to write to DPR while it is NOT ready OR
  - When there is an attempt to write to DBR while it is NOT ready OR
  - When there is an attempt to write to DSR while it is NOT ready OR
  - When data time stamp register is updated with new time stamp value OR
  - When the sync time stamp read register is updated with a new time stamp.
- PSI5 Message Overwrite Interrupt **(Status Flags in PSI5_OWSR)** : This is asserted when any of the programmed storage locations in the memory (max 32) have an unread PSI5 message that is overwritten by a new upcoming PSI5 message. Corresponds to OWSR.
- PSI5 Error interrupt **(Status Flags in PSI5_EISR)** : This is asserted when any of the programmed storage locations in the memory (max32) have an error in the PSI5 message. It is used only for PSI5 messages.
- DMA Interrupt **(Status Flags in PSI5_DSR)** :
  - When the DMA transfer corresponding to conf2, conf3 or conf4 finishes OR
  - When the DMA transfer corresponding to SMC message gets over OR
  - When there is an FIFO_FULL/Underflow in the PSI5 RAM register area OR
  - When there is an underflow in the SMC message area.
- Global Interrupt: Single interrupt ORing all above interrupt events.

56.4.5.1 Error conditions

- C: CRC/parity error on received data, evaluated after recalculating CRC on received data and comparing with received CRC or recalculating parity on received data and comparing with received parity.
- E: Electrical error during any Tbit period (excluding Messaging field M0M1) during frame reception (not applicable during Idle state); that is, if at least one bit is absent during its Tbit period.
- EM: Electrical error on M0M1 field.
- T: Timing error during frame reception violates the slot boundary. Here, all the corner cases and conditions are taken acre of (for example, the isolation of correct slot to correct message if the message is too early or too late with respect to its expected position, the crossing of the slot boundary when one frame overlaps the other, and so on).
- F: No frame received during a particular slot time in case of sync mode.

56.4.6 DMA support

NOTE

DMA master ID replication mode is not allowed together with PSI5.

- The PSI5 module generates separate DMA transfer requests for PSI5 message/ diagnostic status and SMC messages.
- A single DMA request is used for PSI5 messages and diagnostic data. The request is triggered based on the selected DMA configuration (either PSI5 message or Diagnostic data or both). After choosing the configuration, data is available on respective DMA pop-up registers.
- DMA requests for PSI5 messages and diagnostic registers are based on the watermark level of message buffers (to be treated as FIFO for the DMA). PSI5 message buffer FIFOs get data from the PSI5 receiver in the order they are received.

- DMA requests for SMC messages are based on successful storage of each SMC frame to the message buffers. The SMC message buffers get data from SMC extraction logic in fixed round-robin arbitration sequence.
- Please see Single DMA request for PSI5/diagnostic message buffers for PSI5 DMA handling and Single DMA request for SMC received messages for SMC DMA handling

56.4.6.1 Single DMA request for PSI5/diagnostic message buffers

A common DMA request (per PSI5 block) is generated for PSI5 message/diagnostic buffers. The depth (up to 32 in present context) of the message buffer is programmable via the MEM_DEPTH filled in the PCCR. The width of each location of the PSI5 message buffer is 64 bits. When reading PSI5 message through the DMA, the 32-bit DPMR is sequenced with the data from the PSI5 message buffer. When reading the diagnostic registers through the DMA, the 32-bit DDSR is sequenced as NDSR followed by EISR. The DMA operation will happen as follows:

- Based on the DMA configuration chosen, one of the three DMA transfer sequence is initiated:
  - PSI5 buffer followed by diagnostic data sequenced to DPMR
  - PSI5 data sequenced to DPMR
  - Diagnostic buffer data sequenced to DDSR
- The DMA request is asserted when the number of messages stored in the buffer crosses the configured watermark number of messages.
- DMA request is deasserted once the "watermark" number of messages have been read.
- If the number of unread messages is still greater than the watermark programmed, then the DMA request is reasserted.
- The received message data is read from a common memory-mapped 32-bit DMA PSI5 message register (DPMR). Thus, a single PSI5 message (64 bits wide) will require two IPS read operations. The diagnostic data is read either through the DPMR or through the DDSR (single 32-bit register) by the DMA controller via the IPS interface.
- It is assumed that the DMA Controller's Transfer Control Descriptor (TCD) would be set to transfer bytes equal to the messages indicated by watermark level, as described in DMA_PM_DS _WM[4:0] in DMA Control Register (PSI5_DCR). It is assumed

that when responding to a DMA request, the DMA controller will read faster than the rate at which messages are received and stored in the buffer/FIFO which will cause the DMA request to deassert.

- The next received message will be updated on the common memory map register once the previous message is read by the DMA (by the DMA sequencer).
- The store signal from the synchronization logic will push the message into the memory-mapped RAM registers and in parallel also into the PSI5 receive register. Figure 56-22 shows the format in which the messages will be stored in any message buffer (RAM registers) and finally when being read from DMA access register.
- For more details about DMA programming, please refer to PSI5 Channel Control Register (PSI5_PCCR), DMA Control Register (PSI5_DCR), DMA Status Register (PSI5_DSR), DMA PSI5 Message Register (PSI5_DPMR) and DMA Diagnostic Status Register (PSI5_DDSR).

56.4.6.2 Single DMA request for SMC received messages

A separate DMA request (each channel) is generated for the SMC message buffer. Each SMC received messages would be stored in the internal registers and read out by DMA controller via a common memory-mapped DMA SMC Frame Register (DSFR) (single 32-bit register for each message buffer). The data flow will happen as follows:

- A request is asserted when the system buffer successfully receives one complete SMC message, and remains asserted until all complete messages have been read. Data is read from the DMA PSI5 Message Register in the memory map.
- It is the job of an internal sequencing logic to provide the next complete received message. The internal sequencer works in a round-robin fashion checking for the slot-specific registers for each SMC message. Thus the sequence will be slot1--slot2-- slot3-- slot4--slot5--slot6--slot1 and so on. In whichever slot it encounters the first complete SMC message the DMA request would be asserted and the sequencer will wait for this data to be read before moving on to the next slot in its loop. If a particular slot message remains unread and a new SMC message for the same slot comes in then the previous message would be overwritten and the OW bit would be set.

- The DMA controller should be programmed to read only one message in one DMA transfer. Otherwise, if it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur. User software should ensure there is no overflow.
- For more details about DMA programming please refer "PCCR-PSI5 Channel Control Register" on page 267,"DCR-DMA Control Register" on page 272,"DSR-DMA Status Register" on page 276 and "DSFR-DMA SMC Frame Register" on page 284

56.4.7 Message read through interrupt generation

There is a separate interrupt request for received messages for each PSI5 channel. Each PSI5 channel can be configured individually to generate an interrupt on reception of messages. An interrupt is asserted when the corresponding PSI5 channel has received a complete message (PSI5 or SMC). Please see Interrupt handling for more details about interrupts. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing the corresponding PSI5 channel which is enabled to give out messages via interrupts through the IPS Interface. In response to these interrupts, the CPU is expected to read interrupt status register for individual PSI5 Channel (depending on which interrupt was asserted) and store it in system memory.

56.5 Initialization information

56.5.1 Initialization

56.5.1.1 Sensor startup and initialization

After each power-on or under-voltage reset, the sensor performs an internal initialization which is divided into three phases:

- Initialization Phase1: No data transmission.

- Initialization Phase 2: Transmission of type code and serial number of sensor.
- Initialization Phase 3: Transmission of "Sensor Ready" or "Sensor Defect" or other sensor specific data.

As this PSI5 implementation is targeted towards powertrain devices/sensors the standard initialization phase is modified and tuned for those applications. The comparison of the original scheme and enhanced schemes are shown in the figure below. The following figure also describes that the initialization content is the same as defined in V1.3, and the only modification is that it is transmitted using the SMC channel when a fast startup is required. "Fast Initialization Phase" below means that the sending of first sensor data is fast, but the sending of sensor initialization data will actually be much slower.

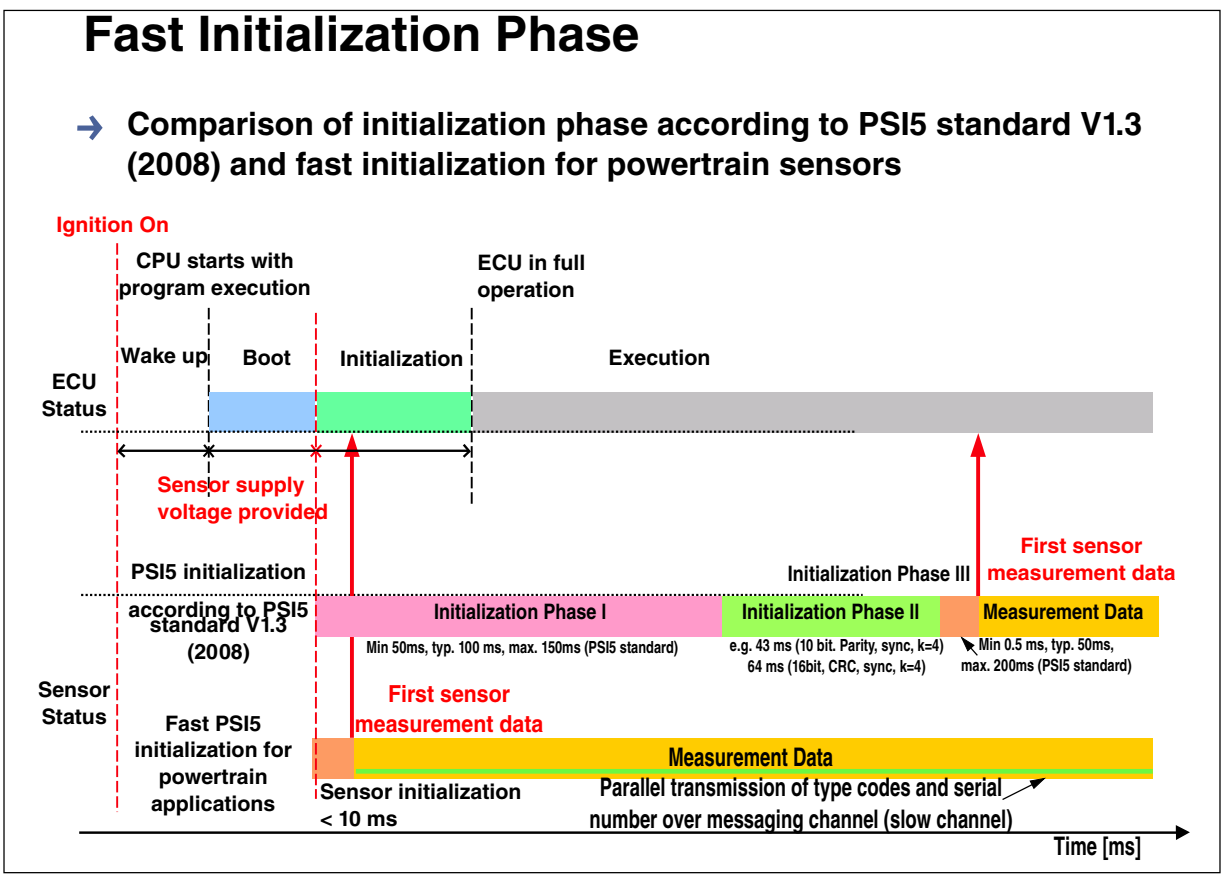

Figure 56-28. Fast initialization phase

56.6 Design Assumptions and Limitations

56.6.1 Assumptions

- Slot Configuration Register would always be programmed with valid number of bits for frame configuration.
- There will be no Timing error bits (T) in async mode. Only CRC Error (C) and Electrical Error (E) bits would be appended to message. There is no time out condition for the Manchestor decoder in case of Async mode. 'NFR' bit is not set in Async mode.

56.6.2 Limitations

As this is a PSI5 receiver, designed primarily to only receive the PSI5/SMC data and store as it is into the RAM buffer. So, it would not be responsible neither to recognize the content of the received messages nor do any decision making based on the content. Similarly, for Command it would not recognize the content of command and would transmit as it is writing into corresponding DSR and reception of PSI5 messages would not in any way depend on the content of command as far as PSI receiver is concerned. Its the responsibility of SW to sequence the issue of commands across the PSI5 channels and thereby recognize the content of received message and infer it.

56.7 Miscellaneous descriptions

56.7.1 Internal SYNC Pulse generation and coordination across PSI5 channels

Each PSI5 channel has the Channel Target Pulse Registers (CTPR) and Channel Initialize Pulse Register (CIPR). The CTPR defines the period of the internal sync pulse generation and the CIPR defines the initial offset time with respect to the sync pulse trigger. The sync pulse trigger can be generated from either the PSI5_GCR[CTC_GED] global bit or the PSI5_PCCR[CTC_ED] channel specific bit.

When staggering of the channels is required then the PSI5_GCR[CTC_GED] global bit is used as a common trigger for all the PSI5 channels in which PSI5_PCCR[CTC_GED_SEL] bit is set to 1. Setting this bit to 1 triggers the internal sync pulse generators of all the PSI5 channels and the trigger of each channel is then automatically staggered with respect to the other channel, depending on the value of the CIPR.

When the specific PSI5 channel is not to be kept as a part of staggered channels, then the channel-specific PSI5_PCCR[CTC_GED_SEL] bit has to be kept as 0. The channel in this case, has to be triggered locally by writing a 1 to the PSI5_PCCR[CTC_ED] of that specific channel. This triggers the internal Sync Pulse Generator of that specific channel without affecting other channels.

Following is the procedure for starting the internal Sync Pulse Generators:

- If in Normal mode, then stop and reset all Channel Trigger Counters (CTCs) by setting the global PSI5_GCR[CTC_GED] bit to 0 or the channel specific PSI5_PCCR[CTC_ED] to 0.
- Enter Config mode.
- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a "0" to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, please see Section 54.3.2.34, Counter Target Pulse Register (PSI5_CTPR), Section 54.3.2.35, Counter Initialize Pulse Register (PSI5_CIPR) and Sync Pulse Trigger Generation.

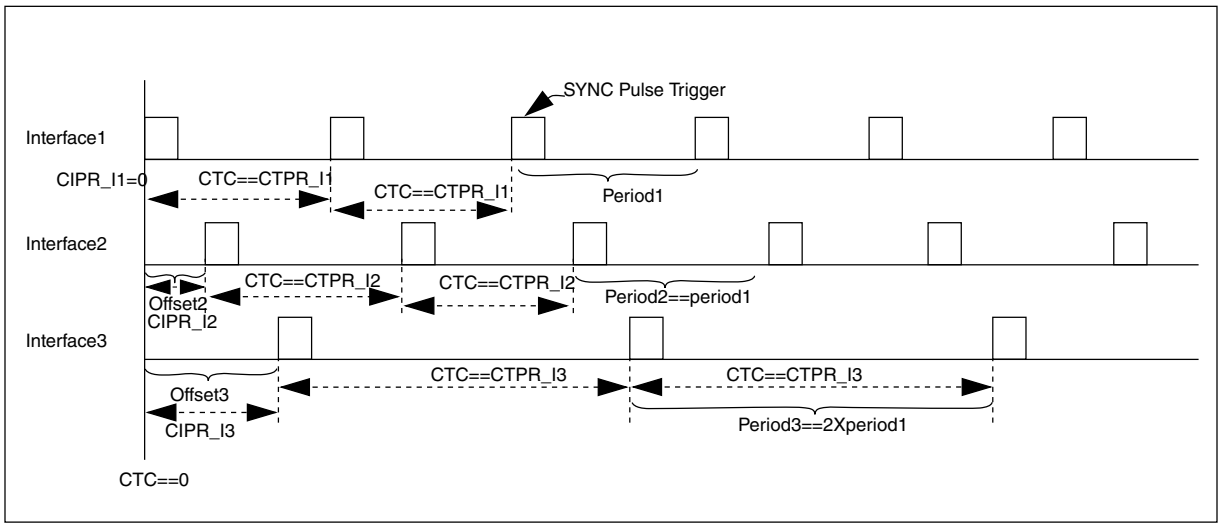

Figure 56-29. CIPR and CTPR

Figure 56-30 shows the various parameters (CIPR/CTPR, and so on) and the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

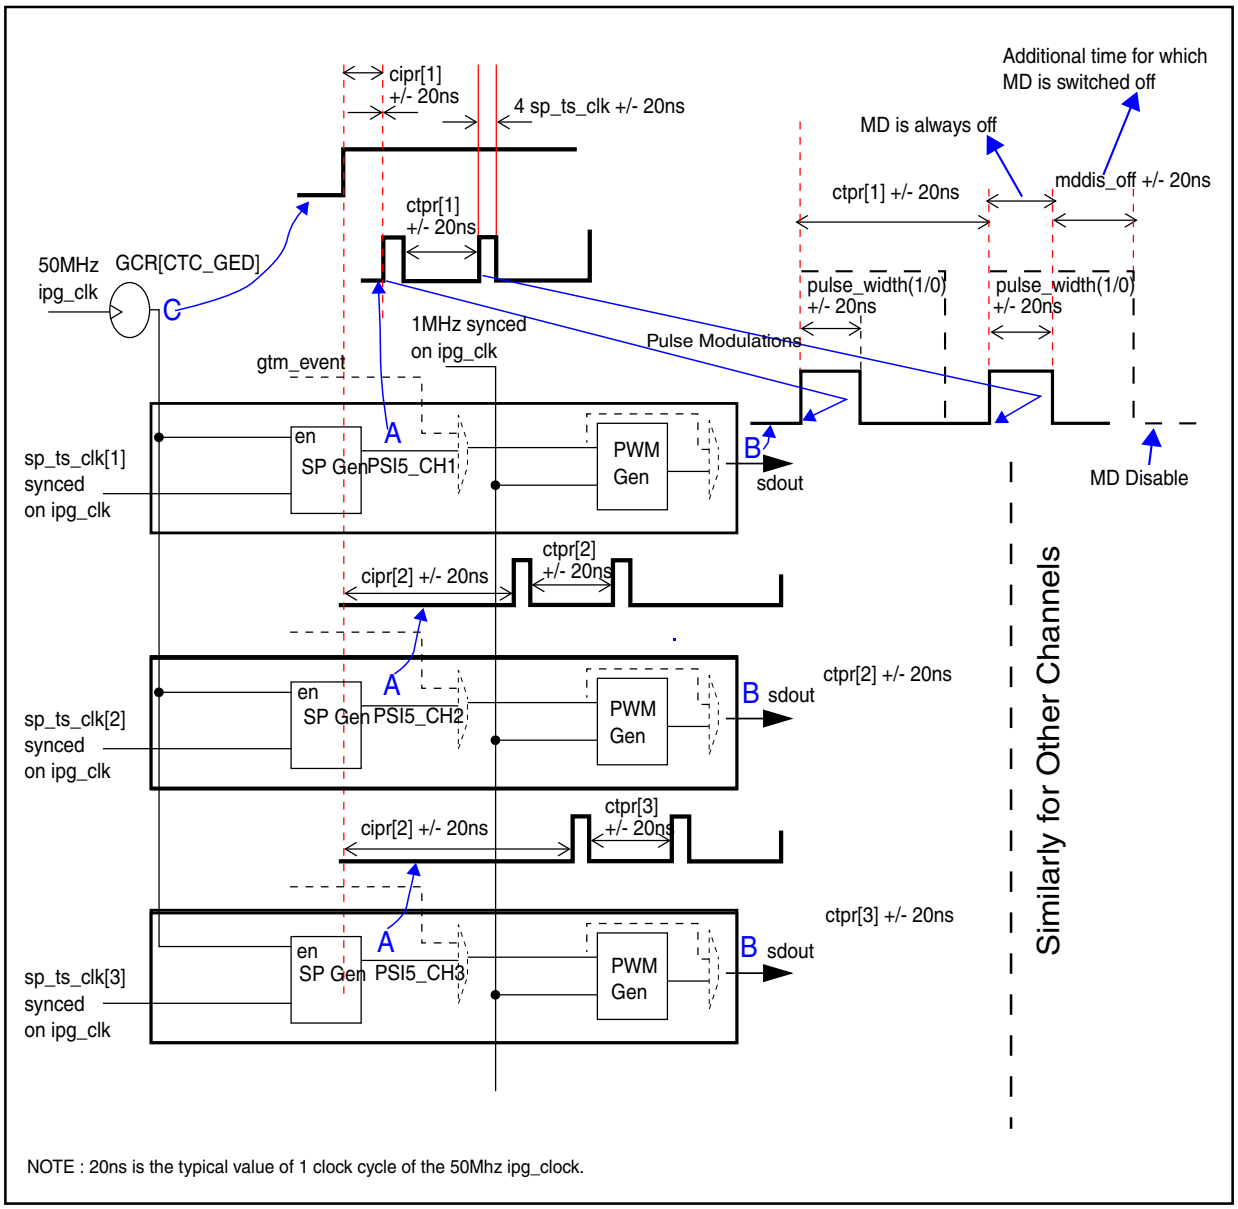

Figure 56-30. Sync Pulse Generation Parameters and Jitters

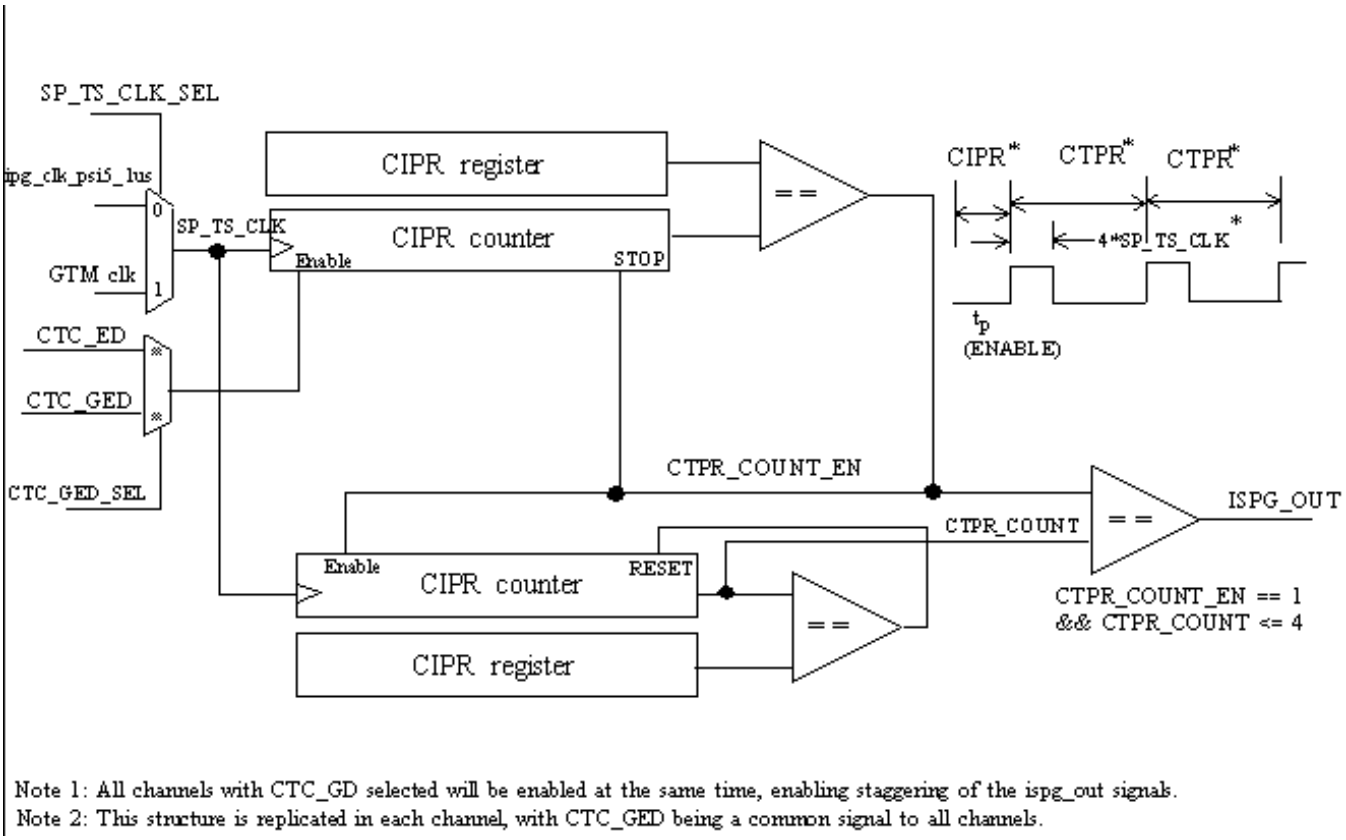
Figure 56-30 shows the various jitters.



Note 1: All channels with CTC_GD selected will be enabled at the same time, enabling staggering of the ispg_out signals.
Note 2: This structure is replicated in each channel, with CTC_GED being a common signal to all channels.

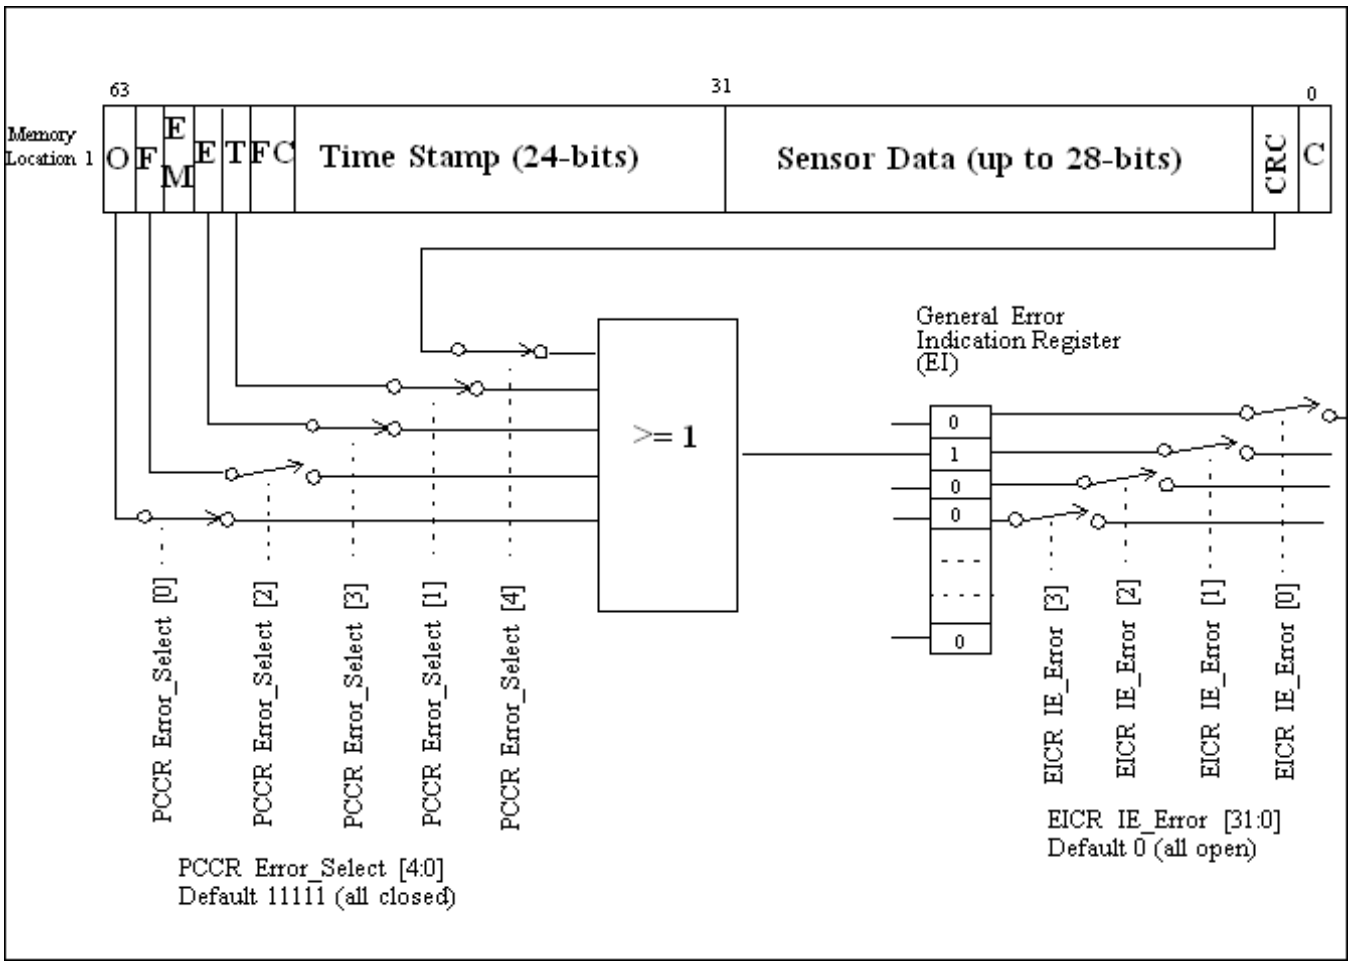

Figure 56-38. Implementation of EI Diagnostic Register

Chapter 57
Peripheral Sensor Interface-Support Module (PSI5-S)

57.1 Introduction

The PSI5 support IP (PSI5-S) module is used to interface directly to a UART compatible PSI5 transceiver over a high speed UART link. The transceiver is required to implement a compliant PSI5 module for all vehicle applications as is currently defined in the PSI5 protocol specification V2.0.

PSI5 messages from sensors received by the transceiver are decomposed into UART bytes and sent to the PSI5-S which in turn reconstructs the PSI5 messages from the UART packet, and makes them available for the application in system RAM.

ECU-to-sensor commands are sent from the PSI5-S module to the transceiver, which in turn generates the appropriate logical 1's and 0's in the SYNC pulses sent on the bus. The PSI5-S supports all command formats of the PSI5 V2.0 including the "tooth gap" method and "variable length" pulses.

At the system level, the PSI5-S supports one transceiver with up to seven PSI5 channels. Apart from these seven channels, there is an eighth channel available for special purposes, including direct communication with the transceiver and storage of corrupt messages.

57.1.1 Overview

PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make PSI5 also suitable for many other automotive sensor applications. The development goal of PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented license free.

The main features of PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of the PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 kbit/s or optional 189 kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module can be configured to support the following PSI5 features:

- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module requires the physical and data link layer of the PSI5 to be implemented outside its interface. It also requires the PSI5 information to be embedded in the form of UART packet, from where it reconstructs the PSI5 message.

The module receives PSI5 message, from up to seven PSI5 channels each with upto six sequential frames. This is achieved via the external UART compliant transceiver. The PSI5 message in each of these frames are decomposed into three-to-six UART bytes (depending on PSI5 data payload) and streamed on a UART link at up to 6.25 Mbit/s to the PSI5-S module. In addition, via the PSI5-S interface, the application sends commands to the transceiver. The transceiver interprets them as either SYNC pulse commands (which will result in short, long or no SYNC pulses on the PSI5 bus), configuration commands (which will result in updates to the transceiver configuration) or diagnostic commands (which will result in the transceiver responding directly over the UART connection). In addition to the seven channels above there is an additional Channel, known as Channel0, which is used for special purposes like storing the direct responses from the transceiver or storing the unrecoverable messages.

The PSI5-S consists of three main functional blocks.

1. UART front end - Used as PSI5-S front end. When PSI5 functionality is not required then it is possible to use this as a standard UART (without LIN) also.
2. Message Recovery Unit - consisting of two state machines.
   - The first state machine interprets the input UART data stream and rebuilds the PSI5 message contained in the up to six UART bytes and also checks for the status of the correct reception of PSI5 message.
   - The second state machine sends SYNC pulse commands via the UART TxBuffer, to the external UART compliant transceiver, which in turn outputs SYNC pulses (short, long, or no SYNC pulse) on the PSI5 bus used to synchronize sensor responses in a bus configuration, and where required, also sends commands to sensors as defined in the PSI5 protocols V2.0.
3. PSI5 message interface - It is composed of two MRU buffers, MRU buffer1 and MRU buffer2. Both of them are collectively referred to as MRU output buffer. The MRU buffer1 is internal to the IP and not accessible from outside the IP. It is three word deep. MRU buffer2 is accessible to the application and is 4 word deep. MRU buffer2 can be read by the DMA interface, to transfer the stored PSI5 messages, to Channel specific mailboxes in system RAM directly.

Note

: General Description

- The location in system RAM where the messages are stored are referred to as the Mailbox. The mailbox is divided on the basis of channel and each channel is divided on the basis of slots on the PSI5 bus. Thus Mailbox1,location1 would mean Mailbox location for Channel1 and Slot No "1". This is also denoted by $MBOX_1$, LOC_1 or MBOX1, LOC1. This terminology would be followed in the subsequent sections of the doc.

  Each "location" of each mailbox channel is made up of 3x32 bits. The maximum size of each mailbox can be 6 "locations". There are 8 such mailboxes. For channels operating in asynchronous mode, the whole of the Mailbox would act like a ring buffer and all the 6 locations would be filled in that manner.

Mailbox0 only has two locations MBOX0,LOC0 and MBOX0,LOC1. MBOX0,LOC0 is reserved for messages intended for Channel0(used for transceiver specific messages) while MBOX0,LOC1 contain "unrecoverable" messages for any channel. Other 4 locations of the MBOX0 are reserved.

- Also a "UART byte" would mean the "byte" that is received by the UART receiver. "UART packet" would mean the group of UART bytes from which the PSI5 message would be extracted. "PSI5 message" means the message contained in the MRU buffers which contains the actual PSI5 message along with the timestamp and the error status bits.

Figure 57-1 shows the block diagram of the PSI5-S module.

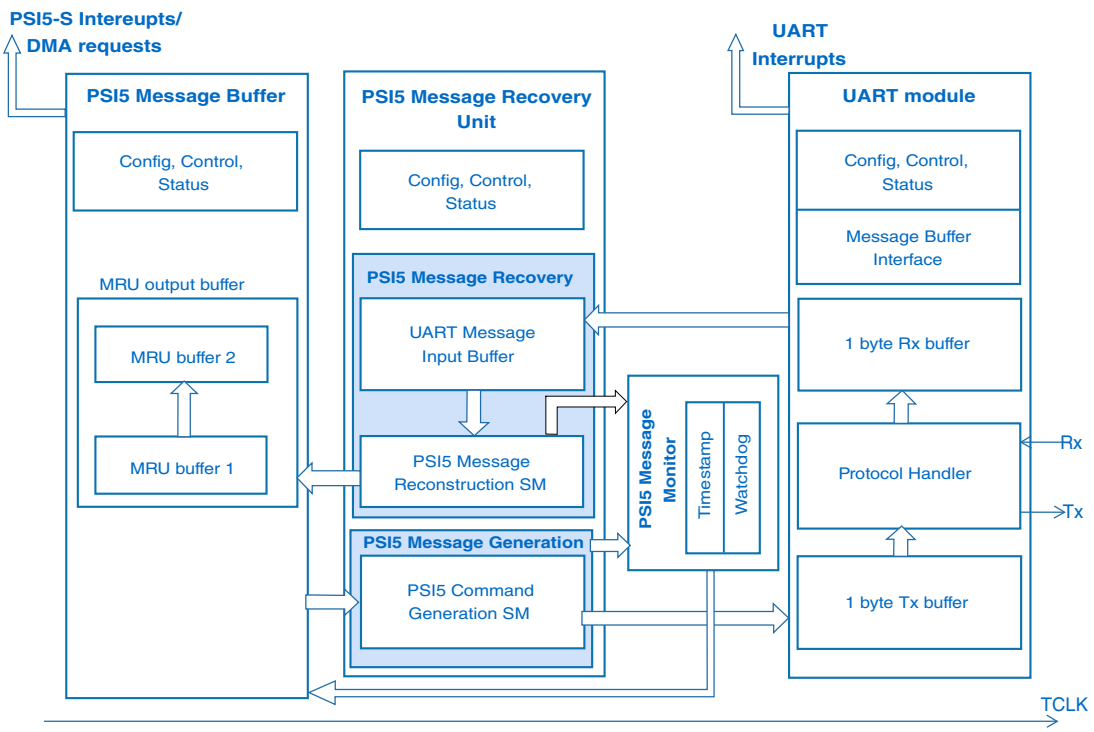

Figure 57-1. PSI5-S digital interface block diagram

57.1.2 Features

- IPS interface for register read/write (big endian).

- Support for up to 7 PSI5 channels(Channel1 to Channel7) with each channel supporting up to 6 different Frame Streams (Slots). Each of the Frame Streams can be individually configured for Parity/CRC, payload Length, Synchronous/ Asynchronous Operation, TimeStamp Capture event, Timestamp A or Timestamp B selection.
- Additional Channel0 for special functions.
- Supports bidirectional full duplex operations, via the UART Rx and Tx links.
- Provision of Extended CRC (XCRC) to check the coherence of the UART packet that comprise the PSI5 message.
- Message Reconstruction Unit (MRU) buffer2 (consisting of four 32-bit words). Three of these words contain the PSI5 messages (PSI5 message payload, Message Status flags, Time Stamp) and the fourth one contains the mailbox address to which the three PSI5 words need to be transferred.
- A 24-bit time stamp register, clocked with either the module clock or the GTM clock (gtm_trig). The time stamp appended to the PSI5 message in the MRU, can be configured to be, either the one that is captured when a new PSI5 message is detected, or the one that is captured when the Output ECU to Sensor command is transferred from the UART TX buffer to the UART Tx Shift register.
- IPS interface DMA support, for transferring the data in the MRU output buffer to system memory.
- Downstream Data Shift Register (DDSR) on per channel basis supporting the following:
    - Application can write the ECU to Sensor commands to the DDSR.
    - Supports automatic addition of the start bits/stuff bits /CRC calculation to the contents of DDSR.
    - Provision of resetting and rejecting the contents of DDSR at any stage of command transmission.
- Support for conversion of the logic levels contained in the DDSR, to UART commands to be sent to the transceiver.
- Provision of writing the Software calculated commands directly to the UART TX Buffer. This can be used for direct writing of the transceiver status and/or diagnostic commands.

- Configurable UART message idle time counter, that indicates to the PSI5 MRU when an idle time at least as long as the configured length (number of bit times), has occurred on the Rx line.
- Provision of configuring the PSI5-S front-end as a standalone UART module, when the PSI5-S module is disabled. In this mode the module, does not have any relation with the PSI5 protocol.
- Support of up to 6.25 Mbit/s UART Rx Baud Rate.
- An output clock for the PSI5 transceiver UART interface.

57.1.3 PSI5-S Global Modes of operation

The PSI5-S module can be configured in 4 different global modes of operation. These are UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. These global modes can be entered by programming the PS_GLCR[GLOBAL_MODE] bits appropriately. Figure 57-2 shows the state transition diagram for these bits.

The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as the "PSI5-S" modes. Please see Figure 57-2. Once the PS_GLCR[GLOBAL_MODE] bits are appropriately configured for the "PSI5-S" modes, the information that the intended mode of operation is fully achieved is reflected by the setting of the PS_GLSR[GL_MODETR_DONE] status bit. An interrupt can also be generated for this event, in case the PS_GLCR[GL_MODETR_DONE_EN] bit is set to "1". Thus, only when PS_GLSR[GL_MODETR_DONE] goes to "1" it should be considered that the IP has entered the desired "PSI5-S" mode.

This bit is reset to "0" when the mode is changed from any of the PSI5-S modes to the UART_STDALONE mode.

Following are the descriptions of the different global modes.

57.1.3.1 Standalone UART mode (UART_STDALONE mode)

This is the default state after the module reset. In this mode, only the PS_GLCR[GLOBAL_MODE] register bits and the registers of the UART module are accessible for writing. This is the mode which is to be used when the PSI5-S front end has to be used as a standalone UART. This state indicates that the UART will now function as a standard UART and the PSI5-S core will be disabled. In this state, the PSI5-

S register space is not accessible (except PS_GLCR[GLOBAL_MODE] registers) and any access to the registers of PSI5-S module (except PS_GLCR[GLOBAL_MODE] registers and UART specific registers) will generate transfer error.

57.1.3.2 Disable mode (PS_DISABLE)

PS_Disable mode in the PSI5 reduces power consumption. In this mode the RX, TX and common time base counters are disabled for any operation. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see Table 57-1 for the details of these bits. Note that when entering PS_Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter is however reset when entering Disable mode.

In "PS_Disable" mode, only PS_GLCR[GLOBAL_MODE] register bits are accessible for read/write. Accessing any other register bits will generate transfer error.

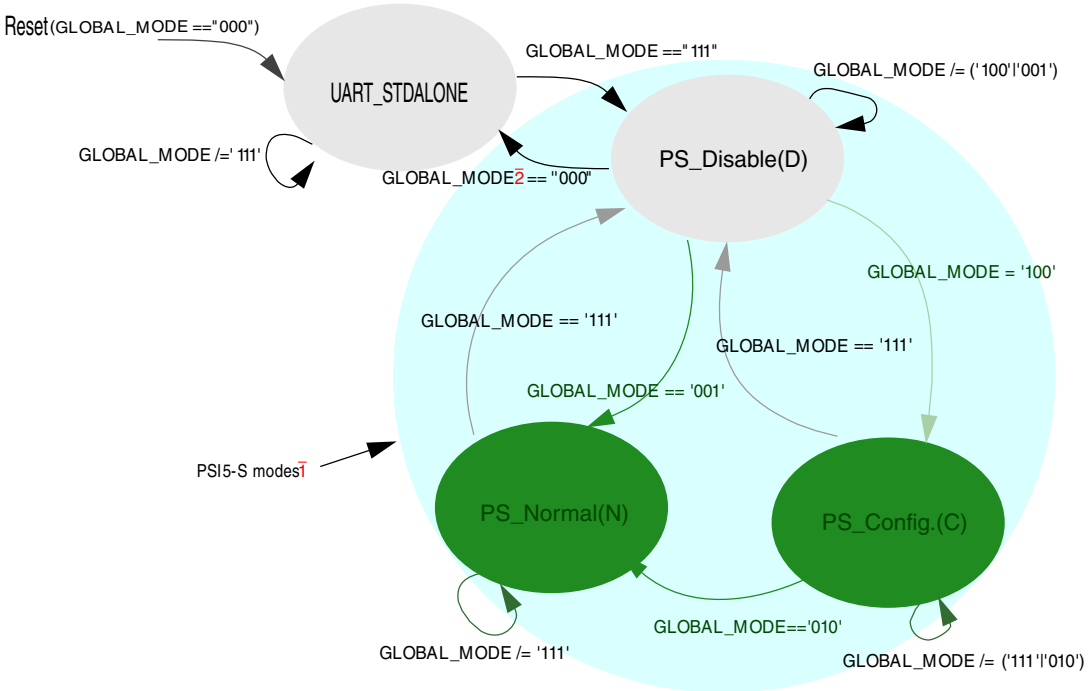
There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter "Configuration/Normal mode" based on the value of the PS_GLCR[GLOBAL_MODE] bits.

57.1.3.3 Configuration mode (PS_CONFIG mode)

In the configuration mode all PSI5 global, channel specific configuration/control registers and UART registers can be written. The receiver and transmitter sub-blocks remain disabled in this mode. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see Table 57-1 for the details of these bits.

57.1.3.4 Normal mode (PS_NORMAL mode)

In PS_NORMAL mode, the receiver and the transmitter blocks become active, error handling is enabled, UART starts its operation and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see Table 57-1 for the details of these bits.Note that there are still some register bits that can be written in this mode also. Please refer to the detailed register description.



1 PSI5-S module can be configured in 4 different Global modes of operation . These are UART_STDALONE , PS_NORMAL,PS_CONFIG and PS_DISABLE . The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as “PSI5-S” modes.

2 PS_GLSR[GL_MODETR_DONE] status bit is reset to “0” when the transition occurs from PS_DISABLE to UART_STDALONE mode .

Figure 57-2. Operating modes

Table 57-1. State transition Table

Present State	PS_GLCR (State Variables)			Next State
	PS_GLCR[GLOBAL_MODE(2)]	PS_GLCR[GLOBAL_MODE(1)]	PS_GLCR[GLOBAL_MODE(0)]	
UART_STDALONE	1	1	1	PS_Disable
PS_Disable	0	0	0	UART_STDALONE
PS_Disable	0	0	1	PS_Normal
PS_Disable	1	0	0	PS_Config
PS_Config	1	1	1	PS_Disable
PS_Config	0	1	0	PS_Normal
PS_Normal	1	1	1	PS_Disable

57.1.4 PSI5-S System Modes of operation

Various modes of operation are discussed in the following sections.

57.1.4.1 Stop mode

For PSI5-S modes:

In this mode, upon the STOP request from the system level the IP generates a system level acknowledgement with the information that the clocks to the IP can be switched off. The process of the same is as described below.

At the PSI5-S Rx side, as soon as stop mode request is received by the IP then the current PSI5 message under construction (in the internal PSI5 message extraction logic) is immediately saved to the MRU output buffer1. Thus the assertion of the stop mode acts like a "forced" flushing for the current PSI5 message completion. Depending on the state of the PSI5 message under construction, the resultant PSI5 message might or might not have errors. Any byte that is being received by the UART is henceforth rejected. The internal PSI5 message extraction logic goes back to an "idle" state and remains so till the STOP mode request remains asserted.

At the PSI5-S Tx side, on the reception of the stop mode request, the internal sync pulse generation counters are stopped immediately (DDSR trigger counters) and no further command bits are shifted onto the UART Tx side. The UART Tx completes the current byte that is being transmitted and enters the idle state. No further transmissions take place.On deassertion of the stop mode, once the clocks restarts, the transmission of the commands resumes from where they had halted.

Once both the above processes are complete the IP generates acknowledgement for switching of the clocks to the PSI5-S IP.

For UART STDALONE mode:

For this please refer to the separate documentation describing the standalone LINFLEX module.

57.1.4.2 Debug mode

The IP enters this mode on system request.Any register can be read or written to by the debugger. The IP can enter the debug mode in addition to it being in any of the other modes (Uart Standalone/Disable/Normal/Config). In this mode the hardware clearing of the register PS_WDGTSSR remains disabled and any read of this register has no effect on the contents of this register.Apart from this there is no other difference as to whether the IP is in debug mode or not in the debug mode of operation.

57.2 External signal description

S.No	Name	Function	I/O	Pull-up
	Signals to/from pads			
1.	ipp_ind_linrx	LINUART receive pin. Used for Receiving UART bytes from transceiver which contain information to enable the rebuilding of the PSI5 message within the packet of between three and six UART bytes	I	Active
2.	ipp_do_lintx	LINUART transmit pin. Used for transmitting command bytes from TxFIFO to transceiver for generation of SYNC pulses (long, short or no) on the PSI5 bus or direct diagnostic/ status commands for the transceiver itself	O	Passive
3.	ipp_port_en_tx	LINUART transmission port enable:Connected to the enable pin of the pad which is to be used for "LINTX" functionlaity. When "1" it indicates that the IP is doing transmit of data.	O	Passive
4.	ipp_psi5_uart_tclk	Transceiver clock output, which drives the UART interface on the transceiver. The clock output frequency is configurable between 4 and 8 x UART baud rate on the interface between PSI5-S and transceiver.Frequency can be controlled at the system level through the Clock Generator Module (MC_CGM). The duty cycle of the transceiver clock is between 40% and 60%	O	Passive
IPS Interface				
Clocks and Reset				
49.	ipg_clk_ps_en	This is the clock enable signal that is used to gate the IP input, "ipg_clk_ps", at the system level. When "1", it indicates to the system that the "ipg_clk_ps" should be available. In stop mode this signal retains its previous state.	O	

57.3 Transfer Error Generation

The IP generates transfer error cases in a number of scenarios:

1. Trying to write to any register in the PS_DISABLE mode (apart from PS_GLCR and PS_GLSR registers) will result in the generation of the transfer error.
2. Trying to write to any "Read Only" registers (those which have "R, R, R" in all the D, C, N columns in the memory map table in Memory map and register description) will generate a transfer error in any of the PS_DISABLE, PS_NORMAL and PS_CONFIG modes. Apart from the above “Read Only” registers , trying to write to

any register bits outside there intended mode of operation(Normal/Config) would be ignored without the generation of any transfer error. For bit level operation and mode access of each register, please see UART register configuration and PSI5-S Register description in Memory map and register description section.

3. Trying to access (R/W) any register space, which are declared as reserved in the table in Memory map and register description section or which is unimplemented, will generate a transfer error.
4. Reading of any register in any mode and if that register is NOT in unimplemented/ reserved space, then a transfer error will not be generated.
5. Trying to write to any PSI5-S register (starting from locations 0x00B4, but apart from PS_GLCR and PS_GLSR registers) in the UART_STANDALONE mode, will generate a transfer error.
6. In UART Standalone mode, the UART behaves as a standalone IP and for detailed transfer error cases in this mode, the UART standalone documentation should be referred to.

57.4 Memory map and register description

UART register configuration

This section contains information of the UART registers (registers with address offset FBF7_4000 to FBF7_405C) that are specifically required for correct functioning of the IP in the “PSI5-S” modes.

In order to operate the PSI5-S module, the UART configuration registers need to be programmed with appropriate values. The values that are required for different register fields are defined in the following register descriptions. Some bits have to be programmed with definite values of “1” or “0” only. This configuration has to be strictly followed for a predictable operation ofthe PSI5-S core. All these bits should be programmed in the PS_CONFIG mode before enabling the UART RX or the TX paths.

In the following UART register description “PS_NOUSE_BIT” against a bit name and bit description, means that the specific register bit is present in the UART module but it is NOT REQUIRED in the PSI5-S modes of operation. For correct operation in the PSI5-S modes , the corresponding register bit might be required to be programmed as “1” or a “0” ; the same would be mentioned in the bit description.

Note that a bit with “PS_NOUSE_BIT” against its description would still be required in the UART STANDALONE mode. For detailed information of the UART register bit functioning in the UART STANDLONE mode, please refer to the separate document describing the standalone LINUART module.There are some other register bits which

dont have a “PS_NOUSE_BIT” against them. These can be programmed as required. A bit mentioned as “Reserved” would mean that neither it is available in the UART STANDLONE mode nor in the PSI5-S modes.

PSI5-S Register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

PS_GLCR[GLOBAL_MODE] are the only register bits that can be written in the PS_DISABLE mode.

All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error.

The registers with address offset FBF7_40B4 onwards are under this category of registers.

NOTE

In the "PSI5S Memory Map" table below, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot wherein writing a 1 causes an effect on the register bit while writing a 0 has no effect ; a read always returning a 0”. The access shown in this table are for Disable mode. For knowing access for all the registers in Config mode and Normal mode, please refer to the Register Access in Different Modes.

NOTE

All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable.

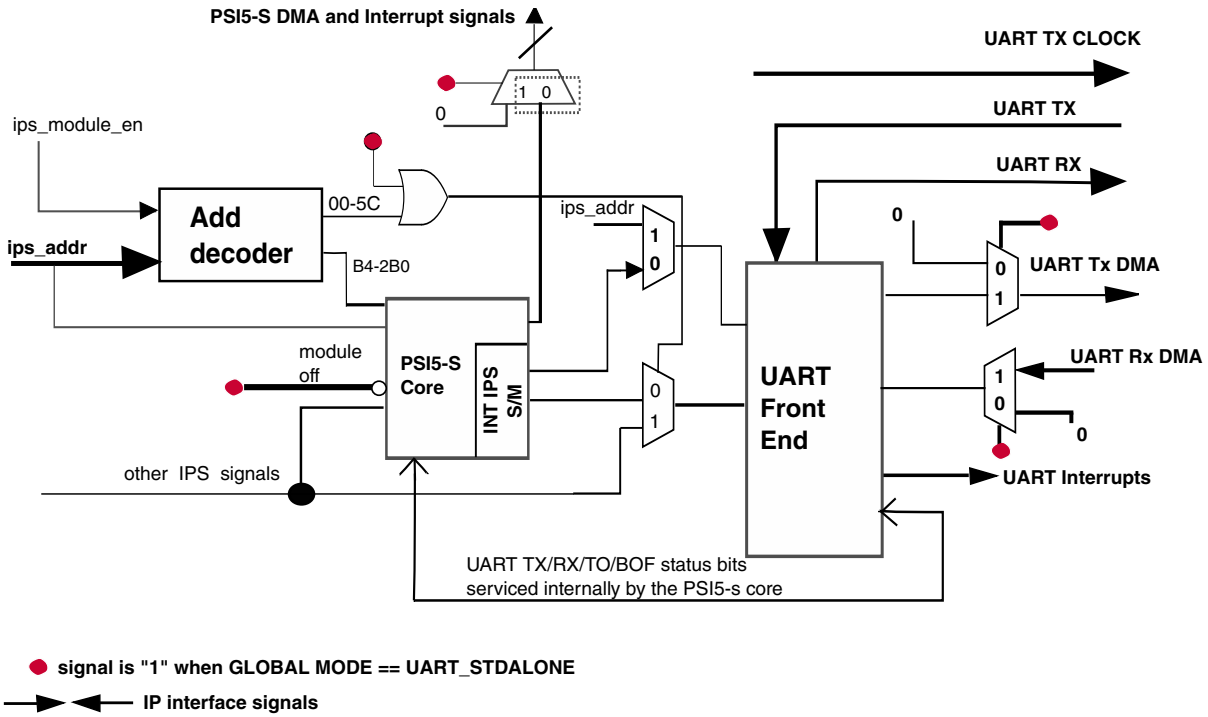


Figure 57-3. LINUART interaction with the PSI5-S core

PSI5S memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PSI5-S LIN Control Register 1 (PSI5S_LINCR1)	32	R/W	0000_0092h	57.4.1/2979

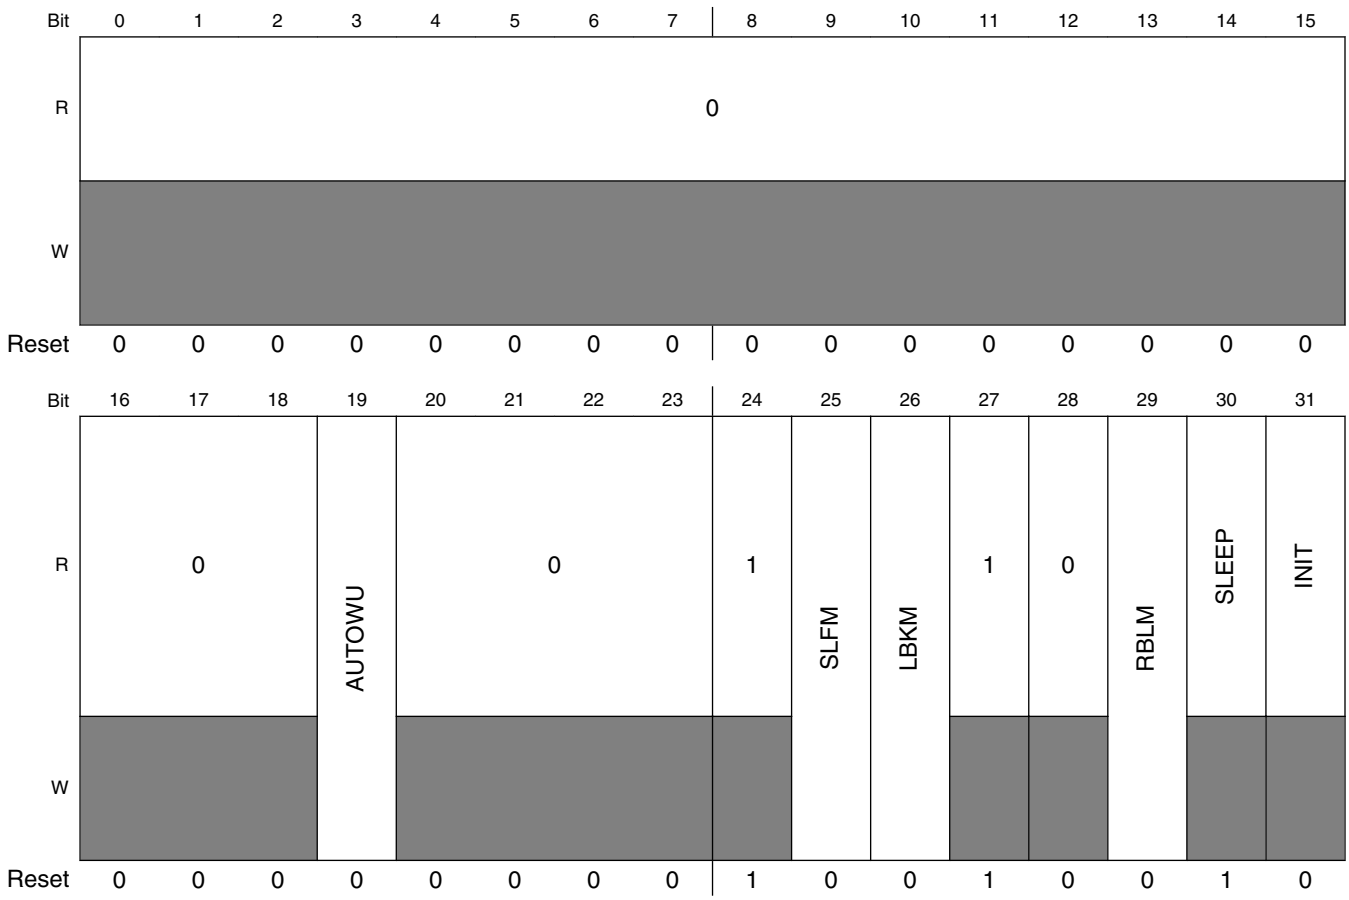
57.4.1 PSI5-S LIN Control Register 1 (PSI5S_LINCR1)

The PS_LINCR1 register contains control bits used to configure features of the PSI5-S UART Front end.

Address: FBF7_4000h base + 0h offset = FBF7_4000h



PSI5S_LINCR1 field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 AUTOWU	PS_NOUSE_BIT Always program as "0" in PSI5-S modes.
20–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

Table continues on the next page...

PSI5S_LINCR1 field descriptions (continued)

Field	Description
25 SLFM	Self test mode To be used along with the LBKM bit. When this bit is set then in addition to the Loop Back mode ; the "ipp_do_lintx" is driven to "1" . 0 Self test mode disabled 1 Self test mode enabled
26 LBKM	Loop Back mode Programmed in PS_CONFIG mode. When set then then the "ipp_do_lintx" output is internally looped back and connected to "ipp_ind_linrx" pin . 0 Loop Back Mode disabled 1 Loop Back mode enabled
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 RBLM	PS_NOUSE_BIT Always program as 0 in PSI5-S modes.
30 SLEEP	PS_NOUSE_BIT **NOTE:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standlone mode. **NOTE:** This bit is read as “1” in PS_DISABLE mode but is read as “0” in PS_NORMAL and PS_CONFIG mode.
31 INIT	PS_NOUSE_BIT **NOTE:** This bit is Read Only Bit in PSI5-S modes and R/W in UART Standlone mode. **NOTE:** This bit is read as “0” in PS_DISABLE and PS_NORMAL mode , and “1” in PS_CONFIG mode.

57.4.2 PSI5-S LIN Interrupt enable register (PSI5S_LINIER)

Address: FBF7_4000h base + 4h offset = FBF7_4004h

PSI5S_LINIER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZIE	Stuck at Zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 No interrupt 1 Interrupt generation enabled
17 OCIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **NOTE:** This bit is also writeable in PS_NORMAL mode.
18–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FEIE	Frame Error Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (FEF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 No interrupt 1 Interrupt generation enabled
24 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 No interrupt 1 Interrupt generation enabled
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 WUIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes. **NOTE:** This bit is also writeable in PS_NORMAL mode.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 TOIE	Timeout Interrupt Enable An interrupt is generated if this bit is set and the Timeout Flag (TO) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core **NOTE:** This bit is also writeable in PS_NORMAL mode.

Table continues on the next page...

PSI5S_LINIER field descriptions (continued)

Field	Description
	0 No interrupt 1 Interrupt generation enabled.
29 DRIE	Data Reception complete Interrupt enable An interrupt is generated if this bit is set and the Data Recieved Flag (DRF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 No interrupt 1 Interrupt generation enabled
30 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in PS_UARTSR is set. This interrupt can be used by the Application for debugging when it wants to read the byte that is under transmission. This byte can be read from the PS_BDRL[DATA_TX[0]] location. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core. **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 No interrupt 1 Interrupt generation enabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.3 PSI5-S LIN Status Register (PSI5S_LINSR)

This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes. For PSI5-S modes, always program with 0x0000_00000 in Config Mode. For Normal and Disable Mode, please refer to "Registers Access in Different Modes" table.

Address: FBF7_4000h base + 8h offset = FBF7_4008h

PSI5S_UARTCR field descriptions

Field	Description
0 MIS	PS_NOUSE_BIT Always program as "1" in PSI5-S modes.

Table continues on the next page...

PSI5S_UARTCR field descriptions (continued)

Field	Description
1–3 CSP	Configurable Sample Point These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the range of values shown in Table 57-2 for a certain over sampling rate. For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper funtionality, OSR can only take values 4, 5, 6 and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.
8 ROSE	Reduced Over Sampling Enable The default value of this bit is 0. 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate.
9–11 NEF	PS_NOUSE_BIT Always program as "000" in PSI5-S modes.
12 PCE_TXDTU	In PSI5-S mode Parity Control Enable for Tx path(In UART STANDLONE mode used to disable UART timeout-Refer to LINUART stanalone documentation for more details) Can be programmed in PS_CONFIG mode only and when PS_UARTCR[0] == 1. When programmed as "1" then a 1 bit additional parity bit is added to the transmitted 8 bits of UART data, so a total of 9 bits including partity are present between a start and a stop bit , in the transmitted data When programmed as "0" then total of 8bits data is present between a start and a stop bit in the transmitted data. 0 Parity generation for Tx path disabled. 1 Parity generation for Tx path enabled.
13–14 SBUR	PS_NOUSE_BIT Always program as "00" in PSI5-S modes.
15 WLS	PS_NOUSE_BIT Always program as "0" in PSI5-S modes.
16–18 TDFLTFC	PS_NOUSE_BIT Always program as "000" in PSI5-S modes.
19–21 RDFLRFC	PS_NOUSE_BIT Always program as "000" in PSI5-S modes.
22 RFBM	PS_NOUSE_BIT Always program as "0" in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
23 TFBM	PS_NOUSE_BIT Always program as "0" in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
24 WL1	PS_NOUSE_BIT

Table continues on the next page...

PSI5S_UARTCR field descriptions (continued)

Field	Description
	Always program as "0" in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
25 PC1	Parity Control {PC1,PC0} Can be programmed only in the PS_CONFIG mode only and when PS_UARTCR[UART] == 1 . 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths.
26 RxEn	Receiver Enable This bit can be programmed only when PS_UARTCR[0] == 1. 0 Receiver disabled 1 Receiver enabled
27 TxEn	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when when PS_UARTCR[UART] == 1
28 PC0	Parity Control {PC1,PC0} Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1 . 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths.
29 PCE_Rx	Recieve Parity check enable. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1. When programmed as "1" then a 1 bit additional parity bit is expected along with the recieved 8 bits of UART data, so a total of 9 bits including partity are expected between a start and a stop bit , in the recieved data. When programmed as "0" then total of 8bits data is expected between a start and a stop bit in the receieved data. 0 Disable the parity checking on the Rx path 1 Enable the parity checking on the Rx path
30 WL0	PS_NOUSE_BIT Always program as "1" in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
31 UART	PS_NOUSE_BIT Always program as "1" in PSI5-S modes.

Table continues on the next page...

PSI5S_UARTCR field descriptions (continued)

Field	Description
	Can be programmed in PS_CONFIG mode only

57.4.5 PSI5-S UART Mode Status Register (PSI5S_UARTSR)

PSI5S_UARTSR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated on the UART interrupt lines if the SZIE bit in PS_LINIER is set.
17 OCF	PS_NOUSE_BIT Read Only Bit.
18 PE3	PS_NOUSE_BIT Read Only Bit.
19 PE2	PS_NOUSE_BIT Read Only Bit.
20 PE1	PS_NOUSE_BIT Read Only Bit.
21 PE0	Parity Error flag for Data0 byte These bits indicate if there is a Parity Error in the recieved byte. No interrupt is generated if this error occurs. This flag is automatically cleared by hardware. The software can poll this flag for debugging purposes. 0 No parity error 1 Parity error in the corresponding received byte
22 RMB	PS_NOUSE_BIT Read Only Bit.

Table continues on the next page...

PSI5S_UARTSR field descriptions (continued)

Field	Description
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). FEF is automatically cleared by hardware. An interrupt is generated if this bit is set and the FEIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and the previous byte has not yet been read from the UART Rx buffer due to some fault in PSI5-S core reading logic. It is automatically cleared by hardware. An interrupt is generated if this bit is set and the BOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	PS_NOUSE_BIT Read Only Bit.
27 RFNE	PS_NOUSE_BIT Read Only Bit.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs - in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO is automatically cleared by hardware. An interrupt is generated if this bit is set and the TOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
29 DRF	Data Reception Completed Flag DRF is set by hardware in UART buffer mode and indicates that one byte has been recieved and is ready for being read. DRF is automatically cleared by hardware. An interrupt is generated if this bit is set and the DRIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose. It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
30 DTF	Data Transmission Completed Flag DTF is set by hardware in UART buffer mode and indicates that data transmission is completed. DTF is automatically cleared by hardware. When the SW desires to write the commands directly to the UART Tx buffer for transmission then it can monitor this bit for an indication of when the UART Tx buffer is ready to accept the next 8 bits of the data. An interrupt will be generated if the DTIE bit in PS_LINIER is set.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

57.4.6 PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

The UART baud rate is programmed in two registers: the LIN Integer Baud Rate register(PS_LINIBRR) and the LIN Fraction Baud Rate register(PS_LINFBRR). The baud rate registers can be programmed only during the PS_CONFIG mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

TxBR = RxBR = ipg_baud_clk/ (16 x LDIV) (when UARTCR[ROSE] == 0)

TxBR = RxBR = ipg_baud_clk/UARTCR[OSR] x LINIBRR (when UARTCR[ROSE] == 1)

LDIV is an unsigned fixed point number which comprises the mantissa and the fraction. The mantissa is coded into 20 bits of LINIBRR , and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled(UARTCR[ROSE] ==1) then PS_LINFBRR is not used. Hence, LDIV contains only the integer part programmed in LINIBRR. Following are 2 examples for two different baud rate calculations.

Example 1 :

With UARTCR[ROSE] = 0.

LDIV = 1041.67, ipg_baud_clk = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

TxBR = RxBR = 80 MHz/(16 x 1041.67) = 4.8 Kbit/s

Example 2 :

When UARTCR[ROSE] = 1 :

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, UARCR[OSR] = 4

TxBR = RxBR = ipg_baud_clk/ (UART[OSR] x LDIV) = 80 MHz / (4 x 10) = 2 Mbit/s

Table 57-3. LINFBRR and fraction (LDIV) values

LINFBRR[4:0]	Fraction (LDIV)
0h	0
1h	1/16
...	...

PSI5S_LINFBRR field descriptions

Field	Description
0–27 Reserved	This field is reserved. Reserved Read returns 0.
28–31 FBR	Fractional Baud rates. See Table 57-3.

57.4.7 PSI5-S LIN Integer Baud Rate Register (PSI5S_LINIBRR)

This register consists of control bits that decide the baud rate along with the PS_LINFBRR. It can be programmed only in Initialization mode.

The UART baud rate is programmed in two registers: the LIN Integer Baud Rate register(PS_LINIBRR) and the LIN Fraction Baud Rate register(PS_LINFBRR). The baud rate registers can be programmed only during the PS_CONFIG mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

TxBR = RxBR = ipg_baud_clk/ (16 x LDIV) (when UARTCR[ROSE] == 0)

TxBR = RxBR = ipg_baud_clk/UARTCR[OSR] x LINIBRR (when UARTCR[ROSE] == 1)

LDIV is an unsigned fixed point number which comprises of the mantissa and the fraction. The mantissa is coded into 20 bits of LINIBRR , and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled(UARTCR[ROSE] ==1) then PS_LINFBRR is not used. Hence LDIV contains only the integer part programmed in LINIBRR. Following are 2 examples for two different baud rate calculations.

Example 1 :

With UARTCR[ROSE] = 0.

LDIV = 1041.67, ipg_baud_clk = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

TxBR = RxBR = 80 Mhz/(16 x 1041,67) = 4.8 Kbit/s

Example 2 :

When UARTCR[ROSE] = 1 :

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, UARCR[OSR] = 4

TxBR = RxBR = ipg_baud_clk/ (UART[OSR] x LDIV) = 80 MHz / (4 x 10) = 2 Mbit/s

Table 57-4. LINIBRR and mantissa (LDIV) values

PSI5S_BDRM field descriptions

Field	Description
0–7 DATA_RX3	PS_NOUSE_BIT

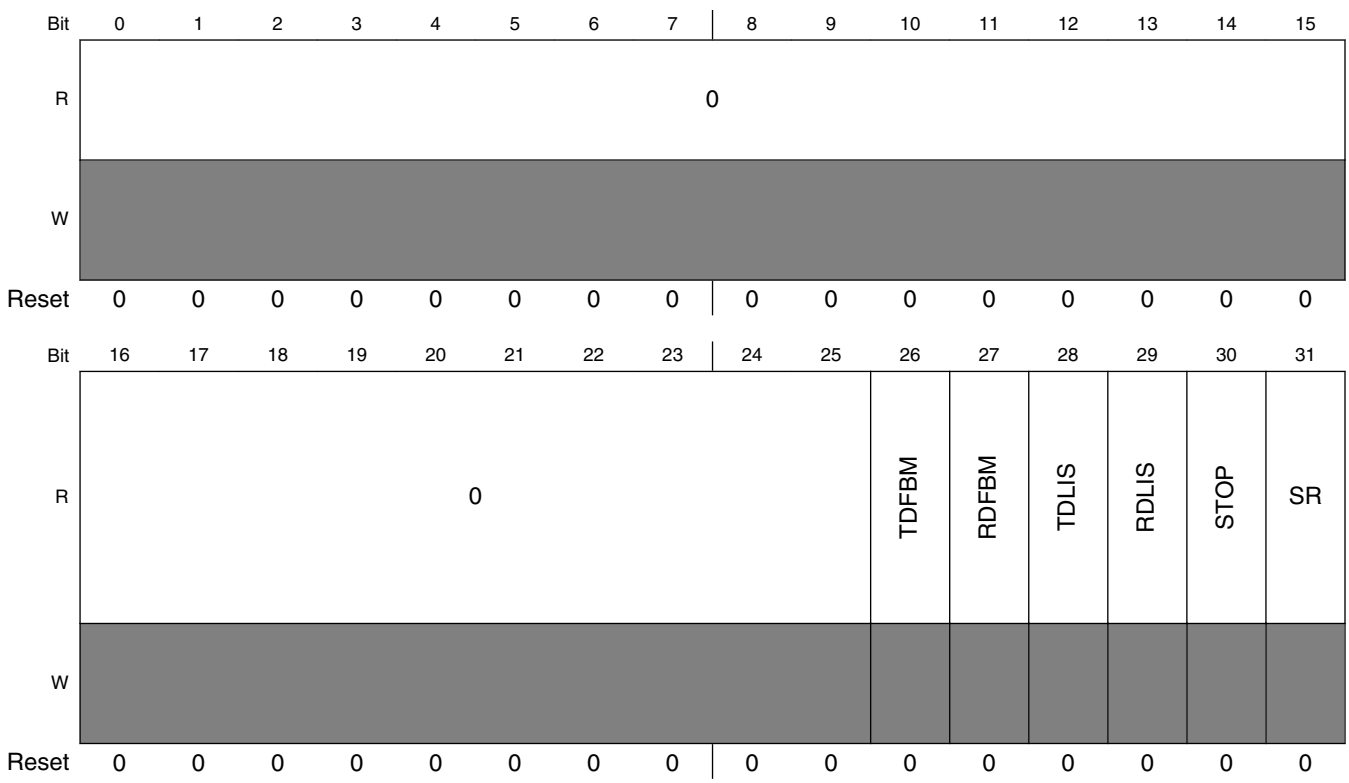
Table continues on the next page...

PSI5S_BDRM field descriptions (continued)

Field	Description
	Always read as "0" in fully configured PSI5-S mode. (All UART control registers are programmed as mentioned in this document.)
8–15 DATA_RX2	PS_NOUSE_BIT Always read as "0" in fully configured PSI5-S mode. (All UART control registers are programmed as mentioned in this document).
16–23 DATA_RX1	PS_NOUSE_BIT Always read as "0" in fully configured PSI5-S mode. (All UART control registers are programmed as mentioned in this document).
24–31 DATA_RX0	Recieve data byte for Rx Recieve data byte of the data field. This register can be read by the application for debugging purpose since it gives the byte that has been recieved by the UART core and will be send to the PSI5-S core.

57.4.11 PSI5-S Global Control register (PSI5S_GCR)

Address: FBF7_4000h base + 4Ch offset = FBF7_404Ch



PSI5S_GCR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

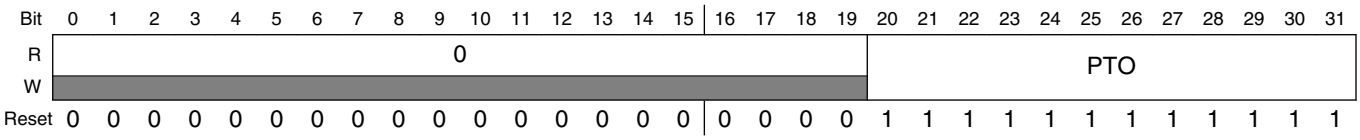
PSI5S_GCR field descriptions (continued)

Field	Description
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB : Register bit can be read in any mode, written only in PS_CONFIG mode. 0 The first bit of transmitted data is LSB - in other words, the first bit received is mapped on LSB bit (of DATA_TX in PS_BDRL register) 1 The first bit of received data is MSB - in other words, first bit received is mapped on MSB bit (of DATA_TX in PS_BDRL register)
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB : Register bit can be read in any mode, written only in PS_CONFIG mode. 0 The first bit of transmitted data is LSB - in other words, the first bit received is mapped on LSB bit (of DATA_RX in PS_BDRM register) 1 The first bit of received data is MSB - in other words, first bit received is mapped on MSB bit (of DATA_RX in PS_BDRM register)
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only). Register bit can be read in any mode, written only in PS_CONFIG mode. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) . Register bit can be read in any mode, written only in PS_CONFIG mode. 0 Received data is not inverted 1 Received data is inverted
30 STOP	PS_NOUSE_BIT Always program as "0" in PSI5-S modes.
31 SR	Soft reset SR executes a soft reset of the UART controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. Register bit can be written only by software in PS_CONFIG mode. Bit is always read 0 by software.

57.4.12 PSI5-S UART Preset Timeout Register (PSI5S_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed to monitor the idle state of the reception line. This register can be written by software any time.

Address: FBF7_4000h base + 50h offset = FBF7_4050h



PSI5S_UARTPTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. The register must be programmed to a value of "Idle Timeout required in terms of number of bits recieved " at that particular baud rate. Refers also to register UARTCTO.

57.4.13 UPSI5-S ART Current Timeout register (PSI5S_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see Section 1.3.3.12, PSI5-S UART Preset Timeout Register (PS_UARTPTO) to monitor the idle state of the reception line.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with baud clock frequency of TxBR/RxBR. Also refer NOTE which follows Section 1.3.3.7, LIN Integer Baud Rate Register (PS_LINIBRR).
- Is automatically enabled when UARTCR[RXEN] = 1

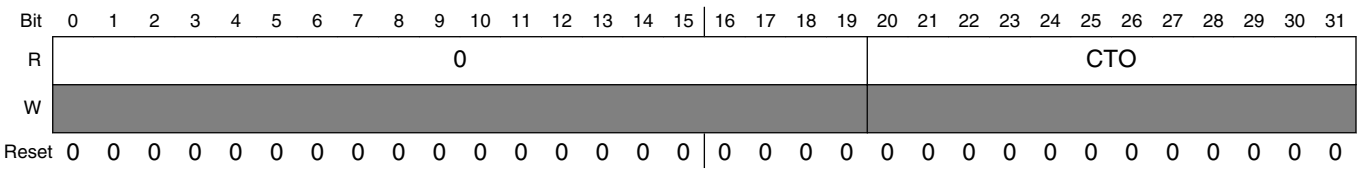
NOTE

Due to internal synchronization there is a delay between 4 to 6 clock cycles of “ipg_clk_ps”, for the internal counter’s value (which is clocked with baud frequency of TxBR/RxBR) to reflect on to UARTCTO

UARTCTO is reset when:

- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written.
- When the PSI5-S goes in PS_DISABLE mode.

Address: FBF7_4000h base + 54h offset = FBF7_4054h



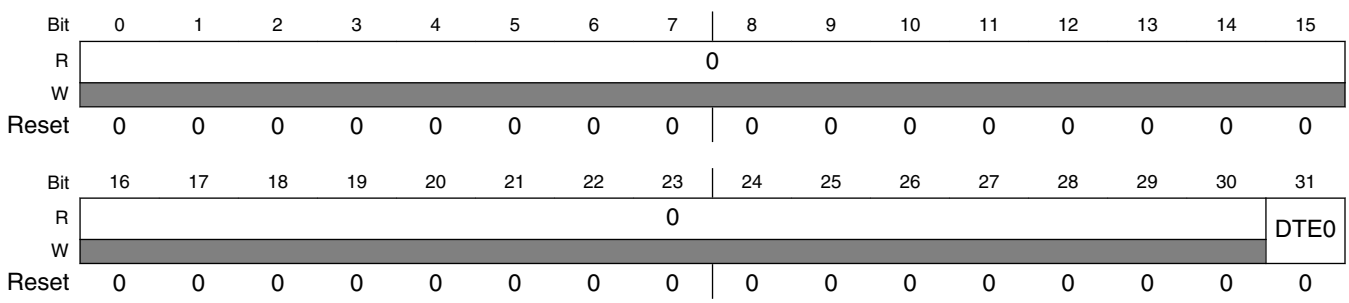
PSI5S_UARTCTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 CTO	Current Timeout CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

57.4.14 DMA Tx Enable Register (PSI5S_DMATXE)

This register enables the DMA TX interface. This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes. For PSI5-S modes, always program with 0x0000_00000 in Config Mode. For Normal and Disable Mode, please refer to "Registers Access in Different Modes" table.

Address: FBF7_4000h base + 58h offset = FBF7_4058h



PSI5S_DMATXE field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 DTE0	PS_NOUSE_BIT Always program with "0" in PSI5-S modes

57.4.15 DMA Rx Enable Register (PSI5S_DMARXE)

This register enables the DMA RX interface. This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes. For PSI5-S modes, always program with 0x0000_00000 in Config Mode. For Normal and Disable Mode, please refer to "Registers Access in Different Modes" table.

Address: FBF7_4000h base + 5Ch offset = FBF7_405Ch

31 DRE0	PS_NOUSE_BIT Always program with "0" in PSI5-S modes

57.4.16 PSI5-S UART Tx Idle Delay Time Register (PSI5S_PTD)

This register is used to add a programmable idle time between the data that is transmitted on the UART Tx line. The duration of this delay is programmable between 1 to 16 bit times.The programmable delay is such that when the normal ECU to Sensor communication(no direct command) is happening , then it comes into play between each byte of transmitted data , When the ECU to Sensor direct command is used then this delay comes into play between each direct command. The direct commands can be programmed as 1,2 and 4 bytes depending on the PS_GLCR[DIRCMD_LEN] register. For more information please see the SectionPSI5-S ECU to Sensor Direct Command Write register (PSI5S_DIRCMD) and SectionPSI5-S Global Control Register (PSI5S_GLCR) details.

Address: FBF7_4000h base + 60h offset = FBF7_4060h

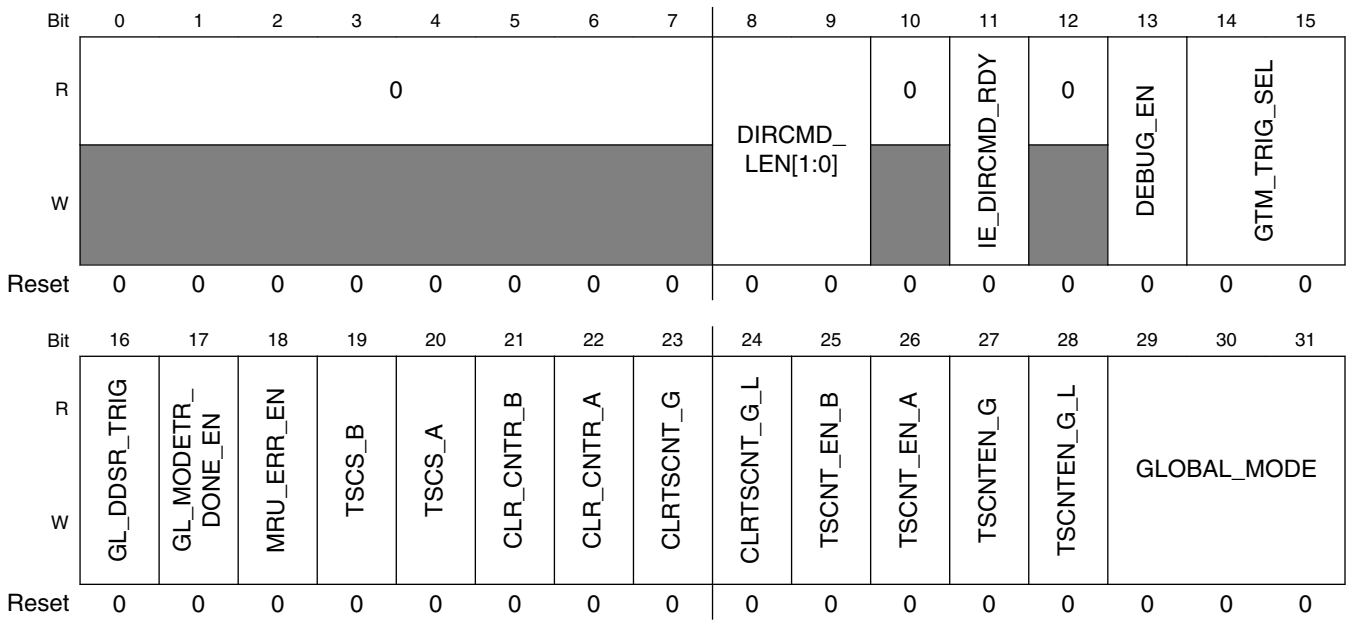
PSI5S_PTD field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–30 IFD	Interframe Delay. The idle time added between the UART data on the TX line is IFD+1 bit times. The UART data can be sized to be of either one byte or 1,2 and 4 bytes.
31 EN	IFD Enable 0 The IFD is active in the UART Tx path. 1 The IFD is inactive.

57.4.17 PSI5-S Global Control Register (PSI5S_GLCR)

The Global Control Register (PS_GLCR) provides control functions for all the PSI5-S channels simultaneously.

Address: FBF7_4000h base + B4h offset = FBF7_40B4h



PSI5S_GLCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–9 DIRCMD_ LEN[1:0]	Direct Command Length Register. This defines the length of the Direct Command that is transferred to the UART Tx line. The Direct command is written to the PS_DIRCMD register in the format {DIRCMD_BYTE3, DIRCMD_BYTE2, DIRCMD_BYTE1, DIRCMD_BYTE0}. Following is the bit description : **NOTE:** The idle time between the commands is still governed by the PS_PTD register in the LINUART module. **NOTE:** This register is also writeable in the NORMAL mode. 00 1 byte command : 1 byte {DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx. Rest bytes of the PS_DIRCMD are ignored. 01 2 byte command : 2 bytes {DIRCMD_BYTE1,DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx without any idle time between DIRCMD_BYTE1 and DIRCMD_BYTE0. Rest byte of the PS_DIRCMD are ignored. 10/11 4 byte command : 4 bytes {DIRCMD_BYTE3,DIRCMD_BYTE2,DIRCMD_BYTE1,DIRCMD_BYTE0} of the PS_DIRCMD is transferred to the UART Tx line without any idle time between these bytes.

Table continues on the next page...

PSI5S_GLCR field descriptions (continued)

Field	Description
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 IE_DIRCMD_RDY	Interrupt enable bit for DIRCMD_RDY. **NOTE:** This bit is also writeable in PS_NORMAL mode. 0 PS_GLCR[DIRCMD_RDY], when goes as “1” , does not generateany interrupt on the “ipi_ps_glbl” interrupt line. 1 PS_GLCR[DIRCMD_RDY], when goes as “1” , generates an interrupt on the “ipi_ps_glbl” interrupt line.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 DEBUG_EN	Debug enable bit. For debug mode operation please refer Debug mode 0 The IP does not enter the debug mode when a request is made to the IP for entering into the debug mode. It continues its normal operation. 1 The IP enters the debug mode immediately, as soon as a request is made to the IP for entering into the debug mode.
14–15 GTM_TRIG_SEL	GTM_TRIG_SEL bits. These bits are used to select the trigger for the Timestamp counters as shown in Figure 57-21. The gtm trigger signals control the frequency of operation of the timestamp counters. In other words they control the clocking(clkA and clkB) of the timestamp counters A and B. 00 gtm_trig[0] is selected for clocking the timestamp counter. 01 gtm_trig[1] is selected for clocking the timestamp counter. 10 gtm_trig[2] is selected for clocking the timestamp counter. 11 gtm_trig[3] is selected for clocking the timestamp counter.
16 GL_DDSR_TRIG	This is the global shift trigger of all the DDSRs of each channel. When the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] == 1 , only then is this bit effective, else this bit has no effect. **NOTE:** If bit is subsequently set after being cleared , then the counters will restart and the offsets in PS_DDTRIG_PERR and PS_DDTRIG_OFFR registers will be applied again. This bit is also writable in PS_NORMAL mode 0 Shift triggers of all the DDSR registers are halted (default state). If bit is cleared during runtime, PS_DDTRIG_PERR and PS_DDTRIG_OFFR counters are reset. 1 The shift triggers of all the DDSR's start synchronously.
17 GL_MODETR_DONE_EN	Interrupt enable for PS_GLSR[GL_MODETR_DONE] bit. This bit is also writable in PS_NORMAL and PS_DISABLE modes. 0 No interrupt is generated on setting of the PS_GLSR[GL_MODETR_DONE] bit 1 Generates the interrupt when PS_GLSR[GL_MODETR_DONE] bit is set.
18 MRU_ERR_EN	Enables the interrupt for MRU overwrite when the unread contents of MRU Buffer1 are overwritten by a new message **NOTE:** This bit is also writable in ps_normal mode 0 MRU overwrite error is not enabled 1 MRU overwrite error is enabled
19 TSCS_B	This bit controls the selection of clock input to timestamp counter B, either by the external periodic clock or by the GTM module

Table continues on the next page...

PSI5S_GLCR field descriptions (continued)

Field	Description
	0 External clock(ipg_clk_ps_ts) is selected 1 gtm_trig is selected as the clock.
20 TSCS_A	This bit controls the selection of clock input to timestamp counter A, either by the external periodic clock or by the GTM module 0 External clock(ipg_clk_ps_ts) is selected 1 gtm_trig is selected as the clock.
21 CLR_CNTR_B	This bit will reset timestamp counter B when PS_GLCR[CLRTSCNT_G] is not set This bit is a one shot and is always read as 0. **NOTE:** This bit is also writable in ps_normal mode 1 Timestamp counter B is reset
22 CLR_CNTR_A	This bit will reset timestamp counter A when PS_GLCR[CLRTSCNT_G] is not set This bit is a one shot and is always read as 0. **NOTE:** This bit is also writable in ps_normal mode 1 Timestamp counter A is reset
23 CLRTSCNT_G	This bit controls the global clearing of the TimeStamp counters A and B when CLRTSCNT_G_L == 1. When CLRTSCNT_G_L == 0 then this bit has no effect. This bit is a one shot and is always read as 0. **NOTE:** This bit is also writable in ps_normal mode 1 Both time stamp counter are cleared at the same time.
24 CLRTSCNT_G_L	This bit control whether the timestamp counters counter A and B are cleared simultaneously or independently: 0 Timestamp counters A and B are cleared independently. When PS_GLCR[CLR_CNTR_A] == 1 timestamp counter A is cleared. When PS_GLCR[CLR_CNTR_A]== 1 timestamp counter B is cleared. 1 Both timestamp counter are cleared simultaneously as soon as CLRTSCNT_G== 1.
25 TSCNT_EN_B	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G] is not set **Note:** This bit is also writable in ps_normal mode 0 Timestamp counter A not enabled 1 Timestamp counter B is enabled
26 TSCNT_EN_A	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G] is not set **NOTE:** This bit is also writable in ps_normal mode 0 Timestamp counter A not enabled 1 Timestamp counter A is enabled
27 TSCNTEN_G	This bit controls the global trigger of the TimeStamp counters A and B when TSCNTEN_G_L == 1. When TSCNTEN_G_ == 0 then this bit has no effect. **NOTE:** This bit is also writable in ps_normal mode 0 Both time stamp counters are disabled simultaneously 1 Both time stamp counter start simultaneously.

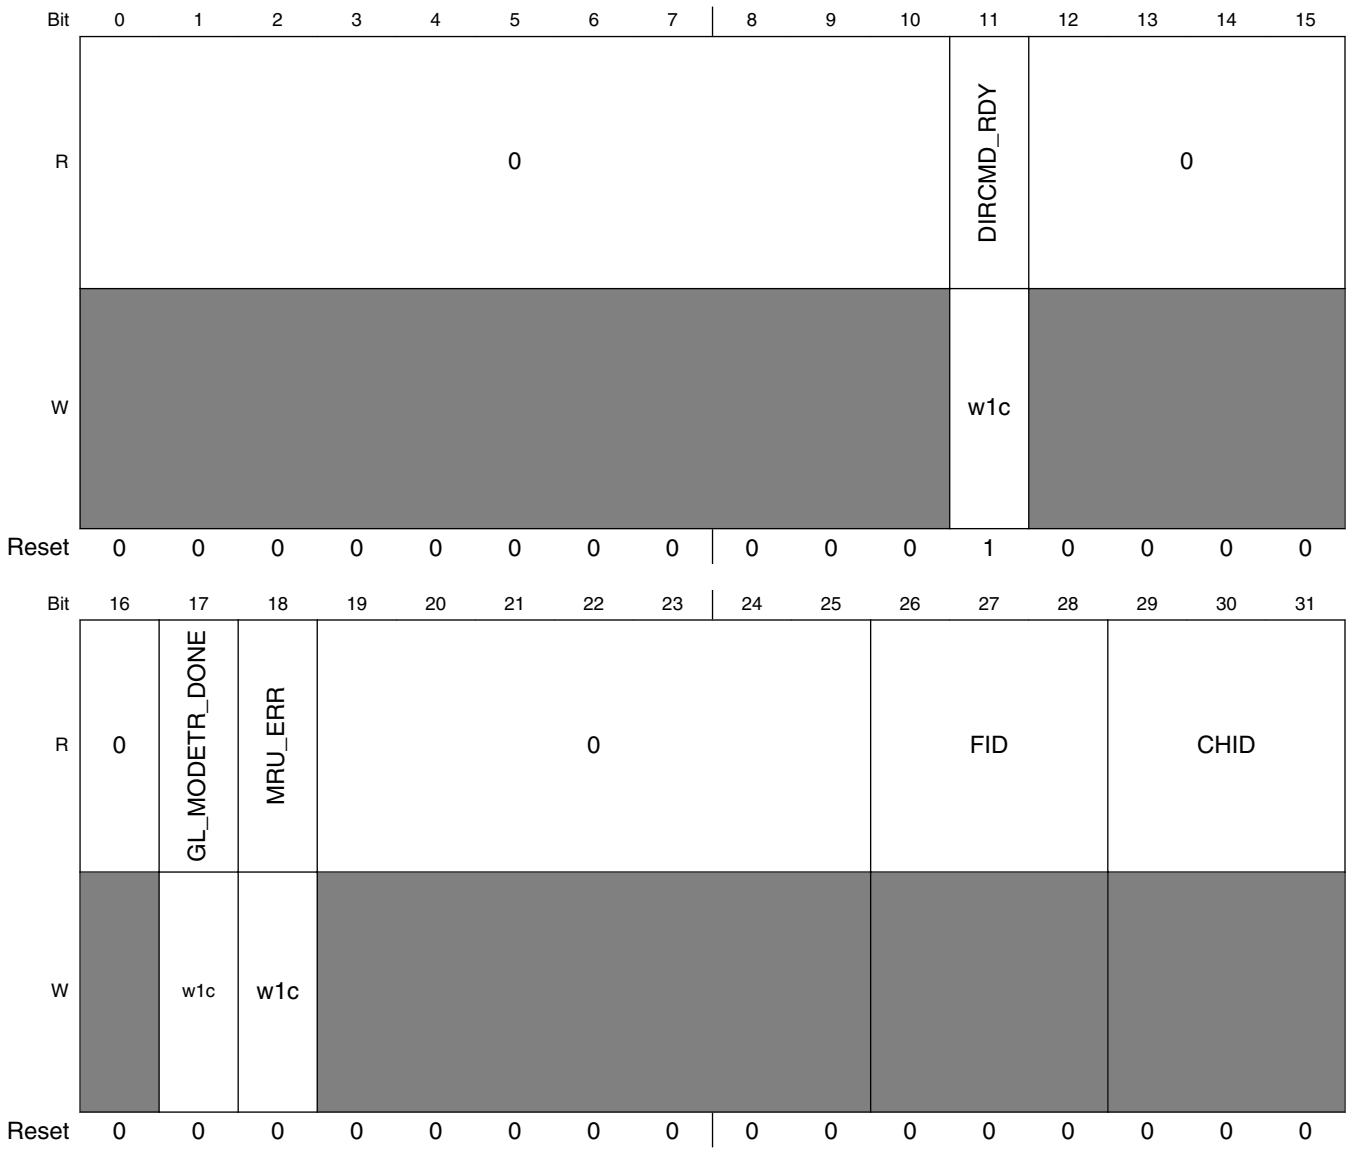
Table continues on the next page...

PSI5S_GLCR field descriptions (continued)

Field	Description
28 TSCNTEN_G_L	This bit control whether the timestamp counters counter A and B are started simultaneously or independently 0 Timestamp counters A and B are started independently. When PS_GLCR[TSCNT_A_EN] == 1 timestamp counter A starts. When PS_GLCR[TSCNT_B_EN] == 1 timestamp counter B starts. 1 Both timestamp counter are triggered simultaneously as soon as TSCNTEN_G == 1.
29–31 GLOBAL_MODE	These are the bits which decide Global Mode of the IP. There are four modes, UART_STDALONE, PS_DISABLE,PS_CONFIG and PS_NORMAL. For the details of modes related to the bit setting of GLOBAL_MODE, please refer Table 57-1. **NOTE:** This bits are writable in all modes

57.4.18 PSI5-S Global Status Register (PSI5S_GLSR)

Address: FBF7_4000h base + B8h offset = FBF7_40B8h



PSI5S_GLSR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 DIRCMD_RDY	Bit used to indicate the “Ready for Direct Command write” status.

Table continues on the next page...

PSI5S_GLSR field descriptions (continued)

Field	Description
	Once the command is written to the PS_DIRCMD, then a “w1c” to this register should be done so that the command written to the PS_DIRCMD register is queued for UART transmission with the highest priority. When the command has been transferred from thie register to the UART, then this bit goes as “1”. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1”, then this event generates an interrupt on the ipi_ps_glbl line. **NOTE:** This bit is also writeable in the PS_NORMAL mode. 0 Direct Command that is written to the PS_DIRCMD register is currently under processing. Any further command written to the PS_DIRCMD register would be rejected without any information. 1 The PS_DIRCMD register is empty and the application can write the direct ECU to sensor transceiver command to the PS_DIRCMD register.
12–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 GL_MODETR_DONE	This bit indicates , as to when the global mode transitions , as programmed by PS_GLCR[GLOBAL_MODE] have actually been accomplished : This bit is cleared by w1c. The bit is also writable in PS_NORMAL and PS_DISABLE mode. This bit is reset to "0" when the mode is changed from PS_DISABLE to the UART_STDALONE mode. 0 The intended global mode , as programmed in the PS_GLCR[GLOBAL_MODE] register bits , is under processing. 1 The global mode as programmed in the PS_GLCR[GLOBAL_MODE] have been accomplished
18 MRU_ERR	This bit shows whether unread MRU buffer1 contents have been overwritten by a new message: This bit is cleared by w1c. The bit is also writable in PS_NORMAL mode. 0 no overwrite occurred 1 overwrite occurred
19–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–28 FID	Points to the frame whose data in MRU buffer 1 was overwritten
29–31 CHID	Points to the channel whose data in MRU buffer 1 was overwritten

57.4.19 PSI5-S CHANNEL_BASE_ADDRESS (PSI5S_CH_BASE_ADDR)

Address: FBF7_4000h base + BCh offset = FBF7_40BCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

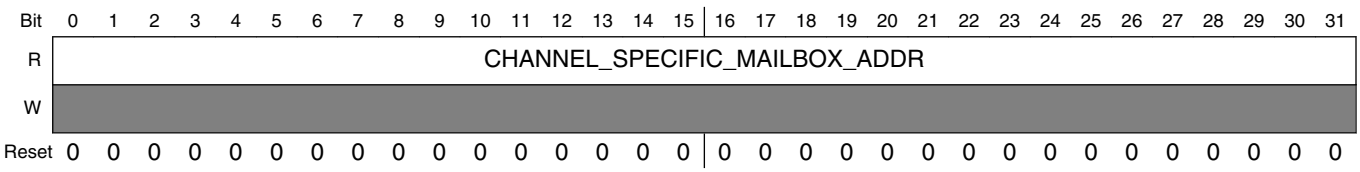
PSI5S_CH_BASE_ADDR field descriptions

Field	Description
0–31 MAILBOX_ BASE_ADDR	This register will provide the base address of the mailbox in the system RAM.This value needs to be programmed by the software.

57.4.20 PSI5-S MRU OUTPUT BUFFER2 REGISTER0 (PSI5S_MRU_BUF2_REG0)

Address: FBF7_4000h base + C0h offset = FBF7_40C0h



PSI5S_MRU_BUF2_REG0 field descriptions

Field	Description
0–31 CHANNEL_ SPECIFIC_ MAILBOX_ADDR	This register will provide the channel specific mailbox address corresponding to channel and slot for which data has been received.This value is computed by the IP based on the PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] and FID,CID. Following is the formula used to calculate this address: • For messages with CID==0 in the header byte, destined for Channel0 location0, the value is PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] • For "unrecoverable" messages destined for Channel0,location1, the value is PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]+0xC • For other messages with CID = 1 to 7 the value can be calculated as (PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] + (6*4*3(MSG_CH_ID)+(MSG_FRAME_ID)*4*3)) When using the DMA for reading the MRU buffer, this register forms the Access1 of the DMA transfer.

57.4.21 PSI5-S MRU OUTPUT BUFFER2 REGISTER1 (PSI5S_MRU_BUF2_REG1)

Address: FBF7_4000h base + C4h offset = FBF7_40C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	SCI_F_ERR	SCI_P_ERR	HD_ERR	ERR		CRC_ERR_P_ERR	CRC			XCRC_ERR	XCRC					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5S_MRU_BUF2_REG1 field descriptions

Field	Description
0–3 DCI	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 R_UVL_ERR	Message underflow. It is set when less than three UART bytes are received in the UART packet. In case of XCRC error the message is treated as unrecoverable and written in mail box location1 of channel 0 Please refer to PSI5-S Message Extraction for more details. 0 no error occurred 1 error occurred
6 N_ERR	Indicates that the number of UART bytes in the recieved UART packet does not match the number specified in Channel Configuration Register A indicated by CID and FID i.e. the number of UART bytes does not match the value programmed in PS_MSGA_CHCID[FFID_bytes]. Also please see the content about byte recalculation in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR). Please refer to PSI5-S Message Extraction for more details. 0 no error occurred 1 error occurred
7–9 CHID	Indicates Channel id of PSI5 message present in the UART header byte.
10–12 FID	Indicates Frame ID of PSI5 message present in the UART header byte.
13 R_OVL_ERR	Message overflow.It is set when more than six UART bytes are received in the UART packet.The message may be recoverable(XCRC_ERR == 0) or unrecoveranle (XCRC_ERR==1). Please refer to PSI5-S Message Extraction for more details. 0 no error occurred 1 error occurred
14 F_WD_ERR	Frame watchdog error in the received PSI5 message. In case there is no XCRC error in the recieved message, then this bit will be the same as the PS_WDGTSSR[F_WD_ERR[CID]] bit , where CID is the channel ID of the recieved PSI5 message. In case the recieved PSI5 message has an XCRC error, then this bit will be the logical OR of all the PS_WDGTSSR[F_WD_ERR[CHn]] bits, i.e., in this case, it will be “PS_WDGTSSR[F_WD_ERR[1]] OR PS_WDGTSSR[F_WD_ERR[2]] OR....PS_WDGTSSR[F_WD_ERR[7]]”. Please see PSI5-S Watchdog Operation, PSI5-S channel message configuration register B (PSI5S_MSGB_CH*n*) and PSI5-S Watchdog Error Status and Watchdog Timestamp status register (PSI5S_WDGTSSR) for more details. **NOTE:** Whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set, PS_WDGTSSR(which is a hardware clearing register) should always be read. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective “CID”, whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID.This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit. 0 no error occurred 1 error occurred

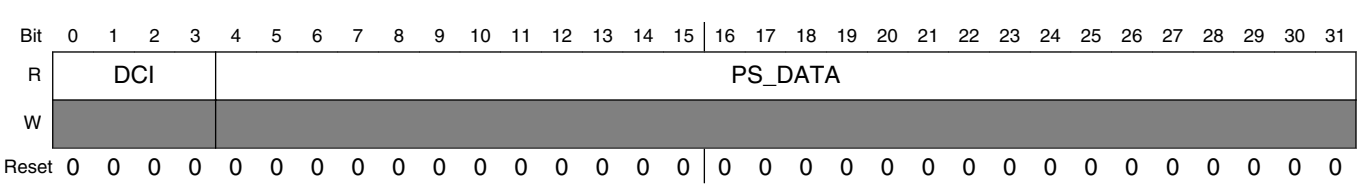
Table continues on the next page...

PSI5S_MRU_BUF2_REG1 field descriptions (continued)

Field	Description
15 SCI_O_ERR	UART overrun error has occured in at least one UART byte of the recieved UART packet , due to which some UART byte has been lost. 0 no error occurred 1 error occurred
16 SCI_F_ERR	UART framing error has occured in the current recieved UART packet. 0 no error occurred 1 error occurred
17 SCI_P_ERR	UART message parity error has occured in at least one UART byte of the recieved UART packet. 0 no error occurred 1 error occurred
18 HD_ERR	This bit is set when any of the ERR[1:0] is "1" and indicates a transceiver error. 0 no error occurred 1 error occurred
19–20 ERR	Transceiver error flags received in the Message header byte of the UART packet indicated by CID and FID
21 CRC_ERR_P_ERR	Indicates whether "PSI5 message " crc_err or the parity error in the PSI5 message indicated by CID and FID has occured . The Parity is taken as even for PSI5 caculation : **NOTE:** This bit always remains "0" for messages having CID and FID both as "0". 0 no crc_error/parity error has occurred 1 indicates crc_error/Parity Error has occurred
22–24 CRC	Contains the recieved CRC or Parity Bits of the PSI5 message, of indicated by CID and FID
25 XCRC_ERR	Indicates xcrc_err in the received UART packet : 0 no xcrc_error occurred 1 indicates xcrc_error occurred
26–31 XCRC	This is the value of xcrc received in the last six bits of the UART byte, which occurs just before the information of a "new UART packet recieved" has been generated. Please refer to PSI5-S UART Message Structure and PSI5-S XCRC Handling for more details.

57.4.22 PSI5-S MRU OUTPUT BUFFER2 REGISTER2 (PSI5S_MRU_BUF2_REG2)

Address: FBF7_4000h base + C8h offset = FBF7_40C8h



PSI5S_MRU_BUF2_REG2 field descriptions

Field	Description
0–3 DCI	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
4–31 PS_DATA	PSI5 data bits extracted from the recieved UART bytes.

57.4.23 PSI5-S MRU OUTPUT BUFFER2 REGISTER3 (PSI5S_MRU_BUF2_REG3)

Address: FBF7_4000h base + CCh offset = FBF7_40CCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

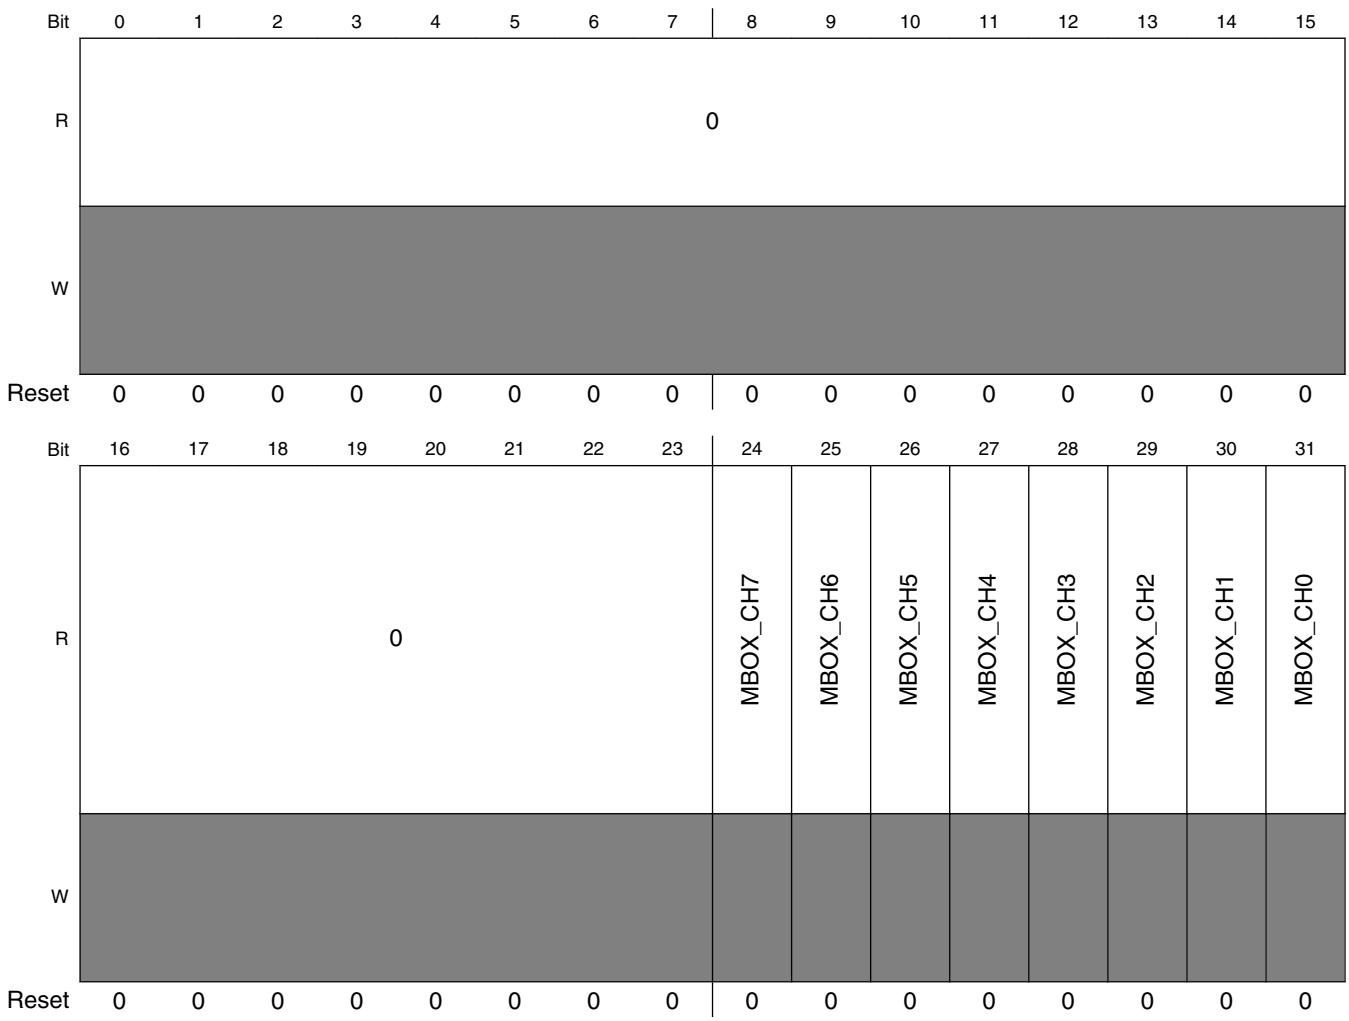
PSI5S_MRU_BUF2_REG3 field descriptions

Field	Description
0–3 DCI	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 TIMESTAMP	Time stamp value appended based on the various timestamp bit settings in the PS_GLCR register,PS_PCCR_CH[n] register and the errors occurred. For more details please refer toPSI5-S Watchdog Operation.

57.4.24 PSI5-S Mbox Status Irq (PSI5S_MBOX_SR_IRQ)

Please refer to Figure 57-18 also.

Address: FBF7_4000h base + E0h offset = FBF7_40E0h



PSI5S_MBOX_SR_IRQ field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 MBOX_CH7	When set it Indicates at least one message in mailbox 7 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH7[F(0-5)_READ] bits i.e. MBOX_CH7 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel7 are cleared.

Table continues on the next page...

PSI5S_MBOX_SR_IRQ field descriptions (continued)

Field	Description
25 MBOX_CH6	When set it Indicates at least one message in mailbox 6 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH6[F(0-5)_READ] bits i.e. MBOX_CH6 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel6 are cleared.
26 MBOX_CH5	When set it Indicates at least one message in mailbox 5 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH5[F(0-5)_READ] bits i.e. MBOX_CH5 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel5 are cleared.
27 MBOX_CH4	When set it Indicates at least one message in mailbox 4 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH4[F(0-5)_READ] bits i.e. MBOX_CH4 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel4 are cleared.
28 MBOX_CH3	When set it Indicates at least one message in mailbox 3 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH3[F(0-5)_READ] bits i.e. MBOX_CH3 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel3 are cleared.
29 MBOX_CH2	When set it Indicates at least one message in mailbox 2 is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH2[F(0-5)_READ] bits i.e. MBOX_CH2 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel2 are cleared.
30 MBOX_CH1	When set it Indicates at least one message in mailbox 1is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH1[F(0-5)_READ] bits i.e. MBOX_CH1 = F0_READ OR F1_READ OR .....F5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel1 are cleared.
31 MBOX_CH0	When set it Indicates at least one message in mailbox 0is pending for read by the application. This bit is a "read status" of the OR of PS_MBOX_SR_CH0[F(0-1)_READ] bits i.e. MBOX_CH0 = F0_READ OR F1_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel0 are cleared.

57.4.25 PSI5-S Error Status Irq (PSI5S_ERR_SR_IRQ)

Please refer to Figure 57-18 also.

PSI5S_ERR_SR_IRQ field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 R_UVL_ERR	When set indicates that message underflow error(number of UART bytes recieved are less than 3) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_UVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_UVL_ERR] bit.

Table continues on the next page...

PSI5S_ERR_SR_IRQ field descriptions (continued)

Field	Description
	Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
23 N_ERR	When set indicates that N_ERR (Number of UART bytes are not equal to PS_MSGA_CHn[Fn_byte]) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[N_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[N_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
24 R_OVL_ERR	When set indicates that message Overflow error(number of UART bytes recieved have exceeded 6) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_OVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_OVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
25 F_WD_ERR	When set indicates that Frame Watchdog error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[F_WD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[F_WD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
26 SCI_O_ERR	When set indicates that UART Overrun error(from the UART side) is present in the message currently present in MRU buf2. When "1" , then this bit indicates that some UART byte belonging to the concerned UART packet , has been overwritten by another UART byte and is lost. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_O_ERR] bit.

Table continues on the next page...

PSI5S_ERR_SR_IRQ field descriptions (continued)

Field	Description
	This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_O_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
27 SCI_F_ERR	When set indicates that UART Framing error is present in the message currently present in MRU buf2. If this bit is set then it indicates to the application that the synchronisation of the UART module is lost and any subsequent UART bytes recieved will be error prone. In this case the application is required to reset the UART module by using the PS_GCR[SR] bit. Subsequently it should restart the transmission. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_F_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_F_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
28 SCI_P_ERR	When set indicates that UART parity error is present in the message currently present in MRU buf2. This bit will be set when there is a parity error in any UART byte using which the concerned UART packet was formed. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
29 HD_ERR	When set indicates that Header error(E0/E1) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[HD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[HD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.

Table continues on the next page...

PSI5S_ERR_SR_IRQ field descriptions (continued)

Field	Description
30 CRC_ERR_P_ERR	When set indicates that PSI5 CRC/Parity error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** This bit always remains "0" for messages having CID and FID both as "0". **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.
31 XCRC_ERR	When set indicates that XCRC error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[XCRC_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[XCRC_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. The bit is also writable in PS_NORMAL mode. **NOTE:** If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.

57.4.28 PSI5-S Watchdog Error Status and Watchdog Timestamp status register (PSI5S_WDGTSSR)

NOTE

All bits of PS_WDGTSSR register are self clearing on read. This implies that in case this register is read by the application before the corresponding PS_WDGTSSR[F_WD_ERR_STATUS[CHn]] has had a chance to be sent in the next upcoming PSI5 message, then this bit would be sent as a “0” in this upcoming PSI5 message.

Address: FBF7_4000h base + 128h offset = FBF7_4128h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	F_WD_ERR_STATUS							0	WDTS_STATUS							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	WDTS_STATUS															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5S_WDGTSSR field descriptions

Field	Description
0–6 F_WD_ERR_ STATUS	These bits give the watchdog error status for the watchdog of each corresponding channel. Thus, F_WD_ERR_STATUS[1] will give the watchdog error status for watchdog of channel1. Similarly, F_WD_ERR_STATUS[2] will give the watchdog error status for watchdog of channel2 and so on till F_WD_ERR_STATUS[7], which gives the watchdog error status for watchdog of channel7. As soon as the watchdog of the corresponding channel has a watchdog overrun error, the error status is latched in the corresponding bits of this register. **NOTE:** PS_WDGTSSR is a hardware cleared register. These bits are automatically cleared by the hardware when PS_WDGTSSR is read by the application. This register should ALWAYS be read

Table continues on the next page...

PSI5S_WDGTSSR field descriptions (continued)

Field	Description
	whenever the PS_MRU_BUF2_REG1[F_WD_ERR] bit is set. Failing to do so will result in the PS_MRU_BUF2_REG1[F_WD_ERR] bit continuing to be set for respective “CID” whenever the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit is set. This would happen in subsequent messages saved to the mailbox even though no further watchdog error has occurred for the respective CID. This happens since for each received PSI5 message in the MRU buffers the status of the corresponding PS_MRU_BUF2_REG1[F_WD_ERR] is picked from the PS_WDGTSSR[F_WD_ERR_STATUS[CID]] bit.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 WDTS_STATUS	Timestamp value of that specific channel , the timestamp of which is captured when the watchdog error of that specific channel has occured. This register always contains the timestamp value corresponding to the last occuring Watch Dog error. If due to bad programming watchdog error of more than one channel happen simultaneously then this register contains the timestamp value of the highest channel. For each channel , whether Time Stamp A or B is captured depends on the value of PS_MSGA_CHn[TIMESTAMP_A_B_SEL] register bit. **NOTE:** These bits are automatically cleared by the hardware when any of the bits of PS_WDGTSSR is read by the application.

57.4.29 PSI5-S ECU to Sensor Direct Command Write register (PSI5S_DIRCMD)

NOTE

A “w1c” should be done on the PS_GLSR[DIRCMD_RDY] so that the command written on the PS_DIRCMD register is queued for transmission on the UART TX line. As soon as any ongoing transmission on the UART TX is finished, the PS_DIRCMD starts being transmitted on the UART Tx line. When PS_GCR[TDFBM] = 0, then the bits on the UART Tx line are shifted in the following sequence “DIRCMD_BYTE0[0],DIRCMD_BYTE0[1]....DIRCMD_BYTE3[0]....DIRCMD_BYTE3[7]” with DIRCMD_BYTE0[0] being shifted first.

Address: FBF7_4000h base + 12Ch offset = FBF7_412Ch

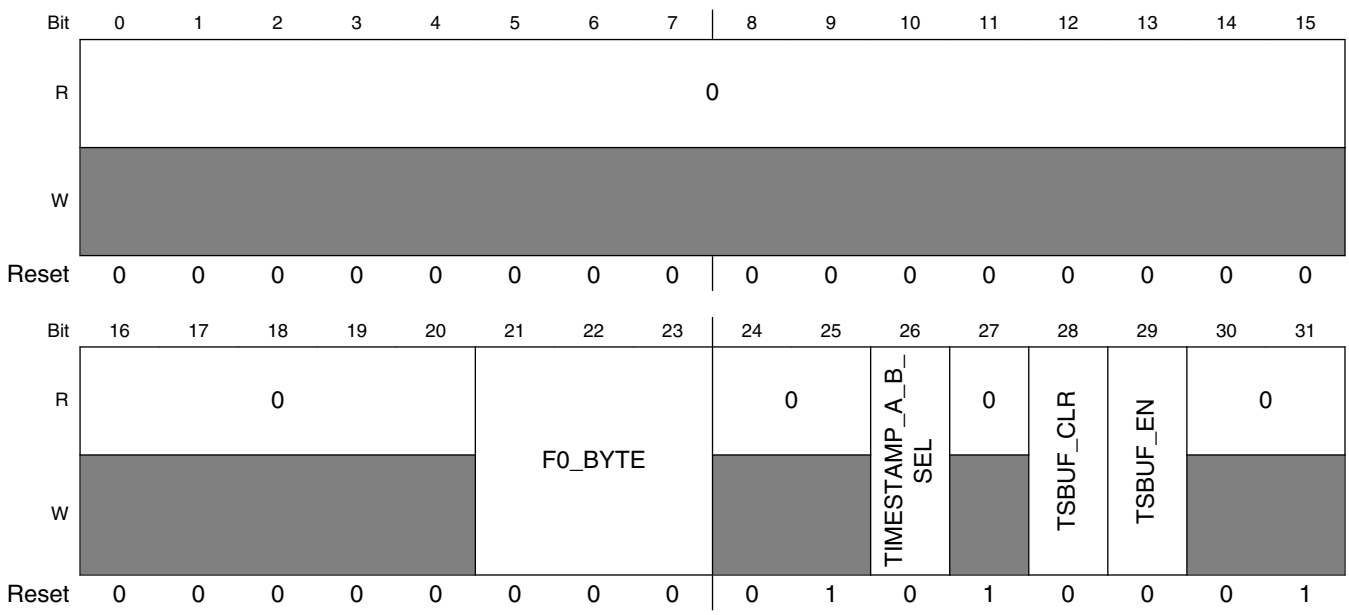
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	DIRCMD_BYTE3[7:0]								DIRCMD_BYTE2[7:0]								DIRCMD_BYTE1[7:0]								DIRCMD_BYTE0[7:0]							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5S_DIRCMD field descriptions

Field	Description
0–7 DIRCMD_ BYTE3[7:0]	Byte3 of the Direct Command. The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **NOTE:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is “1”.
8–15 DIRCMD_ BYTE2[7:0]	Byte2 of the Direct Command. The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **NOTE:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is “1”.
16–23 DIRCMD_ BYTE1[7:0]	Byte1 of the Direct Command. The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **NOTE:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is “1”.
24–31 DIRCMD_ BYTE0[7:0]	Byte0 of the Direct Command. The Direct Command is a special ECU to Sensor command that is directly written by the CPU for transmission to the UART. **NOTE:** These bits can also be written in the PS_NORMAL mode.These bits can only be written when the PS_GLSR[DIRCMD_RDY] is “1”.

57.4.30 PSI5-S channel 0 message configuration register A (PSI5S_MSGA_CH0)

Address: FBF7_4000h base + 16Ch offset = FBF7_416Ch



PSI5S_MSGA_CH0 field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 F0_BYTE	Number of UART bytes comprising one UART packet. Applicable only to special messages having CID = 0 in their Message Header. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled and a message with the corresponding frame ID is not expected to occur. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TIMESTAMP_A_B_SEL	Whether the Timestamp corresponding to TimeStamp Counter A or B, is appended to messages targetted for Channel0: 0 Timestamp counter A 1 Timestamp counter B
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared, the buffer remains clear till the event to capture time stamp is triggered. This bit is one shot and is always read as "0". **NOTE:** This bit is also writeable in PS_NORMAL mode. 1 TimeStamp buffer is cleared.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value "0" or is refreshed on a timestamp "capture event" 0 Timestamp buffer maintains value "0" 1 Timestamp buffer responds to a "capture event" and captures the respective timestamp value.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

PSI5S_MBOX_SR_CH0 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 F1_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when an unrecoverable message(with the CID = 0 and FID=1) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC1) by the DMA , has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC1) by the DMA , has one or more _ERR bits set.
27 F1_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode. 0 No overwrite of unread message in MBOX0,LOC1. 1 Indicates that there is an unread message stored in MBOX0,LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.
28 F1_READ	MBOX0,LOC1 is reserved for any unrecoverable message(XCRC_ERR has occurred or it is an "illegal message"). It can correspond to any channel from 1 to 7. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode. 0 No unread message in MBOX0,LOC1. 1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX0,LOC1 by the DMA.
29 F0_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when a transceiver message(with the CID = 0 and FID=0) is read from the MRU_BUF2. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC0) by the DMA , has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC0) by the DMA , has one or more _ERR bits set.
30 F0_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode. 0 No overwrite of unread message in MBOX0,LOC0. 1 Indicates that there is an unread message stored in MBOX0,LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.
31 F0_READ	MBOX0,LOC0 is reserved for a transceiver message . It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode.

Table continues on the next page...

PSI5S_MBOX_SR_CH0 field descriptions (continued)

Field	Description
	0 No unread message in MBOX0,LOC0. 1 It indicates that the message that has just been read from PS_MRU_BUF2 will be stored in MBOX0,LOC0 by the DMA.

57.4.33 PSI5-S channel message configuration register A (PSI5S_MSGA_CH*n*)

PSI5S_MSGA_CH*n* field descriptions

Field	Description
0 L_PC_EN	Selects whether the parity/CRC selection for a PSI5 message is to be controlled globally on a channel basis (through the G_PC bits) or locally on a per frame basis (through the L_PC[frame] bits) 0 Parity/CRC option controlled globally through the G_PC bit 1 Parity/CRC option controlled locally through the L_PC[frame] bits individually for message of each frame.
1–3 F5_BYTE	Number of bytes in UART packet for message corresponding to frame 5. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F5_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
4 L_PC5	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message

Table continues on the next page...

PSI5S_MSGA_CH*n* field descriptions (continued)

Field	Description
	0 Parity selected for message for frame5 1 CRC selected for PSI5 message for frame5.
5–7 F4_BYTE	Number of bytes in UART packet for message corresponding to frame 4. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F4_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
8 L_PC4	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame4 1 CRC selected for PSI5 message for frame4
9–11 F3_BYTE	Number of bytes in UART packet for message corresponding to frame 3. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F3_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
12 L_PC3	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame3 1 CRC selected for PSI5 message for frame3.
13–15 F2_BYTE	Number of bytes in UART packet for message corresponding to frame 2. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F2_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
16 L_PC2	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame2 1 CRC selected for PSI5 message for frame2.
17–19 F1_BYTE	Number of bytes in UART packet for message corresponding to frame 1. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F1_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
20 L_PC1	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame1 1 CRC selected for PSI5 message for frame1

Table continues on the next page...

PSI5S_MSGA_CH*n* field descriptions (continued)

Field	Description
21–23 F0_BYTE	Number of bytes in UART packet for message corresponding to frame 0. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F0_payload] is immaterial. Please see the information in PSI5-S LIN Fractional Baud Rate Register (PSI5S_LINFBRR) that explains the recalculation of Fn_bytes.
24 L_PC0	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame0 1 CRC selected for PSI5 message for frame0.
25 MODE	This bit selects the operating modes between sync and async for the channel. 0 Synchronous 1 Asynchronous
26 TIME_STAMP_A_B_SEL	Decides whether Timestamp Counter A or B, value is captured in the local timestamp buffer, whenever a "capture event" occurs: 0 Timestamp counter A 1 Timestamp counter B.
27 TMSG_TCMD	Whether the timestamp is recorded when the message is received or when the channel command is moved from the TxFIFO to the UART Tx register (emulates a sync pulse) 0 Timestamp recorded based on "emulated" sync pulse. 1 Timestamp recorded based on message header byte received
28 TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared, the buffer remains clear till the event to capture time stamp is triggered. This bit is one shot and is always read as "0". **NOTE:** This bit is also writeable in PS_NORMAL mode. 1 TimeStamp buffer is cleared.
29 TSBUF_EN	This bit controls whether timestamp buffer maintains a value "0" or is refreshed on a timestamp "capture event" 0 Timestamp buffer maintains value "0" 1 Timestamp buffer responds to a "capture event" and captures the respective timestamp value.
30 G_PC	This bit globally selects the Parity or the CRC option for all the Frames of that particular channel provided L_PC_EN is set "0" 0 Parity option selected globally for messages of all frames. 1 CRC option selected globally for messages of all frames.
31 CH_EN	PSI5 Channel Enable. This bit decides if the IP takes the data belonging to the specific channel as "legal" or "illegal". 0 Concerned PSI5 channel is disabled.Any data occurring with a CID value of a disabled channel is treated as an "illegal message" and send to Channel 0 unrecoverable message area(MBOX0,LOC1) 1 Concerned PSI5 channel is enabled.Any data occurring with a CID value of an enabled channel can either be treated as "legal" or "illegal". Please see PSI5-S Message extraction for the definition of legal

Table continues on the next page...

PSI5S_MSGA_CH*n* field descriptions (continued)

Field	Description
	and illegal messages. Legal messages are sent to MBOXCID,LOCFID while illegal messages are sent to MBOX0,LOC1

57.4.34 PSI5-S channel message configuration register B (PSI5S_MSGB_CH*n*)

NOTE

Fn_byte recalculation

The IP expects legal values to be programmed for Fn_byte field. If this is not followed then the IP reprogrammes the registers with default values. Whenever the value of “Fn_byte” field becomes 1 or 2 it is defaulted to 3 and value of 7 is defaulted to 6. This updation happens once the IP enters the PS_NORMAL mode.

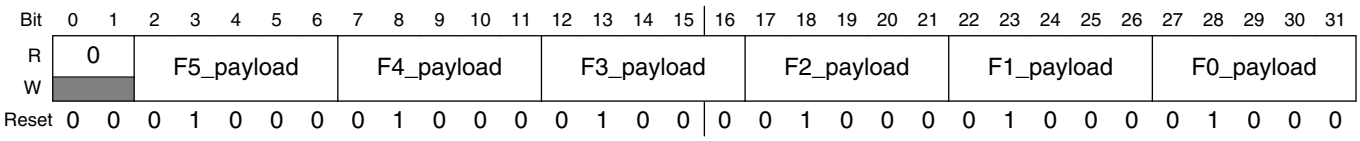
In addition to the above , the following checks are also performed.

By default the IP will expect that there is coherence between the expected number of bytes calculated through the “minUARTbytes” and the number of bytes in the “Fn_byte” field. Please see Figure 57-5 for definition of “minUARTbytes”. If there is no coherence (i.e. the above two calculations do not match) then the IP does the following recalculation:

- When Programmed Fn_byte > “minUARTbytes” , then the IP will expect that the additional extra bytes would be stuffed with 0s from the transceiver. Rest of the checking will be done as described in PSI5-S "Recoverable and Unrecoverable" Messages Structure.
- When Fn_byte < “minUARTbytes”, then the “Fn_bytes” is internally “increased” such that the expanded “Fn_bytes” is now equal to minUARTbytes”. Please see Figure 57-5 for definition of “minUARTbytes”. Using this expanded “Fn_bytes” value the message that would be arriving is analyzed. This would mean that no data bits are lost. Rest of the checking will be done as described in PSI5-S "Recoverable and Unrecoverable" Messages Structure.

The “recaculated” Fn_byte field is automatically updated by the IP once the IP enters the NORMAL mode of operation. For the subsequent occurence in the document , all references to “Fn_byte” would mean the recalculated value of “Fn_byte”.

Address: FBF7_4000h base + 194h offset + (60d × i), where i=0d to 6d



PSI5S_MSGB_CH*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–6 F5_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 5. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
7–11 F4_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 4. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
12–16 F3_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 3. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
17–21 F2_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 2. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
22–26 F1_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 1. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
27–31 F0_payload	Number of bits in the Payload region of the PSI5 message corresponding to frame 0. Legal values are between 8 and 28. Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

PSI5S_MBOX_SR_CH*n* field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 F5_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message(with the CID = n and FID=5) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC5) by the DMA, has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC5) by the DMA, has one or more _ERR bits set.
15 F5_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode.

Table continues on the next page...

PSI5S_MBOX_SR_CH*n* field descriptions (continued)

Field	Description
	0 No overwrite of unread message in MBOX[n],LOC5. 1 Indicates that there is an unread message stored in MBOX[n],LOC5 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.
16 F5_READ	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode. 0 No unread message in MBOX[n],LOC5. 1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC5.
17 F4_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ registe. It is updated when the corresponding message(with the CID = n and FID=4) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC4) by the DMA , has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC4) by the DMA , has one or more _ERR bits set.
18 F4_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode. 0 No overwrite of unread message in MBOX[n],LOC4. 1 Indicates that there is an unread message stored in MBOX[n],LOC4 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.
19 F4_READ	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode. 0 No unread message in MBOX[n],LOC4. 1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC4.
20 F3_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message(with the CID = n and FID=3) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC3. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC3) by the DMA, has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC3) by the DMA, has one or more _ERR bits set.
21 F3_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC3. This bit is also writeable in ps_normal mode. 0 No overwrite of unread message in MBOX[n],LOC3. 1 Indicates that there is an unread message stored in MBOX[n],LOC3 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.

Field	Description
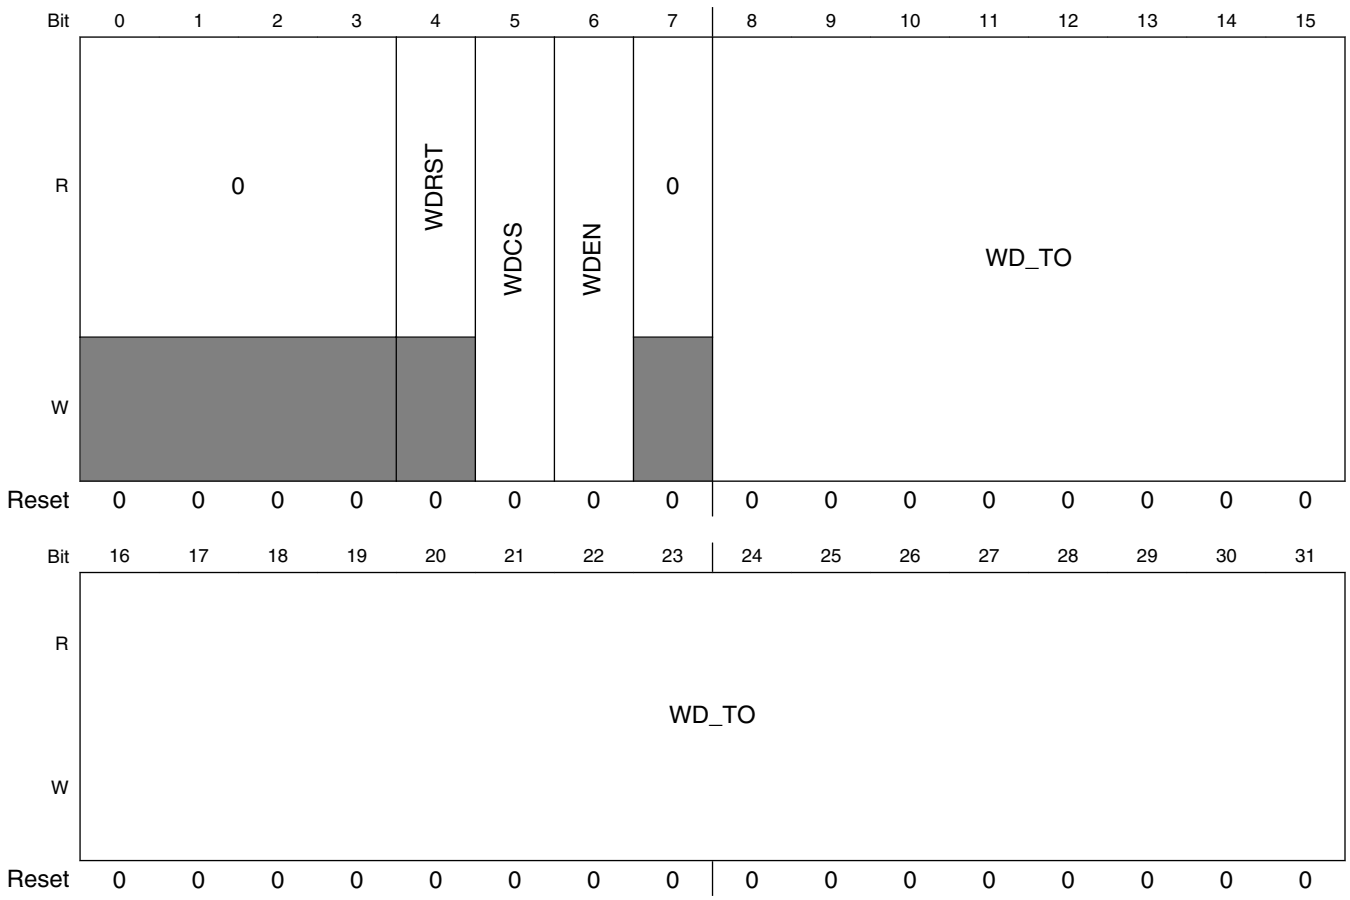
	0 No unread message in MBOX[n],LOC1. 1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC1.
29 F0_ERR	This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register. It is updated when the corresponding message(with the CID = n and FID=0) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode. Please refer to Figure 57-18 also. 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC0) by the DMA , has ALL the "_ERR" bits as "0". 1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC0) by the DMA , has one or more _ERR bits set.
30 F0_OV	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode. 0 No overwrite of unread message in MBOX[n],LOC0. 1 Indicates that there is an unread message stored in MBOX[n],LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA.
31 F0_READ	It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode. 0 No unread message in MBOX[n],LOC0. 1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC0.

57.4.36 PSI5-S channel watchdog configuration register (PSI5S_WD_CFGR_CH*n*)

Address: FBF7_4000h base + 1A0h offset + (60d × i), where i=0d to 6d



PSI5S_WD_CFGR_CH*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WDRST	Resets watchdog counter for the channel This bit is one shot and is also writable in ps_normal mode. It is always read as 0. It will reset the watchdog counter and the counter will be reloaded with the value of WD_TO and automatically start counting again.
5 WDCS	This will select either GTM or module clock for watchdog counter of the channel. Please see Figure 57-21. 0 ipg_clk_ps_wd Clock 1 gtm_trig is selected as the clock.
6 WDEN	The watchdog counter for each channel can be started, stopped. This bit is also writable in ps_normal mode

Table continues on the next page...

PSI5S_WD_CFGR_CH*n* field descriptions (continued)

Field	Description
	0 watchdog counter stopped. It maintains its value. 1 watchdog counter started
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 WD_TO	This indicates the watchdog time out value. The watchdog generates an overrun error, in case the watchdog is not refreshed before the watchdog counter reached the WD_TO value. The Watchdog is refreshed in a different manner depending on whether the PSI5-S channel is in asynchronous mode or synchronous mode as described below: In Asynchronous mode: As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled, then the counter starts immediately. Whether the WD has to be "refreshed" or "not to be refreshed", is analyzed when the XCRC is calculated. In case the XCRC is correct, the watchdog is refreshed (It is not STOPPED), else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In case of watchdog overrun error, the counter is refreshed. In Synchronous Mode: As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled, then the counter starts immediately. Thereby, it is re-loaded, either on the occurence of a sync pulse or the watchdog overrun error. In case the event for this load is the Sync Pulse, then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured(enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FFID_byte] is not equal to “0”. The packet counter is, however, incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured“, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered. In both the above modes, the watchdog can always be refreshed using a software reload. **NOTE:** The watchdog counter is enabled ONLY if the channel is enabled.

57.4.37 PSI5-S DDSR Trigger offset register channel (PSI5S_DDTRIG_OFFR_CH*n*)

Address: FBF7_4000h base + 1A4h offset + (60d × i), where i=0d to 6d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PSI5S_DDTRIG_OFFR_CH*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PSI5S_DDTRIG_OFFR_CH*n* field descriptions (continued)

Field	Description
16–31 DDTRIG_OFFR	These bits configure the delay between the "shift trigger" of the various DDSRs across different channels. The value in this register governs the delay after which the specific DDSR would be triggered once the Global Shift trigger (PS_GLCR[GL_DDSR_TRIG]) is written to "1" and the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] is set to "1" for that channel. There is an internal counter which is clocked on the "ipg_clk_ps_ddtrig" clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The "start" of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register

57.4.38 PSI5-S DDSR Trigger period register channel (PSI5S_DDTRIG_PERR_CH*n*)

Address: FBF7_4000h base + 1A8h offset + (60d × i), where i=0d to 6d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																DDTRIG_PERR															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PSI5S_DDTRIG_PERR_CH*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 DDTRIG_PERR	These bits configure the "shift trigger" period for the DDSR of that specific channel. The value in this register governs the period with which the data for the DDSR of that particular channel would be shifted out. There is an internal counter which is clocked on the "ipg_clk_ps_ddtrig" clock. The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset, a shift trigger is generated for the DDSR. The "start" of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register . **NOTE:** This register should be programmed to be greater than or equal to 2.

57.4.39 PSI5-S ECU to Sensor Control Register (PSI5S_E2SCR_CH*n*)

The following table corresponds to the CMD_TYPE field of this register.

Table 57-5. CMD_TYPE meanings

CMD_TYPE	PSI5 Frame	Number of bits writable by the Application in the DDSR
"000" - 0	Short Frame with 31 "1s" as the start condition[1]	6 LSBs of DDSR_L
"001" - 1	Short Frame with 5 "0s" as the start condition[1]	6 LSBs of DDSR_L
"010" - 2	Long Frame with 31 "1s" as the start condition[1]	16 LSBs of DDSR_L
"011" - 3	Long Frame with 5 "0s" as the start condition[1]	16 LSBs of DDSR_L
"100" - 4	X-Long Frame with 31 "1s" as the start condition[1]	22 LSBs of DDSR_L
"101" - 5	X-Long Frame with 5 "0s" as the start condition[1].	22 LSBs of DDSR_L
"110" - 6	XX-Long	24 LSBs of DDSR_L
"111" - 7	Illegal	

1. The start condition (31 “1s” or 5 “0s”) is automatically taken care by the hardware and should NOT be written to the registers as part of the command; neither is this visible in any register.

Address: FBF7_4000h base + 1ACh offset + (60d × i), where i=0d to 6d

PSI5S_E2SCR_CH*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–5 CMD	Bits for the ECU-to-sensor "CMD" format. They refer to the command send to the UART Tx logic, when a "1" is shifted from the DDSR register **NOTE:** This bit is writable only in PS_CONFIG mode.

Table continues on the next page...

PSI5S_E2SCR_CH*n* field descriptions (continued)

Field	Description
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–11 ACMD	Bits for the ECU-to-sensor "ACMD" format. They refer to the command send to the UART Tx logic, when a "0" is shifted from the DDSR register. **NOTE:** This bit is writable only in PS_CONFIG mode.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CH_TRIG	This controls that the DDSR of the specific channel is triggered locally. This bit controls the shifting when PS_E2SCR_CHn[GL_TRIG_SEL] is 0. **NOTE:** This bit is also writable in PS_NORMAL mode. 0 Stop the DDSR from shifting the commands. The counters corresponding to DDTRIG_PERR and the DDTRIG_OFFR are reset. 1 Start the "shift trigger" of the DDSR.
15 GL_TRIG_SEL	This bit controls whether the DDSR shift trigger is a global trigger or a local channel trigger. **NOTE:** This bit is writable only in PS_CONFIG mode. 0 The DDSR shift trigger is a local channel trigger dependent on the bit CH_TRIG. 1 The DDSR shift trigger is a global triggerdependent on PS_GLCR[GL_DDSR_TRIG].
16 DEFAULT_SYNC	Decides the value to which the DDSR should default to when PS_E2SSR_CHn[DDSR_RDY] == 1. When DDSR_RDY == 1 then the default shift (whether it is CMD or ACMD) is based on the value of this bit. **NOTE:** This bit is writable only in PS_CONFIG mode
17 DDSR_SHIFT_SEL	DDSR Shift Selection: This is used to select the shift trigger for the DDSR registers. Please see Figure 57-21 for more details. 0 The shift trigger is from internal DDSR counters which are clocked from either the “gtm_trig” or the ipg_clk_ps_ddtrig. 1 The input signal “gtm_trig” directly acts as the shift trigger of the DDSR registers.
18 DDSR_CLR	Used for rejecting the contents of the DDSR register. As soon as this bit is written to "1" the contents of DDSR are immediately rejected and defaulted to "0" after the completion of the current ACMD or the CMD transmission. PS_E2SSR_CHn[DDSR_RDY] goes to 1 and value of PS_E2SCR_CHn[DEFAULT_SYNC] starts getting shifted. This bit is one shot (W1S). **NOTE:** This bit is also writable in PS_NORMAL mode.
19 DDSR_CLK_SEL	Selects which clock clocks shift logic of the DDSR, for shifting the bits for command transmission: 0 ipg_clk_ps_ddtrig Clock 1 gtm_trig is selected as the clock.
20 CMDTR_SW_CTRL	This bit decides that once the command is ready for transmission (indicated by the setting PS_E2SSR_CHn[CMDPR_BZY] to 1), then when should the actual transmission start: **NOTE:** This bit is also writable in PS_NORMAL mode.

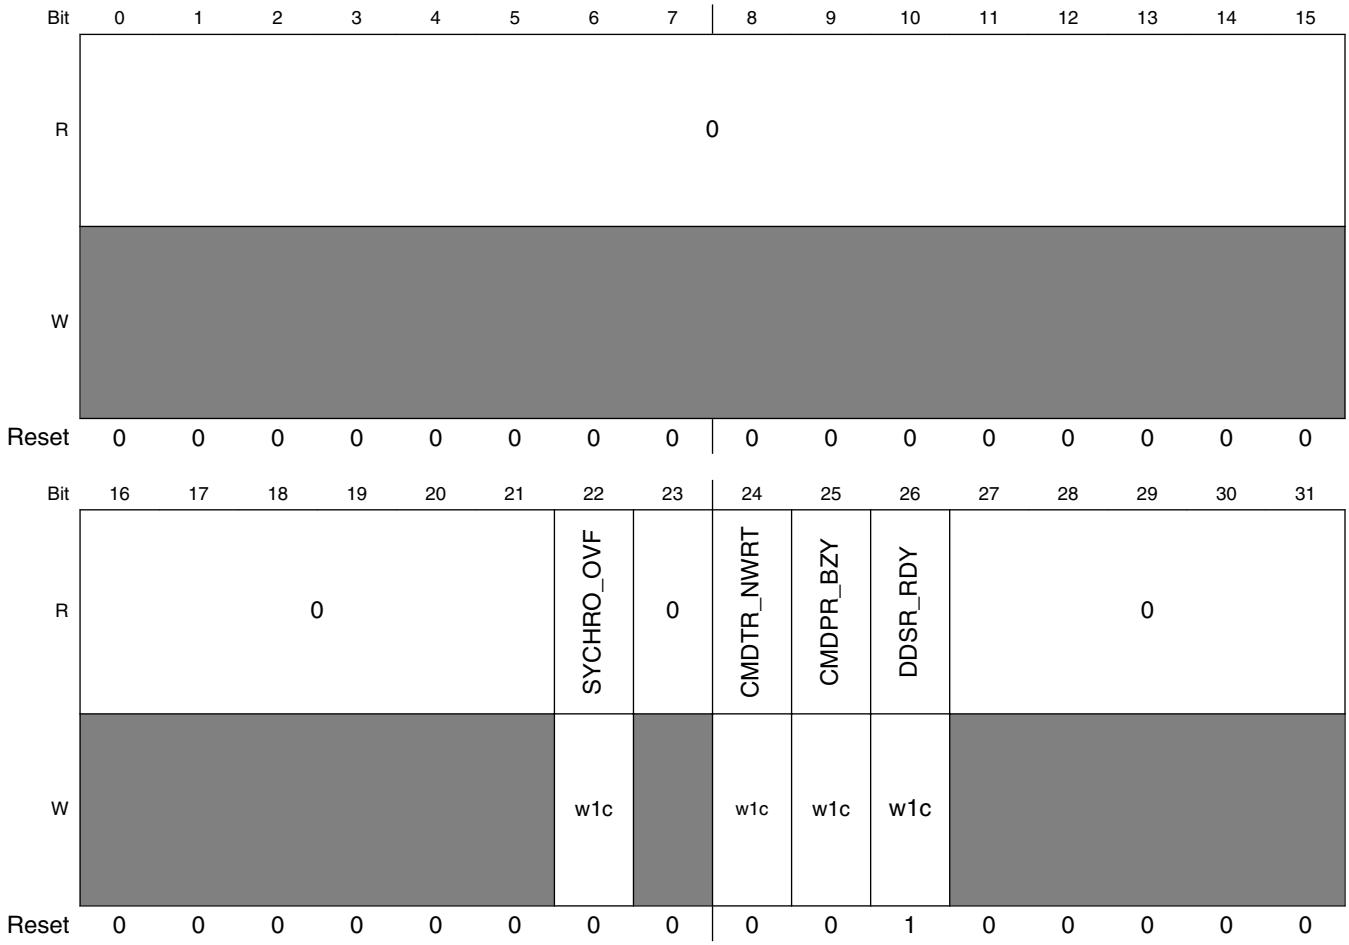
Table continues on the next page...

PSI5S_E2SCR_CH*n* field descriptions (continued)

Field	Description
	0 The actual transmission of command remains suspended, even though the command is ready in the DDSR. 1 The command transmission starts once the PS_E2SSR_CHn[CMDPR_BZY] becomes 1, and the internal shift logic is available.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 SYNCHRO_OVF_IE	Synchro overflow interrupt enable. 0 No interrupt is generated when PS_E2SSR_CHn[SYNCHRO_OVF] is set to “1”. 1 Generate an interrupt when PS_E2SSR_CHn[SYNCHRO_OVF] is set to “1”.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CMDTR_NWRT_IE	Interrupt Enable for DDSR being attempted to be written when it is still not empty i.e PS_E2SSR_CHn[DDSR_RDY] == 0 yet an attempt to write to DDSR is made. **NOTE:** This bit is also writable in PS_NORMAL mode. 0 Disable the interrupt 1 Enable the interrupt
25 CMDPR_BZY_IE	Interrupt Enable for DDSR getting updated with the internally processed complete command (with CRC, stuff bits, start bits getting appended) **NOTE:** This bit is also writable in PS_NORMAL mode. 0 Disable the interrupt 1 Enable the interrupt
26 DDSR_RDY_IE	Interrupt Enable for DDSR getting empty and ready for receiving new command. **NOTE:** This bit is also writable in PS_NORMAL mode 0 Disable the interrupt 1 Enable the interrupt
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 CMD_TYPE	See Table 57-5. The start condition (31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command; neither is this visible in any register.

57.4.40 PSI5-S ECU to Sensor Status Register (PSI5S_E2SSR_CH*n*)

Address: FBF7_4000h base + 1B0h offset + (60d × i), where i=0d to 6d



PSI5S_E2SSR_CH*n* field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 SYCHRO_OVF	This bit gets set whenever due to any reason(like too less DDTRIG period) , sync pulse of a channel comes before the previous sync pulse of the same channel has actually shifted its data. It can be used to detect sync pulse overflow. If PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to “1” then this can also be used to generate an interrupt on the ipi_ps_e2s_ch[n] line where “n” is the specific channel number. 0 No synch pulse overflow has occured in the specific channel. 1 Synch Pulse overflow has occured for the specific channel.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CMDTR_NWRT	Status of Command written to the DDSR:

Table continues on the next page...

PSI5S_E2SSR_CH*n* field descriptions (continued)

Field	Description
	0 Command written to the DDSR has been accepted for processing. 1 Command written to the DDSR is rejected as an attempt to write to it has been made when DDSR_RDY == 0.
25 CMDPR_BZY	Command Processing Busy Status. This bit along with the DDSR_RDY bit can be used to check the status of the command that is being processed in the DDSR. Note that when DDSR_RDY goes to "1" then this bit goes to "0". So it represents the above status conditions ONLY when DDSR_RDY is "0". 0 DDSR is busy with command processing. For this status DDSR_RDY should alse be read as "0". 1 DDSR is ready with the processed command complete with CRC/start bits/stuff bits.The transmission of the same would start if PS_E2SCR_CHn[CMDTR_SW_CTRL] == 1. For this status DDSR_RDY should also be read as "0".
26 DDSR_RDY	Status for DDSR getting empty and ready for receiving new command. 0 DDSR is not ready and is busy with either the command processing or the command transmission 1 DDSR is empty and ready for receiving a new command.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.41 PSI5-S channel1 ECU to Sensor Downstream Data Shift Register High (PSI5S_DDSR_H_CH*n*)

Address: FBF7_4000h base + 1B4h offset + (60d × i), where i=0d to 6d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

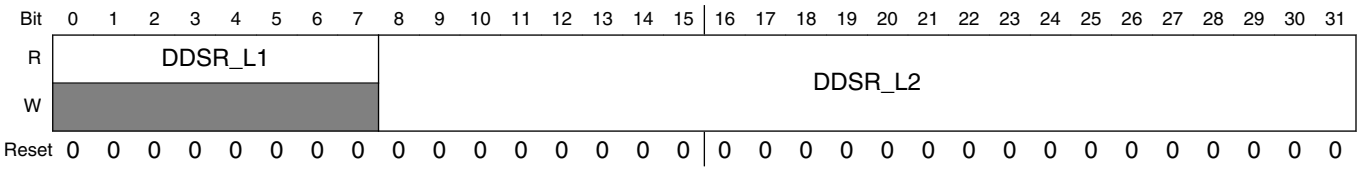
PSI5S_DDSR_H_CH*n* field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 DDSR_H	Upper High bits of the 43 bit complete DDSR register. These bits are updated by the hardware and software cannot write to these bits. They can be read by the software to check for the processed command after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1".

57.4.42 PSI5-S channel1 ECU to Sensor Downstream Data Shift Register Low (PSI5S_DDSR_L_CH*n*)

Address: FBF7_4000h base + 1B8h offset + (60d × i), where i=0d to 6d



PSI5S_DDSR_L_CH*n* field descriptions

Field	Description
0–7 DDSR_L1	8 bits of the DDSR_L that can only be read by the Application. These 8 bits are automatically updated by the hardware . They can be read by the software to check for the processed command after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1".
8–31 DDSR_L2	Lower 24 bits of the DDSR register that are written by the Application as well as updated by the hardware once the command processing is over. Though all the 24 bits can be wriiten by the software , yet only those number of bits as governed by PS_E2SCR_CHn[CMD_TYPE] are actually taken for processing. This register can be read by the software to check for the processed command, after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1". **NOTE:** These bits are also writable in the PS_NORMAL mode.

1. Register has significance in UART STANDLONE mode. This document would only mention the bit field names in the corresponding register description. For detailed bit description and the functioning of this register in UART modes(sleep,init and normal) belonging to UART STANDLONE mode, please refer to the separate documentation describing the standalone LINFLEX module.
2. Not all register bits are of this type. Please see the register bit description for more details.
3. Register Bits are automatically hardware cleared on read of any bit of this register.

57.5 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The UART compatible transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. Figure 57-4 shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

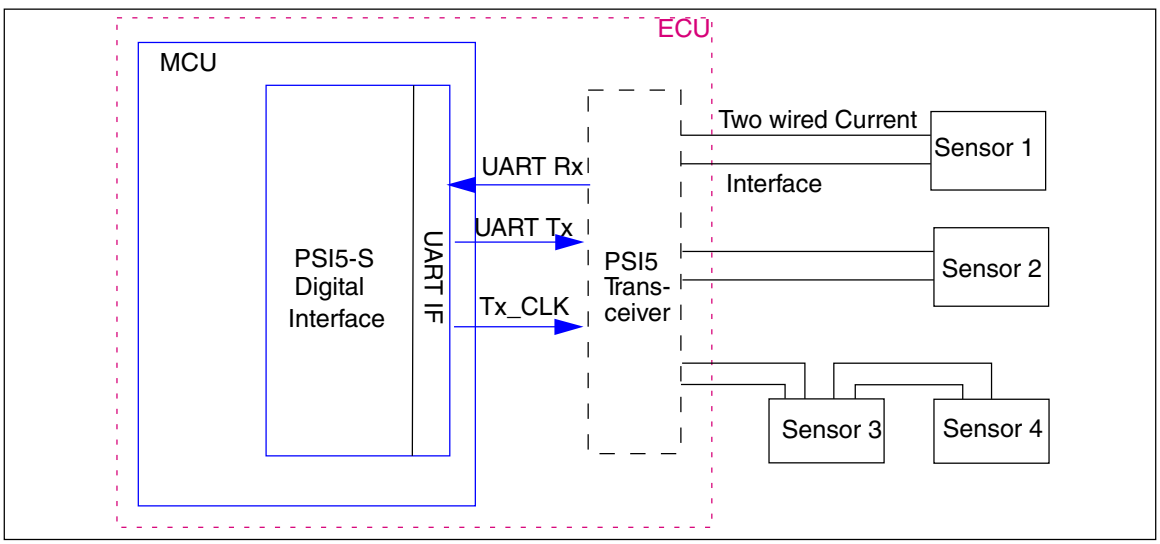

Figure 57-4. System setup (peripheral sensor connected to device)

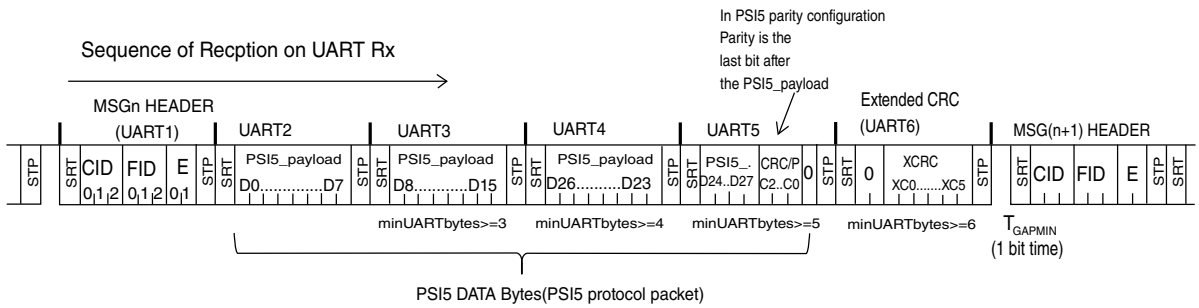
The ECU (Electronic Control Unit) comprises PSI5-S digital interface and the UART compatible PSI5 transceiver (present externally). The PSI5-S digital interface communicates with the PSI5 Transceiver though the UART interface as shown in Figure 57-4. When conducting the Sensor To ECU communication, the external transceiver converts the sensor data to the UART packet format before sending it to the PSI5-S module. The IP extracts the PSI5 Frames from the input UART Packet.

57.5.1 PSI5-S UART Message Structure

The transceiver sends a UART message packet consisting of between three to six UART bytes which contains information to allow rebuilding of the PSI5 message as well as the message itself and has a CRC which protects the complete packet (XCRC).

Each byte is made up of one start bit, eight data bits and one stop bit - no parity is included in the UART byte. Figure 57-5 shows the PSI5-S UART packet structure.



Total Message Payload(TMPL) = header_bits(8)+PSI5_payload(8-28bits) +CRC/P(3/1 bit)+XCRC(6bits)
minUARTbytes=CEIL(TMPL/8) where CEIL gives the largest integer greater than or equal to TMPL/8
PSI5_payload is the value obtained from PS_MSGA_CHn[Fn_payload] register bits.
XCRC(Extended CRC) can occupy any byte from UART3 to UART6 depending on the number of bytes received.

Figure 57-5. PSI5-S Packet Structure

The UART packet is made up of the following:

- MSGnHEADER: This is the message header byte which includes the indication of which channel the PSI5 message was received on (3-bit CID), the slot on that channel in which the message was received (3-bit FID) and transceiver error indication bits (2-bit E)
- PSI5 DATA bytes - minimum one, maximum four, depending on the data payload region of the PSI5 message (8 - 28 bits) and whether parity (1-bit) or CRC (3-bit) is configured for the PSI5 message. In the above example shown in Figure 57-5 it is taken as 28 bits and 4 UART bytes are shown(UART2-UART5). Messages having CID and FID both as "0s" do not have the CRC/Parity field in them. Such messages only have the message header, payload and the xcrc fields.
- XCRC- 6-bits - This is the extended CRC which protects the UART packet. Note that any bits between the end of the PSI5 message payload and the XCRC are 'stuffed' with '0's. This can also be seen in Figure 57-5. For details about XCRC handling please refer PSI5-S XCRC handling.
- Example to calculate the minUARTbytes (for messages NOT having CID and FID both as 0):
  - Fn_payload = 14 with PSI5 CRC option: TMPL = 8+14+3+6=31, minUARTbytes=CEIL(3.8)=4.

    These input data stream is interpreted as **UART1**(header),**UART2**(D[0:7]),**UART3**(D[8:13],CRC[2:1]), **UART4**(CRC[0],0,XCRC[0:5]).
  - Fn-payload = 13 with PSI5 Parity option: TMPL=8+13+1+6=28,minUARTbytes=CEIL(3.5)=4.

These input data stream is interpreted as
UART1(header),**UART2**(D[0:7]),**UART3**(D[8:12],Paritybit,00),
UART4(00,XCRC[0:5]).

Note the "0" stuffing between the parity bit and the XCRC. The XCRC is always in the last 6 bits of the last byte.

- Example to calculate the minUARTbytes (for messages having CID and FID both as 0):
  - F0_payload = 8: TMPL = 8+8+0+6=22, minUARTbytes=CEIL(2.75)=3

    These input data stream is interpreted as

    UART1(header),**UART2**(D[0:7]), **UART3**(00,XCRC[0:5]).
  - F0_payload = 10: TMPL = 8+10+0+6=24, minUARTbytes=CEIL(3)=3

    These input data stream is interpreted as

    UART1(header),**UART2**(D[0:7]), **UART3**(D[8:9],XCRC[0:5]).

57.5.2 PSI5-S Received Message handling

The message handling in the IP can be divided in three parts:

- PSI5 message extraction:

  This decides when a UART packet has been received with the correct header byte, and then how to extract the information from this UART packet form a complete PSI5 message.
- PSI5 "recoverable" and "unrecoverable messages":
- This differentiates the PSI5 messages received above, into "recoverable" and "unrecoverable" messages.
- PSI5 message storage and Mailbox transfer:

  This ensures the transfer of the PSI5 message to the correct location in the system RAM, once the PSI5 message has been correctly differentiated into "recoverable" and "unrecoverable" messages.Following sections detail the above 3 parts:

57.5.2.1 PSI5-S Message extraction

Once a UART start bit is detected after the idle timeout (the idle time between message packets on the UART interface i.e. the number of bit times between message packets in the range of at least 1 to 16, configurable in the UART module through the PS_UARTPTO register) has occurred, the UART bytes are subsequently sampled. They are being received by an internal state machine in the MRU, which checks for the formation of a complete UART packet, its coherence and extraction of the PSI5 message from the UART packet. Also please see Figure 57-6 for further understanding of this section.Each UART packet that is received can be considered as "recoverable" or "unrecoverable". Demarcation between the two is explained subsequently. Following are the sequence of steps performed as each UART byte is being received:

1. There is a 6 byte UART message input buffer into which the UART bytes from the UART Rx register are written as they are received. A 3-bit UART message counter is incremented on the reception of each byte in UART message packet i.e. each UART byte received between idle time counter indications.
2. All the subsequent UART bytes in the UART packet are stored internally till any of the following events occurs:
   - UART Timeout i.e. bus idle time is detected.
   - Framing Error from the UART.
   - Number of UART bytes that are received as reported through the UART message counter described in "1" above, exceed 6.
   - STOP mode request mode is asserted. Please see Stop mode for further details.
3. As soon as any of the events described in pt. 2 above occur, it is assumed that a complete UART packet has been received. The XCRC is then calculated immediately on the received UART packet. Please see PSI5-S XCRC handling for details about XCRC. If there is an XCRC error the message is assumed to be "unrecoverable" and it is sent to $MBOX_0$,LOC_1.The timestamp of the message is captured as is described in TimeStamp. The watchdog error is captured as is described in PSI5-S Watchdog Operation.
4. If there is NO XCRC error, then the CID and FID are extracted from the header byte, and the configured length of the message is determined from the configuration in PSI5 Channel*n* Message Configuration Register A. Following steps are performed.
   - The FID and the CID from the header byte is transferred directly to the PSI5 Frame status word.

- The transceiver error flags (E0,E1) are transferred directly to the PSI5 Frame status word
- The message is then analyzed to see whether it is "LEGAL" or "ILLEGAL".
- Following are the conditions for a "LEGAL" message:

  When the CID and the FID of the received message are both "0s" and PS_MSGA_CH0[F0_byte] is NOT "0" OR

  When the data of an Asynchronous Enabled channel is received with FID = 0 and PS_MSGA_CH_{CID}[F0_byte] is NOT "0" OR

  When the data of a Synchronous Enabled channel is received with legal FIDs(0 to 5) and if the received FID is such that the corresponding PS_MSGA_CH_{CID}[F_{FID}_byte] is NOT 0
- Any received message that does not satisfy the above condition is considered as "ILLEGAL". Illegal Messages are also treated as "unrecoverable" messages and are sent to $MBOX_0$,LOC_1.

  Example can be a message with CID as 0 but FID as 1(illegal because Channel0 is asynchronous and can only have FID equal to 0 messages) or a message received for an enabled synchronous channel but having an FID equal to 7(illegal because FID as 7 is not a legal Frame ID) etc.
- The timestamp of a Legal/Illegal message is captured as is described in TimeStamp. The watchdog error is captured as is described in PSI5-S Watchdog Operation.
- The number of UART bytes received in the UART message packet is compared with the number specified in Message Configuration Register A for the channel indicated by CID and FID in the header byte. If the number of bytes indicated by the message counter does not match PS_MSGA_CH_{CID}[F_{FID}_byte] field, then the status bit N_Err within the PSI5 Frame status word is set. The above "number of bytes received" check is not carried out for an "illegal message".

5. The PSI5 message payload is checked using the PSI5 CRC or parity as per the configuration. Whether the CRC or parity check is correct or not, the PSI5 message payload is written to the PSI5 Sensor Data word and the CRC or parity is written to the PSI5 Frame Status word. Note that the messages which have CID and FID both as "0", are not checked for CRC or parity error. The CRC/Parity error status bits remain "0" for such messages.This above check is NOT done for "illegal messages".

57.5.2.2 PSI5-S "Recoverable and Unrecoverable" Messages

Based on PSI5-S Message extraction, a message is considered "unrecoverable", if the XCRC is incorrect or it is an "illegal message", else the message is considered "recoverable". "Unrecoverable" message indicates that an error has been detected during the assembling phase of the UART packet i.e., during the formation of the UART packet from the individual UART bytes. "Unrecoverable" messages are always stored in PSI5 mailbox $MBOX_0$,LOC_1 in system RAM. "Recoverable" messages are always stored in the Mailbox location pointed out by the CIDn and the corresponding FID fields.

Figure 57-6 describes the treatment of the "Recoverable" and "Unrecoverable" messages. It also details the setting of the various error flags. The various cases for a new PSI5 message reception are:

- Idle Timeout occurence.
- Framing Error Occurence.

  As soon as a framing error has occured , all the UART packets sampled till that instance are assembled to form a PSI5 packet and are transferred to the MRU buffer. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.

- Number of UART bytes recieved exceed 6.

  In this case, any UART bytes recieved after the 6th byte, are totally rejected by the internal PSI5-S state machine. The state machine starts sampling the next UART byte only after the occurrence of an idle Time Out from the UART or after a reset or if the mode of the IP is changed (PS_NORMAL to PS_CONFIG/PS_DISABLE/UART_STANDALONE and then back to PS_NORMAL) or if a stop mode is entered and then exited.

- STOP mode entry:

  Please refer Stop mode). Stop mode entry causes the flushing of the internal PSI5 message buffer and this event is treated like new message completion. Exiting from the stop mode resets the state machine and it becomes ready to respond to the next UART packet. The next UART packet is taken as the header byte of a new PSI5 message.The stop mode, as an event for a new PSI5 message formation is not shown in Figure 57-6.

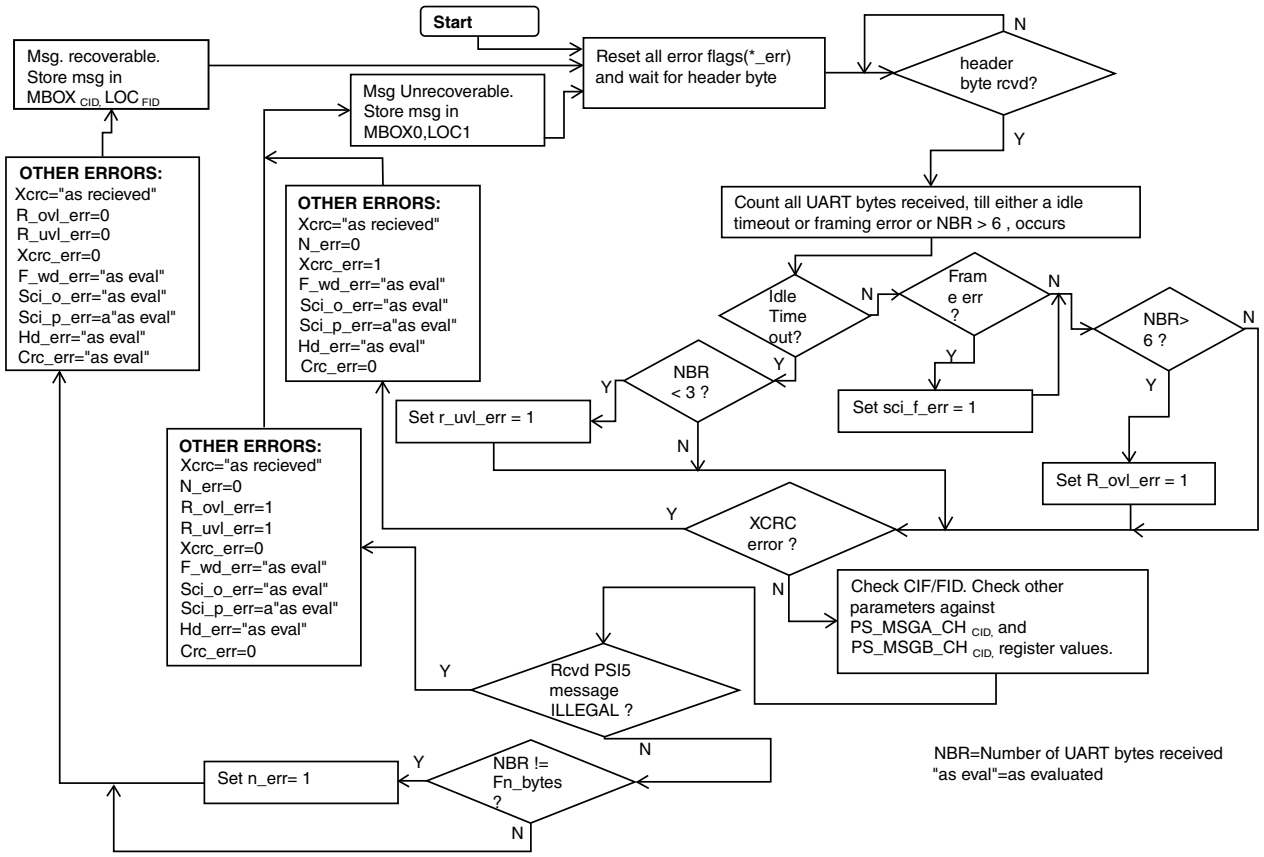


Figure 57-6. PSI5-S message handling and Error Flags

Once the message is correctly deciphered as "Recoverable" or "Unrecoverable" and the various error flags are set, then the Message is finally transferred to the MRU buf2. Once the corresponding message is read from the MRU buf2, the bits in the "PS_MBOX_SR_CH[n]" register are set appropriately. This aids the application to correctly read the concerned message from the Mailbox. PSI5-S Message Storage and Mailbox Transfer describes the PSI5 Message Storage and detection in detail.

57.5.2.3 PSI5-S Message Storage and Mailbox Transfer

Once the message has been correctly deciphered as "recoverable" or "unrecoverable" and the various status bits are set, it is then transferred to the MRU output buffer. The MRU output buffer is a 2 stage buffer differentiated as MRU Buf1 and MRU Buf2. The MRU buf1 is composed of 3,32 bit registers while the MRU buf2 is composed of 4, 32bit registers. Figure 57-7 shows the structure of MRU buf1. It is composed of three internal registers. These registers are not in the addressable space of the IP. When the internal state machine has correctly decoded the PSI5 message, it is transferred to MRU buffer1. It serves to hold the PSI5 message until it is transferred to MRU buf2.

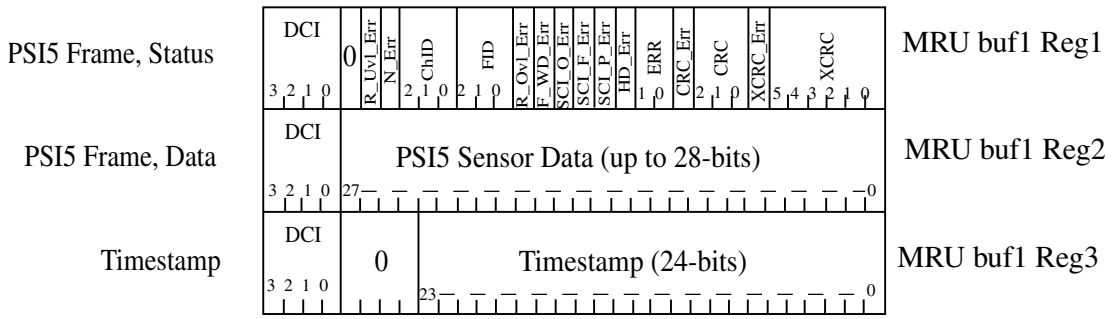

Figure 57-7. MRU buf1 structure

Figure 57-8 shows the structure of MRU buf2. MRU buf2 has one extra location as compared to MRU buf1. This extra location (MRU buf2 Reg0) contains the address of the Mailbox location, where the message contained in the rest of the three locations of MRU buffer2 is to be placed. This specific MRU buf2 structure aids the DMA to perform linked scatter-gather data transfer from the IP. The extra location in the MRU buf2 is automatically updated by the hardware and provides the destination address for the message. This destination is the Mailbox Address at which the message (stored in MRU buf2 (Reg1-Reg3) is to be transferred by the DMA. This destination address is calculated by the IP based on ChID in the message header (or ChID0 in the case of an unrecoverable message), the FID in the message header and Base address of the mailbox in system RAM (provided by CH_BASE_ADDR) register.

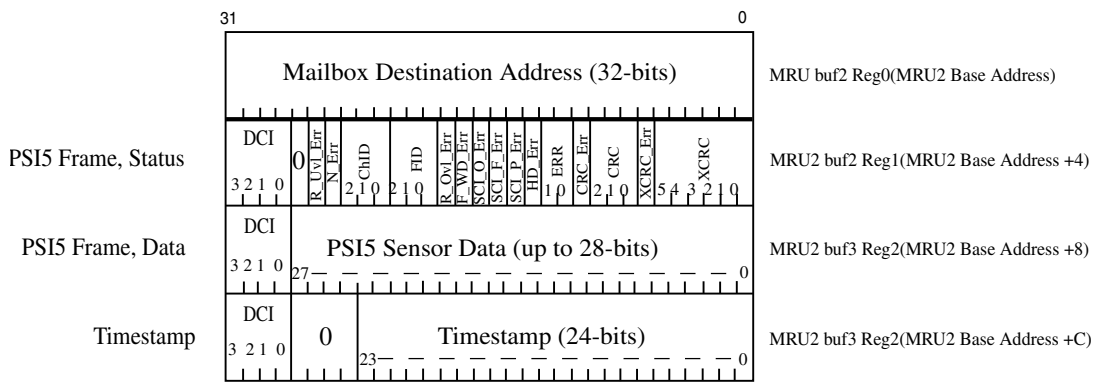

Figure 57-8. MRU buf2 structure

MRU buf2 is in the addressable space of the IP and is read by the DMA when the corresponding DMA request is asserted. The PSI5 message is transferred from the MRU buf1 to the MRU buf2 only when the MRU buf2 has been read completely by the DMA, i.e., all the 4 locations of the MRU buffer2 have been read by the DMA, for the corresponding PSI5 message.

Following are the sequence of operations that are performed, before the message in MRU buf2, gets ready to be accessed by the DMA:

1. The IP decodes the message as detailed in PSI5-S Message extraction and PSI5-S "Recoverable and Unrecoverable" Messages.
2. The corresponding message is available in MRU buf1 along with the various status bits latched internally in the IP. Externally, no interrupt is generated and neither are any status bit updated, when the message is transferred to MRU buf1.When the message is transferred to MRU buf1 a 3 bit DCI (data consistency indicator is added). The DCI is a 3-bit counter that is counted on a reception of each new message in MRU buf1.
3. The IP checks whether MRU buf2 is empty. If it is empty, then the MRU buf1 "Reg1 to Reg3" contents are transferred to the MRU buf2 "Reg1 to Reg3". The corresponding interrupts (except the Message Read from MRU) are also asserted based on the Interrupt Enable settings. Based on the PSI_CH_BASE_ADDR, the CID, FID values and whether an "unrecoverable message" has been received, the IP calculates the contents of MRU buf2 Reg0 register.
    - If CID == 0 then the "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0,LOC0.
    - If "unrecoverable message" is received then "MRU buf2 Reg0" contains the Mailbox Location corresponding to MBOX0,LOC1.
    - In all other cases "MRU buf2 Reg0" contains the Mailbox location corresponding to the $MBOX_{CID}$,LOC_{FID}.
4. Once the calculations in (3), are done the IP asserts the DMA request for Access1. In DMA Access 1, the DMA reads the first location (MRU buf2 Reg0) of the MRU buf2. This single 32-bit access writes the content of MRU buf2 Reg0 into the destination address for the DMA channel performing the second access (Access 2). Access 2 is initiated by the DMA once the Access1 transfer is complete. Access 2 is composed of 3,32-bit accesses of MRU buf2 and it writes the reconstructed PSI5 message along with its status and timestamp to the mailbox, starting at the destination address provided by Access 1.In Access2 the DMA reads the MRU buf2 Reg1,Reg2 and Reg3 in that order.
5. The application can read the PS_MBOX_SR_CH[n] register to get an indication to which mailbox location (or locations) the DMA would transfer the message. Note that "DMA transfer complete" bit/interrupt of the DMA indicates to the application, that the message read by the DMA from the IP has actually been written to the Mailbox.

6. The application should clear the corresponding "Fn_read" bits in the PS_MBOX_SR_CH[n] register once the application has read the corresponding message from the Mailbox. If a PSI5 message gets written to a Mailbox location, with "Fn_read" bit still set at the time at which the DMA has started the Acces1, then the corresponding "Fn_OV" bits are set in the PS_MBOX_SR_CH[n] register.
7. Reference to (3) above, if the MRU buf2 has a pending message and the MRU buf1 also has a message that is ready to be transferred to the MRU buf2 and then a new message gets ready to be written to MRU buf1, then the previous message in MRU buf1 gets overwritten by the new message. The MRU overwrite interrupt is also generated with the setting of the corresponding register bit in the PS_GLSR register. PS_GLSR register contains the CID and the FID of the message that got overwritten by the new message in MRU buf1.
8. When writing an unrecoverable message to the PSI5 mailbox CID0, with the XCRC_ERR bit set, the timestamp that will be used will be the one which is captured at the time XCRC_ERR bit is set. When the unrecoverable message is due to an "illegal message", then the timestamp used would be the one which is captured on the reception of any message i.e., always captured at the end of the header byte of every message.
9. In Asynchronous mode, FID will always be configured to be "0" and the module will use the PSI5 Mailbox for the channel (identified by CID in header) as a ring buffer, incrementing the destination address for each message received and saving up to the last six messages received. The bits of the PS_MBOX_SR_CH[n] register will still indicate the status of each location of the Ring Buffer. The software has to still clear the six bits of this register when it reads the Mailbox location else the overwrite bits would be set in the PS_MBOX_SR_CH[n] register. The message identification mechanism allows software to identify the latest message received

57.5.2.4 PSI5-S Data Payload CRC Recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

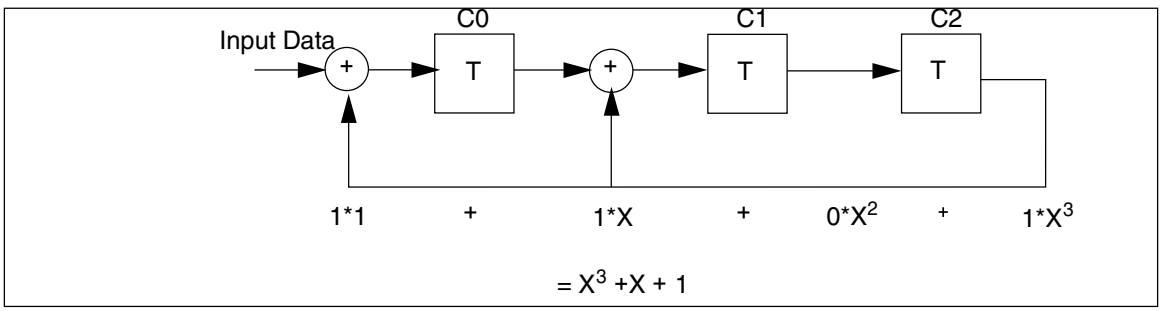

Figure 57-9. CRC calculation scheme

Table 57-7. CRC Calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 57-8. Transmitted and Received Sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 57-9. CRC Re-Calculation (At Receiver Side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 ® Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

57.5.2.5 PSI5-S XCRC handling

The XCRC calculation is triggered on any of the following events (which also indicate the reception of a new UART packet):

- UART idle timeout
- number of UART bytes exceed 6
- UART Framing error
- STOP mode assertion.Please see Stop mode.

When any of the above events occur, the internal XCRC calculator becomes active. Each UART byte that is received, passes through the XCRC calculator on a bit by bit basis, starting from the header byte to the expected XCRC byte. The XCRC is assumed to be the last 6 bits of the last UART byte that is received before the occurrence of any of the above events. Figure 57-10 shows the XCRC calculation algorithm.

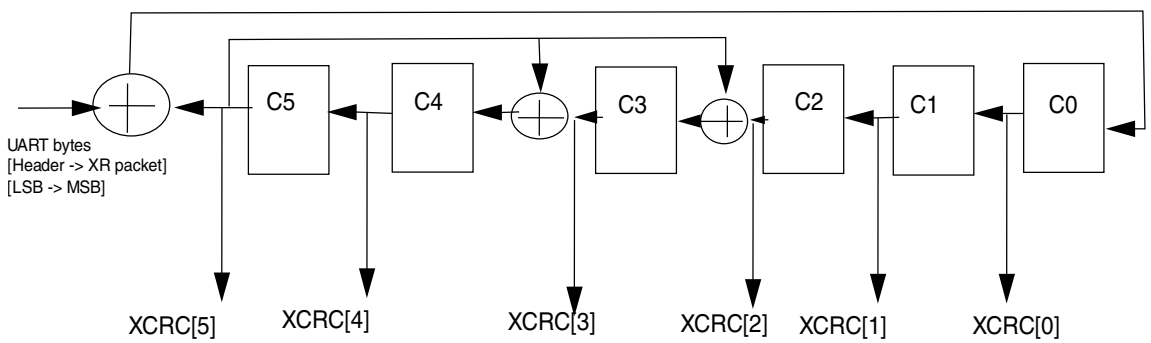

Figure 57-10. XCRC calculation

The UART bytes are shifted starting from the received header to data packets to the XCRC packet. Each of these UART bytes is shifted LSB first into this XCRC calculator. Once all the bytes as denoted by the Fn bytes have been received and the Fnth packet (XCRC) has been shifted completely through this XCRC calculator and if XCRC[5:0] is equal to "0" then it denotes that the XCRC check has passed else there is an XCRC error and the XCRC_ERR bit is set.

The CRC polynomial used is "x6+x4+x3+1" with a binary initialization value of XCRC[5:0] = "010101".

57.5.3 ECU-to-sensor communication

The IP send the commands for the ECU to Sensor communication in terms of UART bytes. It expects the external transceiver to correctly interpret the commands and then generate the appropriate logic 0 or logic 1 on the PSI5 bus. Following are the various PSI5-S ECU to Sensor commands supported by the IP, as shown in Figure 57-11.

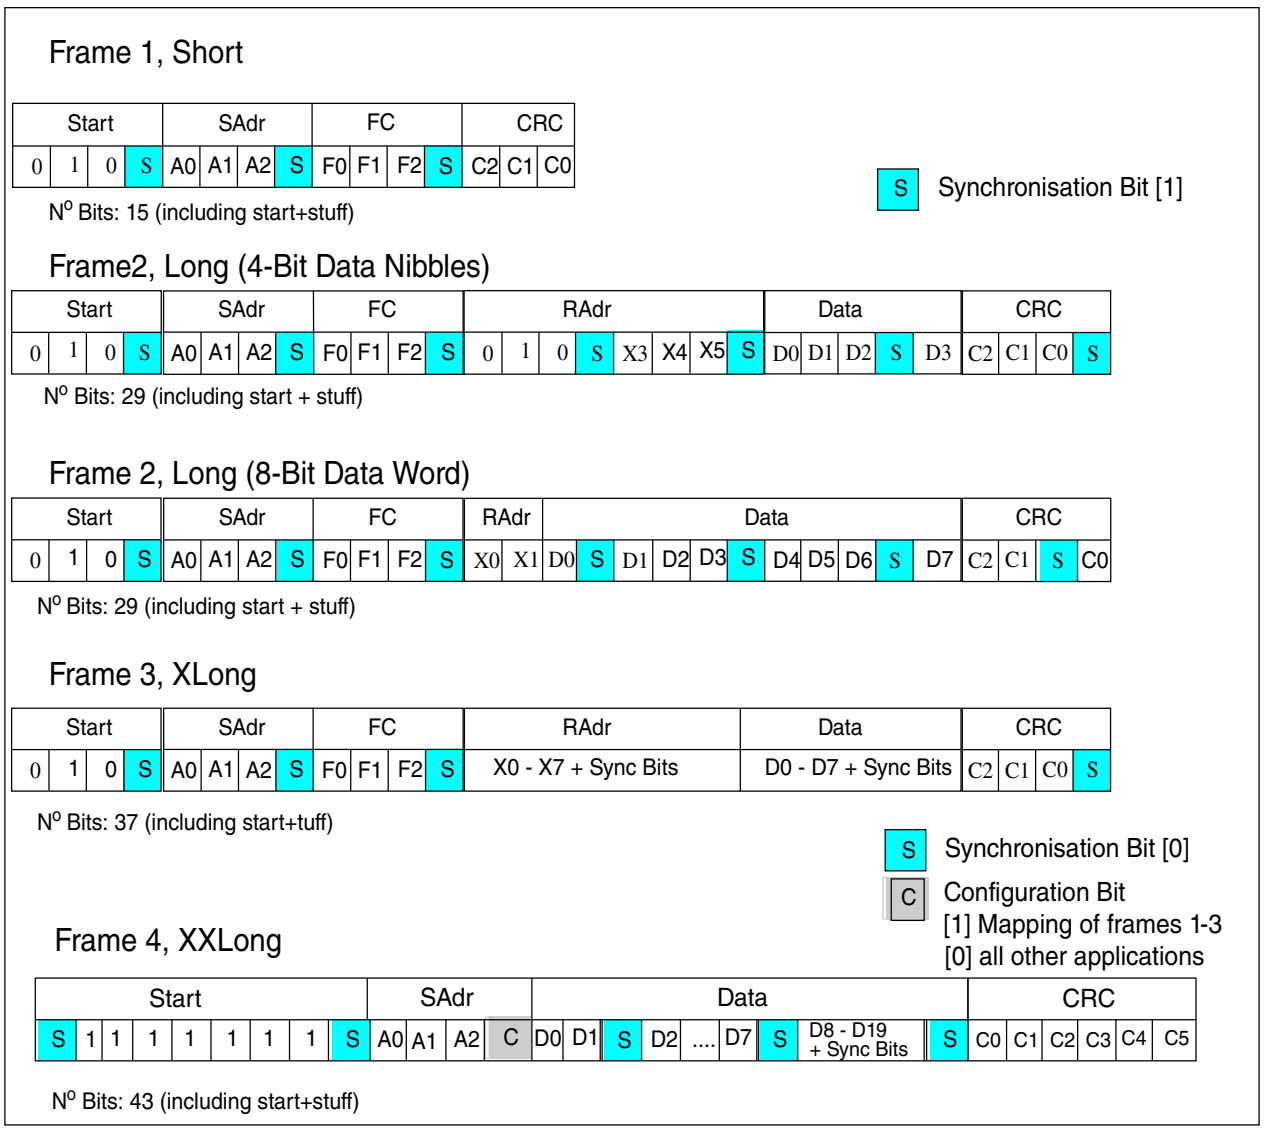

Figure 57-11. Standard Frame Formats Supported

- **Short:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- **"010",S, "A0,A1,A2",S, "F0,F1,F2",S, "C2,C1,C0"** where "010" is the start sequence "S" is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes and "C2-C0" is the CRC. Please refer Figure 57-11 for the frame structure.

- The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]….PS_DDSR[5],000) with PS_DDSR[0] being fed first in the CRC calculator.

- **Long(4bit Data Nibble)**: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- **"010",S, "A0,A1,A2",S, "F0,F1,F2",S, "X0,X1,X2",S, "X3,X4,X5, S, "D0,D1,D2", S,"D3,C2,C1",S, "C0"** where "010" is the start sequence "S" is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,"X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer Figure 57-11 for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0..X5,D0…D3,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]….PS_DDSR[15],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **Long(8bit Data Word)**: It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - **"010",S, "A0,A1,A2",S, "F0,F1,F2",S, "X0,X1,D0",S, "D1,D2,D3, S, "D4,D4,D6", S,"D7,C2,C1",S, "C0"** where "010" is the start sequence "S" is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,"X0-X1" is the Range Address, "D0-D7" is the data and "C2-C0" is the CRC.Please refer Figure 57-11 for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".

- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0..X1,D0…D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]….PS_DDSR[15],000) with PS_DDSR[0] being fed first in the CRC calculator.

- **X-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - **"010",S, "A0,A1,A2",S, "F0,F1,F2",S, "X0,X1,X2",S, "X3,X4,X5", S, "X6,X7,D0",S, "D1,D2,D3",S, "D4,D5,D6",S,"D7,C2,C1",S, "C0"** where "010" is the start sequence "S" is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,"X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer Figure 57-11 for the frame structure.
  - The CRC polynomial used is $x3 + x + 1$ with a binary initialization value of "111(C2:C0)".
  - The transmitter extends the data bits by three zeros (as MSBs).
  - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,F0..F2,X0…X7,D0…D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
  - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]….PS_DDSR[21],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **XX-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - **"011111110", "A0,A1,A2", "C", "D0,D1",S, "D2,D3,D4" D5,D6,D7, S, "D8,D9,D10,D11,D12,D13", S,"D14,D15,D16,D17,D18,D19",S, "C0,C1,C2,C3,C4,C5"** where "011111110" is the start sequence "S" is the stuff bit(0),A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Please refer Figure 57-11 for the frame structure.
  - The CRC polynomial used is $x6 + x4 + x3 + 1$ with a binary CRC initialization value 010101(C5:C0).
  - The transmitter extends the data bits by six zeros (as MSBs).

- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0…A2,D0..D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]….PS_DDSR[23],000000) with PS_DDSR[0] being fed first in the CRC calculator.

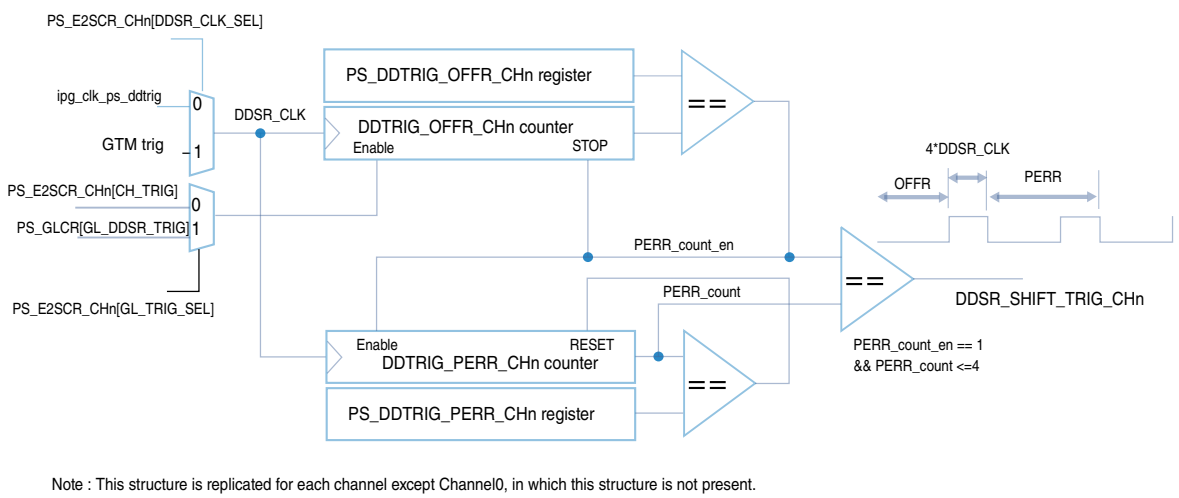
57.5.3.1 PSI5-S ECU to Sensor Command Handling

The ECU-to-Sensor commands can be written to the PSI5 IP in two ways:

1. Direct writing for the special Transceiver commands: This can be used by the software to directly write the transceiver/diagnostic commands without using the internal sync pulse generators. Following procedure should be adopted for this:
   - Application configures the PS_GLCR[DIRCMD_LEN] register for deciding the length of the direct command that is to be written. The length can be 1, 2, or 4 bytes.
   - Application will check for the status flag PS_GLSR[DIRCMD_RDY]. A “1” here would mean that the PS_DIRCMD register is empty and ready to accept the Direct write command. Trying to write to PS_DIRCMD while DIRCMD_RDY is “0”, will be rejected without any information. If the PS_GLCR[IE_DIRCMD_RDY] bit is set to “1” then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line, whenever the PS_GLSR[DIRCMD_RDY] bit goes to “1”.
   - The application then writes the Direct Command to the PS_DIRCMD register. Depending on the PS_GLCR[DIRCMD_LEN] register, only the specific bytes are considered for transmission. Other bytes are ignored.
   - A “w1c” to the PS_GLSR[DIRCMD_RDY] bit would queue the above direct command for UART transmission with the highest priority; and thereafter as soon as any pending current transmission is complete, the internal state machine would start the transfer of this direct command to the UART Tx line. All other channels would internally buffer their pending DDSR transmission and resume only once the above transmission is over.
   - Once the Direct transmission is complete the PS_GLSR[DIRCMD_RDY] status bit would go to “1” and if the corresponding interrupt is enabled in the PS_GLCR register, then an interrupt will also be generated on the “ipi_ps_glbl” interrupt line.
2. Writing to the DDSR (Downstream Data Shift Register):

In this case the application writes the basic command to the DDSR_L and the IP will add the start bits/start condition/CRC/stuff bits before sending this command to the UART Tx FIFO. Following are the details:

- There is one DDSR per channel. The default value of DDSR is dependent on the PS_E2SCR[CMD_TYPE] value. DDSR is composed of two sub registers - DDSR_H (Higher) and DDSR_L (Lower). The application can only write to DDSR_L. The number of bits that can be written in the DDSR_L is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] bit values. Note that Channel0 does not have any DDSR, as it does not support any ECU-to-Sensor communication.
- The "shift trigger" of the DDSR is governed by the values programmed in the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register and the frequency of ipg_clk_ps_ddtrig clock.
- Once the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] are correctly programmed and each channel is programmed to respond to the selected shift trigger (local trigger or global trigger is decided via the bit PS_E2SCR_CHn[GL_TRIG_SEL]), the software has to write to the Global DDSR trigger bit, PS_GLCR[GL_DDSR_TRIG] or the PS_E2CR[CH_TRIG] bit, so as to synchronously start the DDSR triggers of each channel or locally start the DDSR shift triggers of each channel. The DDSR trigger logic gets the trigger signal immediately but it responds after a delay as programmed in the PS_DDTRIG_OFFR_CH[n] register. The shift trigger period is governed by the value programed in the PS_DDTRIG_PERR_CH[n] register. Please see Figure 57-12 for the structure of the logic that generates the internal DDSR shift triggers.



Note : This structure is replicated for each channel except Channel0, in which this structure is not present.

Figure 57-12. DDSR internal shift trigger generator

- The number of bits of DDSR_L that can be written by the application, is dependent on the value of PS_E2SCR_CHn[CMD_TYPE] value.
- When PS_E2SSR_CHn[DDSR_RDY] == 1, then it indicates that the DDSR is empty and is ready to accept a new command. If the PS_E2SCR_CHn[DDSR_RDY_IE] == 1, then this results in the generation of interrupt on the "ipi_ps_e2s_ch[n]" line.
- Attempting to write to DDSR while PS_E2SSR_CHn[DDSR_RDY] == 0 results in the rejection of the new command and setting of the PS_E2SSR_CHn[CMD_NWRT] bit. If the PS_E2SCR_CHn[CMDTR_NWRT_IE] == 1, then this results in the generation of interrupt on the "ipi_ps_e2s_ch[n]" line.
- The application then writes the command to the PS_DDSR_L and writes a "w1c" to the PS_E2SCR_CHn[DDSR_RDY]. This indicates to the internal logic that the command is now ready for further processing. The clock that is used for shifting the contents of the DDSR can be configured through the PS_E2SCR_CHn[DDSR_CLK_SEL] register.
- Depending on the value of PS_E2SCR_CHn[CMD_TYPE], the internal logic adds the start bits/start condition/CRC/bit stuffing and updates the DDSR with the complete command, ready for transmission.
- Once this happens the PS_E2SSR_CHn[CMDPR_BZY] becomes "1". If the PS_E2SCR_CHn[CMDPR_BZY_IE] == 1, then this results in the generation of interrupt on the "ipi_ps_e2s_ch[n]" line. If PS_E2SCR[CMDTR_SW_CTRL] == 0, then the application can check the final value of the command in DDSR, that would actually be transmitted. Once the checking is complete, it can put the PS_E2SCR_CHn[CMDTR_SW_CTRL] to "1", to start the actual transmission. By default PS_E2SCR_CHn[CMDTR_SW_CTRL] is set to "1". Note that the start condition is not a part of the DDSR and its transmission is dependent on the value of the PS_E2SCR_CHn[CMD_TYPE] and is automatically taken care of, by the IP.
- Each bit of the command in DDSR, if it is "1", results in PS_E2SCR_CHn[CMD] being transferred to the UARTTX buffer or if it is "0", results in PS_E2SCR_CHn[ACMD] being transmitted to the UART-TX buffer. The "CMD" and the "ACMD" governs as to how the transceiver has to respond when it receives these values. These will specify to the transceiver whether it should send a short or long SYNC pulse on the PSI5 bus when the application wishes to write to the sensors.

- Once the complete command has been transmitted, the PS_E2SSR_CHn[DDSR_RDY] goes to "1" while PS_E2SSR_CHn[CMDPR_BZY] goes to "0".
- Once the PS_E2SSR_CHn[DDSR_RDY] goes to "1", then default "1s" or default "0s" are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE].
- When PS_E2SSR_CHn[DDSR_RDY] == 1, then it is possible to abort the current transmission by doing a "W1C" of the PS_E2SCR[DDSR_CLR] bit. As soon as this is done, the DDSR is reset to "0", PS_E2SSR_CHn[DDSR_RDY] goes to "1" while PS_E2SSR_CHn[CMDPR_BZY] goes to "0". Once the PS_E2SSR_CHn[DDSR_RDY] goes to "1", then default "1s" or default "0s" are transmitted, depending on the value of PS_E2SCR_CHn[CMD_TYPE]. Note that doing this, "W1C" does not have any effect on the CMD/ACMD transmission that is already under progress in the UART.

- The logic for processing the DDSR contents is shared among all the seven channels. It should be ensured by the software to correctly program the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register contents so that the none of the bits in the command get missed. Also, since (1) is possible, it is up to the application to ensure that the UART TX_BUFFER does not remain busy to the extent that some particular DDSR bit does not get the chance to be shifted out before it gets overwritten by some new DDSR bit.
- The approximate maximum time, beginning from when PS_E2SCR_CHn[DDSR_RDY] is made "0", to the time when the command is available for transmission is less than 1us, provided no other channel has an active command processing ongoing.If commands are written to multiple DDSR registers one after the other, then the time after which the particular channel will again get an access will increase. Note that the irrespective of the sequence in which the PS_E2SCR_CHn[DDSR_RDY] of the channels are cleared, the channels are always searched in a round robin fashion for the status of the respective DDSR_RDY bits. When the internal sequencer find the respective DDSR_RDY as "0" it starts the processing of the corresponding DDSR. The sequencer always goes as Channel1->Channel2->Channel3…Channel7->Channel1…
- The logic that shifts each bit of the DDSRs of each channel is shared among all the channels. When the shift trigger of a particular DDSR is received and if the UART TX Buffer is empty then the particular command bit is transmitted to the UART TX by the appropriate CMD/ACMD. It is possible that at one point of time, CMD/ACMD of more than one channel are pending to be transmitted to the UART TX. In this case the channel with a higher channel number will be given a priority. Thus if channel2 and channel1, both have a pending CMD/ACMD shift, then channel2 would be the first to get an access. Each pending channel would queue up for transmission. It has to be ensured by the software that the internal shift triggers generated through the PS_DDTRIG_PERR_CHn and PS_DDTRIG_OFFR_CHn registers are correctly spaced so that all the channels get an access to transmit their DDSR bits. If a command bit that is desired to be shifted encounters more than one shift triggers (because it did not get shifted on the previous shift trigger) then there is no indication for this loss of synchronization. In general, if the if PS_DDTRIG_PERR is programmed to be greater than 500us(which is a practical PSI5 sync pulse period) then it would be ensured that the bits are correctly transmitted even if all the channels simultaneously transmit their command bits.
- If a command bit that is desired to be shifted, encounters more than one shift triggers (because it did not get shifted on the previous shift trigger), then the PS_E2SSR_CHn[SYNCHRO_OVF] bit gets set, to indicate synchronization

overflow. An interrupt can also be generated if the PS_E2SCR_CHn[SYNCHRO_OVF_IE] bit is set to 1. In general, if PS_DDTRIG_PERR is programmed to be greater than 500 us (which is a practical PSI5 sync pulse period), then it would be ensured that the bits are correctly transmitted even if all the channels simultaneously transmit their command bits.

57.5.4 TimeStamp

The IP provides for two global 24-bit timestamp counters. Each can be clocked by either the module clock or the GTM trigger. The two timestamp counters are detailed as TimeStamp Counter A and B. Please see Figure 57-16. Following are the details:

1. Each channel has an internal TimeStamp buffer that can be configured to capture either the TS counter A or B when it encounters the "capture event". Provided there is no XCRC error in the message, then this Timestamp buffer is appended to the message when it is written to MRU buf1. When there is an XCRC error in the message, then Channel0 timestamp is appended. Please see point number (7) below.
2. The "captured event" for the timestamp buffer of each channel can either be when a "a valid message header is detected" or when "a Command (or Alternate Command) is moved from the UART Tx Buffer to the UART Tx shift register" corresponding to the channel for which this command is being shifted to the UART.
3. The TimeStamp Buffer can be enabled or disabled through the PS_MSGA_CHn[TSBUF_EN] bit. When the TimeStamp buffer is disabled then it no longer responds to "capture events" and always contains the value "0".
4. It is possible to reset each TimeStamp buffer by using the PS_MSGA_CHn[TSBUF_CLR] bit. As soon as this bit is written to "1" the TimeStamp buffer is reset to all "0s" and it remains in this state till it encounters a "capture event".
5. In the case when the reception of message is chosen as the trigger, the time stamp will be captured immediately after the header byte of the UART message packet has been received.
6. In the case when the move of CMD or ACMD from the internal UART Tx Buffer to the UART Tx shift register in the UART module is chosen as the trigger, the timestamp for the intended channel (indicated in the CIDn fields of CMD or ACMD) is valid for all frames received on a channel between moves of CMD or ACMD from the UART Tx Buffer to the UART Tx Register (i.e., for a PSI5 SYNC period).

7. When a XCRC error is detected in any message then the timestamp that is appended with the message is the Channel0 timestamp which is captured at the time when XCRC_ERR has been detected.
8. For "illegal messages", the timestamp value that is captured is the Channel0 Timestamp value, which is captured whenever "a valid message header for that illegal message is detected". Note that the definition of a "legal" or a "illegal" message applies to a PSI5 message only when the concerned UART packet has no XCRC error.
9. In addition to the timestamp buffers described in point number (1) above, there is a separate timestamp capture that occurs in case of a watchdog error. This timestamp is captured in the PS_WDGTSSR[WDGTS_STATUS] bits. The TimeStamp A or B (as programmed in the PS_MSGA_CHn[TIMESTAMP_A_B_SEL]) is captured as soon as the watchdog overrun error occurs for that channel. Please see Watchdog Error Status and Watchdog Timestamp status register (PS_WDGTSSR), for more details.

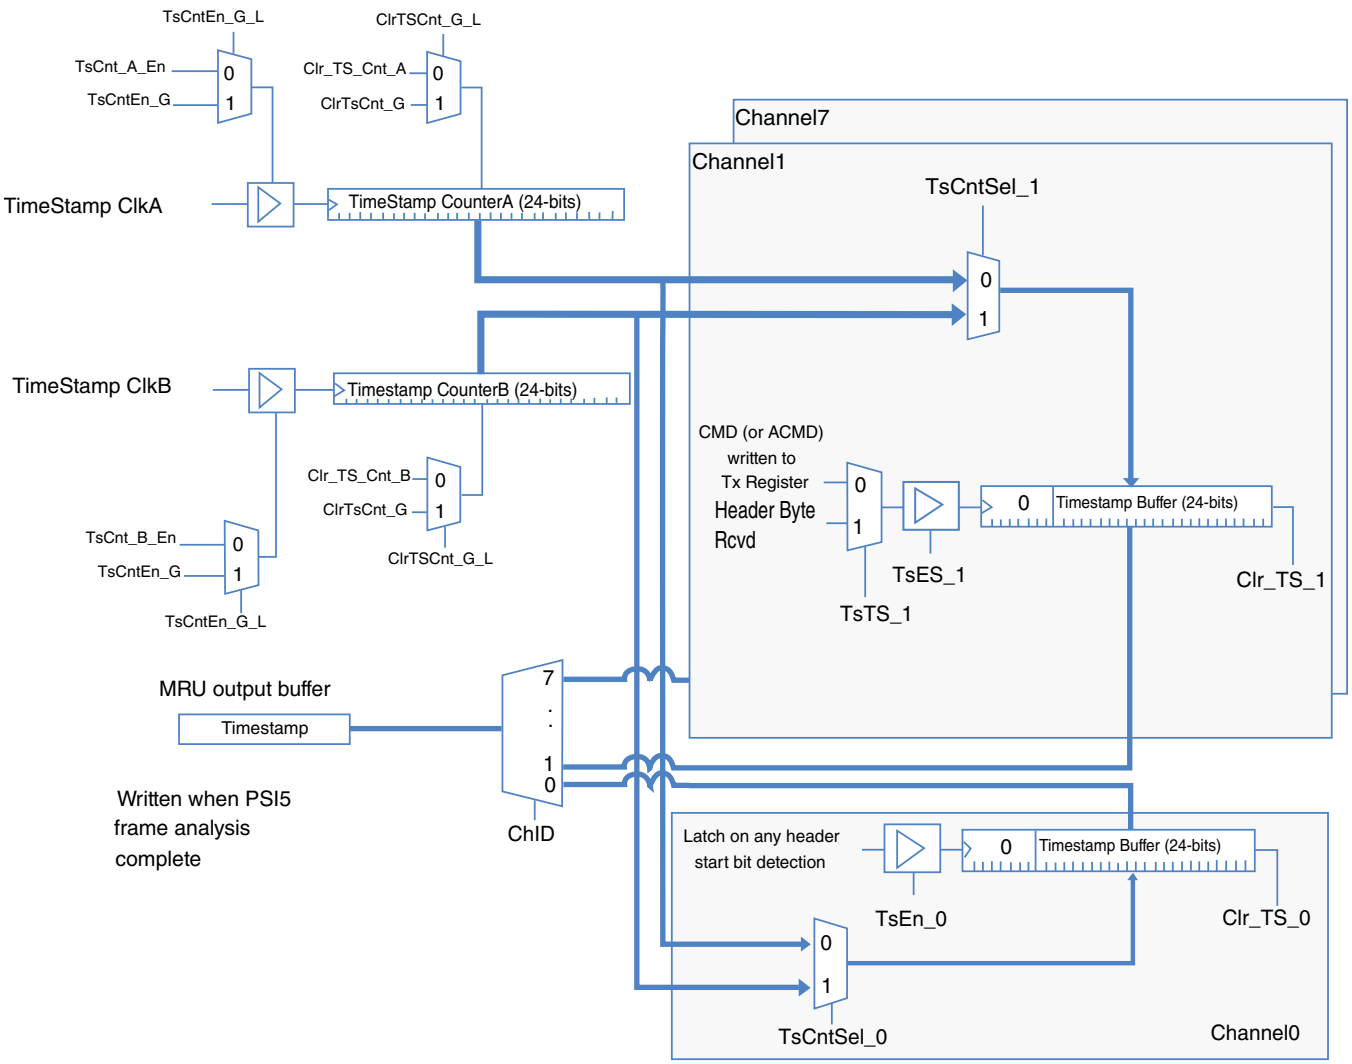

Figure 57-16. TimeStamp Capture

57.5.5 PSI5-S Watchdog Operation

The IP provides a watchdog to keep track of a number of reception parameters. The watchdog counter is a 24 bit down counter. Each channel, except Channel0, contains a watchdog counter. The refresh event for the watchdog is automatically chosen depending on whether the channels mode is synchronous or asynchronous. The watchdog timeout value can be configured in the "WD_TO" bits in the PS_WD_CFGR_CH[n] register. The refresh event for the watchdog are different in the synchronous and asynchronous modes as mentioned below:

- In Asynchronous mode:

As soon as the IP enters the PS_NORMAL mode the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value, and in case the watchdog is enabled then the counter starts immediately. Whether the WD has to be “refreshed(re-loaded)” or “not to be refreshed”, is analyzed when the XCRC is calculated. In case the XCRC is correct, the watchdog is re-loaded (It is not STOPPED) else the WD counter keeps on running normally, eventually leading to a watchdog overrun error. In case of watchdog overrun error, the counter is refreshed.

- In Synchronous Mode:

  As soon as the IP enters the PS_NORMAL mode, the watchdog for each channel is loaded with the PSI5_WD_CFGR_CH[n][WD_TO] value and in case the watchdog is enabled, then the counter starts immediately. Thereby, it is re-loaded, either on the occurence of a sync pulse or the watchdog overrun error. In case the event for this load is the Sync Pulse, then it immediately starts counting again and keeps on counting till it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured (enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CHCID[FID_byte] is not equal to “0”. The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured”, the WD overrun error is generated. In case of a WD overrun error, the counter is stopped and does not start till a Sync Pulse is encountered.

In both the above modes, the watchdog is always refreshed on the occurrence of Watchdog overrun error (F_WD_ERR) or a software reload. Also please refer to PSI5-S channel watchdog configuration register (PSI5S_WD_CFGR_CH*n*).

The watchdog can be started in the NORMAL mode by writing a "1" to the WDEN bit in the PSI5_WD_CFGR_CH[n]. If the watchdog counter is not refreshed by its event and the watchdog counter becomes equal to "0"; the F_WD_ERR flag is set in the PSI5_IRQ_ERR_SR register and the same is also reflected in the PS_MRU_BUF2_REG1 register. An interrupt can also be generated on any of the "ipi_ps_irq[irq_n]" lines depending on the configuration. Note that writing a "0" to WDEN bit disables the watchdog checking mechanism.Figure 57-17 shows the watchdog counter.

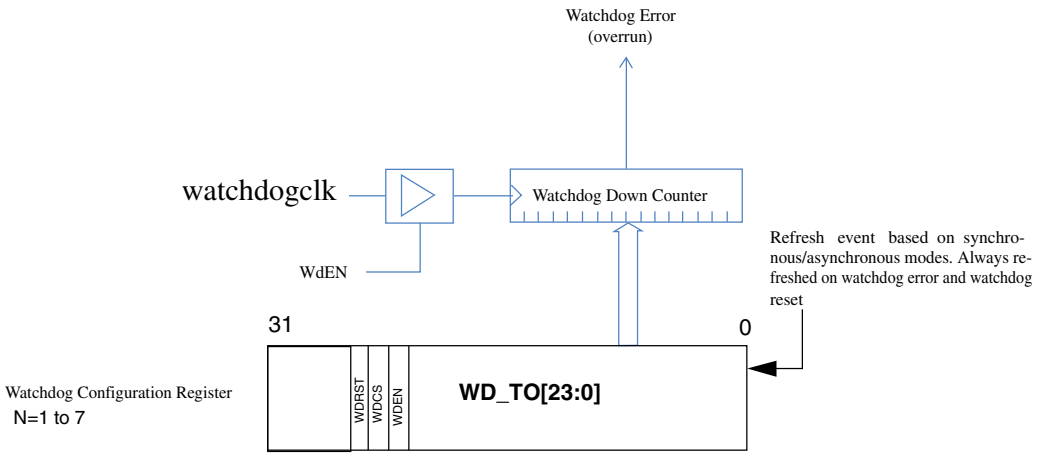

Figure 57-17. Watchdog Counter

As soon as the watchdog overrun error for a particular channel occurs, the status of the watchdog error is immediately latched in the register described in PSI5-S Watchdog Error Status and Watchdog Timestamp status register (PSI5S_WDGTSSR). This watchdog error status(PS_WDGTSSR[F_WD_ERR_STATUS[CHn]]) is also sent to the MRU registers (as F_WD_ERR) as shown in the PSI5 frame status word (shown in Figure 57-7 and Figure 57-8). However this information is sent in the next upcoming PSI5 message packet that occurs for that particular channel, provided this upcoming PSI5 message has no XCRC error. In case the upcoming UART packet has an XCRC error then the Frame watchdog error field in this PSI5 message packet is the "OR" of the F_WD_ERR status of all the channels i.e. OR of all the fields of PS_WDGTSSR[F_WD_ERR_STATUS] bits.

57.5.6 Interrupt handling

Following are the various interrupt signals that represent the various events:

1. PSI5-S general interrupt request (**Status flags in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ**)/ipi_ps_irq[irq_n] where irq_n = 0 to 7 and denotes the irq number.

   There are 8 such interrupts in the IP. Each of these "irq" lines can be configured to respond to any or all of the following events:

   - At least one message of the specific channel has been read by the DMA from the MRU buffer. (The interrupt is configurable to respond to any channel through the corresponding PS_MBOX_SEL_IRQ[irq_n] register)

- When there is a XCRC error in a new packet that is transferred to MRU buffer2 OR
- When there is a CRC or parity error in a new packet that is transferred to MRU buffer2 OR
- When the watchdog Error has been detected in the message just written to MRU buf2 OR
- When the message header has been detected with transceiver error flags OR
- When the PSI5 state machine detects in the UART, the message parity error, the overflow error or the framing error and the corresponding frame is transferred to MRU buffer 2.
- When the "R_OVL_ERR" error occurs in the new packet that is transferred to MRU buffer 2 OR
- When the "R_UVL_ERR" error occurs in the new packet that is transferred to MRU buffer 2 OR
- When the number of bytes received does not match the expected Fn bytes (N_ERR == 1)

  Each of the "ipi_ps_irq[irq_n]" lines can be configured to be asserted on any of the above events by correctly programming the registers PS_MBOX_SEL_IRQ[irq_n] and PS_ERR_SEL_IRQ[irq_n].

  This interrupt is cleared when the corresponding bits in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ are cleared. It is assumed that one event would not be mapped on more than one "irq" lines. If the same event is mapped on more than one "irq" lines then clearing the corresponding status bit in the PS_MBOX_SR_IRQ or PS_ERR_SR_IRQ will clear all the interrupt requests related to that same event.Figure 57-18 shows the interrupt structure for IRQ interrupts.

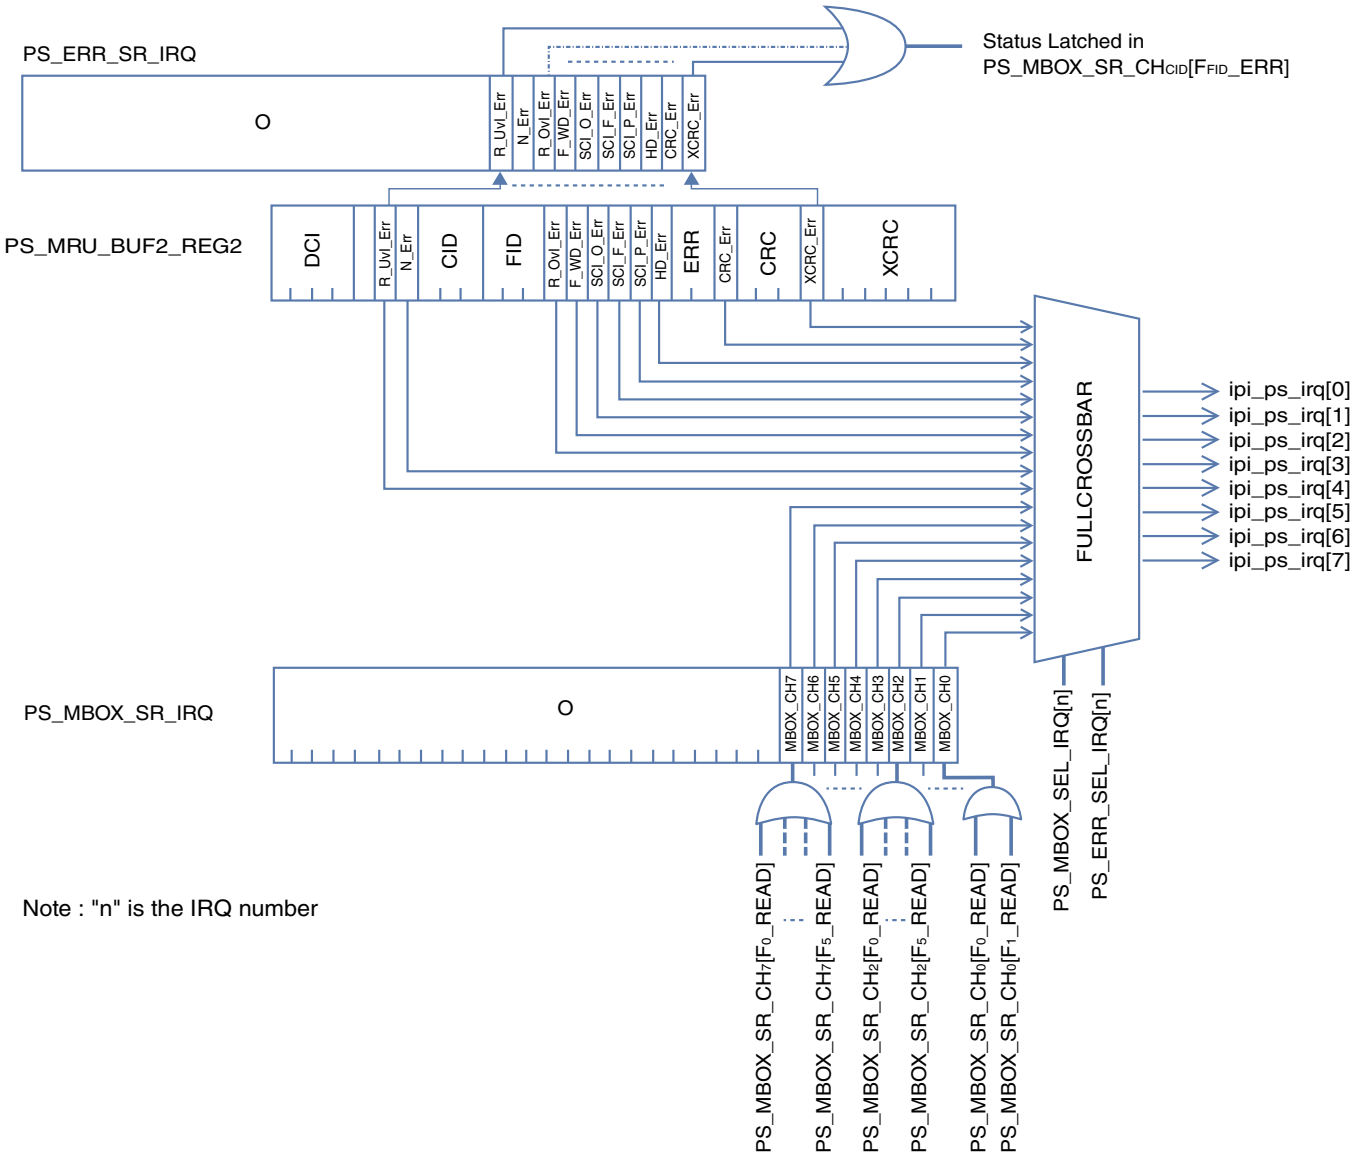

Figure 57-18. IRQ[n] interrupts

2. PSI5-S ECU-to-Sensor interrupt **(Status Flags in PSI5_E2SSR)**/ipi_ps_e2s_ch[n] where n = 1 to 7:

   This interrupt is used for the ECU to Sensor Communications and is generated in the following cases:

   - When the DDSR is empty and is ready to accept a new command new from the application. In this case the PS_E2SSR[DDSR_RDY] bit is set to "1".
   - When the DDSR is still busy (PS_E2SSR[DDSR_RDY] bit is set to "0") and the application attempts to write a new command to the DDSR. The new command is rejected and the PS_E2SSR[CMD_NWRT] bit is set to "1".
   - When the command that is written to the DDSR has finished calculating the CRC/stuff bits/start bits and is ready for transmission the

PS_E2SSR[CMDPR_BZY] goes to "1" leading to the generation of this interrupt.

- When there is a synchronisation overflow in a particular channel (the same data bit encounters 2 sync pulses without getting a chance to shift), then the bit PS_E2SSR_CHn[SYNCHRO_OVF] is set to “1”.

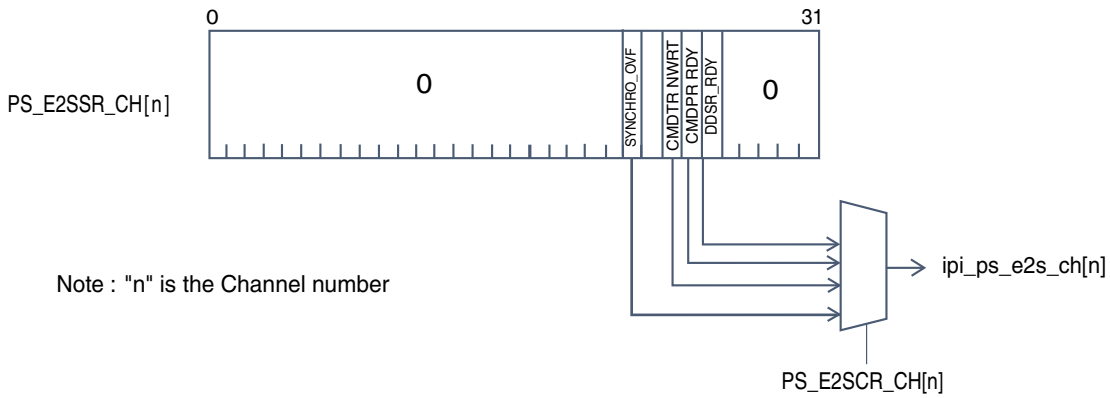

Figure 57-19. ECU to Sensor interrupts

3. Global interrupt (**Status Flags in PS_GLSR**) /ipi_ps_glbl:

   This interrupt is a single interrupt for the whole IP and is generated in the following cases.

   - When the DMA has not completed reading the MRU buffer2; simultaneously there is a pending data in MRU buffer1 that needs to be offloaded to the MRU buffer2 and a new message comes, that overwrites the contents of MRU buffer 1. The channel ID and the Frame ID of the overwritten message can be read from the PS_GLSR registers.
   - When there is any change in the "PSI5-S" global modes of the IP. Thus it is asserted during the following transitions UART_STDALONE to PS_DISABLE, PS_DISABLE to PS_CONFIG, PS_DISABLE to PS_NORMAL and PS_CONFIG to PS_NORMAL. Assertion of this interrupt indicates that the desired mode has been accomplished by the IP.
   - When the “DIRCMD_RDY” bit in the PS_GLSR is set to “1”, indicating that PS_DIRCMD register is ready to accept a new Direct Command write from the CPU.

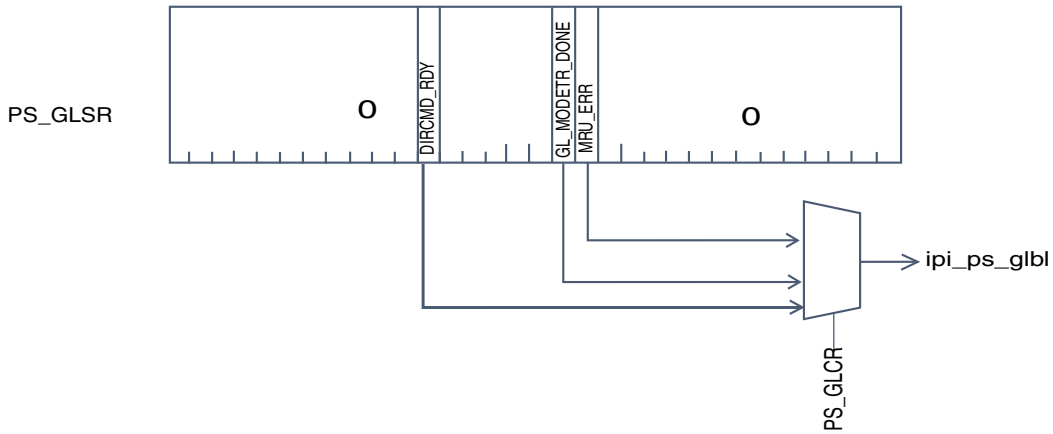

Figure 57-20. Global Interrupts

57.6 PSI5-S Clock and Reset

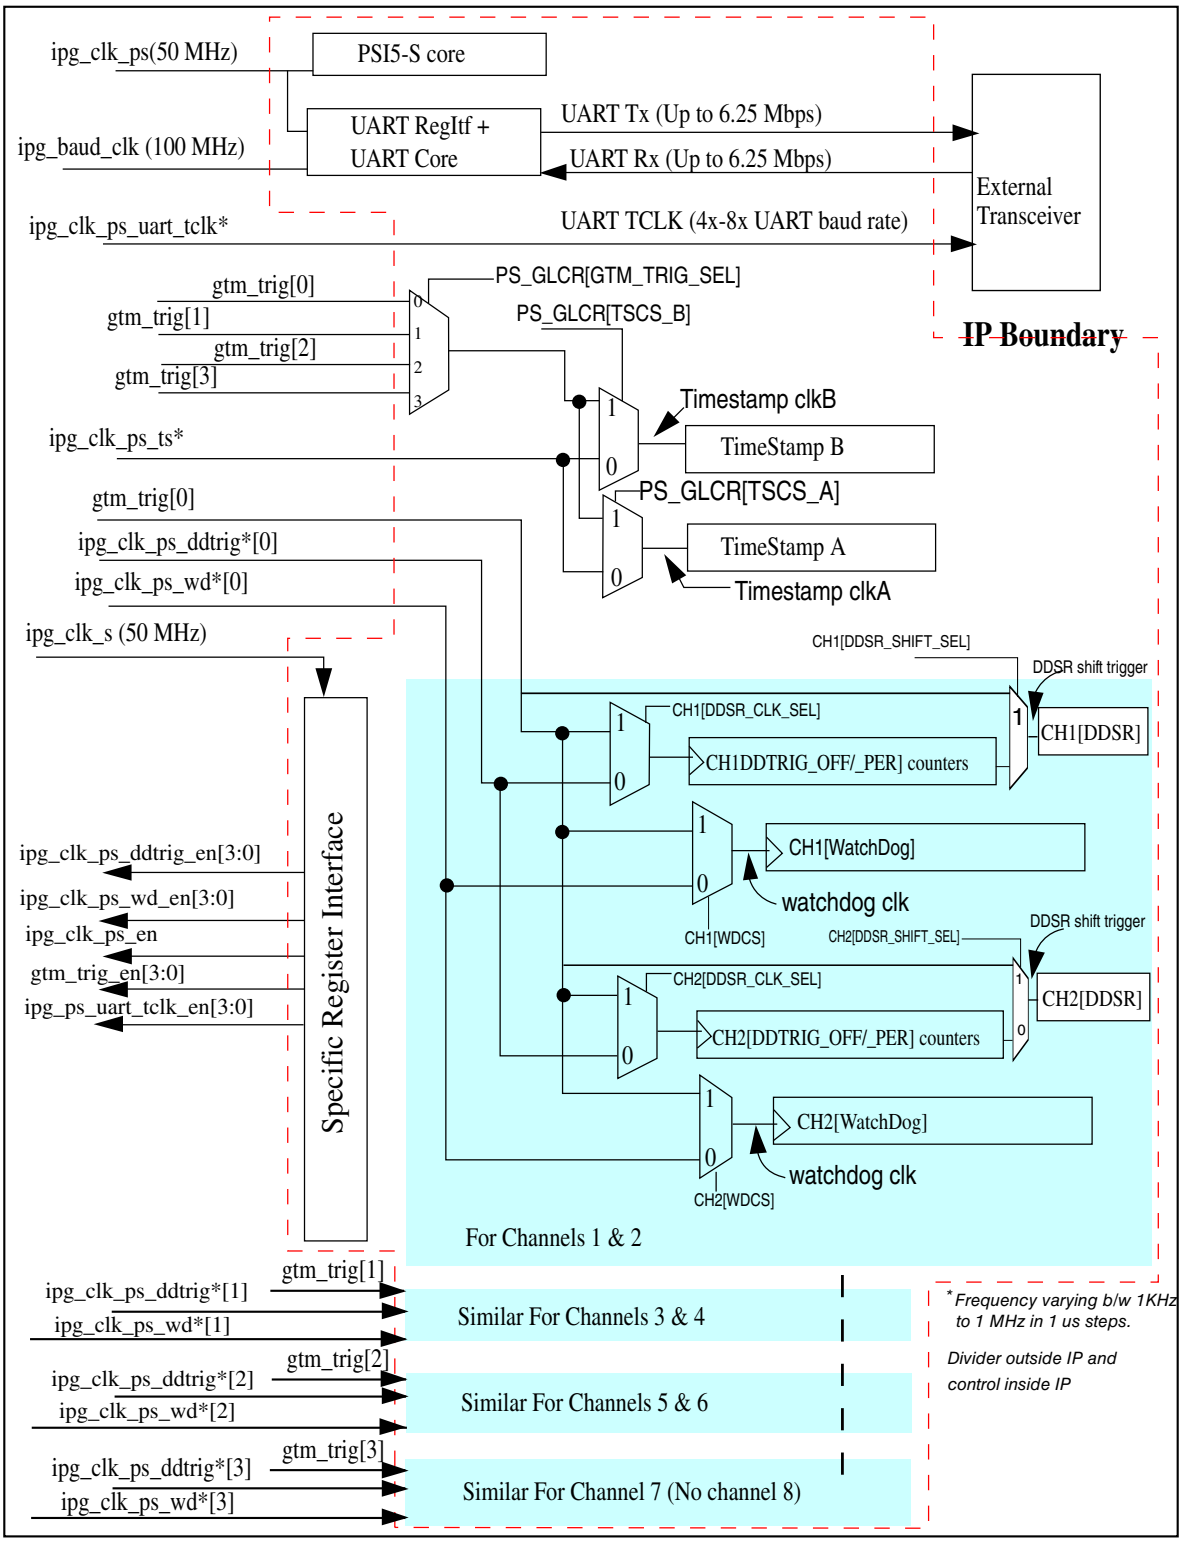

Figure 57-21. Clock distribution in PSI5-S

Figure 57-21 shows the clocking scheme for the PSI5-S IP. It also shows the distribution of various clocks on the basis of channels.

The divider and the control of clock "ipg_clk_ps_ts" is outside the IP, while for the clocks "ipg_clk_ps_wd","ipg_clk_ps_ddtrig" and "ipg_clk_ps_uart_tclk", though the frequency divider is placed outside the IP yet the value of this divider is controlled from inside IP using the "*_clkdivN"signals which are in turn driven by IPS registers of the IP.

For the safe operation of the UART module, the following relation should be satisfied between the "ipg_baud_clk" and "ipg_clk_ps":

ipg_baud_clk > *ipg_clk_ps* > ipg_baud_clk/3

Chapter 58
SENT Receiver (SRX)

58.1 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (http://www.sae.org), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

58.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See the device configuration details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA

    - Programmable option per channel to support reading of messages via DMA or Interrupt
    - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
    - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
    - Separate buffers for storing Fast and Slow Serial Messages
    - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
    - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 3 µs to 90 µs
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.

- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See Clocks and resets for more details on the clocks.

58.1.2 Modes of operation

Modes of operation.

58.1.2.1 Debug mode

In debug mode, message reception will be halted (without waiting for the current message being received to be completed) and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

58.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See System bus clock requirements) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See High frequency receiver clock (protocol clock) requirements) for accurate receive operations.

Note

Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

NOTE

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/ stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

NOTE

The message read registers [Channel ‘n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA), Channel ‘n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC), Channel ‘n’ Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS), Channel ‘n’ Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3), Channel ‘n’ Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2), Channel ‘n’ Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS), DMA Fast Message Data Read Register (DMA_FMSG_DATA), DMA Fast Message CRC Read Register (DMA_FMSG_CRC), DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS), DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)] will appear to lose their contents in the following conditions:

- The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros
- Auto clear functionality is enabled (GBL_CTRL[FAST_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL_CTRL[FAST_CLR] = 0), to allow messages to be read in debug or stop mode.

58.1.3 Block diagram

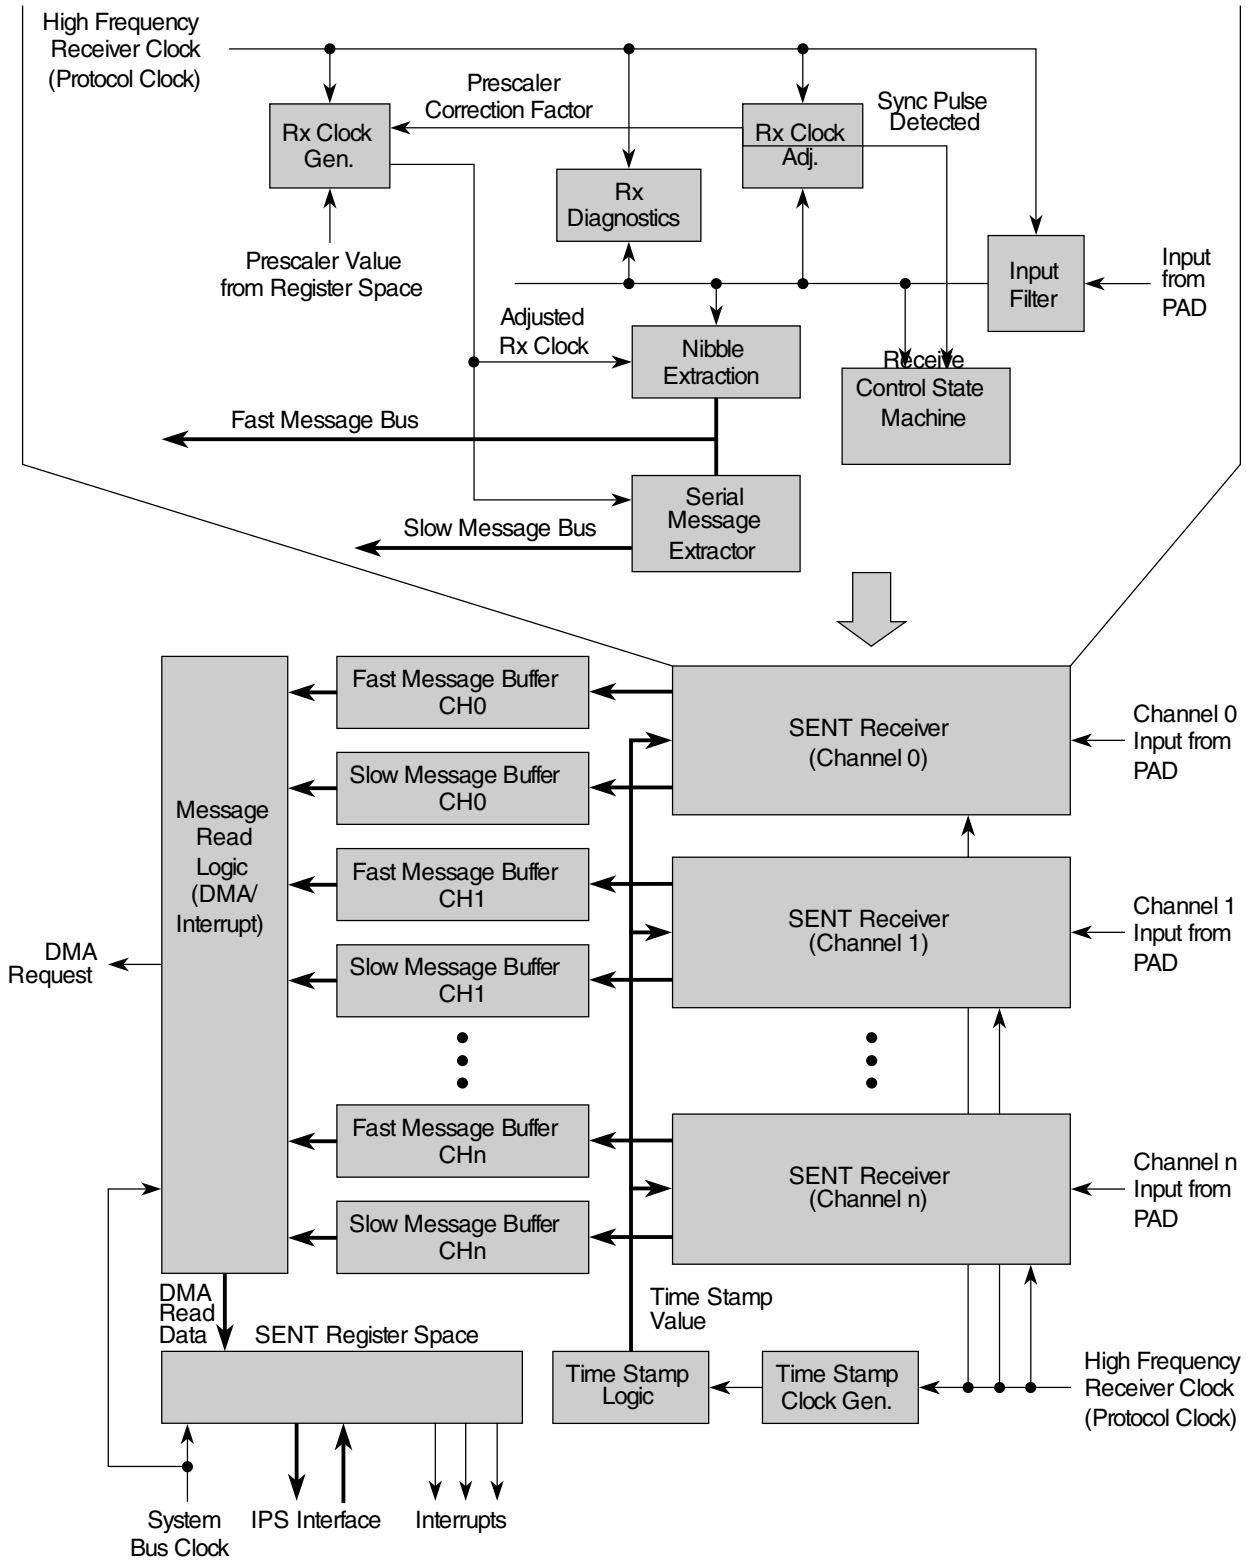

Figure 58-1. SENT Receiver block diagram

58.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. Figure 58-1 shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages.A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

58.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see Functional description.

58.2 External signal description

This section lists all inputs to the SENT Receiver block.

58.2.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT Receiver channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note

The value of CH is device-specific. See the device configuration details.

58.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT Receiver block.

The following table gives an overview on all SENT Receiver registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the device configuration section for details.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

SRX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Global Control Register (SRX_GBL_CTRL)	32	R/W	0000_0010h	58.3.1/3092

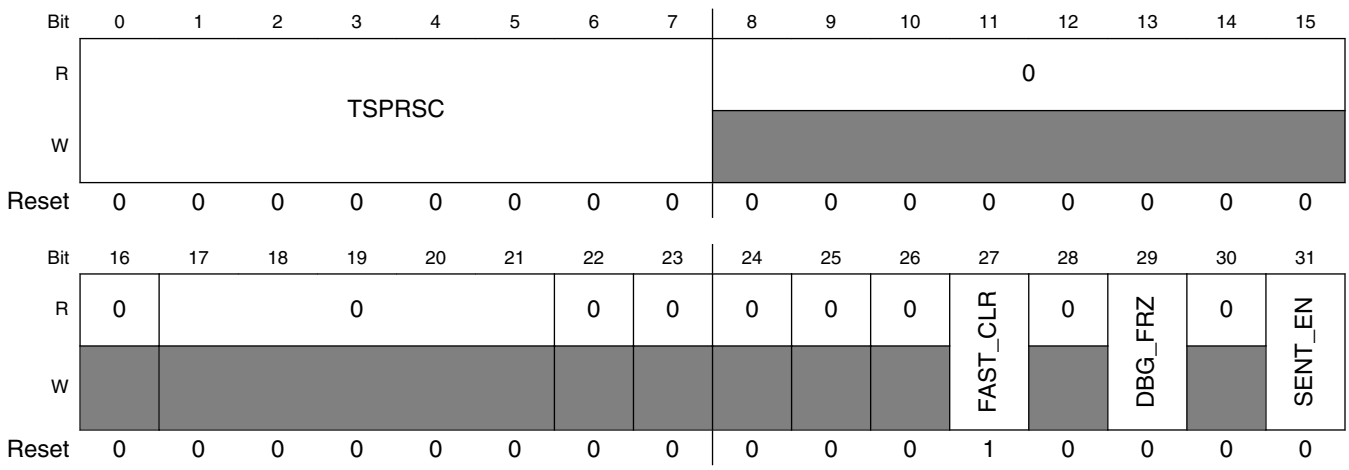
58.3.1 Global Control Register (SRX_GBL_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT_EN bit must be programmed after all other modules settings and control bits have been written to.

Address: 0h base + 0h offset = 0h



SRX_GBL_CTRL field descriptions

Field	Description
0–7 TSPRSC	Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. 1 to 255 - Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 µs. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1 µs clock. Note: Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SRX_GBL_CTRL field descriptions (continued)

Field	Description
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FAST_CLR	Fast Clearing Enable bit. Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. SeeFast Message Ready Status Register (SRX_FMSG_RDY) andSlow Serial Message Ready Status Register (SRX_SMSG_RDY) for details on the ready status bits. 0 Fast Clearing is disabled. Bits will be cleared by writing 1 1 Fast Clearing is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DBG_FRZ	Debug Freeze. This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 No effect in debug mode 1 Freeze in debug mode
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SENT_EN	SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 Entire module is disabled 1 Module is enabled

58.3.2 Channel Enable Register (SRX_CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

NOTE

Reads of bits beyond those for the supported number of channels should be ignored, and these bits must be written to 0.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_CHNL_EN field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 EN_CH	Enable bits for channels 7 to 0. All channels are disabled after reset. User software must program all channel parameters before setting this bit. Once set, other channel parameters in registers should not be changed until this bit is cleared. Only Interrupt Enable and Status bits can be written to. 0 Channel is disabled 1 Channel is enabled. Channel parameter registers are locked for writing

58.3.3 Global Status Register (SRX_GBL_STATUS)

This register provides the status of various conditions in the module that are common across all channels.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SRX_GBL_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 FMDU	Fast Message DMA Underflow: Interrupt Status bit that indicates when there is an underflow in Fast Message buffers in any channel which has DMA enabled. This bit is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0.

Table continues on the next page...

SRX_GBL_STATUS field descriptions (continued)

Field	Description
	0 No underflow 1 Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow: Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 No underflow 1 Underflow occurred
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.3.4 Fast Message Ready Status Register (SRX_FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (viaFast Message DMA Control Register (SRX_FDMA_CTRL)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (viaFast Message Ready Interrupt Control Register (SRX_FRDY_IE)) and the channel is enabled, the message ready status bit in this register will be asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in theGlobal Control Register (SRX_GBL_CTRL) .

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

Address: 0h base + Ch offset = Ch

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRX_FMSG_RDY field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 F_RDY	Fast Message Data Ready Status bits for channels 7 to 0. Each bit indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when DMA is NOT enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). **NOTE:** These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL). The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See SectionGlobal Control Register (SRX_GBL_CTRL) for details on FAST_CLR bit. **NOTE:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. **NOTE:** When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits. 0 No Fast Message is available to be read out via Interrupt 1 Fast Message is available to be read out via Interrupt

58.3.5 Slow Serial Message Ready Status Register (SRX_SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (viaFast Message DMA Control Register (SRX_FDMA_CTRL) andSlow Serial Message DMA Control Register (SRX_SDMA_CTRL)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (viaFast Message Ready Interrupt Control Register (SRX_FRDY_IE) andSlow Serial Message Ready Interrupt Enable Register (SRX_SRDY_IE)) and the channel is enabled, the message ready status bit in this register will be asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST_CLR bit in theGlobal Control Register (SRX_GBL_CTRL).

NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

Address: 0h base + 10h offset = 10h

SRX_DMA_FMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

58.3.14 DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)

The above register (DMA_SMSG_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown inTable 58-1,Table 58-2 andTable 58-3.Table 58-1 andTable 58-2 shows the enhanced serial messages format to be used when reading this register for these two types of messages.Table 58-3 shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

NOTE

If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID and DATA fields.

Address: 0h base + 50h offset = 50h

SRX_DMA_SMSG_BIT3 field descriptions

Field	Description
0–3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to 7.
4 TYPE	Serial Message Type. Indicates the type of Serial Message received 0 Short Serial Message 1 Enhanced Serial Message
5–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 CFG	Configuration bit 'C'. Indicates the type of Enhanced Serial message 0 Enhanced Serial Message with 8-bit ID field 1 Enhanced Serial Message with 4-bit ID field
22–25 ID7_4_ID3_0	ID Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[7:4] and if the 'C' bit is 1, this field is ID[3:0]
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–30 ID3_0_DATA15_12	ID or Data Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12]
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.3.15 DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown inTable 58-1,Table 58-2 andTable 58-3.Table 58-1, andTable 58-2 shows the enhanced serial messages format to be used when reading this register for these two types of messages.Table 58-3 shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRX_DMA_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

58.3.17 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)

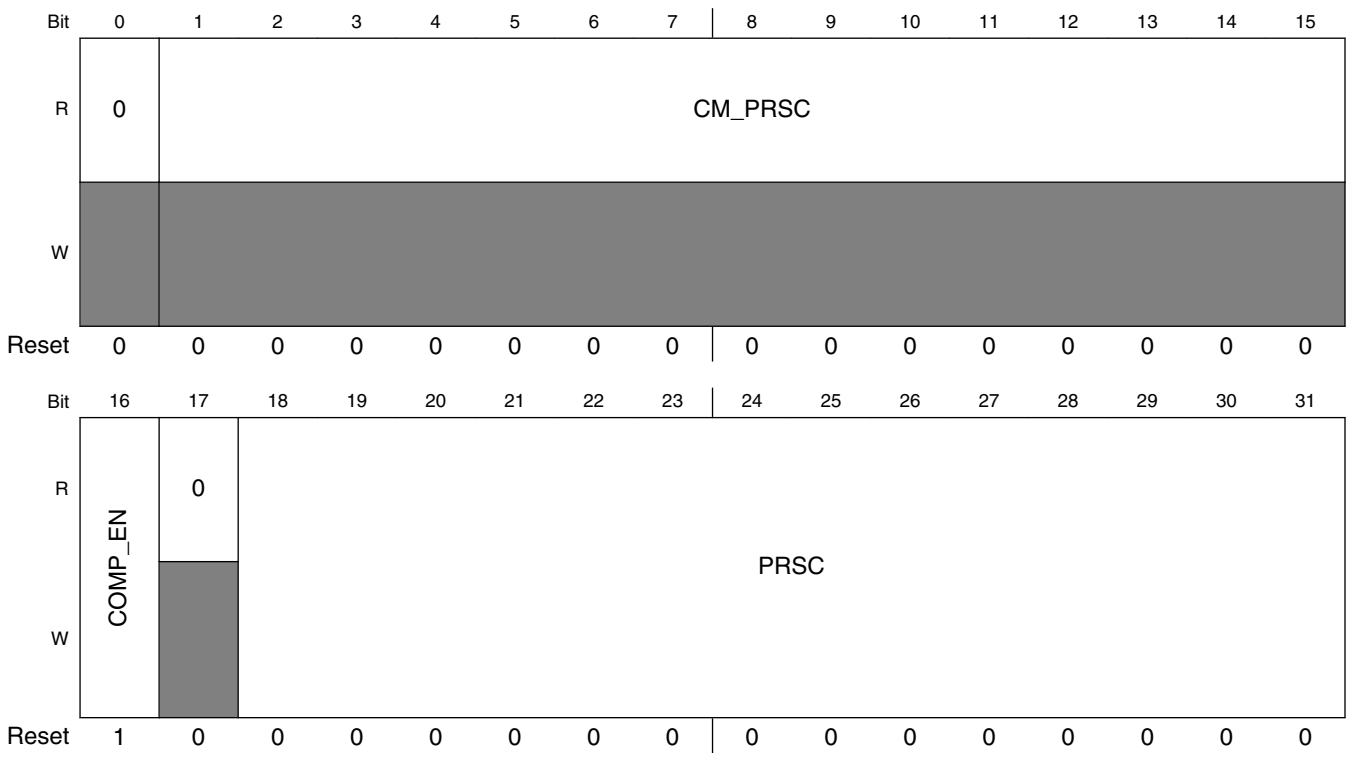
NOTE

The value of the CH is device-specific. See the device configuration section for details.

The SENT Receiver module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock. SeeAdjustment for variation in sensor (Tx) clock for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in theChannel Enable Register (SRX_CHNL_EN) .

Address: 0h base + 60h offset + (16d × i), where i=0d to 7d



SRX_CH*n*_CLK_CTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 CM_PRSC	Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as

Table continues on the next page...

SRX_CH*n*_CLK_CTRL field descriptions (continued)

Field	Description
	Compensated Prescaler Value x High Frequency Receiver Clock Period Note: The value provided in this field is ceil value of actual tick period as measured by the Receiver.
16 COMP_EN	Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 Compensation is disabled 1 Compensation is enabled
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 PRSC	Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (Trx_clk) is not divisible by the high frequency receiver clock (protocol clock) period (Thf_clk), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 Prescaler is bypassed. Should not be used. Non-Zero Value Enables Prescaler The required value is computed by software as follows: $$\text{Prescaler\_value} = \text{floor}\left(\frac{T_{\text{rx\_clk}}}{T_{\text{hf\_clk}}}\right)$$ **Equation 73** (both clock periods taken in µs). Please seeHigh frequency receiver clock (protocol clock) requirements before setting this value. e.g. if the required receiver clock tick period is 43 µs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 µs) then, Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

58.3.18 Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)

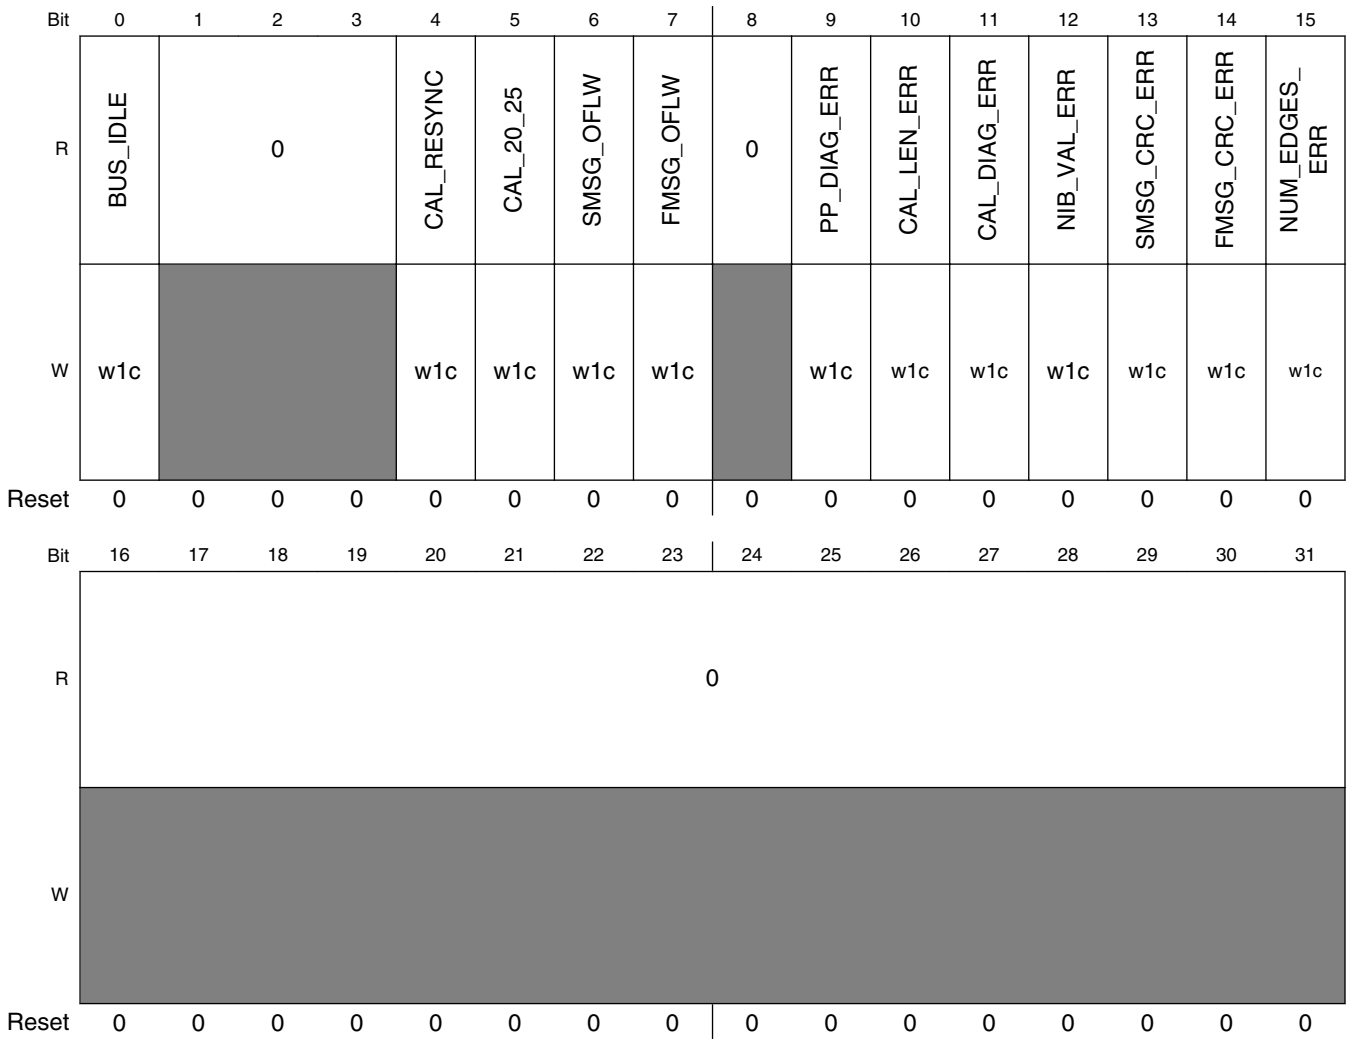
This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in theChannel Enable Register (SRX_CHNL_EN) bit for the corresponding channel.

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 64h offset + (16d × i), where i=0d to 7d



SRX_CH*n*_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value(inChannel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)). CPU should write 1 to this clear this bit once it is read. 0 Bus is not idle 1 Channel has been idle for more than the allowed value
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to

Table continues on the next page...

SRX_CH*n*_STATUS field descriptions (continued)

Field	Description
	assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 No interrupt 1 Interrupt Status condition has occurred
5 CAL_20_25	Calibration Variation 20 - 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between ±20% to ±25% from 56 ticks. 0 No Interrupt 1 Interrupt Status condition has occurred
6 SMSG_OFLW	Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause state machine to halt stopping reception of new messages. 0 No Interrupt 1 Interrupt Status condition has occurred
7 FMSG_OFLW	Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 No Interrupt 1 Interrupt Status condition has occurred
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 PP_DIAG_ERR	This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than ±1.5625% between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
10 CAL_LEN_ERR	This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks ±25%. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
11 CAL_DIAG_ERR	Successive Calibration pulses differ by ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (SeeHigh frequency receiver clock (protocol clock) requirements). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
12 NIB_VAL_ERR	Any nibble data value <0 or >15. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
13 SMSG_CRC_ERR	Checksum error in Slow Serial Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.

Table continues on the next page...

SRX_CH*n*_STATUS field descriptions (continued)

Field	Description
	0 Error Check has passed 1 Error Check has failed
14 FMSG_CRC_ERR	Checksum error in Fast Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
15 NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of "Option 2" for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it. 0 Error Check has passed 1 Error Check has failed
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.3.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained inChannel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in theChannel Enable Register (SRX_CHNL_EN) .

NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 68h offset + (16d × i), where i=0d to 7d

SRX_CH*n*_CONFIG field descriptions

Field	Description
0–3 BUS_IDLE_CNT	Bus Idle Count. This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000 Disabled. 0001 127*2 Receiver Clock Tick Counts 0010 127*4 Receiver Clock Tick Counts 0100 127*8 Receiver Clock Tick Counts 1000 127*16 Receiver Clock Tick Counts
4 IE_CAL_ RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 Interrupt is disabled 1 Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 Interrupt is disabled 1 Interrupt is enabled
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 Interrupt is disabled 1 Interrupt is enabled
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
8 FCRC_CHK_ OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 Check is enabled 1 Check is disabled/off
9 IE_PP_DIAG_ ERR	Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

SRX_CH*n*_CONFIG field descriptions (continued)

Field	Description
10 IE_CAL_LEN_ERR	Calibration pulse is wider than 56 ticks ±25%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
11 IE_CAL_DIAG_ERR	Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
12 IE_NIB_VAL_ERR	Any nibble data value <0 or >15. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
13 IE_SMSG_CRC_ERR	Checksum error in Slow Serial Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
14 IE_FMSG_CRC_ERR	Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
15 IE_NUM_EDGES_ERR	Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel. 0 Interrupt is disabled 1 Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 All Fast Messages will be received even if data nibbles are same 1 Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 20% variation is acceptable 1 25% variation is acceptable
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.

Table continues on the next page...

SRX_CH*n*_CONFIG field descriptions (continued)

Field	Description
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble is XORed)
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 Status and Communication Nibble not included in CRC calculation 1 Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles) 1 Legacy implementation (no additional 0 data nibble XORed)
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse. 0 Detection of Pause Pulse is disabled 1 Detection of Pause Pulse enabled
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 Option 2 i.e. Low Latency Option as per SAE Specification 1 Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24–31 FIL_CNT	Input Filter Sample Count. This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0 No filtering. Input from device's pad is only synchronized 1 Non-Zero Filtering is enabled

58.3.20 Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX_CH*n*_FMSG_DATA)

Address offset: 0x0160 + 0x18 x n

This is register CHn_FMSG_DATA. The contents of this register are same asDMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA) .

NOTE

The value of the CH is device-specific. See the device configuration section for details.

SRX_CH*n*_SMSG_TS field descriptions

Field	Description
0–31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

58.4 Functional description

This section describes the function of the SRX.

58.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the Channel Enable Register (SRX_CHNL_EN). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in Global Control Register (SRX_GBL_CTRL) to generate the time stamping clock
- Rx Prescaler Value in Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL) togenerate the channel's receiver clock
- Compensation enable in Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)
- Channel Configuration settings in the Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)
- Number of Data Nibbles in Channel in the Data Control Register 1 (SRX_DATA_CTRL1)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in Fast Message DMA Control Register (SRX_FDMA_CTRL), Slow Serial Message DMA Control Register (SRX_SDMA_CTRL), Fast Message Ready Interrupt Control Register (SRX_FRDY_IE) and Slow Serial Message DMA Control Register (SRX_SDMA_CTRL)

58.4.2 DMA read logic

The SENT Receiver module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in Time stamp logic.

58.4.2.1 DMA request for Fast Message reading

Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - DMA Fast Message Data Read Register (SRX_DMA_FMSG_DATA)
  - DMA Fast Message CRC Read Register (SRX_DMA_FMSG_CRC)
  - DMA Fast Message Time Stamp Read Register (SRX_DMA_FMSG_TS)
- A fixed round robin sequencing runs, as shown in Figure 58-2, and this logic checks for messages in sequence 0→1→3 →5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

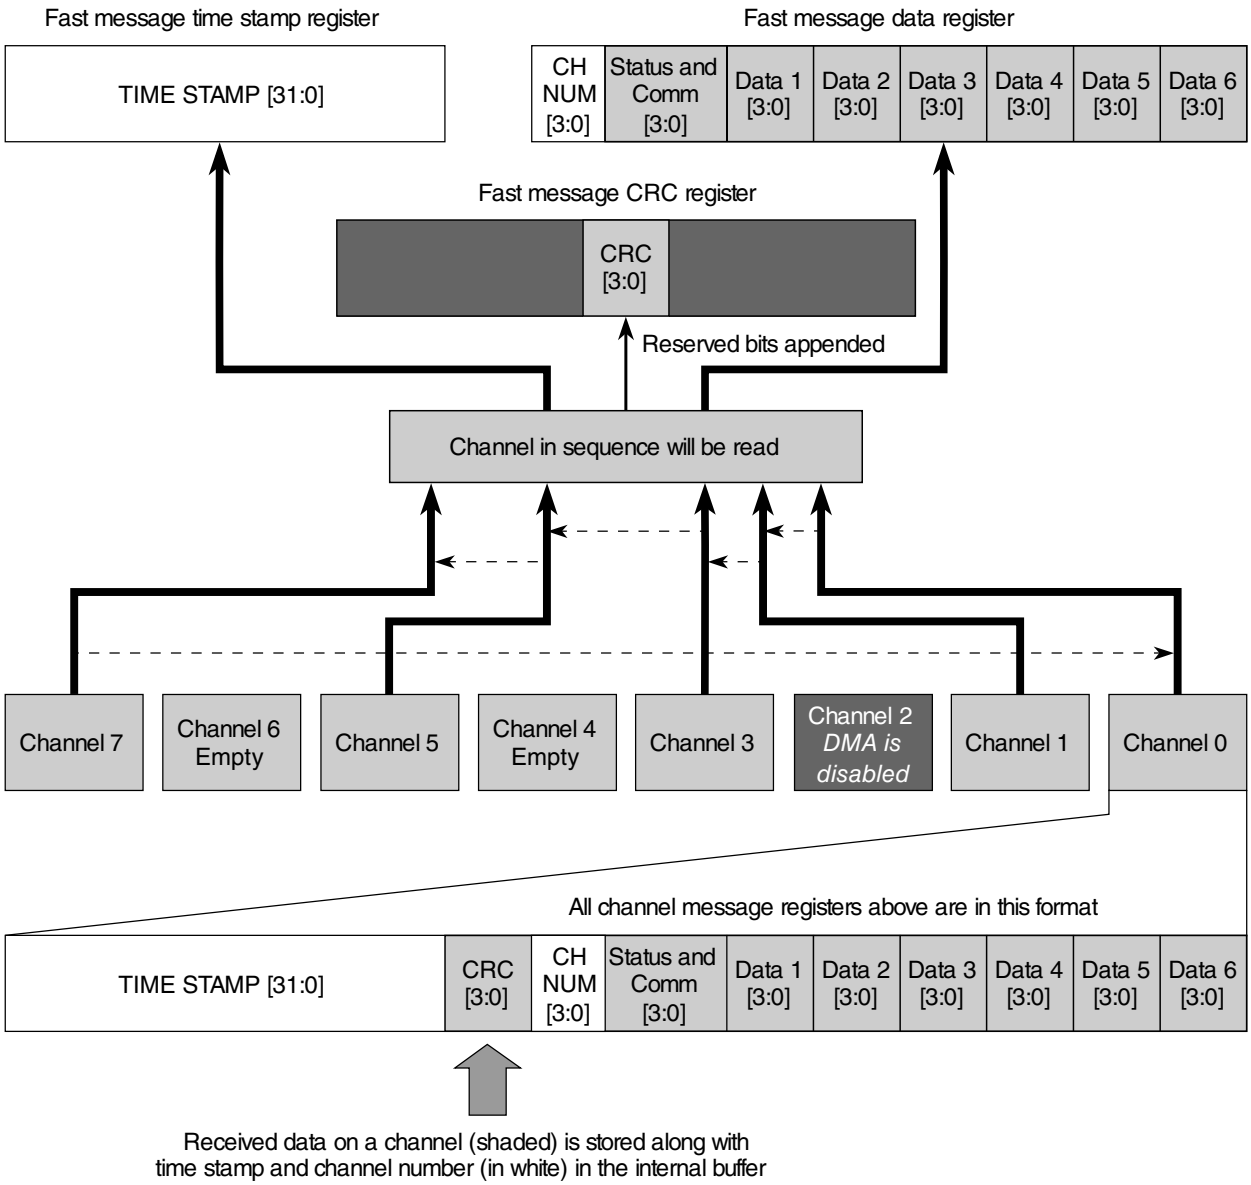

Figure 58-2. Fast Message DMA read logic

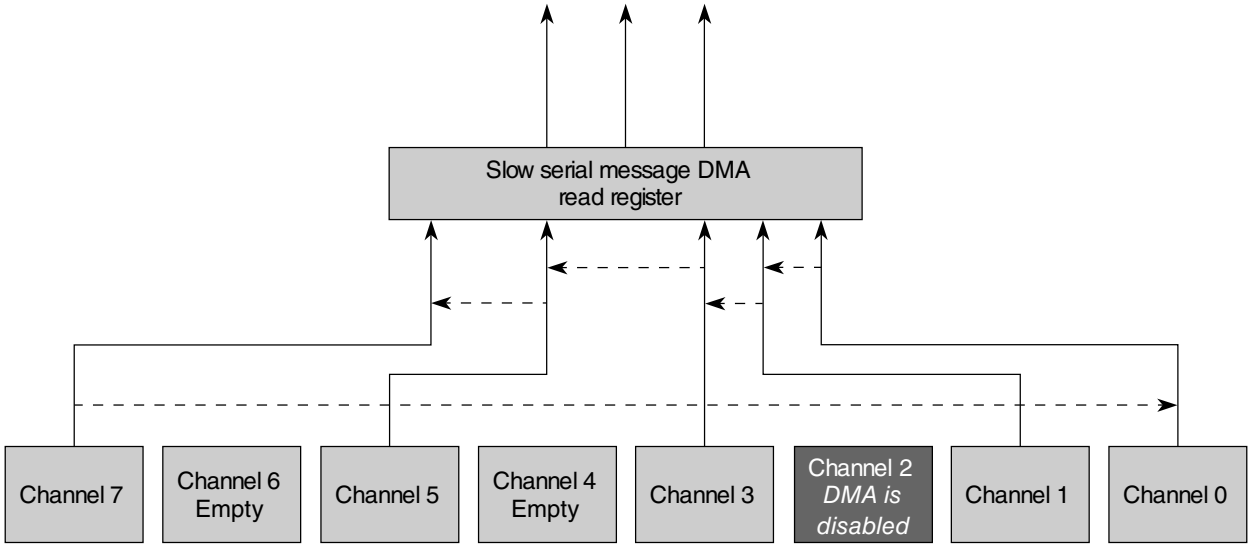
58.4.2.2 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers

- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3)
  - DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)
  - DMA Slow Serial Message Time Stamp Read Register (SRX_DMA_SMSG_TS)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see DMA request for Fast Message reading)

Figure 58-3 shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.



Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

Figure 58-3. Slow Serial Message DMA read logic

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

Table 58-1. Enhanced Serial Message with 8-bit ID field

31	1		16	15	0						0
CH NUM [3:0]	P				0	C	ID [7:4]	0	ID [3:0]		0
		CRC [5:0]			Data Field [11:0]						
TIME STAMP [31:0]											

Table 58-2. Enhanced Serial Message with 4-bit ID field

31	1		16	15	1						0
CH NUM [3:0]	P				0	C	ID [3:0]	0	Data Field [15:12]		0
		CRC [5:0]			Data Field [11:0]						
TIME STAMP [31:0]											

Table 58-1 and Table 58-2 shows the enhanced serial messages. Bit C (shown in figure) or CFG (as shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Table 58-3 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

Table 58-3. Short serial message

31	0	16	15	0
CH NUM [3:0]	P			
		CRC [3:0]	ID [3:0]	Data Field [7:0]
TIME STAMP [31:0]				

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

58.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

58.4.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable

- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

58.4.4 Overflow behavior

This section describes the overflow behavior.

58.4.4.1 Fast messages buffers

Overflow in Fast Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

58.4.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

58.4.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register (Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL)). Software can use this value to determine the variation in Tx Clock.

Note

A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

58.4.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

58.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG)). A timing diagram of the input filter when FIL_CNT is 4, is shown in the following figure.

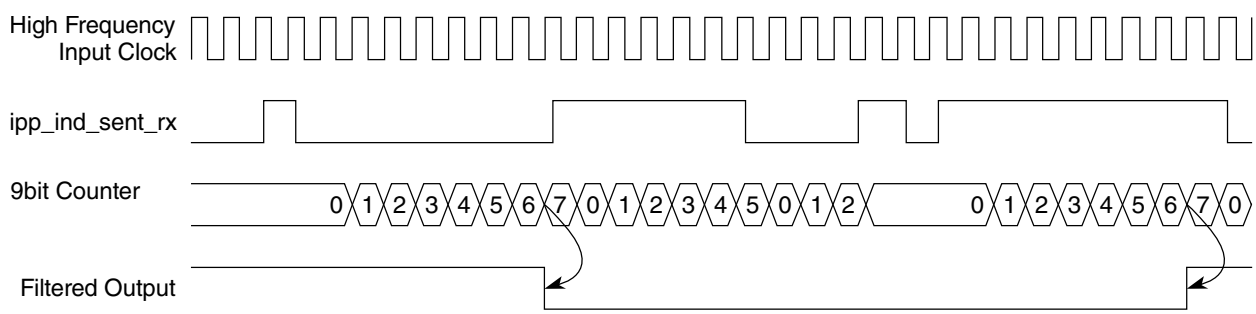


Figure 58-4. Input programmable filter timing diagram

58.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%

- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.
- Any nibble data values measured as < 0 or > 15
- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

58.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

58.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is T_{HF_CLK} and channel tick period is

T_{TX_CLK} then the check will be of 1.5625% ± {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. So it won't allow variance in clock of a channel by 1.5625% - {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

58.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

58.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

58.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new recommended CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

58.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic

to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel ‘n' Configuration Register - CHn_CONFIG[PAUSE_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM_EDGES error can get asserted spuriously (Channel ‘n' Status Register - CHn_STATUS(NUM_EDGES_ERR] = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM_EDGES_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM_EDGES_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM_EDGES_ERR behavior.

Table 58-4. Behavior of NUM_EDGES_ERR

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NIB_VAL_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between.	Ignore both NUM_EDGES_ERR error
FMSG_CRC_ERR	NUM_EDGES_ERR asserted twice	Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are	Ignore both NUM_EDGES_ERR errors

Table continues on the next page...

Table 58-4. Behavior of NUM_EDGES_ERR (continued)

		seen as back to back calibration pulses and no edges in between.	
CAL_LEN_ERR	NUM_EDGES_ERR asserted once	Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted.	Ignore NUM_EDGES_ERR error

Table 58-5. Expected behavior, clarification of NUM_EDGES_ERR cases

First Error Detected	Other error bits asserted	Cause for extra error bits getting asserted	Action
NUM_EDGES_ERR (when edges are less than expected)	NIB_VAL_ERR is asserted	When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.	Ignore the NIB_VAL_ERR
NUM_EDGES_ERR (when edges are more than expected)	NIB_VAL_ERR and PP_DIAG_ERR are asserted	When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted.	Ignore NIB_VAL_ERR and PP_DIAG_ERR

58.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in Global Control Register (SRX_GBL_CTRL)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 µs. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1 µs resolution.

Note

The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

58.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

58.4.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in Channel 'n' Configuration Register (n=0 to (CH-1))

(SRX_CH*n*_CONFIG)). Status bit (bus_idle in Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

58.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

58.5.1 Clocking strategy

The following figure shows the clock domain in which each module is functioning.

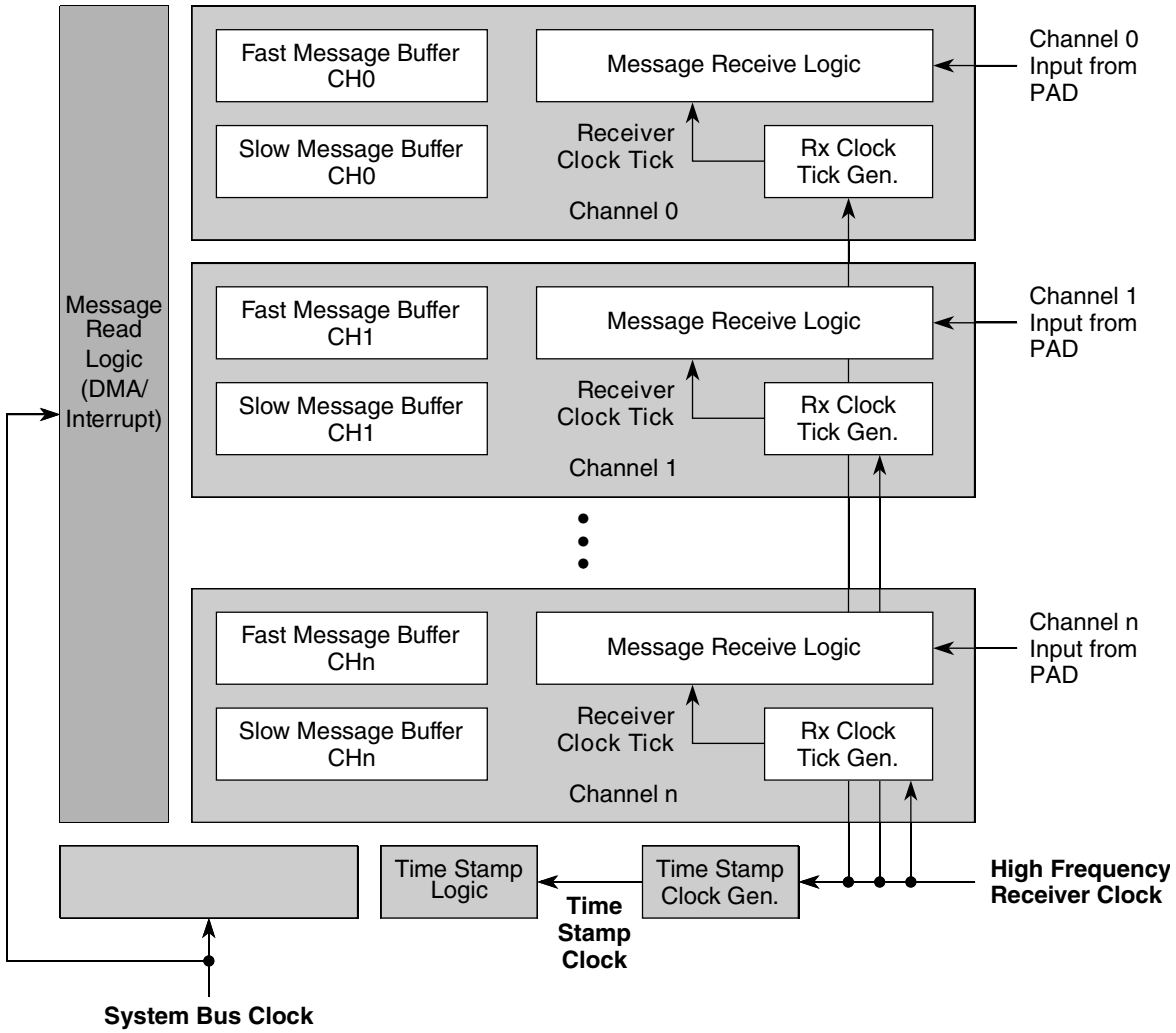

Figure 58-5. SENT Receiver module clock domains

58.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 µs receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 µs (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as $154 \times 2.4 = 369.6$

µs. Now since messages are arriving in parallel, 369.6 µs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that 'N_{CHNL}' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be 369.6/N_{CHNL} µs or ~370/N_{CHNL} µs. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as 'T_{RD}' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$3 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370 / N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

$$3 \times T_{RD} + T_{WAKUP} < 370 / N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS\_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS\_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get

For CPU,

$$(3 \times N_{RD} + N_{ISR}) \times T_{SYS\_CLK} + T_{WAKUP} < 370 / N_{CHNL}$$

(all units is µs)

For DMA,

$$3 \times N_{RD} \times T_{SYS\_CLK} + T_{WAKUP} < 370 / N_{CHNL}$$

(all units is µs)

58.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula: Guard Band > 2.5 * T_{HF_CLK}

where T_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in ns and Guard Band is guard band in ns as specified in SAE specification, at particular transmitter uTick.

Note

T_{HF_CLK} in the above equation should be chosen based on the fastest sensor clock (with minimum guard band as specified in SAE spec) among all channels in the device.

Chapter 59
LINFlexD

59.1 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, and 2.1. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

59.1.1 Glossary and acronyms

Table 59-1. Glossary and acronyms

Term	Description
LIN	Local interconnect network
UART	Universal asynchronous transmitter receiver
ID	LIN identifier field
DMA	Direct memory access
TCD	Transfer control descriptor
IPS	Peripheral Bus Interface
IRQ	Interrupt request
FSM	Finite state machine

Table continues on the next page...

Table 59-1. Glossary and acronyms (continued)

Term	Description
WS	Wait state
SW	Software
CPU	Central processing unit
SoC	System on a chip

59.1.2 References

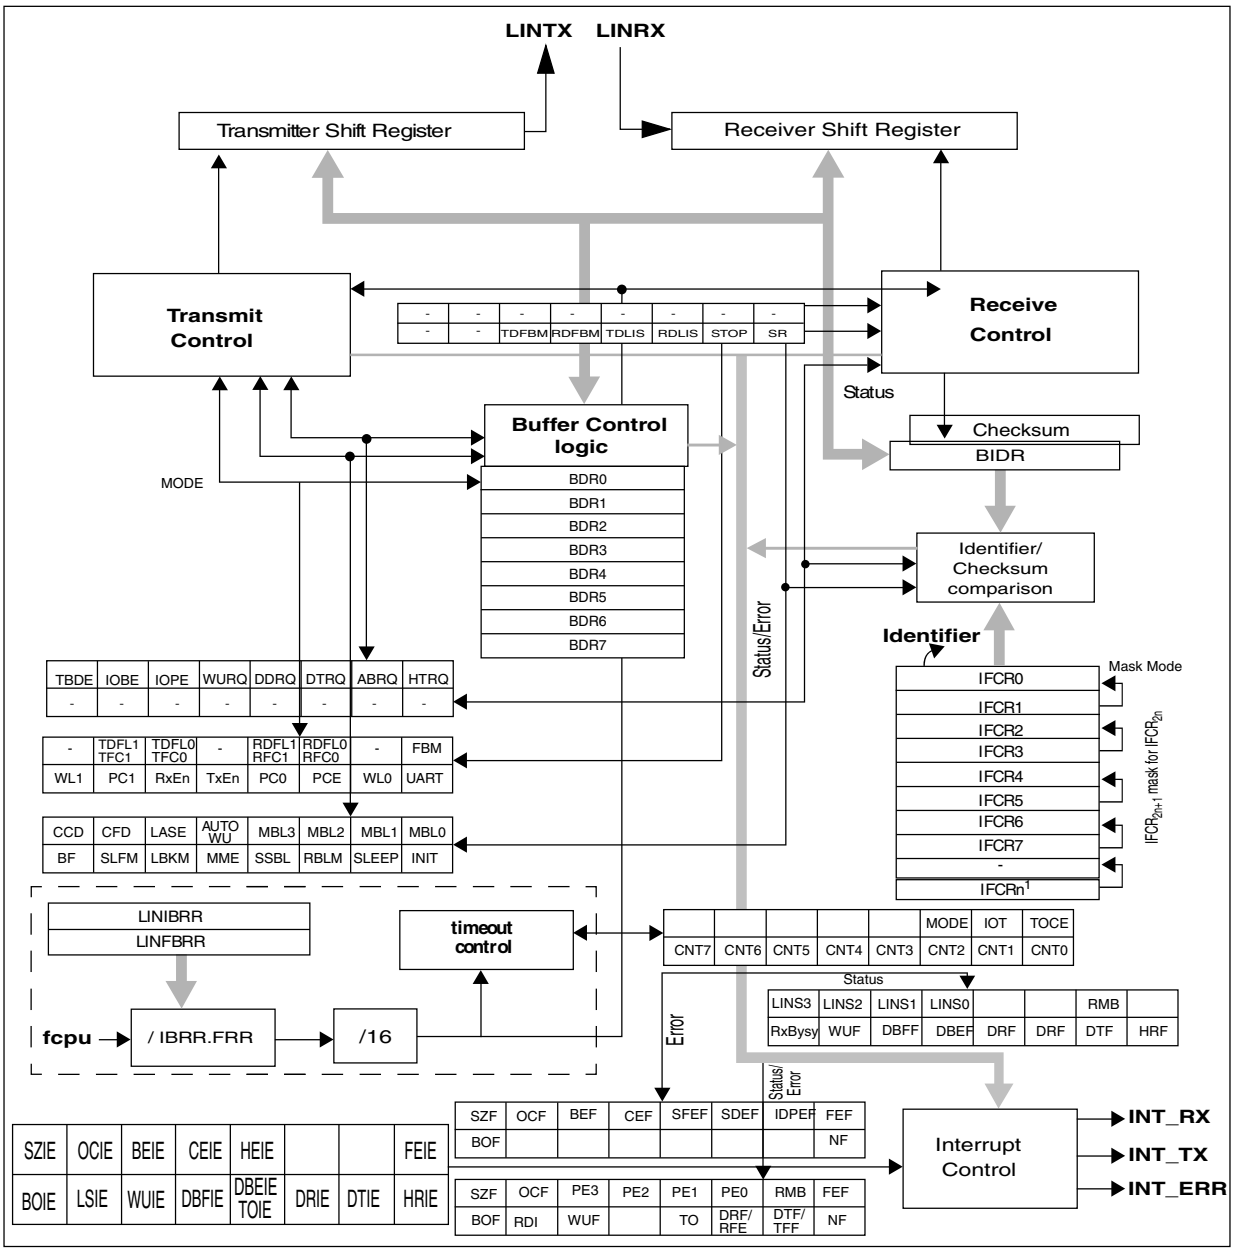

Figure 59-1. Block diagram

Notes:

1: The value of n depends on the no_of_filters. Refer to the chip configuration details to see the number of filters used in this device.

2: For LIN mode N = 16 and N is programmable by user in UART mode.

59.2 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode:Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

59.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection

- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.

59.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers - see Baud rate generation
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s

- Reduced over sampling programmable by the user
- 3:1 majority voting for reduced over sampling of 8

- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

59.3 Functional description

59.3.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

59.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

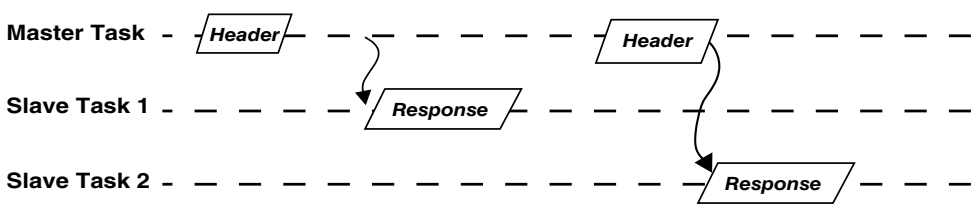

Figure 59-2. Frames

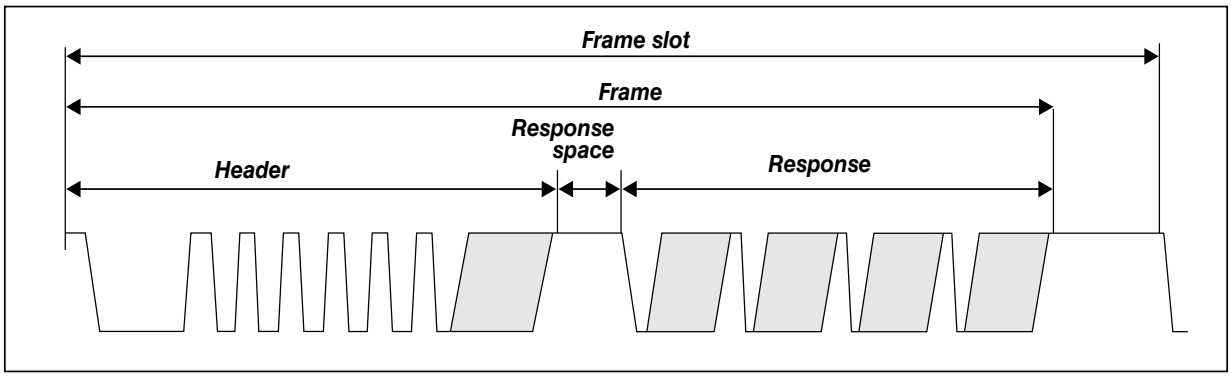

Figure 59-3. Structure of LIN frame

59.3.1.2 Data field

Each byte is transmitted as shown in Figure 59-4. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

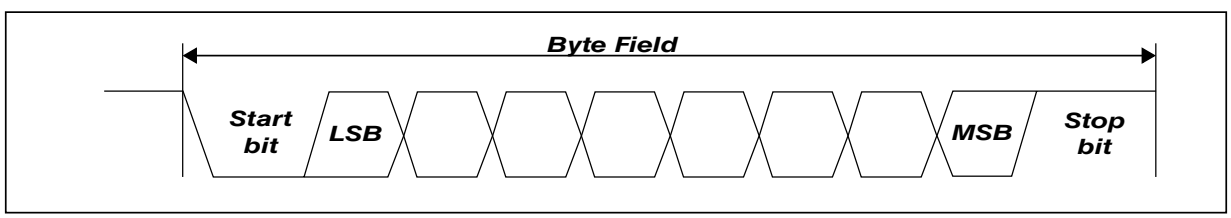

Figure 59-4. Structure of byte field

59.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in Figure 59-5. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

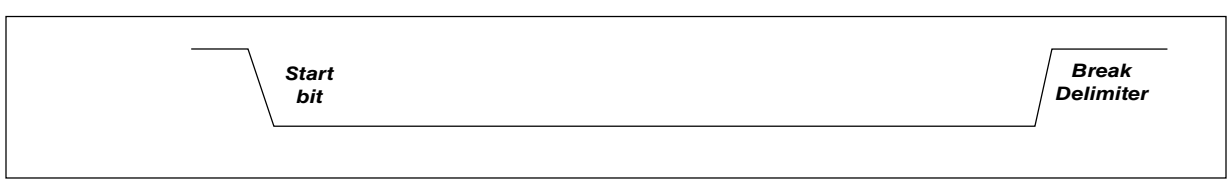

Figure 59-5. Break field

59.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

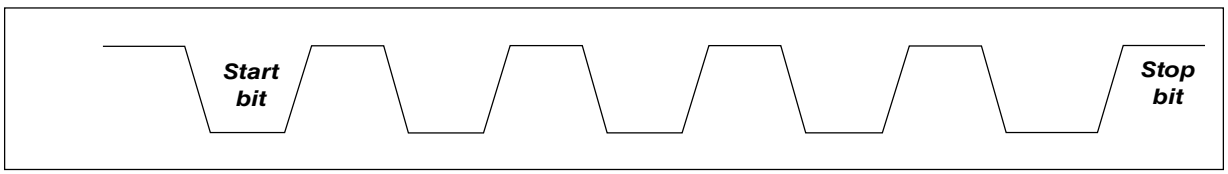

Figure 59-6. Sync byte field

59.3.1.5 Identifer

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

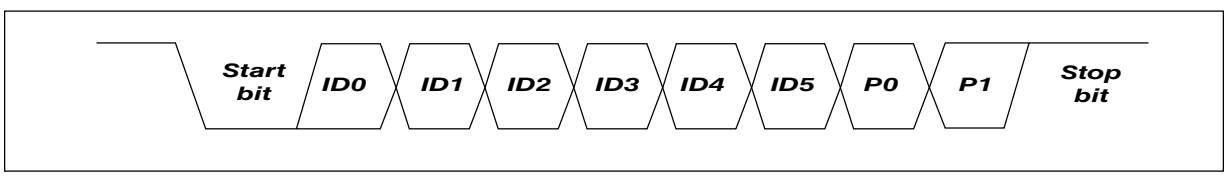

Figure 59-7. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

59.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and is used for communication with LIN 2.0 slaves.

59.3.2 LINFlexD features

59.3.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller software must:

1. Set up the baud rate registers
2. Reset UART bit
3. Select the mode (master or slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter the Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be awakened from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to Wakeup management.

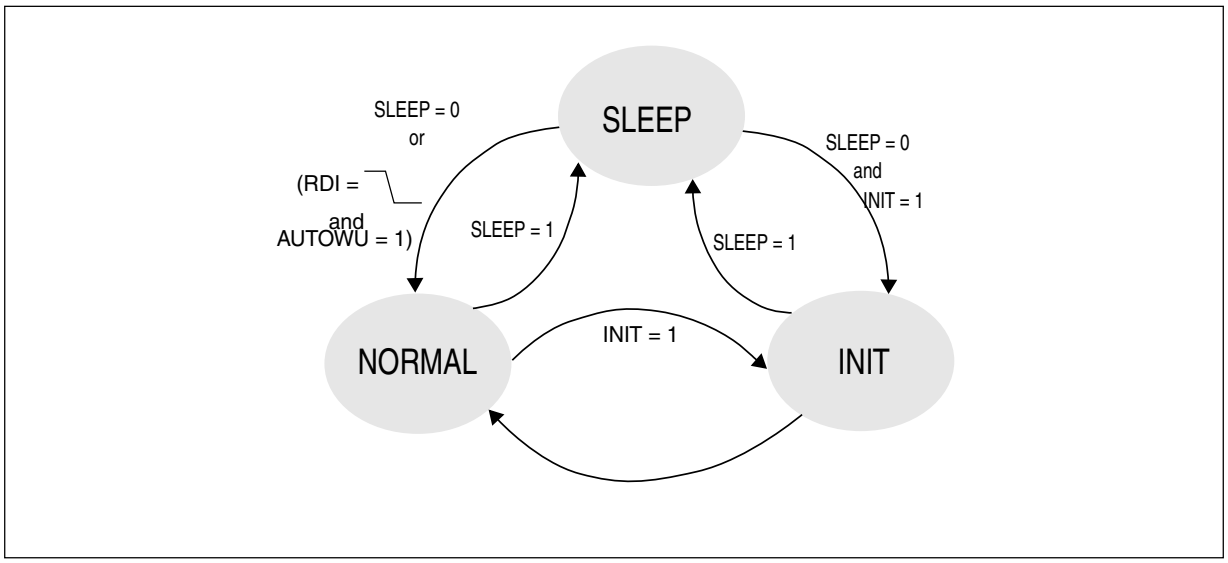

Figure 59-8. Operating modes

59.3.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is an internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

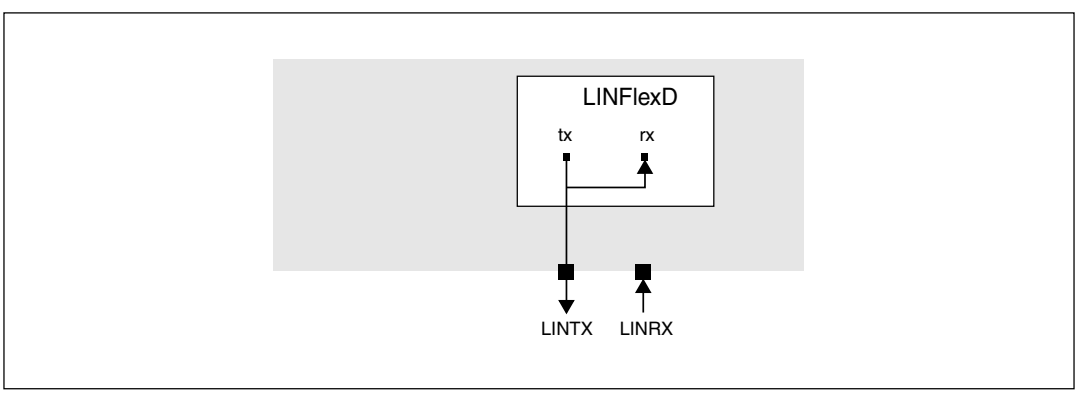

Figure 59-9. LINFlexD in Loop Back Mode

59.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits untill the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDRL and BDRM. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling).

It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to Error handling).

It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

59.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit, and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7].

The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software then you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

59.3.2.5 Errors

59.3.2.5.1 Header error

A header error is an error during the header reception. The error types are:

1. Sync Del error (SDEF)
2. Sync field error (SFEF)
3. Identifier Parity error (IDPEF)

Sync Del error (SDEF)

The delimiter should be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if *HEIE* bit of LINEIER is set.

Sync field error (SFEF)

The SFEF error condition is monitored differently depending on whether autosynchronization (LASE) is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the SFEF flag indicates:

- The deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator).

This check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

If SFEF field is asserted it means that:

D > 14.0625%

If there is no error, it means that:

D < 14.84375%

If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

Overflow during Sync Field Measurement

This check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = '0')

In this case the Sync character is received as a normal character. If the received character is 0x55 then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

Identifier Parity error(IDPEF)

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

59.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CPU cycles. Bit error is not checked during break field transmission.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) - (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note

If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

59.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

59.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

59.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM is set, then the ID along with the data is discarded.

59.3.2.5.6 Timeout error

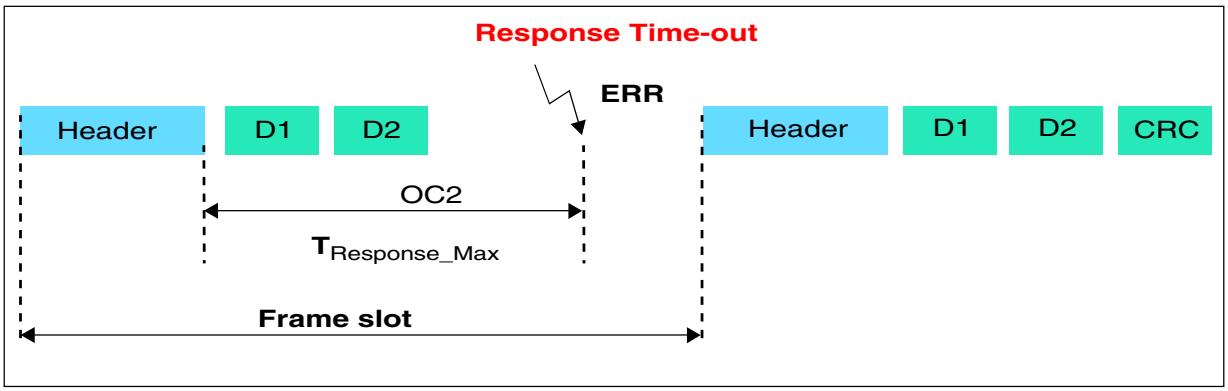

Figure 59-10. Incomplete response (for example, missing checksum)

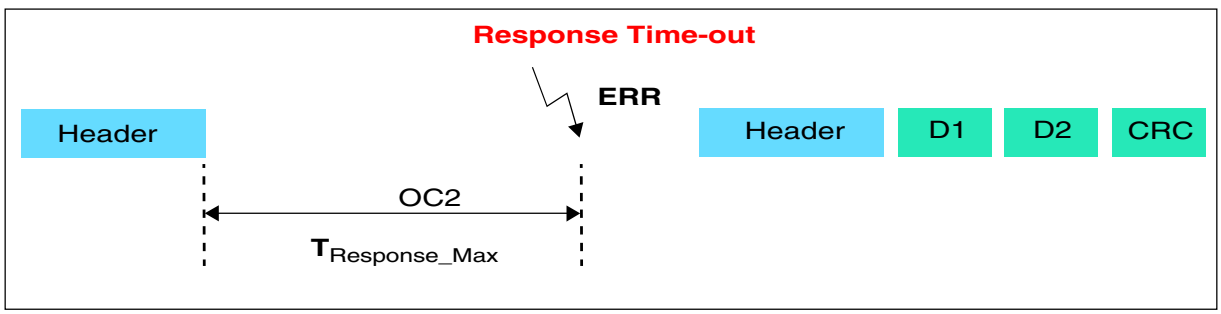

Figure 59-11. No response

Response timeout mechanism

- Master mode
  - OC2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time).

    This loading takes place at the end of id field (and not at the beginning of data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode

- **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time))
- **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
  - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT].
  - At the end of the first_data_byte it is reloaded again according to DFL
  - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length),
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

  Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit
  - If the counter starts after 11 Tbit, the HTO value is 56–11 = 45 Tbit

  The reset value of HTO is 45, and this register can only be programmed in slave mode.

  As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

59.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8^{th}, 9^{th} and 10^{th} samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see LIN Error Status Register (LINFlexD_LINESR).

59.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2n and 2n+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/ reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2n or IFCR2n+1 (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2n is the filter and 2n+1 acts as a mask for it. The FACT bit for filter 2n+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

If there is a match of identifier with the mth filter in any mode, then m+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only untill the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note

If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In mask mode if two filters match with the identifier then the filter having the lower number prevails.

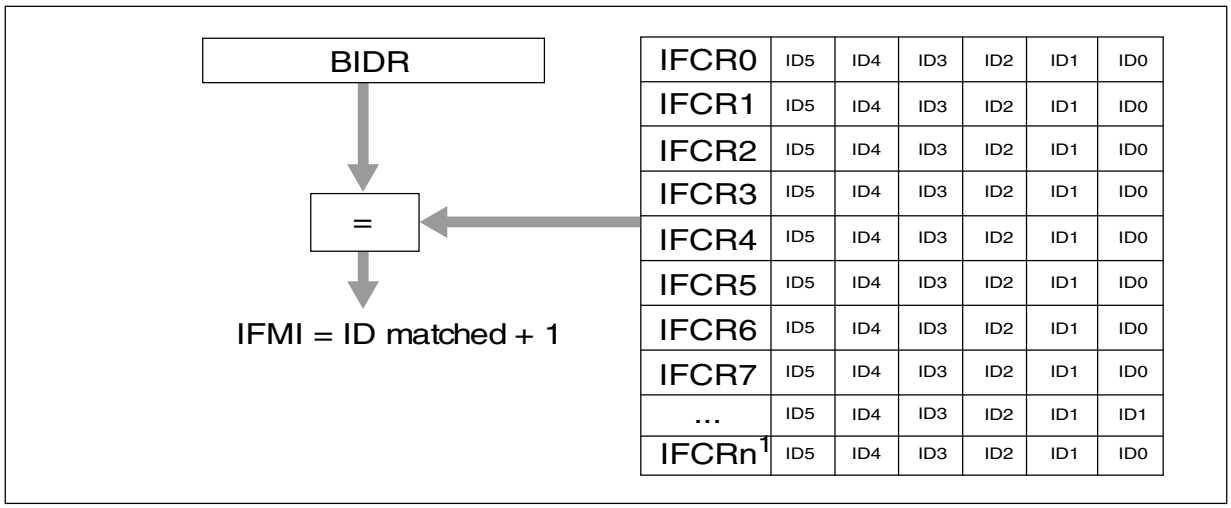

Figure 59-12. Identifier List mode

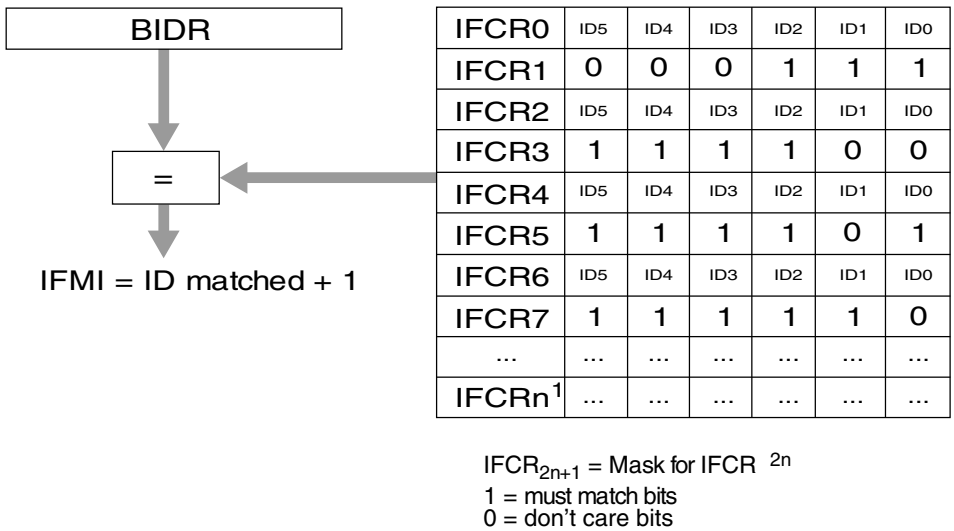

Figure 59-13. Identifier Mask mode

59.3.2.7 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

Table 59-2. Start Detection and Delimiter Detection in receiver

9	8	7	6	5	4	3	2	1	0	Sample_reg
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3

Table continues on the next page...

Table 59-2. Start Detection and Delimiter Detection in receiver (continued)

9	8	7	6	5	4	3	2	1	0	Sample_reg
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x	0	x	0	x	0	start detect
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	delimiter detect
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

59.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to Table 59-2 for the status of the sample register (shift register) when count = 6

2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘0’, then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.

59.3.2.7.2 Break delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to Table 59-2 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘1’, then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

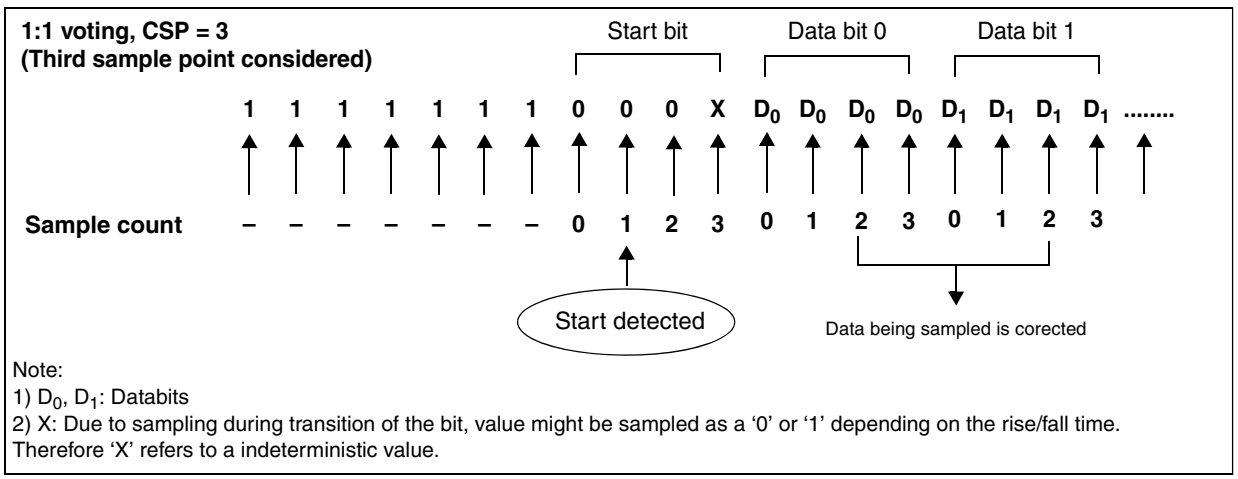

Figure 59-14. Start detection and sampling for over sampling rate = 4 (Case 1)

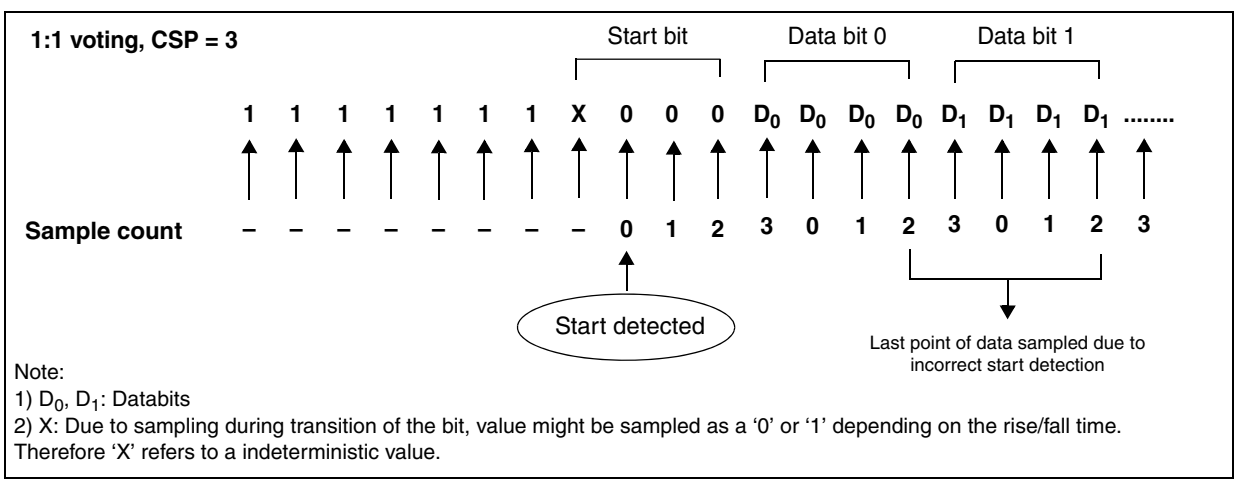

Figure 59-15. Start detection and sampling for over sampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

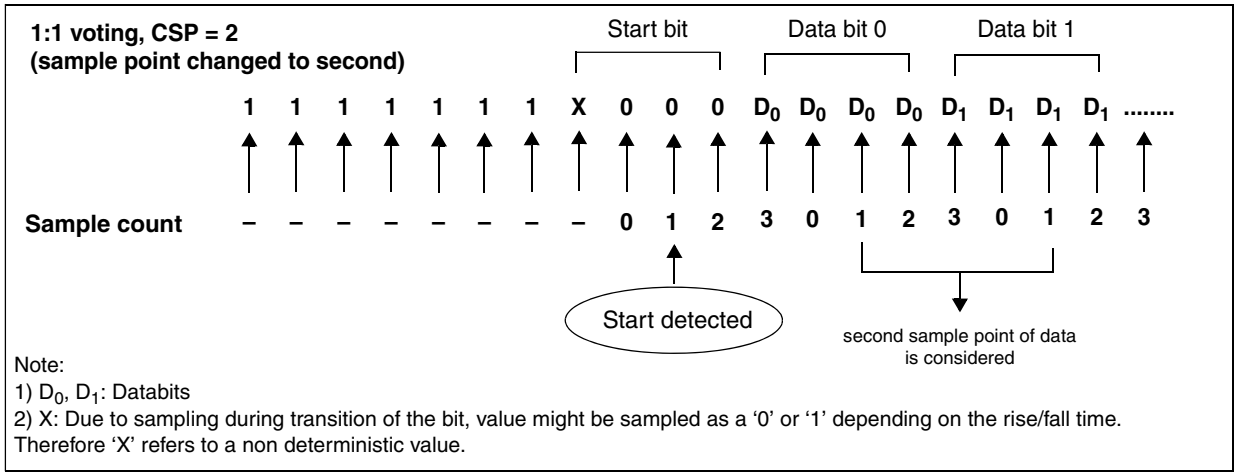

Figure 59-16. Start detection and sampling for over sampling rate = 4 (Case 2b)

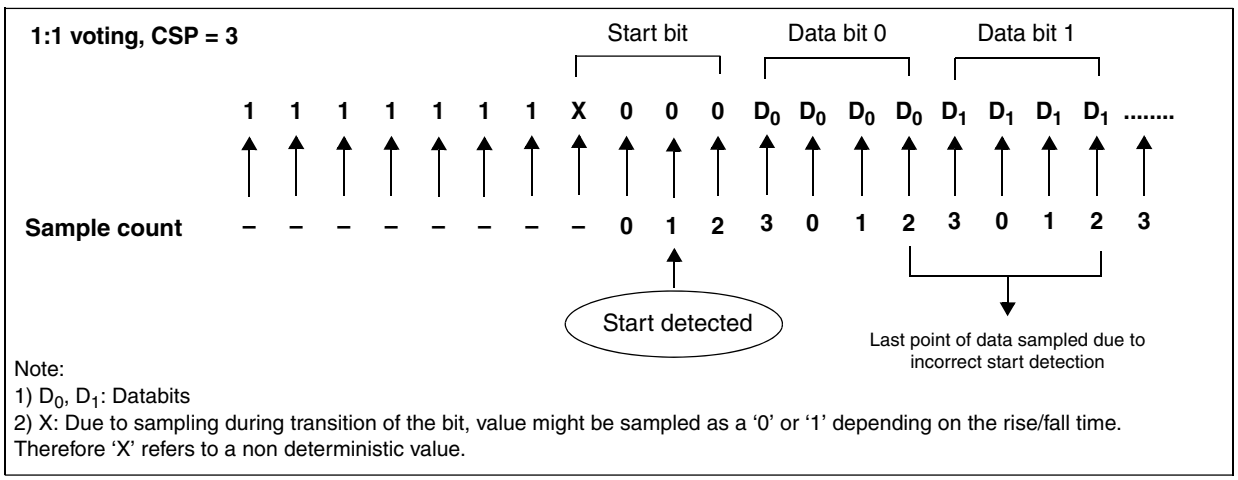

Figure 59-17. Start detection and sampling for over sampling rate = 4 (Case 3)

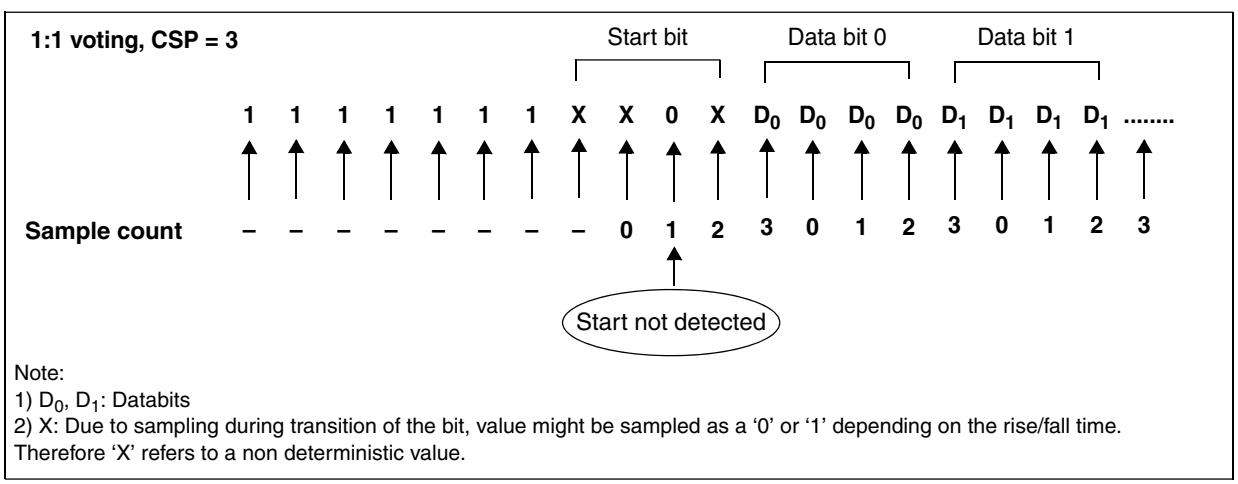

Figure 59-18. Start detection and sampling for over sampling rate = 4 (Case 4)

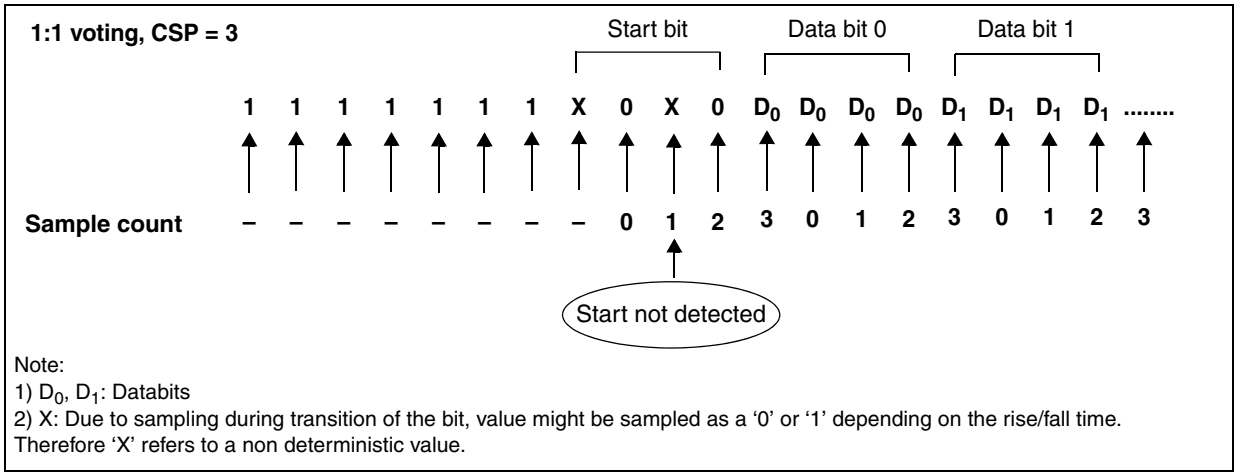

Figure 59-19. Start detection and sampling for over sampling rate = 4 (Case 5)

59.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate Register and the LIN Fraction baud rate register. The Baud Rate Registers can be programmed only during Initialization mode.

Baud rate is calculated with the following formula for both receiver and transmitter.

When ROSE = 1, Tx = Rx = LIN_CLK / (OSR × LDIV). When ROSE = 0, Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled, LINFBRR should not be used and programmed to zero and LDIV contains only the integer part of LINIBRR.

For example: When ROSE = 0 (For LIN and UART mode): LDIV = 468.75 d, LIN_CLK = 36 MHz, LINIBRR = 468 d, LINFBRR = 12 *Baud rate = 36 MHz/ (16 × 468.75) = 4.8 Kbit/s*

For example: When ROSE = 1 (Only for UART mode): LDIV = 10 d, LIN_CLK = 80 MHz, LINIBRR = 4 d, OSR = 4, *Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s*

59.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescalar value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When auto synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

59.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 μs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 μs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1 On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated if WUPIE is set. LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0 On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE bit is set). It is then up to the software to clear the SLEEP bit.

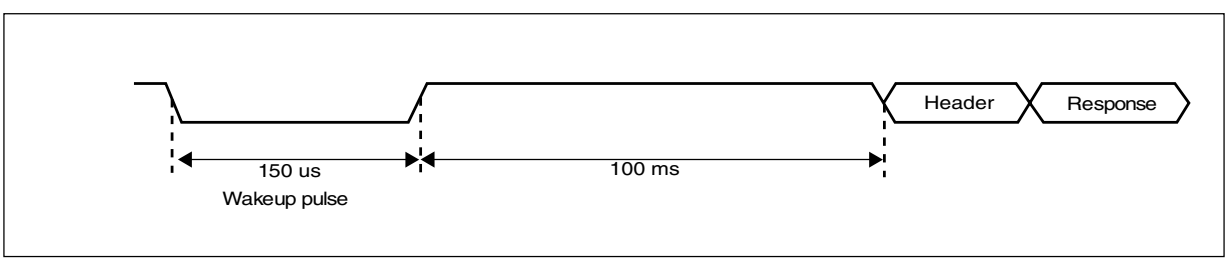

Figure 59-20. Wakeup sequence

59.3.3 Timer

There is an 8-bit counter that is free-running (even in Sleep and Initialization modes) if it is configured in Output Compare mode. There are two software configurable-output compare registers that, upon match with counter value, generate output compare interrupt provided TOCE bit in LINTCSR is set.

If this timer is configured in LIN mode, then software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

59.3.4 UART mode

Main features in the UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 13-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

59.3.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

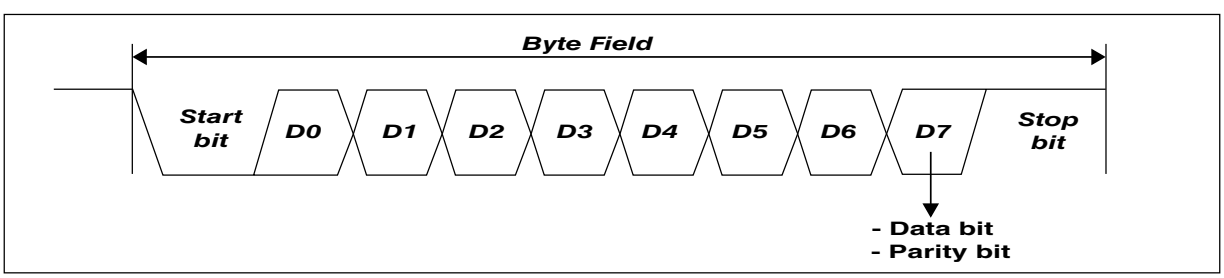

Figure 59-21. UART mode 8-bit data frame

59.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

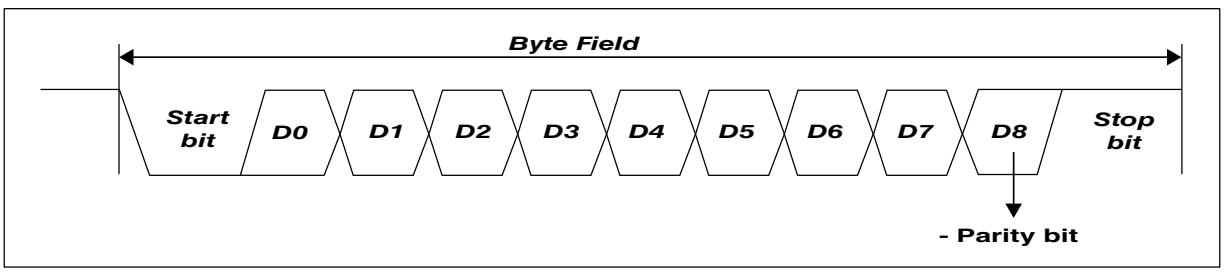

Figure 59-22. UART mode 9-bit data frame

59.3.4.3 16-bit data frames

The sixteenth bit can be a data or a parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

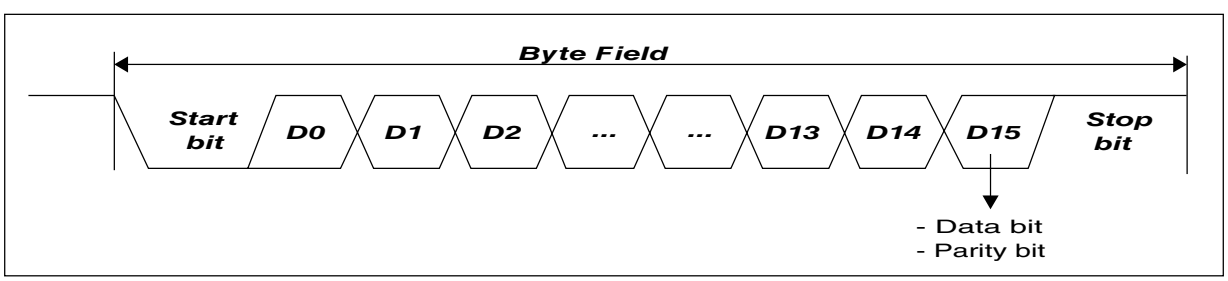

Figure 59-23. UART mode 16-bit data frame

59.3.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

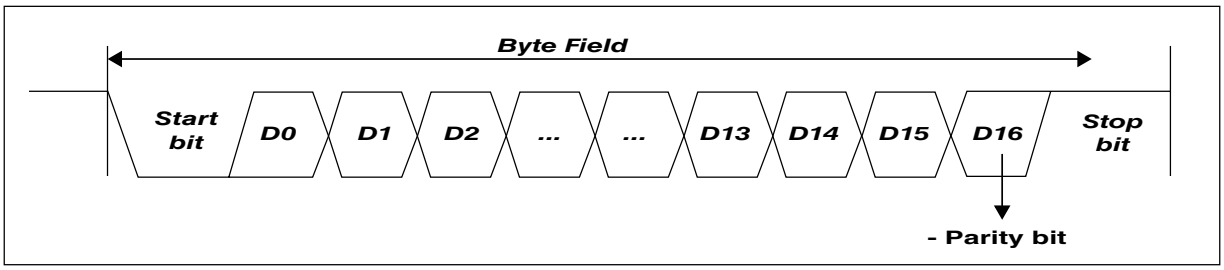

Figure 59-24. UART mode 17-bit data frame

59.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

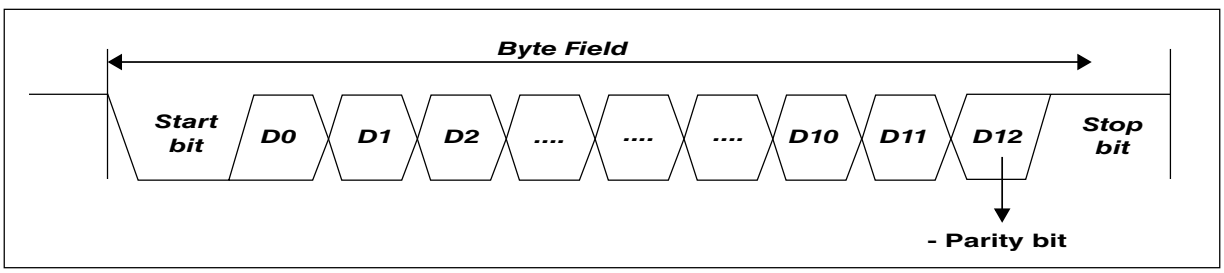

Figure 59-25. UART mode 13-bit data frame

59.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in the following figure:

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

Figure 59-26. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and upper eight bits in BDR1.

The same applies for reception.

59.3.4.7 UART transmitter

UART transmitter

In order to start transmission in the UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the TxEn bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 59-3. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Byte0	BDRL	FIFO	Byte	OK
Write Byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write Half-word0-1	BDRL	FIFO	Byte	IPS transfer error
Write Word	BDRL	FIFO	Byte	IPS transfer error
Write Byte0-1-2-3	BDRL	FIFO	Half-word	IPS transfer error
Write Half-word0	BDRL	FIFO	Half-word	OK
Write Half-word1	BDRL	FIFO	Half-word	IPS transfer error
Write Word	BDRL	FIFO	Half-word	IPS transfer error
Read Byte0-1-2-3	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Half-word0-1	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Word	BDRL	FIFO	Byte/Half-word	IPS transfer error
Write Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Write Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Write Word	BDRL	BUFFER	Byte/Half-word	OK
Read Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Read Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Read Word	BDRL	BUFFER	Byte/Half-word	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

59.3.4.8 UART receiver

UART receiver

The reception of a data byte is started as soon as the user exits initialization mode, sets the RxEn bit, and detects start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-half-words (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. RxEn bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 59-4. BDRM access in UART mode

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Byte4	BDRM	FIFO	Byte	OK
Read Byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read Half-word2-3	BDRM	FIFO	Byte	IPS transfer error
Read Word	BDRM	FIFO	Byte	IPS transfer error
Read Byte4-5-6-7	BDRM	FIFO	Half-word	IPS transfer error
Read Half-word2	BDRM	FIFO	Half-word	OK
Read Half-word3	BDRM	FIFO	Half-word	IPS transfer error
Read Word	BDRM	FIFO	Half-word	IPS transfer error
Write Byte4-5-6-7	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Word	BDRM	FIFO	Byte/Half-word	IPS transfer error
Read Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	OK
Read Half-word2-3	BDRM	BUFFER	Byte/Half-word	OK
Read Word	BDRM	BUFFER	Byte/Half-word	OK
Write Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Word	BDRM	BUFFER	Byte/Half-word	IPS transfer error

Note

Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and data bits of the registers BDRL/BDRM.

Note

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of one reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt will be helpful in identifying which byte has framing error.
- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.

- When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.
- When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

59.3.5 DMA interface

59.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

59.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in Table 59-5 and Table 59-6.

Table 59-5. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)

Table continues on the next page...

Table 59-5. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
BIDR	DFL [5:0]	—	Data field length: • 1 to 8 bytes: normal frames • 1 to 64 bytes: extended frames
	DIR	—	Direction of the data field: • 0 => reception • 1 => transmission
	CCS	—	Checksum type: • 0 enhanced • 1 classic
	ID[5:0]	—	Identifier.
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA. • 0 buffer data is free • 1 buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7. Used for the extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7. Used for the extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received. Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode).
UARTCR	FBM	—	FIFO/Buffer mode • 0 Buffer mode • 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty • 0 Rx FIFO not empty • 1 Rx FIFO empty
	TFF	—	Tx FIFO full • 0 Tx FIFO not full • 1 Tx FIFO full

DMATXE[2**TX_CH_NUM][1]		High	DMA Tx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] -1.
			DMATXE[x] = 0b => TX channel x disabled
			DMATXE[x] = 1b => TX channel x enabled

DMARXE[2**RX_CH_NUM][1]		High	DMA Rx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.

Table 59-5. LINFlexD control/status fields description

Register	Field	Level	Description

			In LIN slave mode: # DMA RX channel = IFMI[3:0] -1.
			DMARXE[x] = 0b => RX channel x disabled
			DMARXE[x] = 1b => RX channel x enabled

1. ** stands for exponentiation.
1. ** stands for exponentiation

Table 59-6. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).
DMA_TEN	LIN slave Tx	DMATXE[x] x = IFMI — 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] x = IFMI — 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in Table 59-7.

Table 59-7. TCD control fields description

TCD Field	Level	Description
CITER[14:0]	—	Current "major" iteration count
BITER[14:0]	—	Beginning "major" iteration count
NBYTES[31:0]	—	Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address

Table continues on the next page...

Table 59-7. TCD control fields description (continued)

TCD Field	Level	Description
DOFF[15:0]	—	Destination address signed offset applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request.
DONE	High	Channel done (the DMA has completed the outer major loop).
D_REQ	High	Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

59.3.5.3 Master node –TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

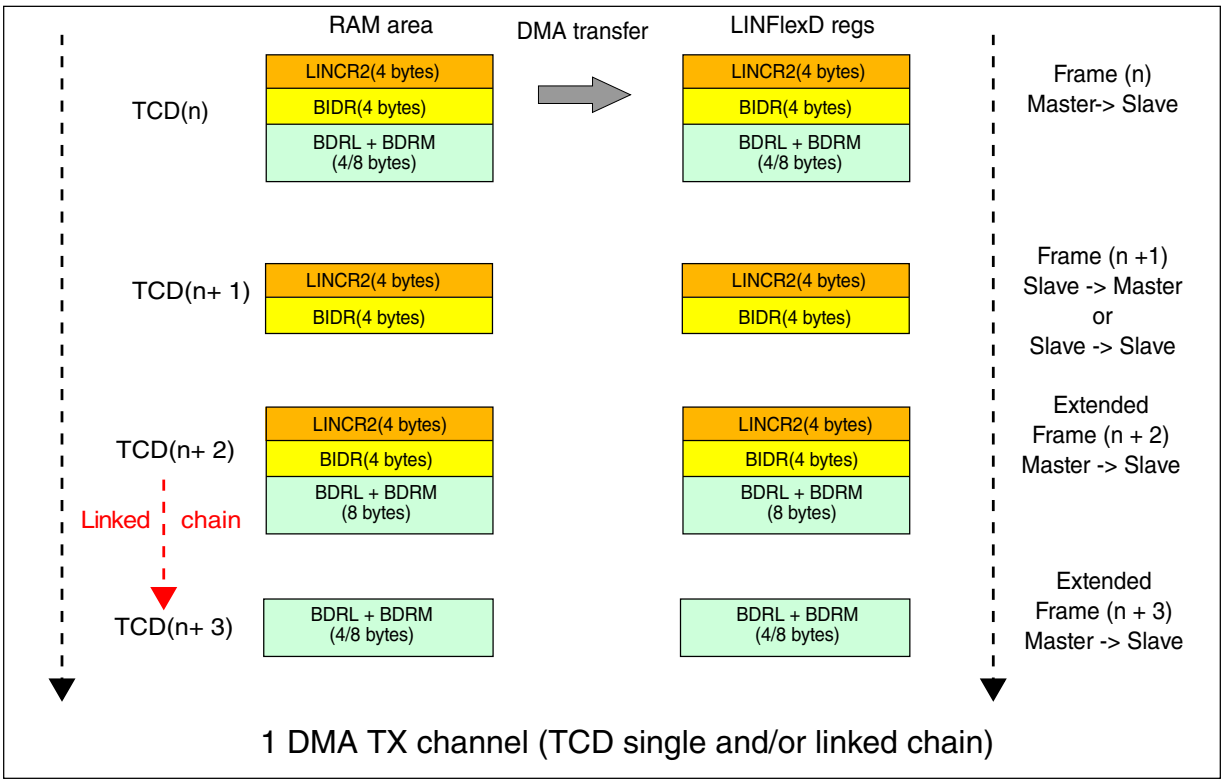

Figure 59-27. Master node –TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

The following table provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 59-8. Master node – Tx mode – Register setting

LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

Table continues on the next page...

Table 59-8. Master node – Tx mode – Register setting (continued)

LIN frame	LINCR2	BIDR
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in Table 59-9. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 59-9. TCD setting – Master node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	-	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	
DADDR[31:0]	-	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

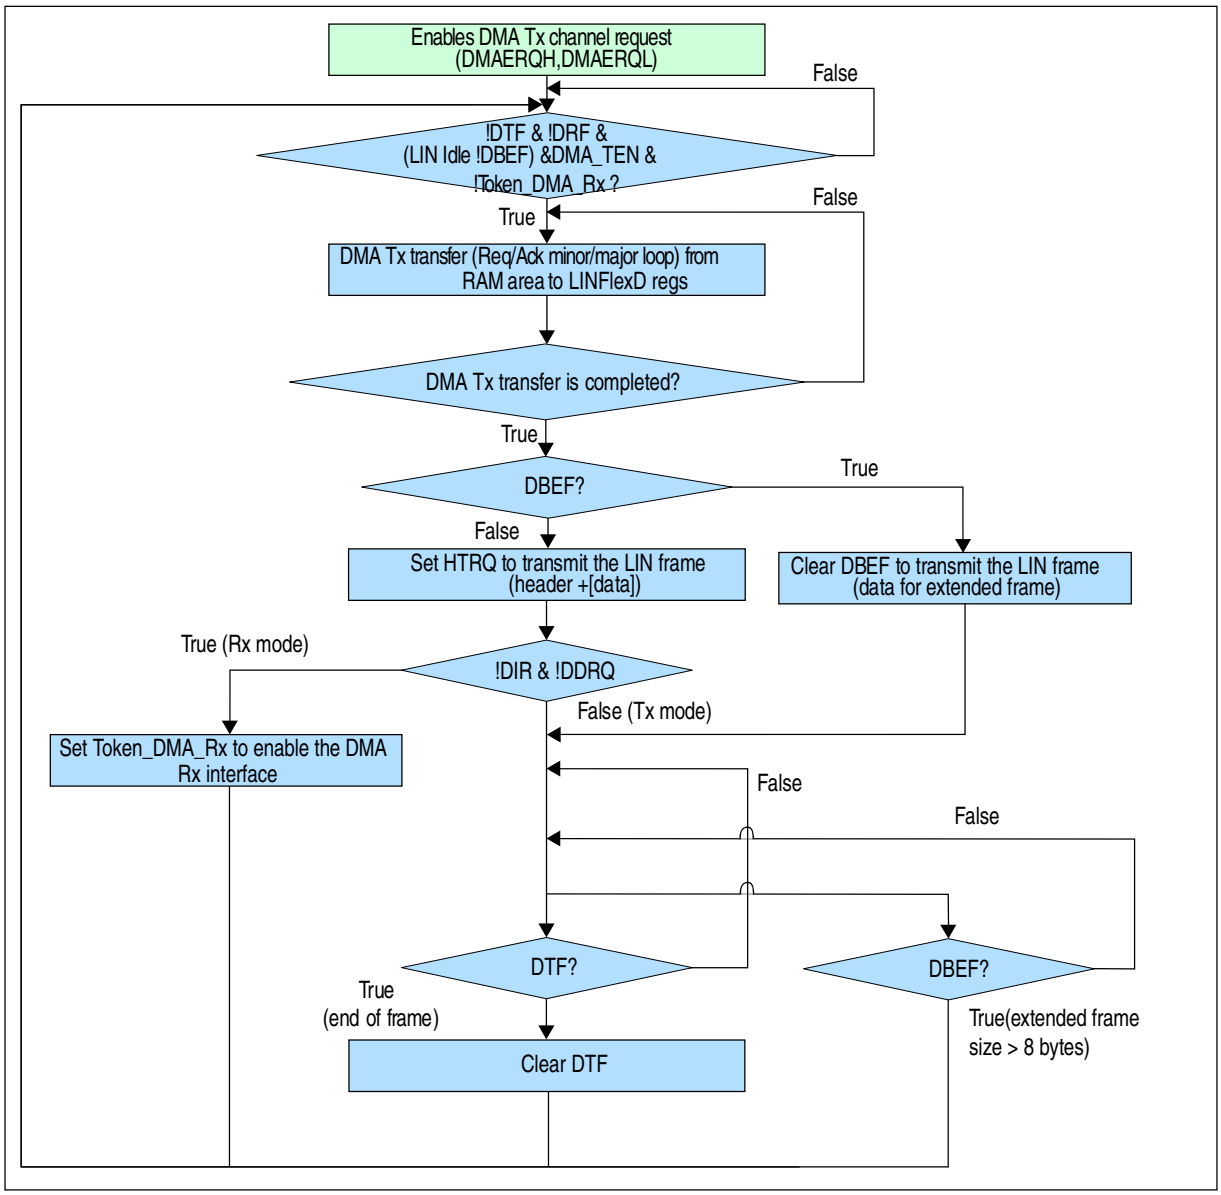

Figure 59-28. Master node – DMA Tx FSM (concept scheme)

59.3.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame , except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

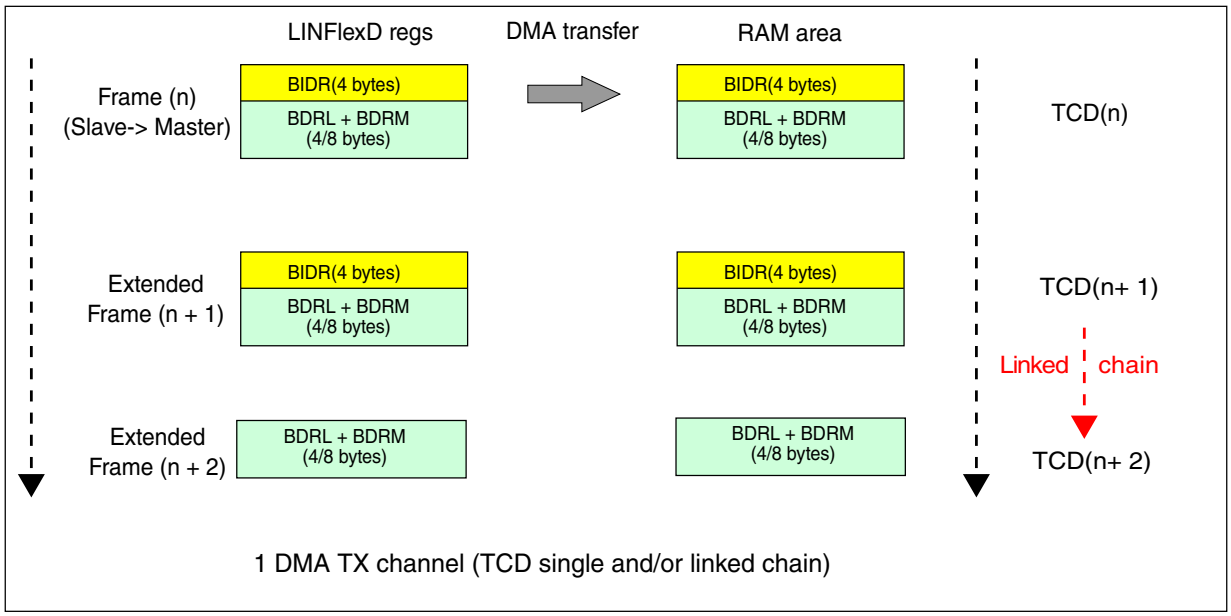

Figure 59-29. Master node – RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in the following figure. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in the next table. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 59-10. TCD setting – Master node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—

D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

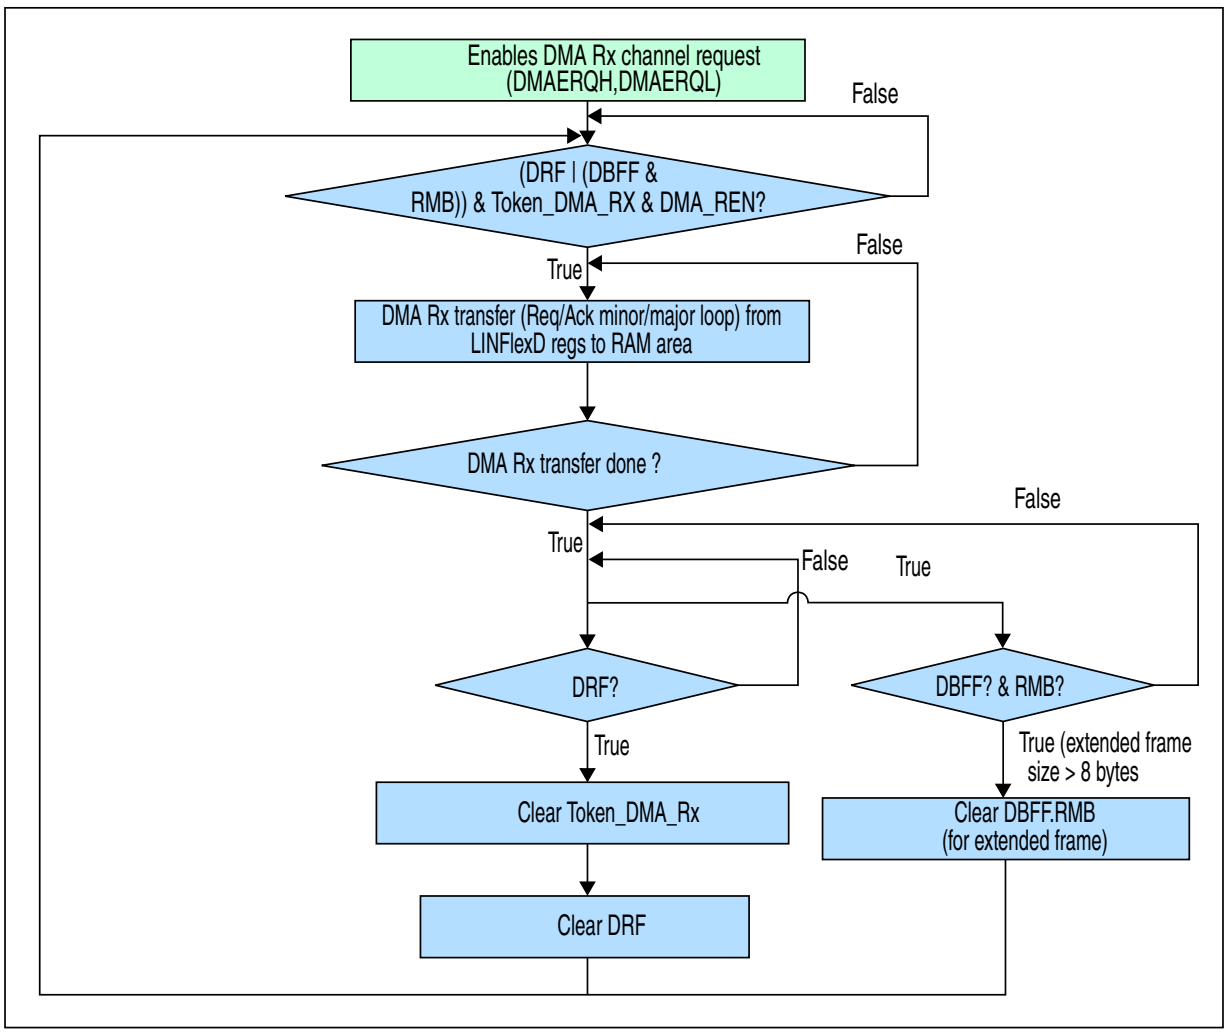

Figure 59-30. Master node – DMA Rx FSM (concept scheme)

59.3.5.5 Slave node – TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

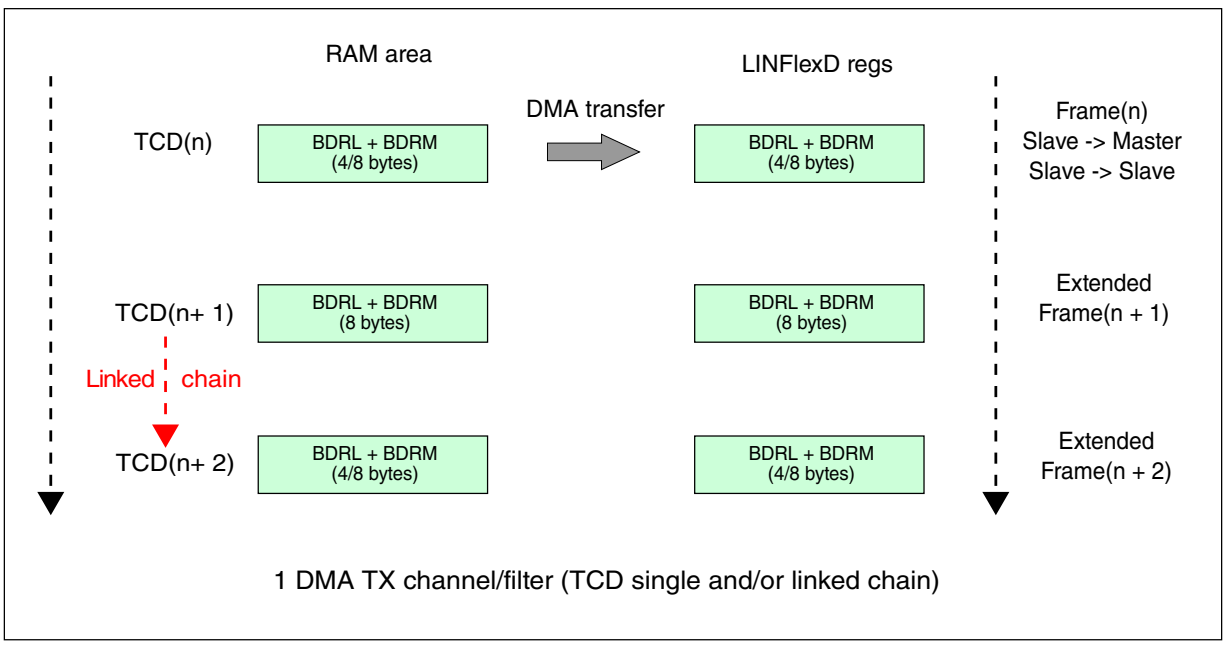

Figure 59-31. Slave node – TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in Table 59-11.

Table 59-11. Slave node – Tx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1.The TCD setting (word transfer) is given in Table 59-12. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 59-12. TCD setting – Slave node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer

INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

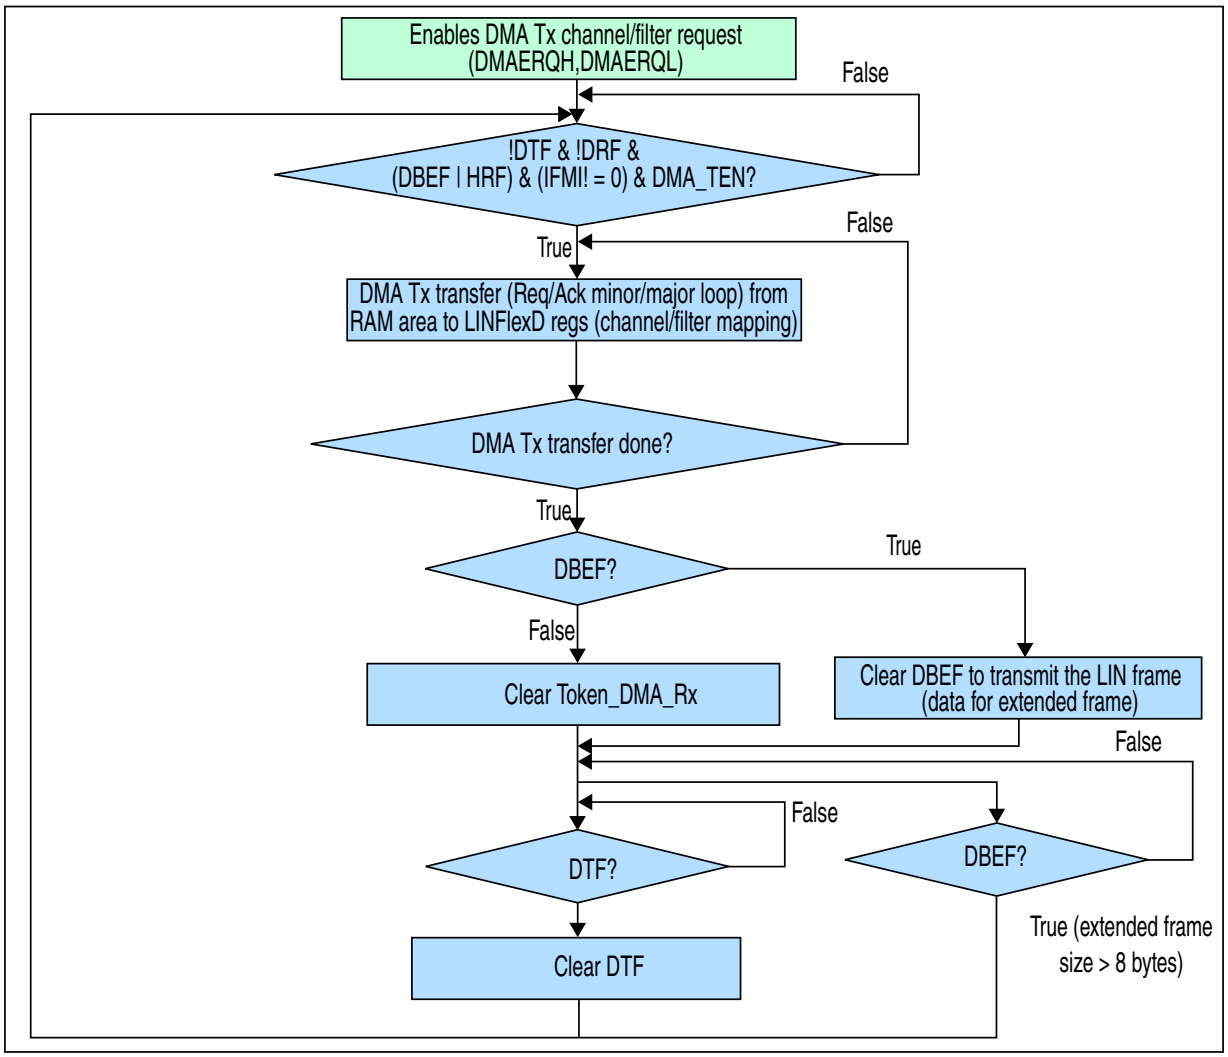

Figure 59-32. Slave node – DMA Tx FSM (concept scheme)

59.3.5.6 Slave node – RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

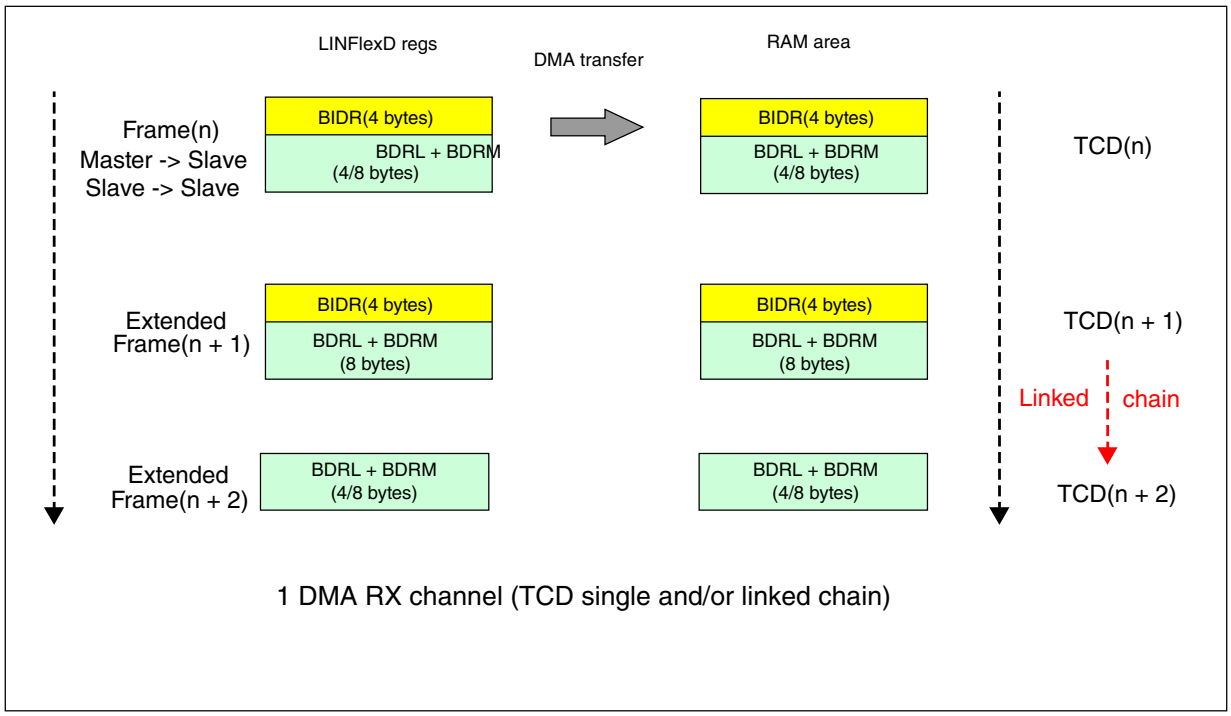

Figure 59-33. Slave node – RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, IFCR registers is given in Table 59-13.

Table 59-13. Slave node – Rx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in the following figure. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in Table 59-14. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 59-14. TCD setting – Slave node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM

DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

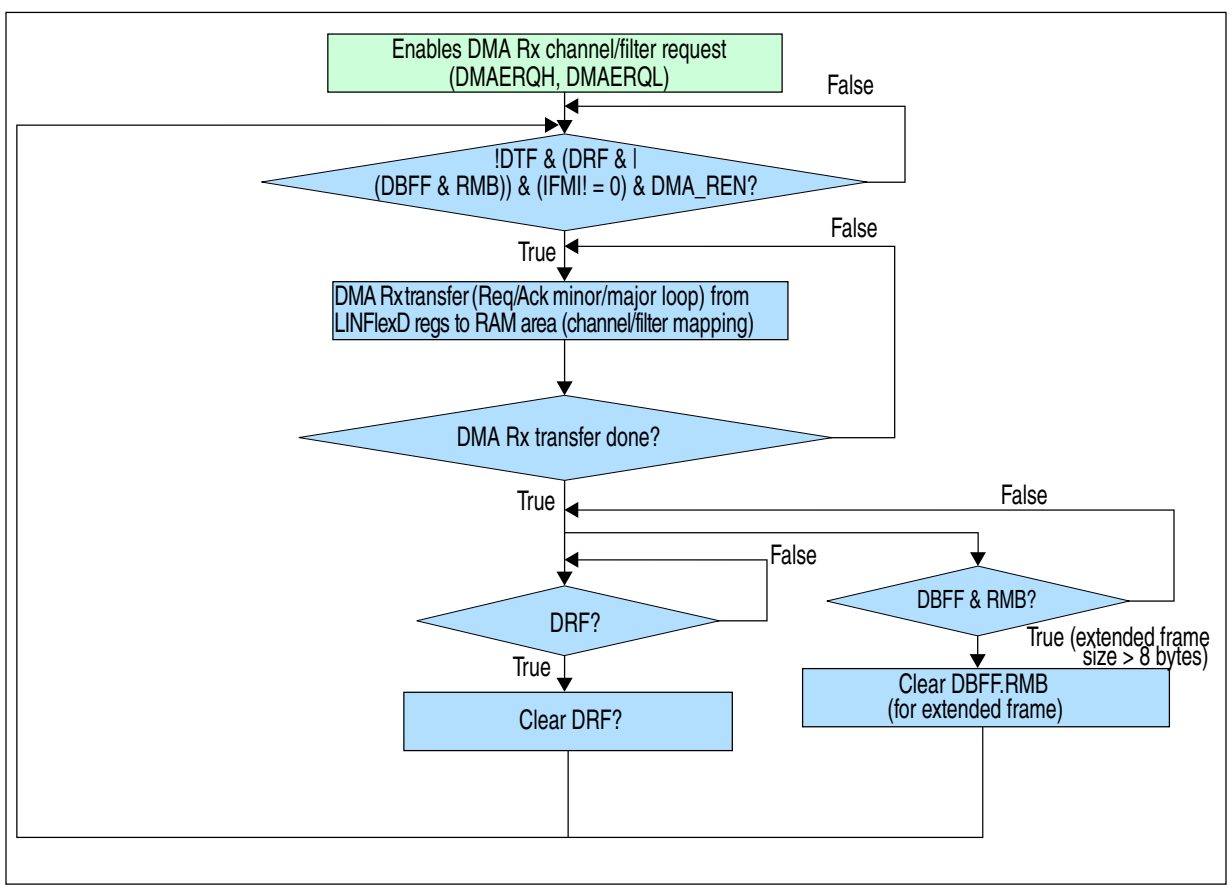

Figure 59-34. Slave node – DMA Rx FSM (concept scheme)

59.3.5.7 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Figure 59-35.

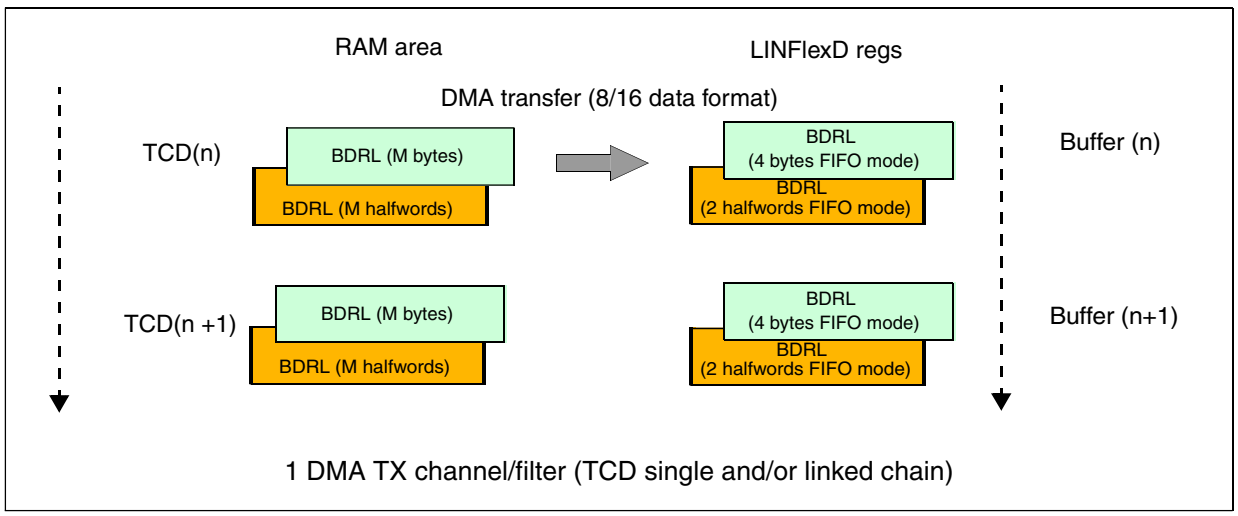

Figure 59-35. UART – TX memory map

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8 bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in Figure 59-36. DMA Tx FSM will move to Idle state if DMATXE[0] = 0.The TCD setting (typical case) is given in Table 59-15. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 59-15. TCD setting – UART – Tx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		RAM address
SOFF[15:0]	1	2	Byte/Half-word increment
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	–M	–M × 2	-
DADDR[31:0]	-		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

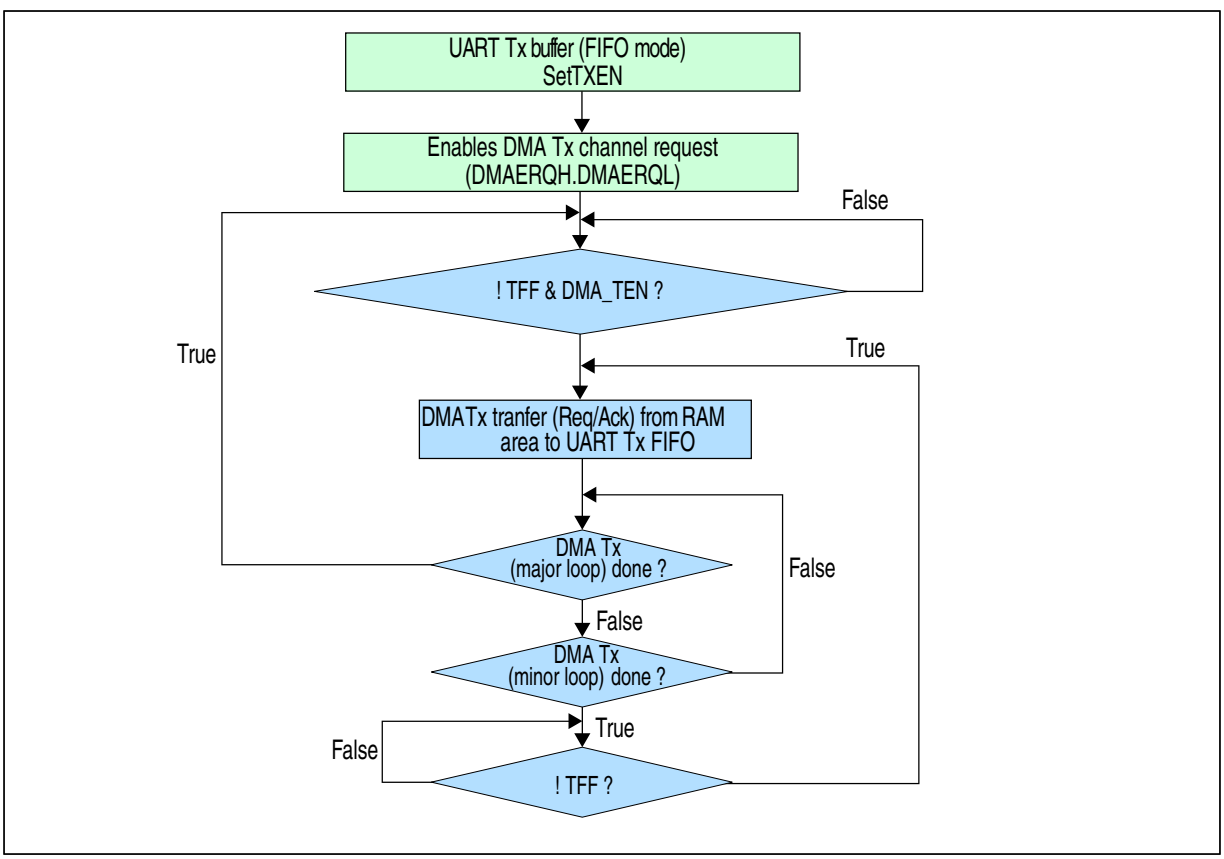

Figure 59-36. UART – DMA Tx FSM (concept scheme)

59.3.5.8 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Table 59-16.

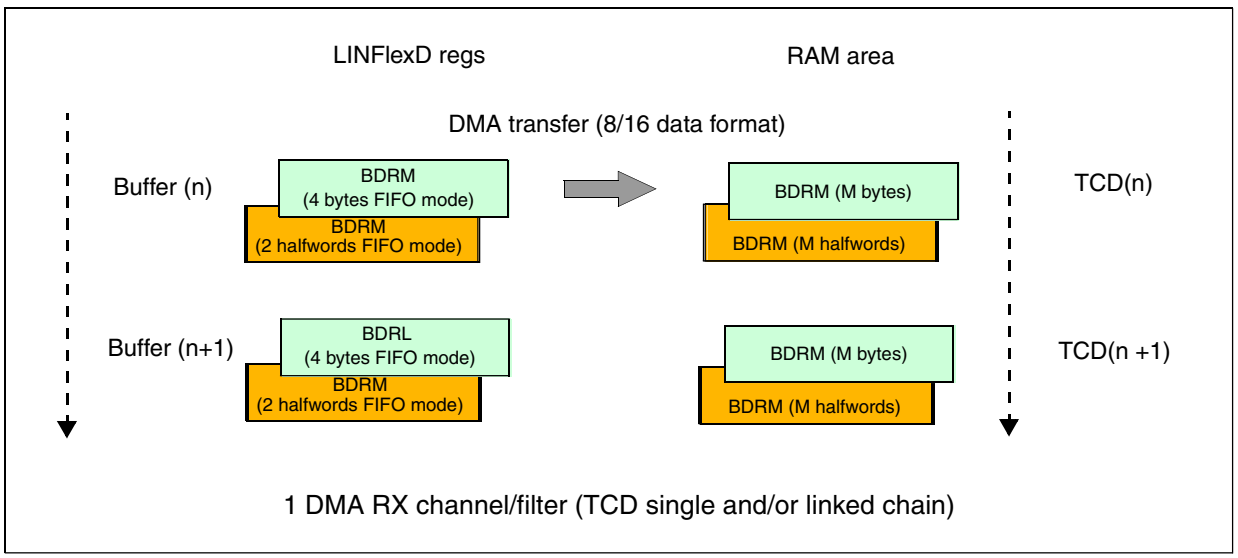

Figure 59-37. UART – RX memory map

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format

This will sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in Figure 59-38. DMA Rx FSM will move to Idle state if DMARXE[0] = 0.The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/ halfword as soon an entry is available in the Rx FIFO. A new software reset bit is

required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 59-16. TCD setting – UART – Rx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	0		
DADDR[31:0]	-		RAM address
DOFF[15:0]	1	2	Byte/Half-word increment
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

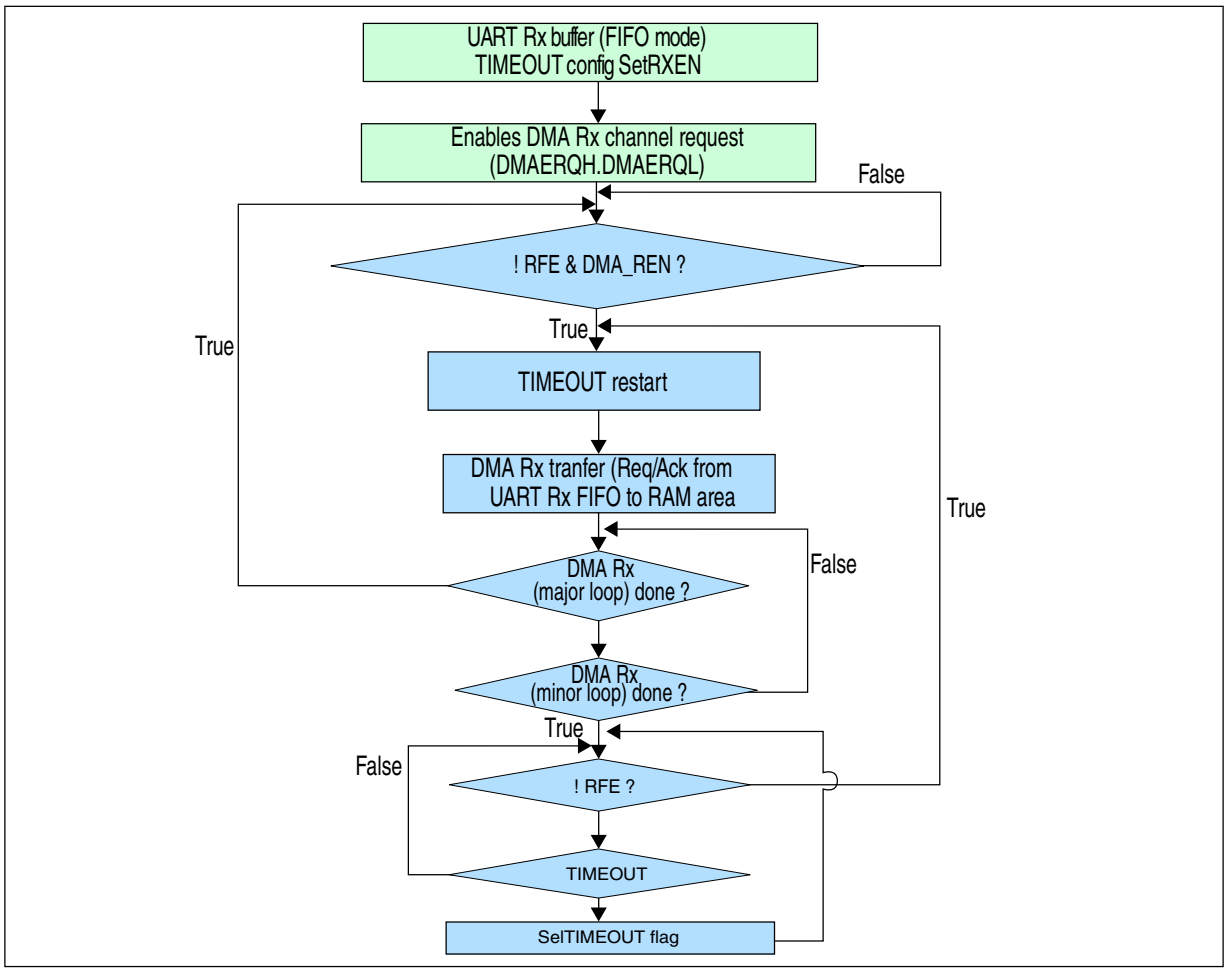

Figure 59-38. UART – DMA Rx FSM (concept scheme)

59.3.5.9 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index)
- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses

- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

59.4 Memory map and register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

NOTE

In Master mode, the registers IFCR0-IFCR15 are not present and the corresponding absolute address of the below register changes as shown in the following table.

Table 59-17. Offsets of the register from offsets 8C to 9C

Register name	Master/slave mode	Master only mode
LINFlexD_GCR	0x8C	0x4C
LINFlexD_UARTPTO	0x90	0x50
LINFlexD_UARTCTO	0x94	0x54
LINFlexD_DMATXE	0x98	0x58
LINFlexD_DMARXE	0x9C	0x5C

NOTE

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in ips_xfr_err being flagged.

LINFlexD memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	LIN Control Register 1 (LINFlexD_LINCR1)	32	R/W	See section	59.4.1/3193

59.4.1 LIN Control Register 1 (LINFlexD_LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

NOTE

When accessing the LINCR1 register, each reserved bit should be written to its original reset value.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CCD	CFD	LASE	AUTOWU	MBL				BF	0	LBKM	MME	SSBL	RBLM	SLEEP	INIT
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	*	0	0	1	0

* Notes:
- MME field: If slave = 0, then MME bit is 1, else MME bit is 0

LINFlexD_LINCR1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CCD	Checksum Calculation disable This bit can be written during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to sent a software calculated checksum/CRC (provided CFD is reset).
17 CFD	Checksum field disable This bit can be configured during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame
18 LASE	LIN Autosynchronization Enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0). Register bit can be read in any mode, written only in initialization mode. 0 Autosynchronization disabled 1 Autosynchronization enabled
19 AUTOWU	Auto Wakeup This bit can be configured during Initialization mode only. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
	0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
20–23 MBL	Master Break Length These bits choose the length of the Sync break to be generated by the master. These bits can be programmed in Initialization mode only. They are read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0000 10-bit break length 0001 11-bit break length 0010 12-bit break length 0011 13-bit break length 0100 14-bit break length 0101 15-bit break length 0110 16-bit break length 0111 17-bit break length 1000 18-bit break length 1001 19-bit break length 1010 20-bit break length 1011 21-bit break length 1100 22-bit break length 1101 23-bit break length 1110 36-bit (cooling) break length 1111 50-bit break length
24 BF	By-pass filter This bit can be programmed during Initialization mode only. **NOTE:** If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode. 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LBKM	Loop Back mode Refer to "Loop back mode" in Test mode . Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Loop Back Mode disabled 1 Loop Back mode enabled
27 MME	Master mode enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. **NOTE:** If generic slave = 0, then this bit will read a '1' always, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
	0 Slave Mode 1 Master Mode
28 SSBL	Slave Mode Sync Break Length This bit can be programmed in Initialization mode only. It is read only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 11 bit break length 1 10 bit break length
29 RBLM	Receiver Buffer Locked mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also. When PSI5S is not in UART_STDALONE mode, SLEEP bit can be set if it is in PS_DISABLE mode else this bit is cleared.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also. When PSI5S is not in UART_STDALONE mode, INIT bit can be set if it is in PS_CONFIG mode else this bit is cleared.

59.4.2 LIN Interrupt enable register (LINFlexD_LINIER)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	SZIE	OCIE	BEIE	CEIE	HEIE	0		FEIE	BOIE	LSIE	WUIE	DBFIE	DBEIETOIE	DRIE	DTIE	HRIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_LINIER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZIE	Stuck at zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR. 0 No interrupt 1 Interrupt enabled
20 HEIE	Header Error Interrupt Enable An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **NOTE:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed.

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
	0 No interrupt 1 Interrupt enabled
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR. 0 No interrupt 1 Interrupt enabled
25 LSIE	LIN state Interrupt enable Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag. 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum
26 WUIE	Wakeup interrupt enable If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated. 0 No interrupt 1 Interrupt enabled
27 DBFIE	Data Buffer Full Interrupt enable An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set. 0 No interrupt 1 Interrupt enabled
28 DBEIETOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode). 0 No interrupt 1 Interrupt enabled
29 DRIE	Data Reception complete Interrupt enable An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
30 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
31 HRIE	Header Received Interrupt

Table continues on the next page...

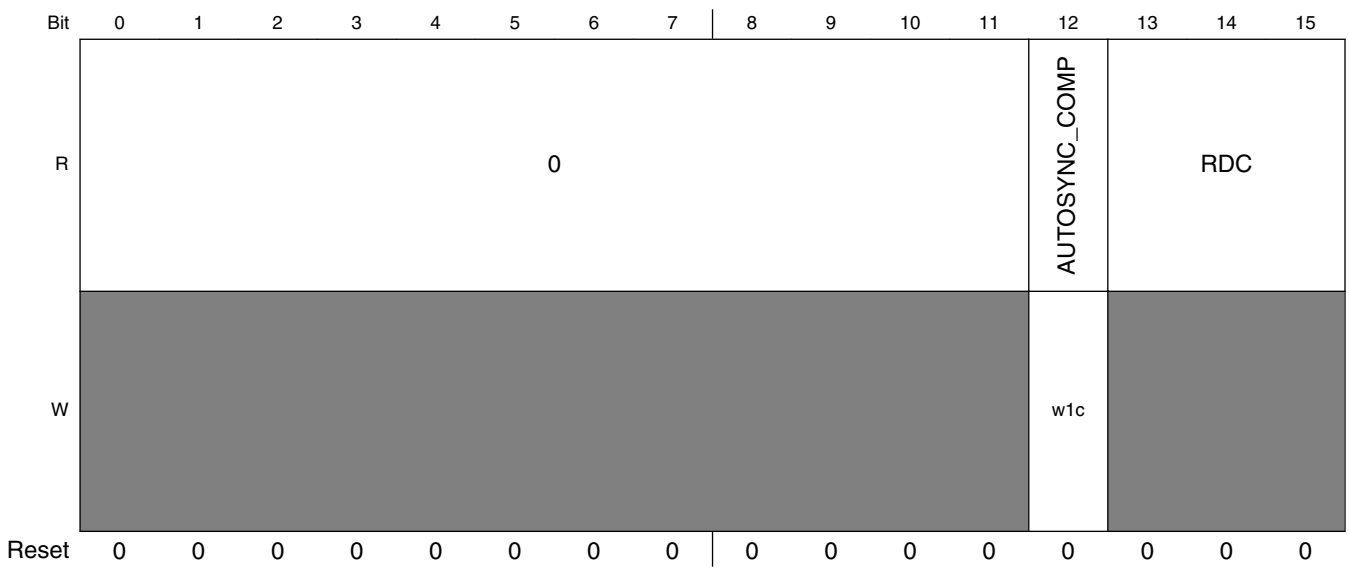
LINFlexD_LINIER field descriptions (continued)

Field	Description
	An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed. 0 No interrupt 1 Interrupt enabled

59.4.3 LIN Status Register (LINFlexD_LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0h base + 8h offset = 8h



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LINS				0		RMB	DRBNE	RXbusy	RDI	WUF	DBFF	DBEF	DRF	DTF	HRF
W	1						w1c	w1c			w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	*	0	0	0	0	0	0

* Notes:
- RDI field: Reset value of RDI reflects the RX pin state

LINFlexD_LINSR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 AUTOSYNC_COMP	AUTOSYNC_COMP This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers can be read in autosynchronization mode. **NOTE:** If autosynchronization is disabled, this bit is reserved.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table continues on the next page...

LINFlexD_LINSR field descriptions (continued)

Field	Description
16–19 LINS	LIN state In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits. **NOTE:** The value of this bit field doesn't change by any write operation to it. Writing 0xF to this bit field clears the Rx interrupt, only when set due to the LIN state event. 0000 Sleep mode: LINFlexD is in Sleep mode, to save power consumption. 0001 Init mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0010 Idle mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0011 Sync break: In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. Note: In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0100 Sync Del: In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0101 Sync Field: In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0110 Identifier Field: In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0111 Header Reception/Transmission: In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 1000 Data Reception/Data Transmission: In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 1001 Checksum: Data transmission/reception completed, checksum transmission/reception ongoing.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXbusy	Receiver Busy flag In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit. 0 Receiver is idle 1 Reception ongoing

Table continues on the next page...

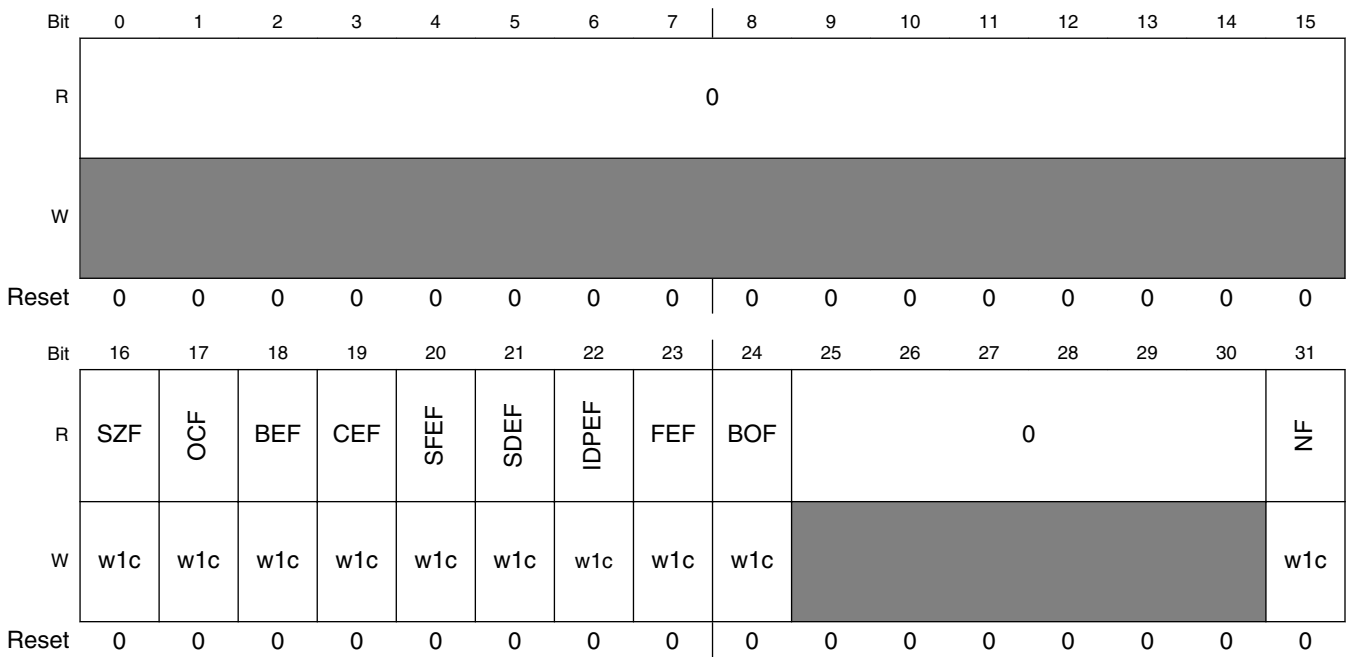
LINFlexD_LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **NOTE:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. 1. When slave is in Sleep mode 2. When master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next 8 bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: a) All filters are inactive and Bypass filter (BF) bit is set b) No match in any filter and Bypass filter (BF) bit is set c) TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

59.4.4 LIN Error Status Register (LINFlexD_LINESR)

Refer to Errors for detailed description of all errors.

Address: 0h base + Ch offset = Ch



LINFlexD_LINESR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0: No output compare event occurred 1: In master mode, LINESR[OCF] flag is set when counter LINTCSR[CNT] has matched the content of LINOCR[OC2]. In slave mode, LINESR[OCF] is set when the content of the counter LINTCSR[CNT] has matched the content of LINOCR[OC1] or LINOCR[OC2]. This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.

Table continues on the next page...

LINFlexD_LINESR field descriptions (continued)

Field	Description
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **NOTE:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
25–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

59.4.5 UART Mode Control Register (LINFlexD_UARTCR)

NOTE

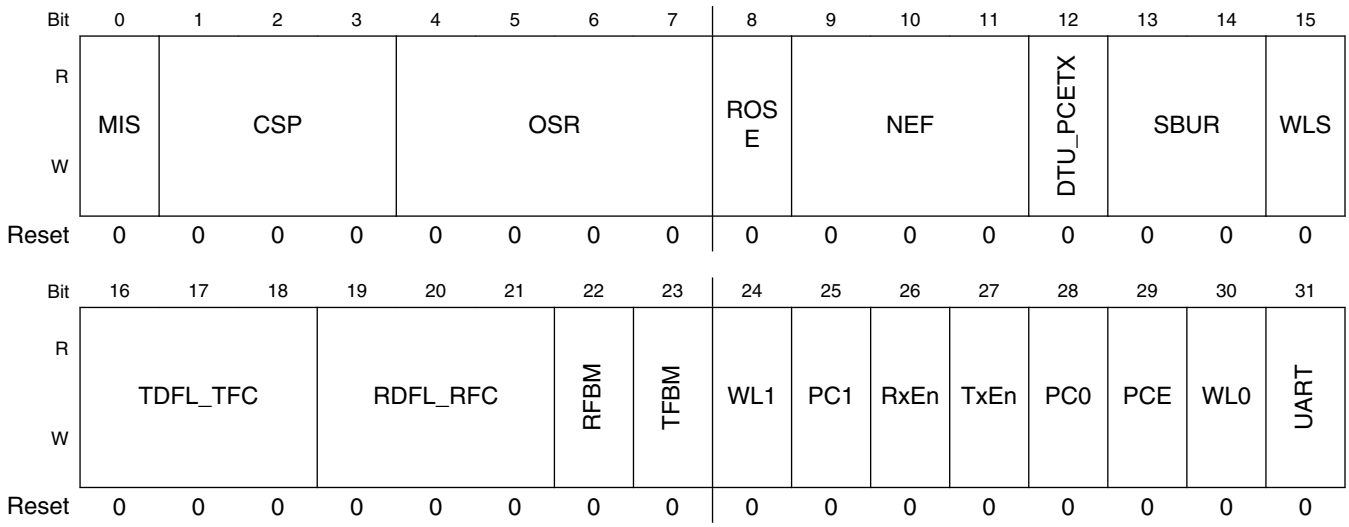
When accessing the UARTCR register, reserved bits should always be written to zero.

NOTE

The LINFlex module does not support communication with Special Word Length in UART mode set (UARTCR[WLS] = 1)

in buffer mode or in FIFO mode with UARTCR[WL1, WL0] = 0,1.

Address: 0h base + 10h offset = 10h



LINFlexD_UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State Register bit can be read in any mode, written only in initialization mode. 0 UARTCTO monitors the number of bits to be received. 1 UARTCTO monitors the idle state of the reception line.
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling. CSP can take the following range of values for a certain over sampling rate: **OSR** / **CSP** 4 / 2,3 5 / 2, 3, 4 6 / 3, 4, 5 8 / NA Register bit can be read in any mode, written only in initialization mode.
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled. Allowed values are: 4, 5, 6 and 8 . Register bit can be read in any mode, written only in initialization mode.
8 ROSE	Reduced Over Sampling EnableRegister bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate.
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received. Register bit is a read/write field.
12 DTU_PCETX	Disable Timeout in UART mode/Parity transmission and checking This bit can be programmed in Initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. **In Buffer mode:** This timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point the DRF bit is also set and num_of_frames (number of frames received), rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts again. The value of counter is 0 when it restarts. **In FIFO mode:** When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart again. The value of counter is 0 when it restarts. Notes: • Disable Timeout causes only the Timer to restart which enables Timeout again. • Timer reset means it resets and starts counting again and the Timeout is enabled. When PSI5S is not in UART_STDALONE mode: 0 Parity transmission and checking disabled 1 Parity transmission and checking enabled When PSI5S is in UART_STDALONE mode: 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. This bit can be programmed in the initialization mode only, when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 reserved
15 WLS	Special Word Length in UART mode This bit can be programmed in initialization mode only when the UART bit is set. If this bit is set, setting WL and PCE bits has no effect in UART reception although parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	Register bit can be read in any mode, written only in Initialization mode. 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support.
16–18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 15 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes Register bit is a read/write field. TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 : empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes Others : reserved TDFLTFC can be programmed and are significative only when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. **NOTE:** When PSI5S is not in UART_STDALONE mode, these bits always reflects the value of PSI5S_GLCR[DIRCMD_LEN] **NOTE:** When a debugger is connected, this counter will decrement if TxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
19–21 RDFL_RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 : Empty 001 : 1 byte

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	010 : 2 bytes/1.5 byte in case of WLS bit setting 011 : 3 bytes 100 : 4 bytes/2x1.5 byte in case of WLS bit setting Others - Reserved RDFLRFC can be programmed and are significative only when the UART bit is set. **NOTE:** In buffer mode, RDFL should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint. **NOTE:** When a debugger is connected, this counter will decrement if RxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
22 RFBM	RFBM Rx Fifo/Buffer mode This bit can be programmed in Initialization mode, only when the UART bit is set. Register bit can be read in any mode, written only in initialization mode. 0 Rx Buffer mode enabled 1 Rx Fifo mode enabled (mandatory in DMA Rx mode)
23 TFBM	Tx Fifo/Buffer mode This bit can be programmed in initialization mode, only when the UART bit is set. Register bit can be read in any mode, written only in initialization mode. 0 Tx Buffer mode enabled 1 Tx Fifo mode enabled (mandatory in DMA Tx mode)
24 WL1	Word Length in UART mode This bit can be programmed in Initialization mode only, when the UART bit is set. Register bit can be read in any mode, written only in initialization mode.

WL1	WL0	Description
0	0	7 bits data + parity
0	1	8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1
1	0	15 bits data + parity
1	1	16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1

25 PC1	Parity Control This bit can be programmed in Initialization mode, only when UART bit is set. Register bit can be read in any mode, written only in initialization mode.

PC1	PC0	Description
0	0	Parity sent is Even
0	1	Parity sent is Odd

R	SZF	OCF	PE				RMB	FEF	BOF	RDI	WUF	RFNE	TO	DRFRFE	DTFTFF	NF
W	w1c	w1c	w1c				w1c	w1c	w1c	w1c	w1c		w1c			w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_UARTSR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. **NOTE:** For Baud rate above 1 Mbit/s, this flag is not usable. 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR
18–21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **NOTE:** Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set). • When PE0 is set, it indicates Parity error in either first or second byte received • When PE2 is set, it indicates Parity error in either third or fourth byte received 0 No parity error 1 Parity error in the corresponding received byte
22 RMB	Release Message Buffer This bit should be cleared by software. This bit will reflect the same value as in LINSR, when in Initialization mode and the UART bit is set. 0 Buffer data is free 1 Buffer data ready to be read by software
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.

Table continues on the next page...

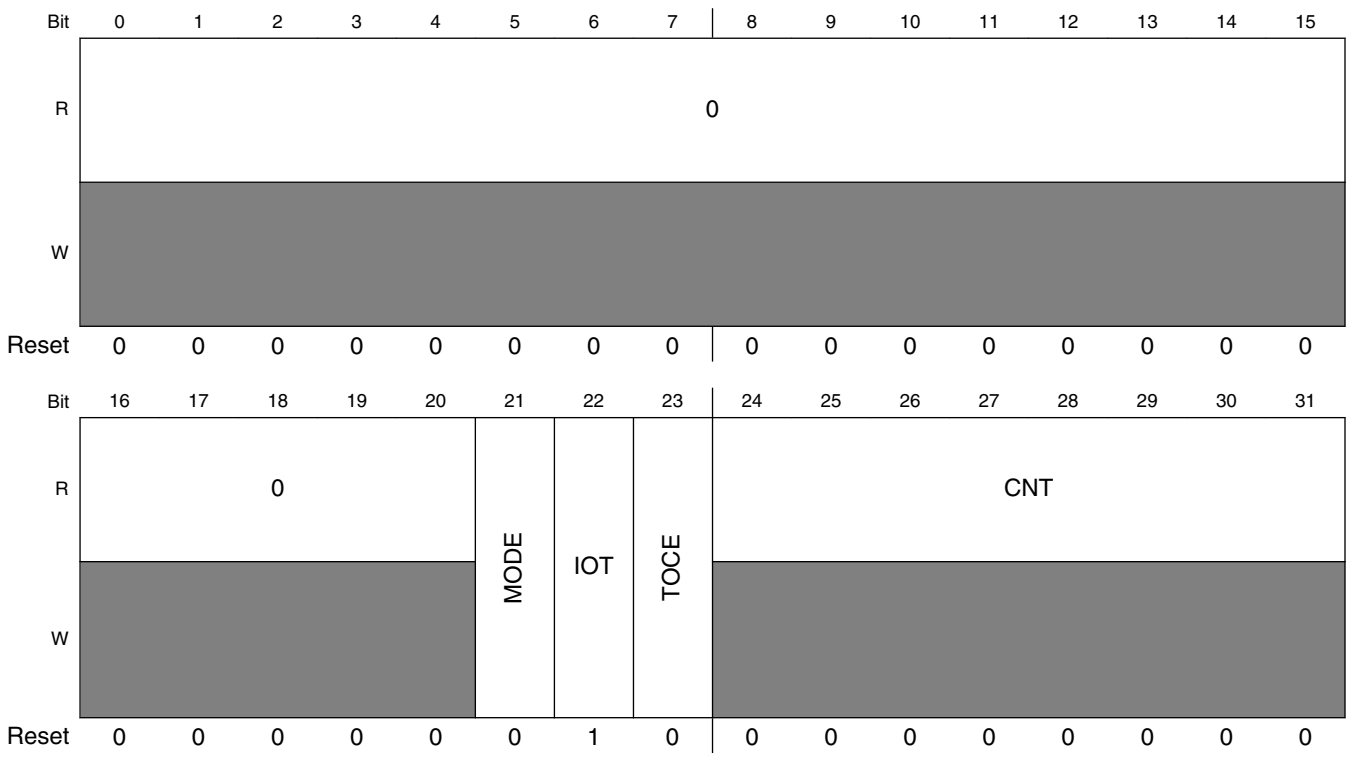
LINFlexD_UARTSR field descriptions (continued)

Field	Description
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRFRFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTFTFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

59.4.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)

This register contains control and status bits for timeout feature.

Address: 0h base + 18h offset = 18h



LINFlexD_LINTCSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 MODE	Time-out counter mode This bit can be configured only during initialization. Register bit can be read in any mode, written only in initialization mode. 0 LIN mode 1 Output compare mode
22 IOT	Idle on timeout Register bit can be read in any mode, written only in initialization mode. This feature is applicable only when MODE bit in LINTCSR is cleared. 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event

Table continues on the next page...

LINFlexD_LINTCSR field descriptions (continued)

Field	Description
23 TOCE	Time-out counter enable TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE. 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs.
24–31 CNT	Counter Value These bits reflect the value of a free-running counter used for timeout. **NOTE:** For proper functionality of this counter, LINIBRR should be >= 5.

59.4.8 LIN Output Compare Register (LINFlexD_LINOCR)

This register contains the value to be compared to the LINTCSR:CNT value. This register is writable by software only in Output Compare Mode.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																OC2								OC1							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

LINFlexD_LINOCR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 OC2	Output compare value 2
24–31 OC1	Output compare value 1

59.4.9 LIN Time-Out Control Register (LINFlexD_LINTOCR)

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				RTO				0	HTO						
W																
Reset	0	0	0	0	1	1	1	0	0	*	*	*	*	*	*	*

* Notes:

- HTO field: HTO reset values:

  HTO resets to 0011100b in Master only mode, if generic slave = 0.

  HTO resets to 0101100b in Master/Slave mode, if generic slave = 1.

LINFlexD_LINTOCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{Response\_Maximum} = 1.4 \times T_{Response\_Nominal}$
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. If Master mode is enabled then these bits will always reflect 28 (1.4 x 10 bits of sync + 1.4 x 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

59.4.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

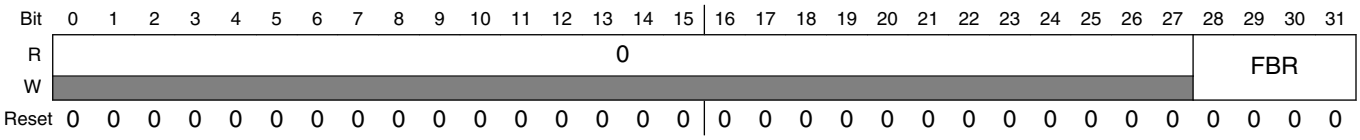
NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

NOTE

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0h base + 24h offset = 24h



LINFlexD_LINFBRR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 FBR	Fractional Baud rates Register bit can be read in any mode, written only in initialization mode. 0000 Fraction(LDIV) = 0 0001 Fraction(LDIV) = 1/16 0010 Fraction(LDIV) = 2/16 0011 Fraction(LDIV) = 3/16 0100 Fraction(LDIV) = 4/16 0101 Fraction(LDIV) = 5/16 0110 Fraction(LDIV) = 6/16 0111 Fraction(LDIV) = 7/16 1000 Fraction(LDIV) = 8/16 1001 Fraction(LDIV) = 9/16 1010 Fraction(LDIV) = 10/16 1011 Fraction(LDIV) = 11/16 1100 Fraction(LDIV) = 12/16 1101 Fraction(LDIV) = 13/16 1110 Fraction(LDIV) = 14/16 1111 Fraction(LDIV) = 15/16

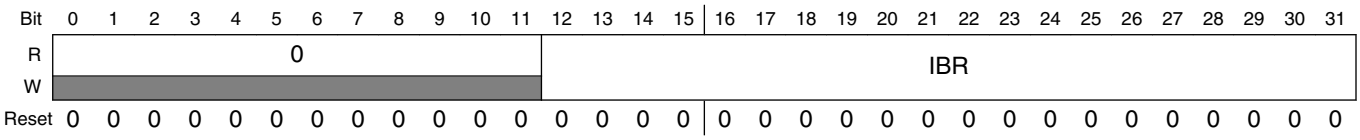
59.4.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)

This register consists of control bits that decide the baud rate along with the LINFBRR. It can be programmed only in Initialization mode.

NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Address: 0h base + 28h offset = 28h



LINFlexD_LINIBRR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 IBR	Integer Baud rates These bits along with the fractional baud rate bits decide the LIN baud rate. IBR = 0h: LIN clock disabled IBR = 1h: Mantissa (LDIV) = 1 ... IBR = FFFFEh: Mantissa (LDIV) = 1048574 IBR = FFFFFh: Mantissa (LDIV) = 1048575 Register bit can be read in any mode, written only in initialization mode.

59.4.12 LIN Checksum Field Register (LINFlexD_LINCFR)

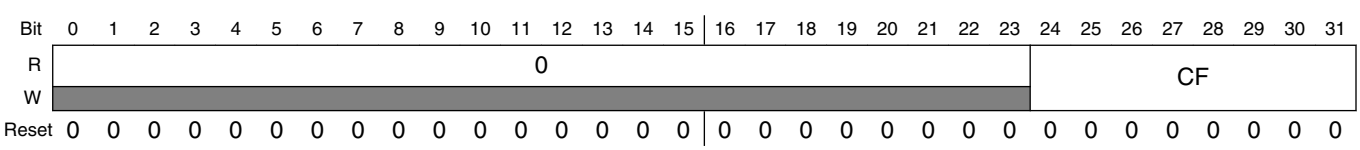
NOTE

There is a delay between 4 to 6 clock cycles of PBRIDGEx_CLK for the internal checksum's value (which is clocked with LIN_CLK/16 * LDIV) to reflect on LINCFR.

This register consists of checksum bits.

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	1	read/write	None
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

Address: 0h base + 2Ch offset = 2Ch



LINFlexD_LINCFR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 CF	Checksum bits When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software.

59.4.13 LIN Control Register 2 (LINFlexD_LINCR2)

This register includes control status bits related to buffer operations.

NOTE

When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TBDE	IOBE	IOPE	WURQ	DDRQ	DTRQ	ABRQ	HTRQ	0							
W																
Reset	0	1	*	0	0	0	0	0	0	0	0	0	0	0	0	0

* Notes:

- IOPE field: When slave = 0, this field always reads ‘0’ and cannot be programmed else this bit is programmable and reset value is 1.

LINFlexD_LINCR2 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TBDE	Two Bit delimiter bit This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits
17 IOBE	Idle on Bit Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine
18 IOPE	Idle on Identifier Parity Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. If generic slave = 0, then this bit will always read a 1 else 0, and cannot be programmed. 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request. Register bit can be read/set by software
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered. Register bit can be read/set by software
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete. Register bit can be read/set by software
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also. Register bit can be read/set by software Register bit can be read/set by software
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **NOTE:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

59.4.14 Buffer Identifier Register (LINFlexD_BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

LINFlexD_BIDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL = Number of data bytes - 1 **NOTE:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copy them in the BDR registers 1 LINFlexD transmits the data from the BDR registers

Table continues on the next page...

LINFlexD_BIDR field descriptions (continued)

Field	Description
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data filed only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = '1').

59.4.15 Buffer Data Register Least Significant (LINFlexD_BDRL)

This register is a part of an 8-byte data buffer.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 FACT	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

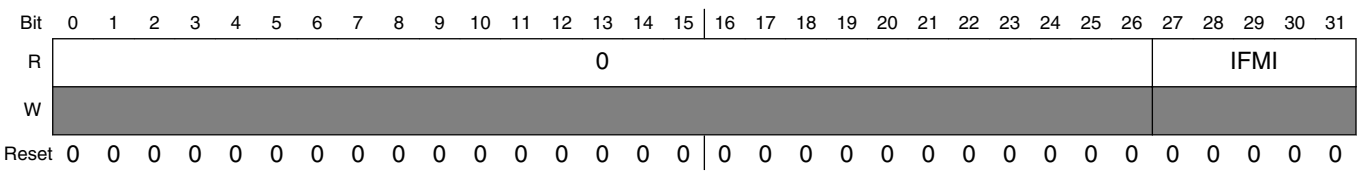
LINFlexD_IFER field descriptions (continued)

Field	Description
	1. In Identifier mask mode, FACT (2n+1) have no effect on the corresponding filters as they act as mask for the Identifier 2n. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **NOTE:** Refer to chip configuration details to see the number of filters used in the device.

59.4.18 Identifier Filter Match Index (LINFlexD_IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address: 0h base + 44h offset = 44h



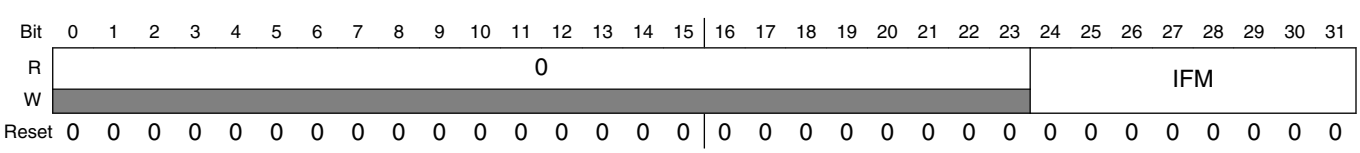
LINFlexD_IFMI field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IFMI	Filter match index Upon a filter match with xth filter – IFMI[4:0] = x+1. On no match IFMI is equal to 00h. This register contains the index corresponding to the received identifier. It can be used to directly write or read the data in SRAM (see Slave mode for more details).

59.4.19 Identifier Filter Mode Register (LINFlexD_IFMR)

This register configures the modes of filters.

Address: 0h base + 48h offset = 48h



LINFlexD_IFMR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 IFM	Filter mode Register bit can be read in any mode, written only in initialization mode. 0 Filters 2n and 2n+1 are in identifier list mode 1 Filters 2n and 2n+1 are in mask mode, where filter 2n+1 is the mask for filter 2n

59.4.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)

This register is read-only in normal mode and can be programmed only in Initialization mode.

Even-numbered instances (IFCR0, IFCR2, IFCR4, ...) of this register act as filters in both Identifier list and Identifier mask modes.

Odd-numbered instances (IFCR1, IFCR3, IFCR5, ...) of this register act:

- As filters in Identifier list mode
- As a mask for the preceding-numbered register in identifier mask mode

Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 15d

LINFlexD_IFCR*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes - 1 Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_IFCR*n* field descriptions (continued)

Field	Description
22 DIR	Direction This bit controls the direction of the data field. Register bit can be read in any mode, written only in initialization mode. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. Register bit can be read in any mode, written only in initialization mode. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. Register bit can be read in any mode, written only in initialization mode.

59.4.21 Global Control Register (LINFlexD_GCR)

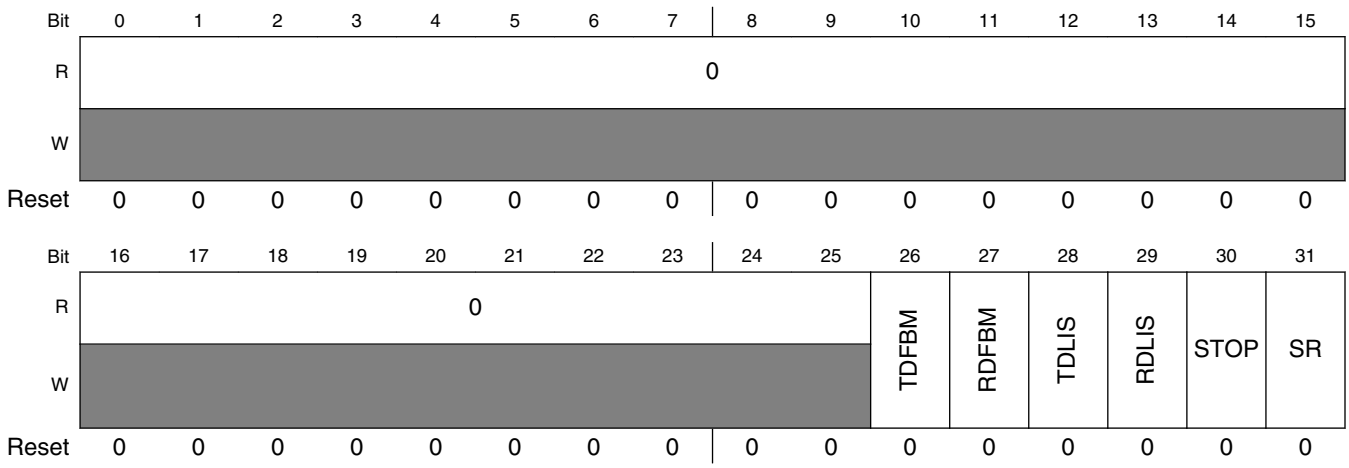
This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

The address offset depends on the no_of_filters. Refer to the chip configuration details for the number of filters used in this device.

Table 59-18. Register fields reset by SR

Register	Comment
LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset
LINESR	All fields are reset
LINTCSR	Only CNT[0:7] is reset
UARTSR	All fields except RFE & TFF are reset
UARTCR	Only TFC & RFC are reset
UARTCTO	All fields are reset

Address: 0h base + 8Ch offset = 8Ch



LINFlexD_GCR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Received data is not inverted 1 Received data is inverted

Table continues on the next page...

LINFlexD_GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). Register bit can be read in any mode, written only in initialization mode. 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). Register bit can be written only be software in initialization mode. Bit is always read 0 by software. Table 59-18 describes the register fields reset by SR.

59.4.22 UART Preset Timeout Register (LINFlexD_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be receivedor to monitor the idle state of the reception line. This register can be written by software any time.

The address offset depends on no_of_filters. Refer to the chip configuration details to see the number of filters used in the device.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																PTO															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

LINFlexD_UARTPTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO.

59.4.23 UART Current Timeout Register (LINFlexD_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see UART Preset Timeout Register (LINFlexD_UARTPTO) to monitor the number of bits received by UARTor to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

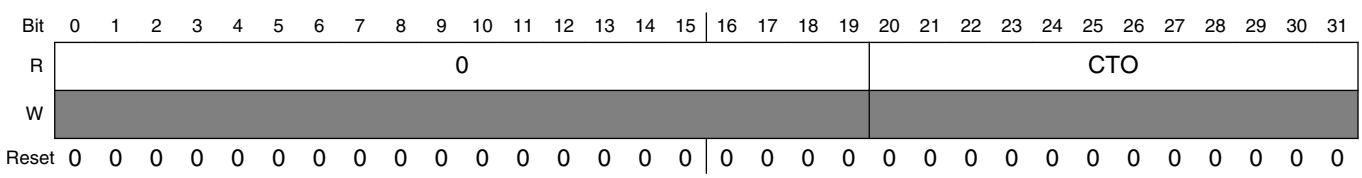
- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 94h offset = 94h



LINFlexD_UARTCTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 CTO	Current Timeout

Table continues on the next page...

LINFlexD_UARTCTO field descriptions (continued)

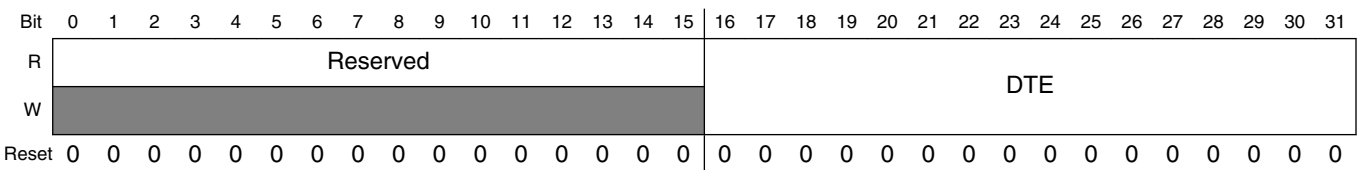
Field	Description
	CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

59.4.24 DMA Tx Enable Register (LINFlexD_DMATXE)

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 98h offset = 98h



LINFlexD_DMATXE field descriptions

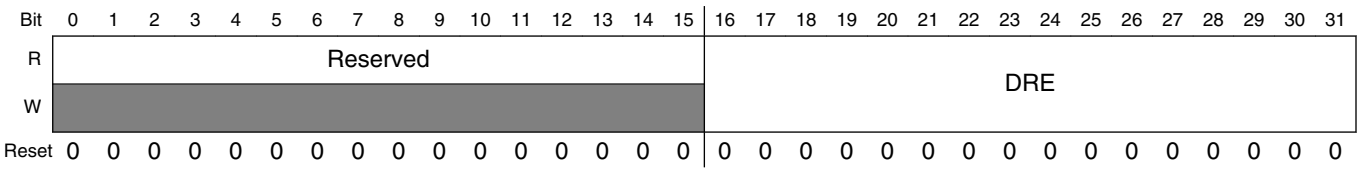
Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{TX\_CH\_NUM}$. These lies from 0 to (31 - $2^{TX\_CH\_NUM}$). Refer to the chip configuration details for the value of TX_CH_NUM used in this device.
16–31 DTE	DMA Tx channel Y enable **NOTE:** The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is [$2^{TX\_CH\_NUM}$ - 1 : 0]. The position of these bits are (32 - $2^{TX\_CH\_NUM}$) to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of TX_CH_NUM used in this device. 0 DMA Tx channel Y disabled 1 DMA Tx channel Y enabled

59.4.25 DMA Rx Enable Register (LINFlexD_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch



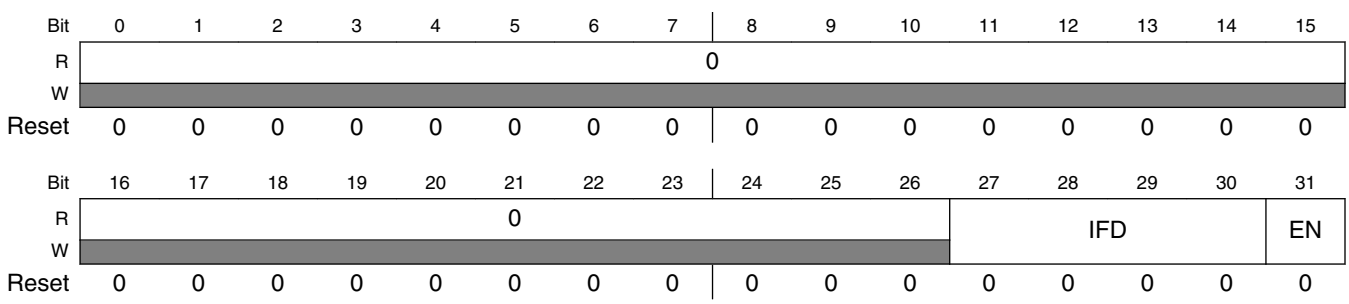
LINFlexD_DMARXE field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{RX\_CH\_NUM}$. These lies from 0 to (31 - $2^{RX\_CH\_NUM}$). Refer to the chip configuration details for the value of RX_CH_NUM used in this device.
16–31 DRE	DMA Rx channel Y enable **NOTE:** The actual size of the register DMARXE depends on the value of the static parameter RX_CH_NUM. The size is [$2^{RX\_CH\_NUM}$ -1 : 0]. The position of these bits are (32 - $2^{RX\_CH\_NUM}$) to 31. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of RX_CH_NUM used in this device. 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled

59.4.26 PSI5-S Tx Delay register (LINFlexD_PTD)

This register can be used to delay the generation of data transmision complete flag by a duration between 1 to 16 bit times.

Address: 0h base + A0h offset = A0h



LINFlexD_PTD field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–30 IFD	Interframe Delay The DTF generation is delayed by IFD+1 bit times. **NOTE:** If generic psi5 = 0, these bits always read 0 and cannot be programmed.
31 EN	Enable **NOTE:** If generic psi5 = 0, this bit always reads 0 and cannot be programmed. 0 DTF generation is not delayed 1 DTF generation is delayed based on IFD field

59.5 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

59.5.1 Master node

LINFlexD acts as Master when the MME bit is set.

59.5.1.1 Transmitter

Transmitter Master Node - Transmitter configuration.

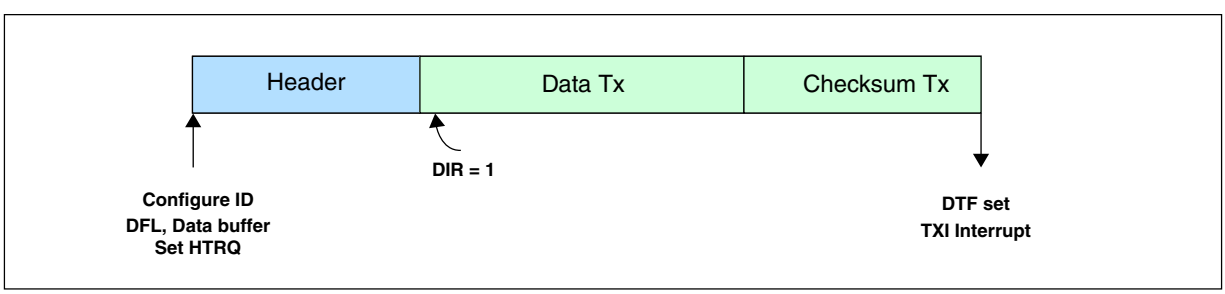


Figure 59-39. Master node – Transmitter configuration

59.5.1.2 Receiver

Receiver Master Mode - RX Configuration

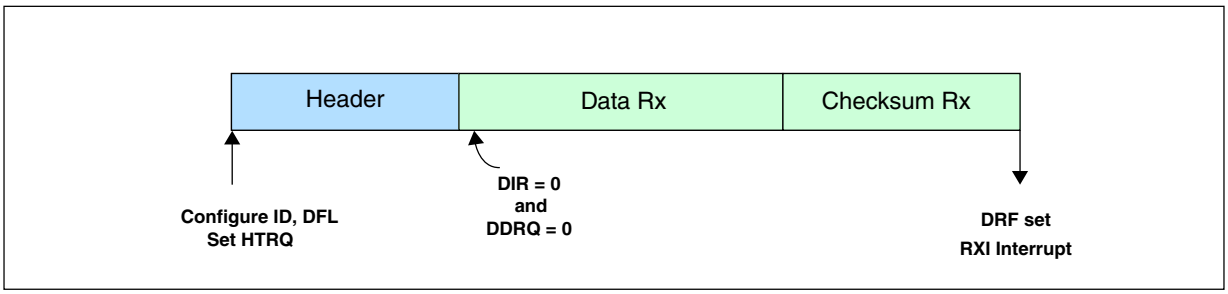

Figure 59-40. Master node – Receiver configuration

59.5.1.3 Transmitter, Bit Error

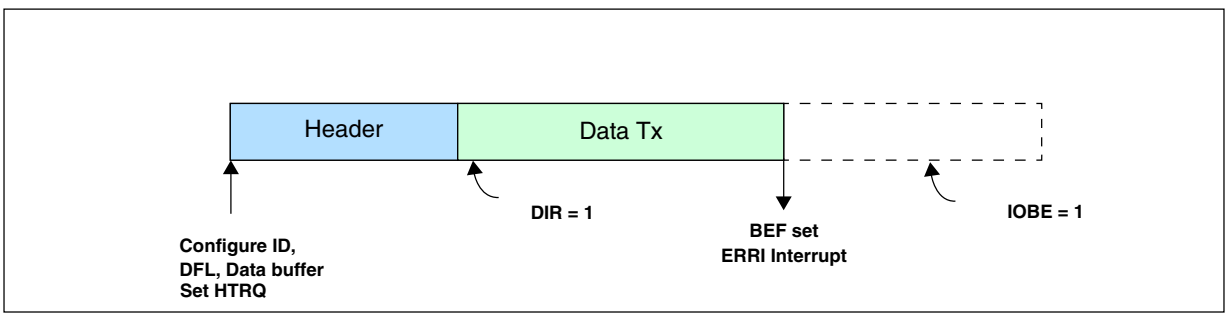

Figure 59-41. Master node – Transmitter, Bit Error configuration

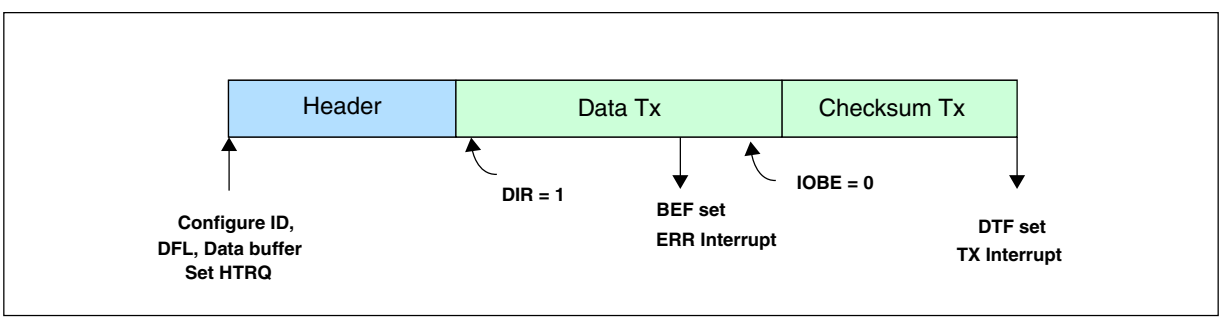

Figure 59-42. Master node – Transmitter, Checksum Error configuration

59.5.1.4 Receiver, Checksum Error

Checksum Error for Receiver.

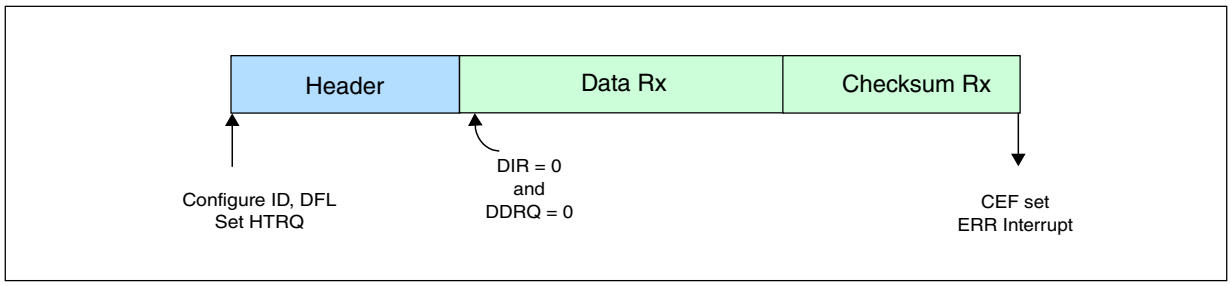

Figure 59-43. Master node – Receiver, Checksum Error configuration

59.5.2 Slave node

Slave node (transmitter).

59.5.2.1 Transmitter (no identifier filters)

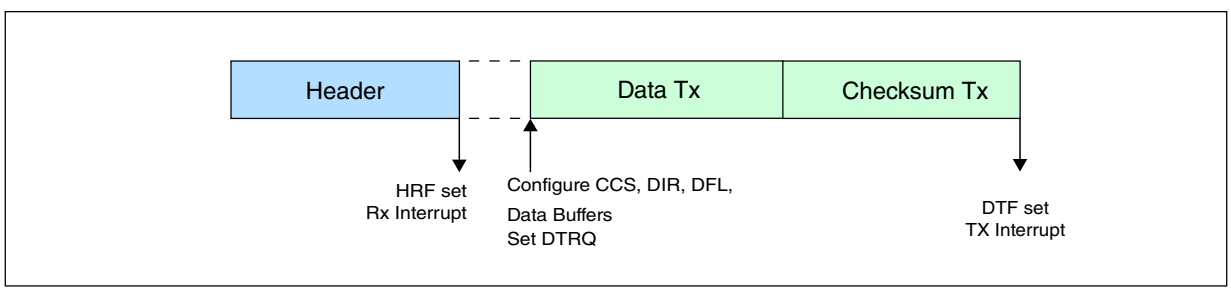

Figure 59-44. Slave node – Transmitter (no identifier filters) configuration

59.5.2.2 Receiver (no identifier filters)

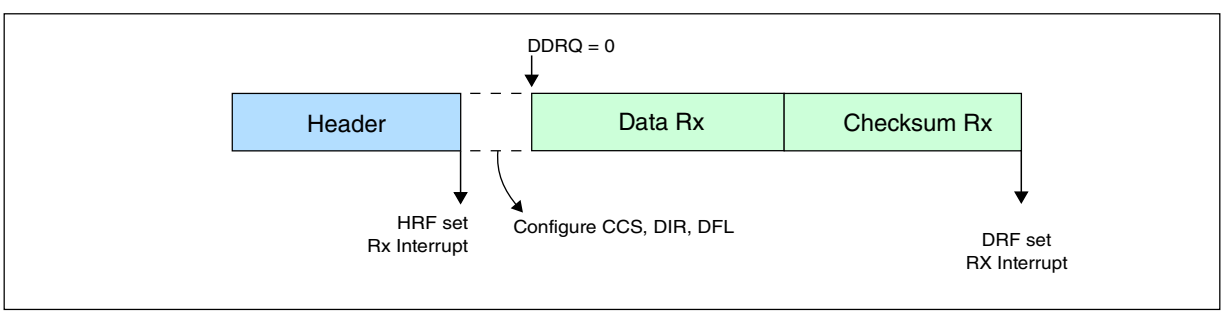

Figure 59-45. Slave node – Receiver (no identifier filters) configuration

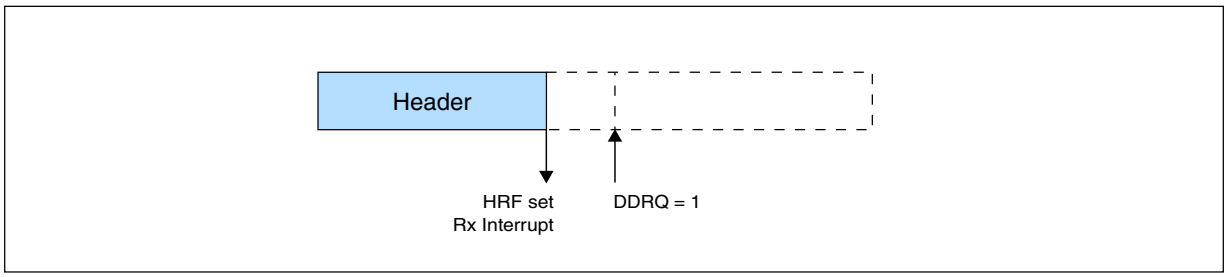

Figure 59-46. Slave node – Receiver (no identifier filters) configuration

59.5.2.3 No filters, Transmitter, Bit error

The following figure shows Slave node - No filters, Transmitter, Bit error configuration.

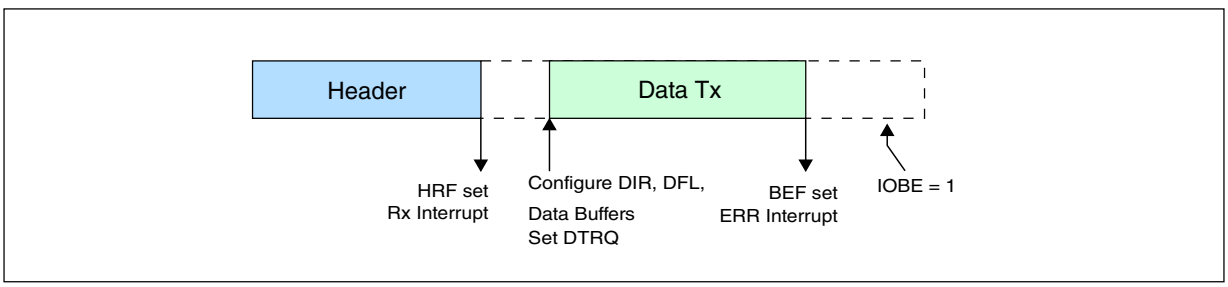

Figure 59-47. Slave node – No filters, Transmitter, Bit error configuration

59.5.2.4 No filters, Receiver, Checksum Error

The following figure shows Slave node - No filters, Receiver, Checksum error configuration.

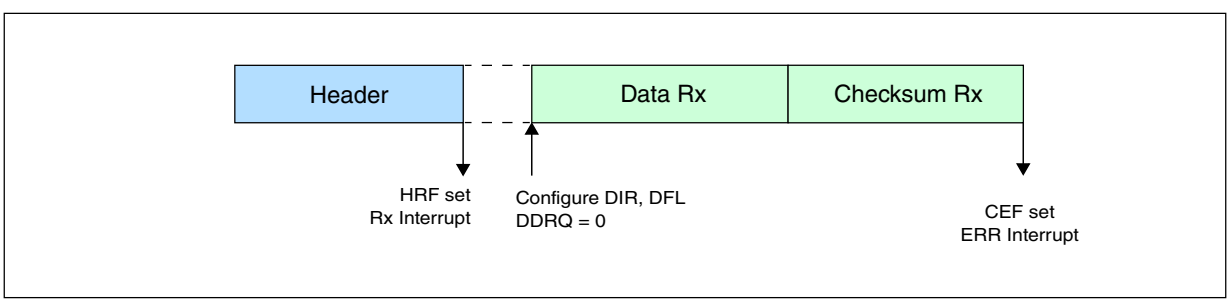

Figure 59-48. Slave node – No filters, Receiver, Checksum error configuration

59.5.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

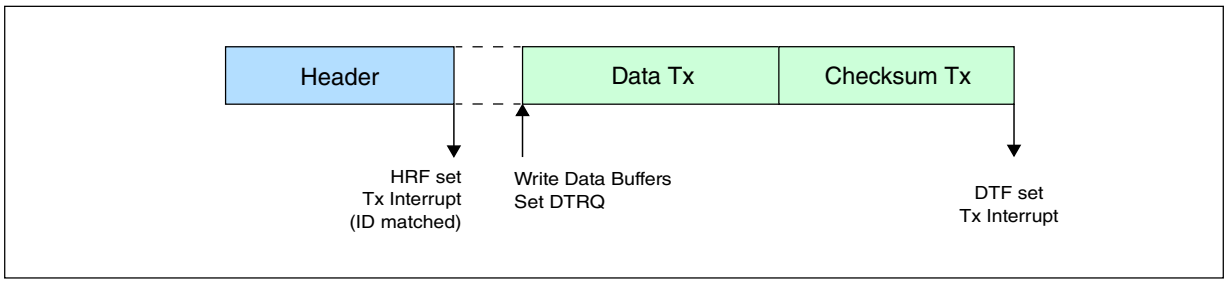

Figure 59-49. Slave node – one TX filter configuration

59.5.2.6 At least one RX filter, BF reset, ID matches filter

The following figure shows Slave node - one RX filter configuration.

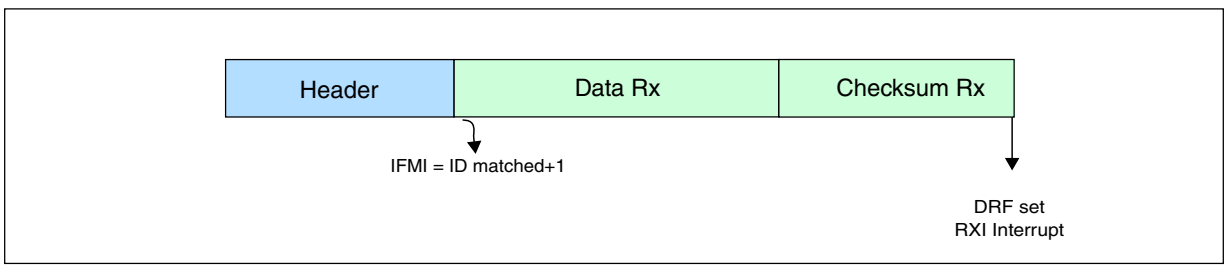

Figure 59-50. Slave node – one RX filter configuration

59.5.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

The following figure shows RX only, TX only, RX and TX filters configuration.

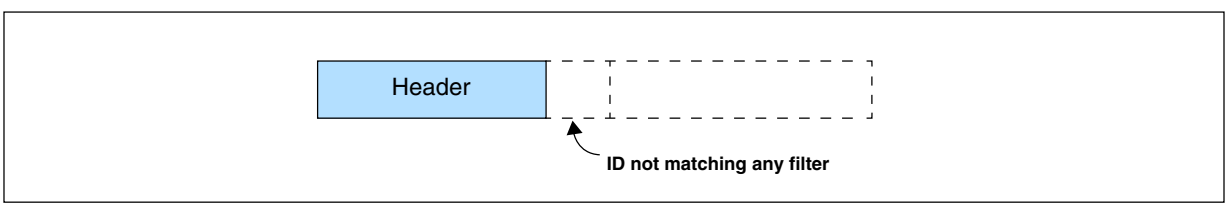

Figure 59-51. RX only, TX only, RX & TX filters configuration

59.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

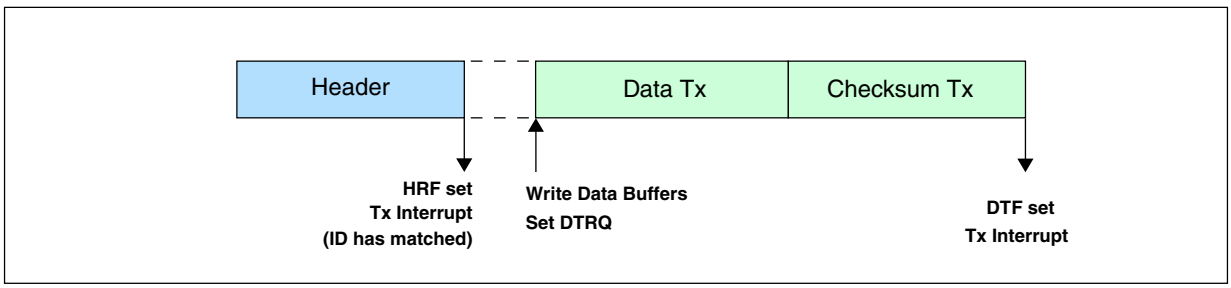

Figure 59-52. TX filter, BF is set configuration – ID has matched

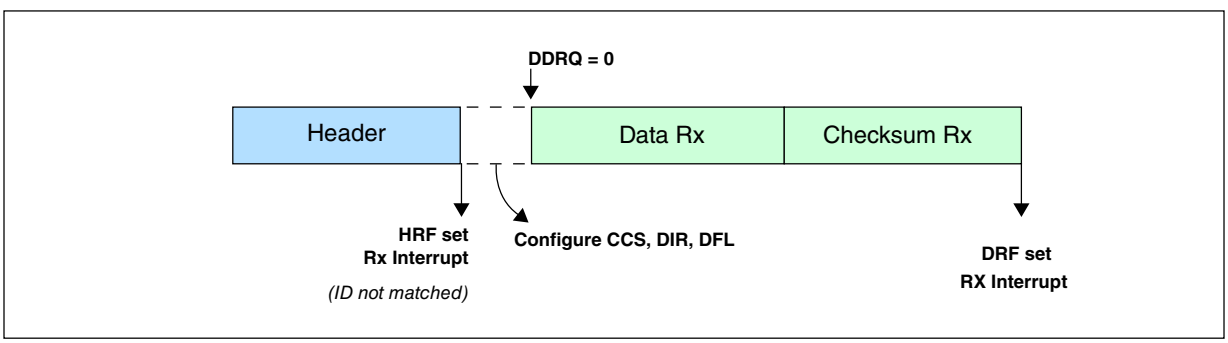

Figure 59-53. TX filter, BF is set configuration – ID not matched

59.5.2.9 RX filter, BF is set

The following figures show RX filter configurations.

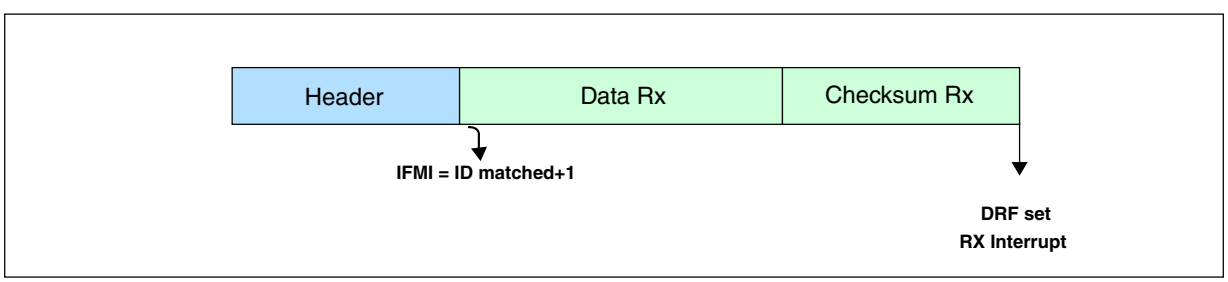

Figure 59-54. RX filter, BF is set configuration – ID matched

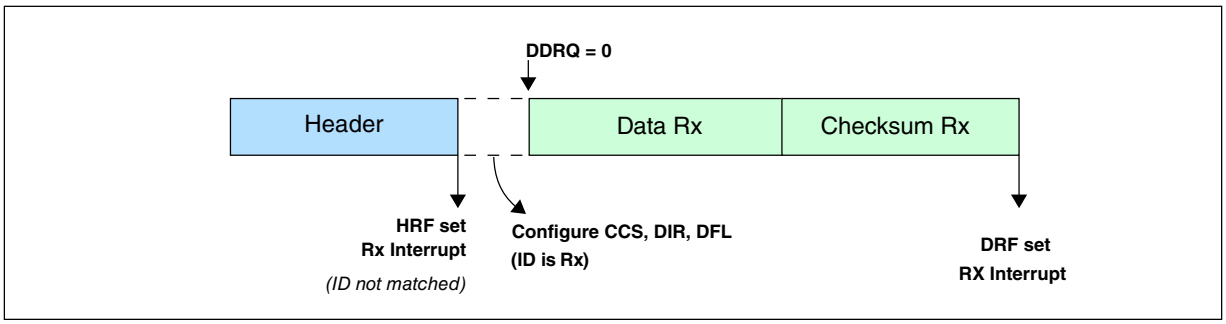

Figure 59-55. RX filter, BF is set configuration – ID not matched (ID is Rx)

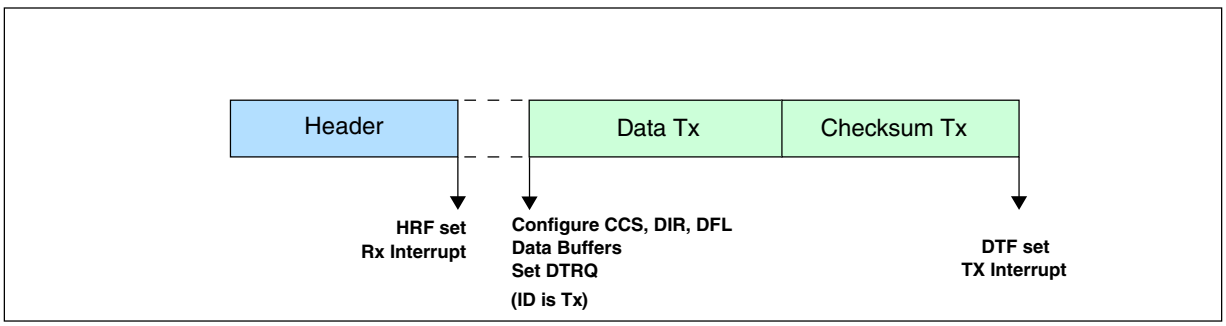

Figure 59-56. RX filter, BF is set configuration – (ID is Tx)

59.5.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

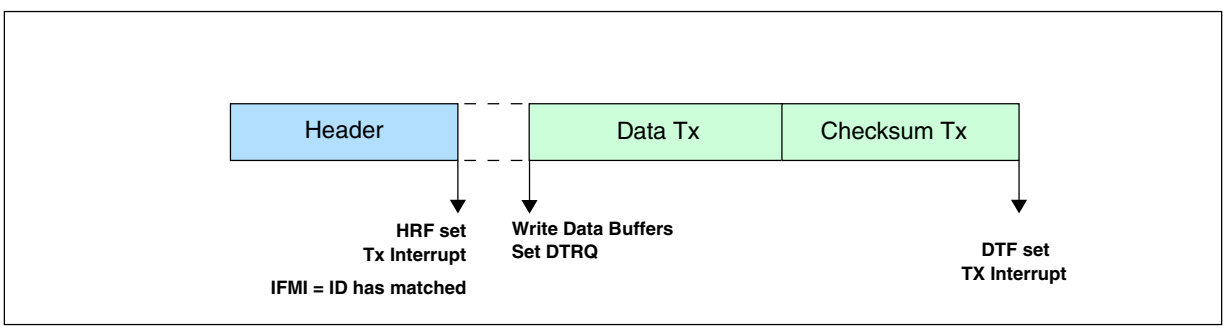

Figure 59-57. TX filter, RX filter, BF set configuration – (ID matched)

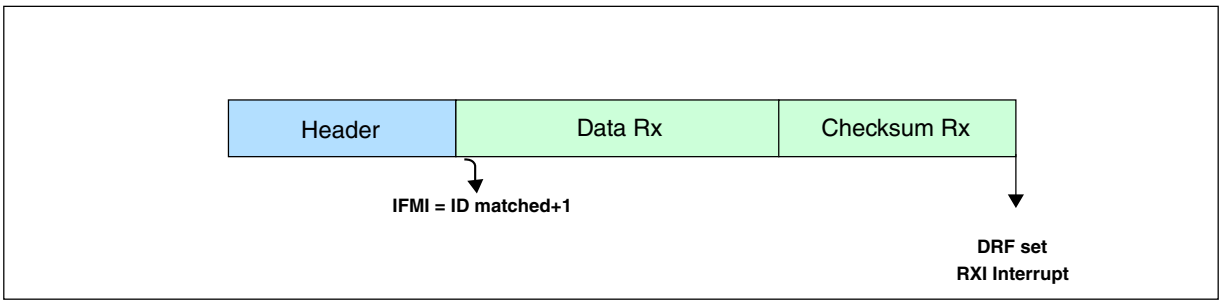

Figure 59-58. TX filter, RX filter, BF set configuration – (ID matched + 1)

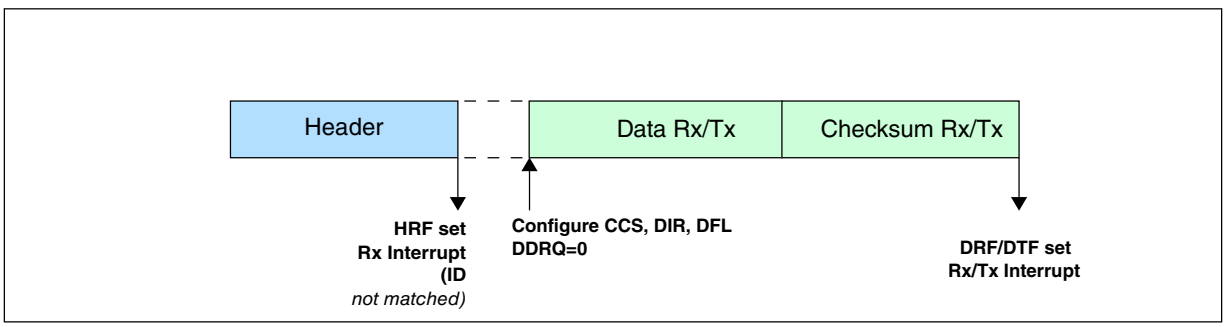

Figure 59-59. TX filter, RX filter, BF set configuration – (ID not matched, RX/TX Interrupt)

59.5.3 Extended frames

The following figure shows Extended frames (RX Interrupt).

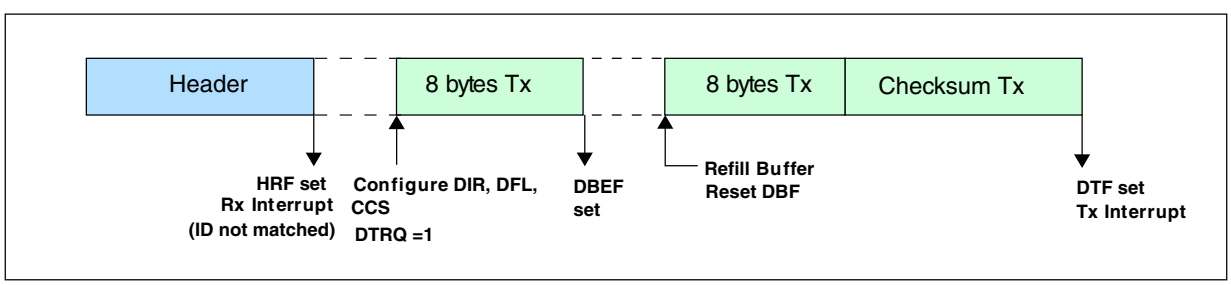

Figure 59-60. Extended frames (TX Interrupt)

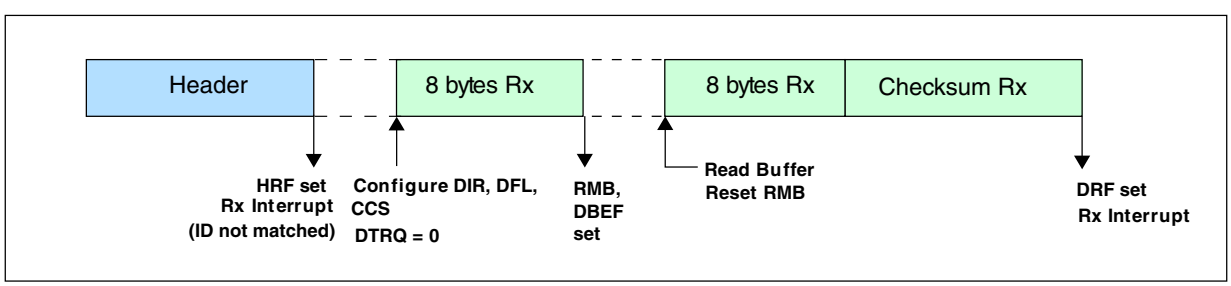

Figure 59-61. Extended frames (RX Interrupt)

59.5.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

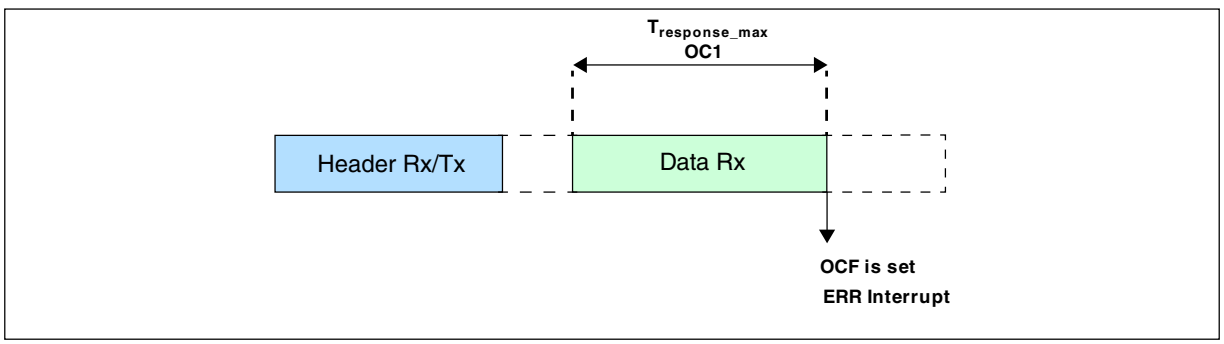

Figure 59-62. Response timeout

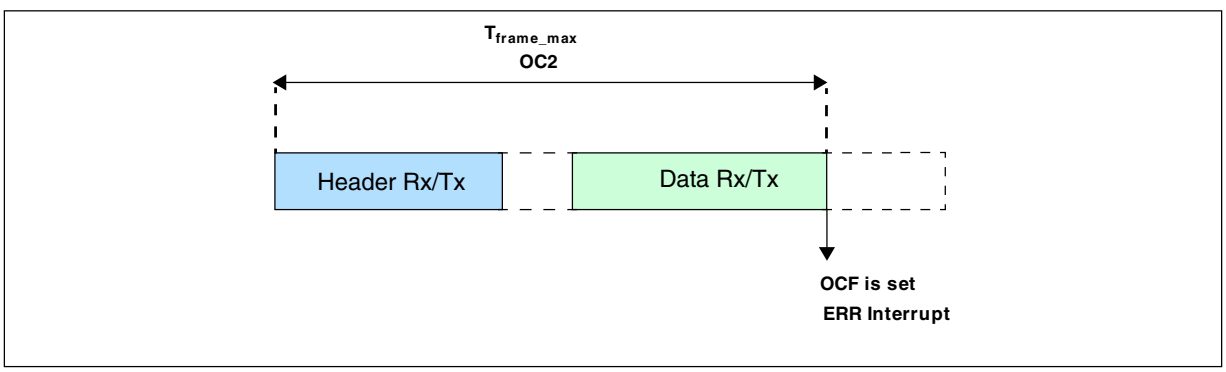

Figure 59-63. Frame timeout

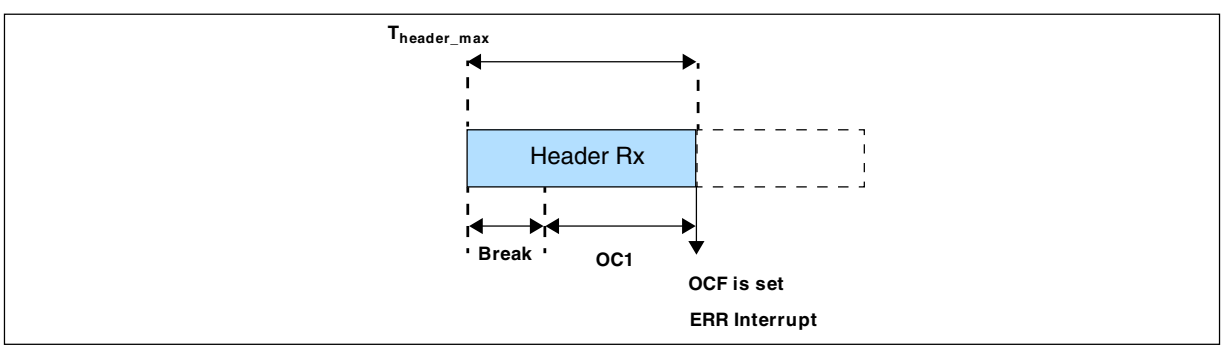

Figure 59-64. Header timeout

59.5.5 UART mode

The following figure shows UART mode configuration.

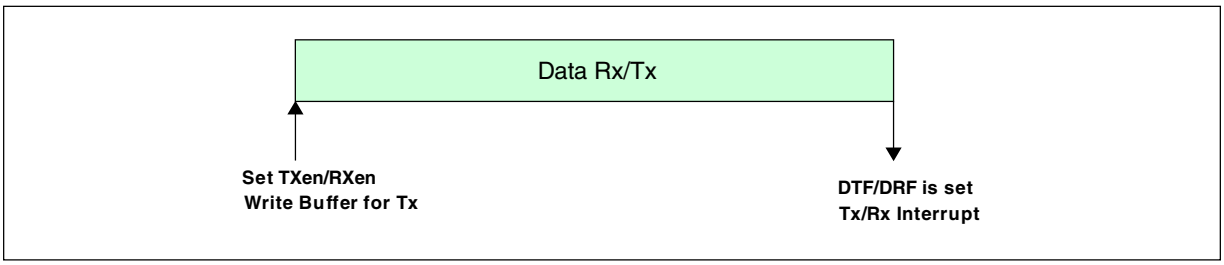

Figure 59-65. UART mode configuration

59.5.6 Interrupts

Interrupt section.

Table 59-19. Interrupts

Interrupt Event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error
Header error	SFEF orSDEF orIDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer Overrun error	BOF	BOIE	Error
UART Timeout error	TO	TOIE	Error
Lin state	Sync Del, Sync Field,Identifier field or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx
Data buffer full	DBFF	DBFIE	Rx
Data buffer empty	DBEF	DBEIE	Tx
Data Reception Complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

The following figure shows an Interrupt Flow Diagram.

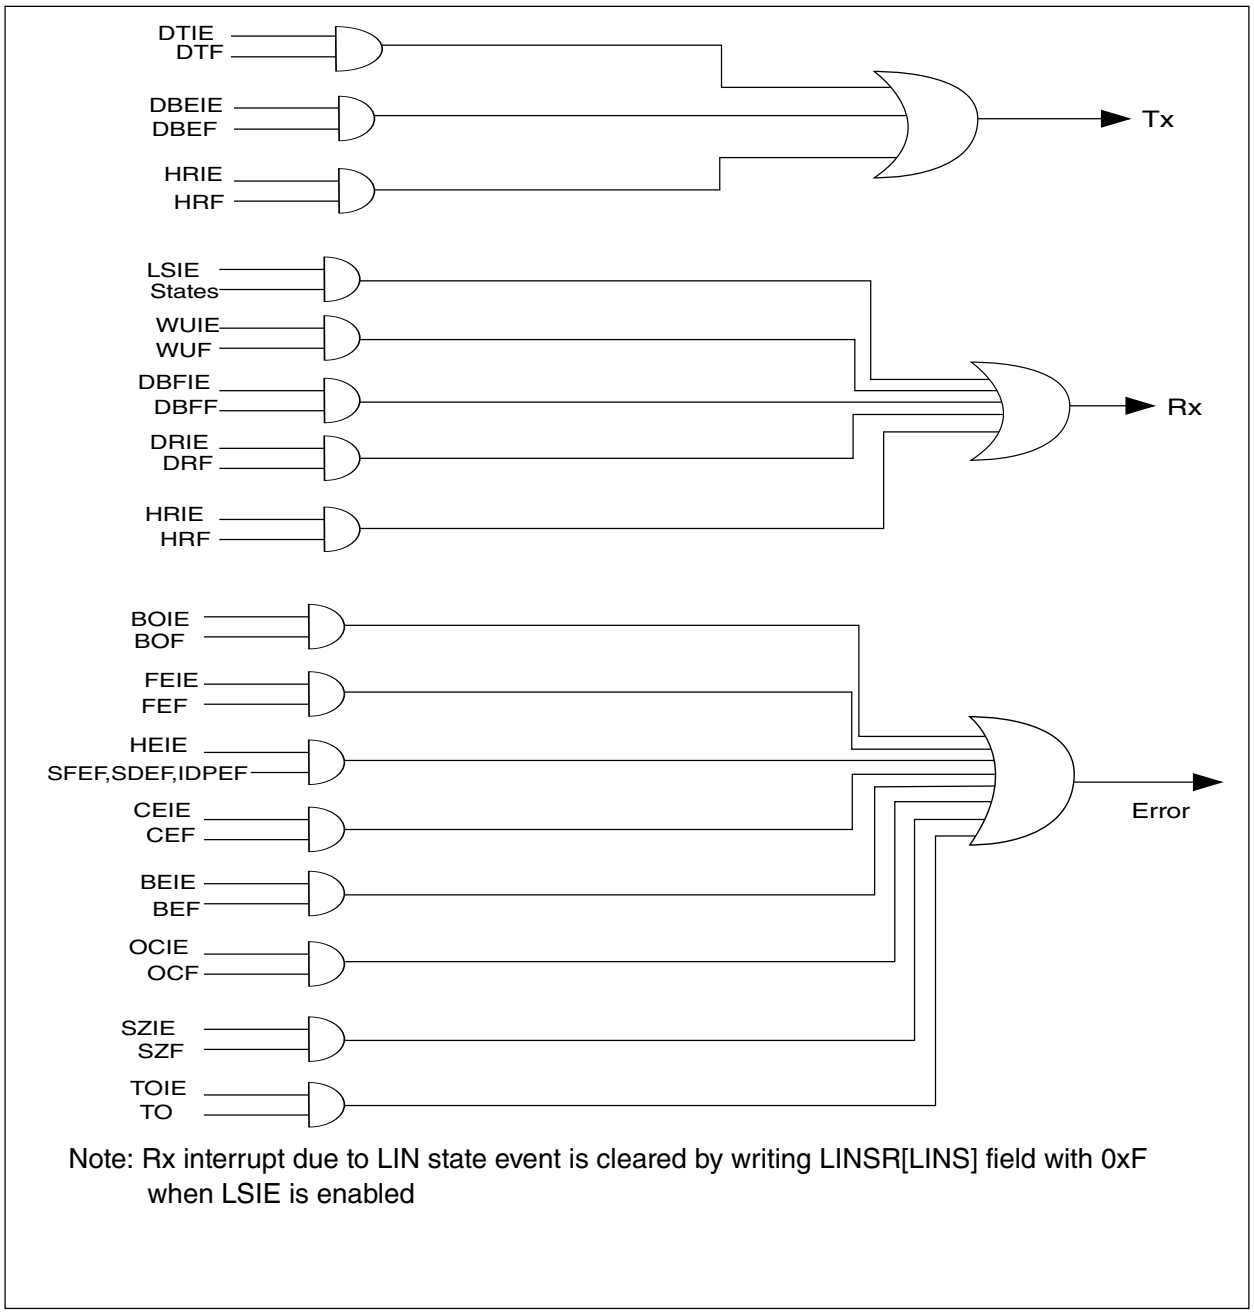

Figure 59-66. Interrupt diagram

59.5.7 LINFlexD Clock Tolerance

1. **Faster receiver tolerance:**
   In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

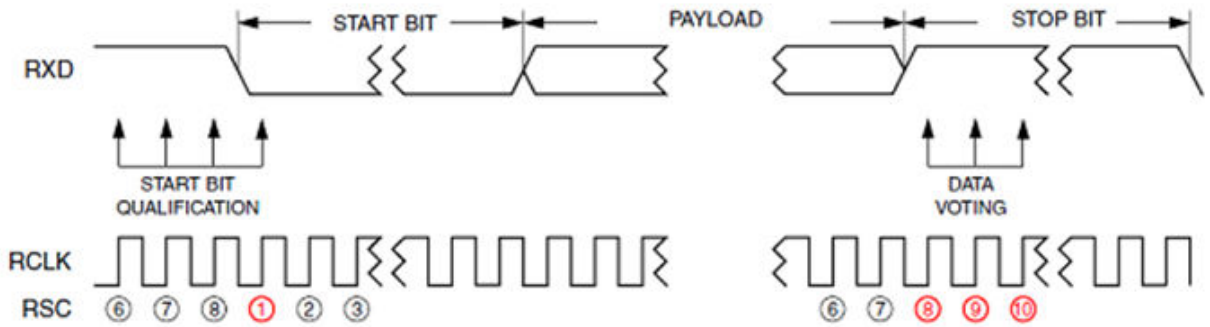

Figure 59-67. Faster receiver

2. **Slower receiver tolerance:**
   In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

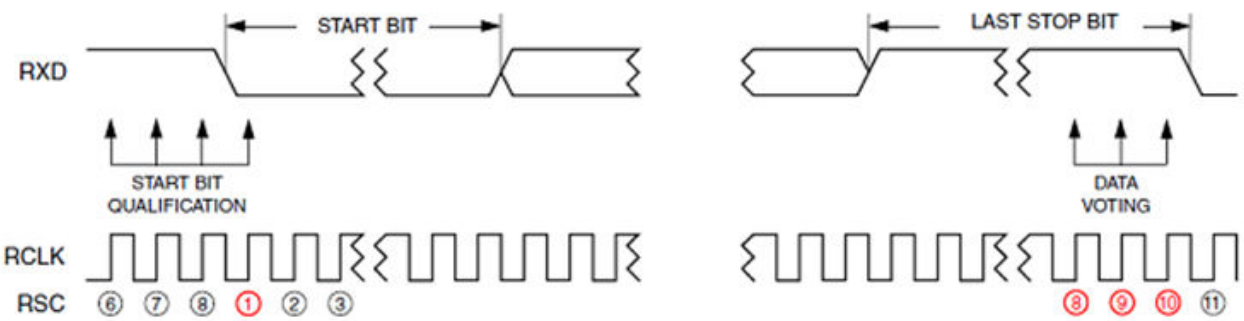

Figure 59-68. Slower receiver

Chapter 60
Reset Generation Module (MC_RGM)

60.1 Introduction

60.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

The following figure shows the MC_RGM block diagram.

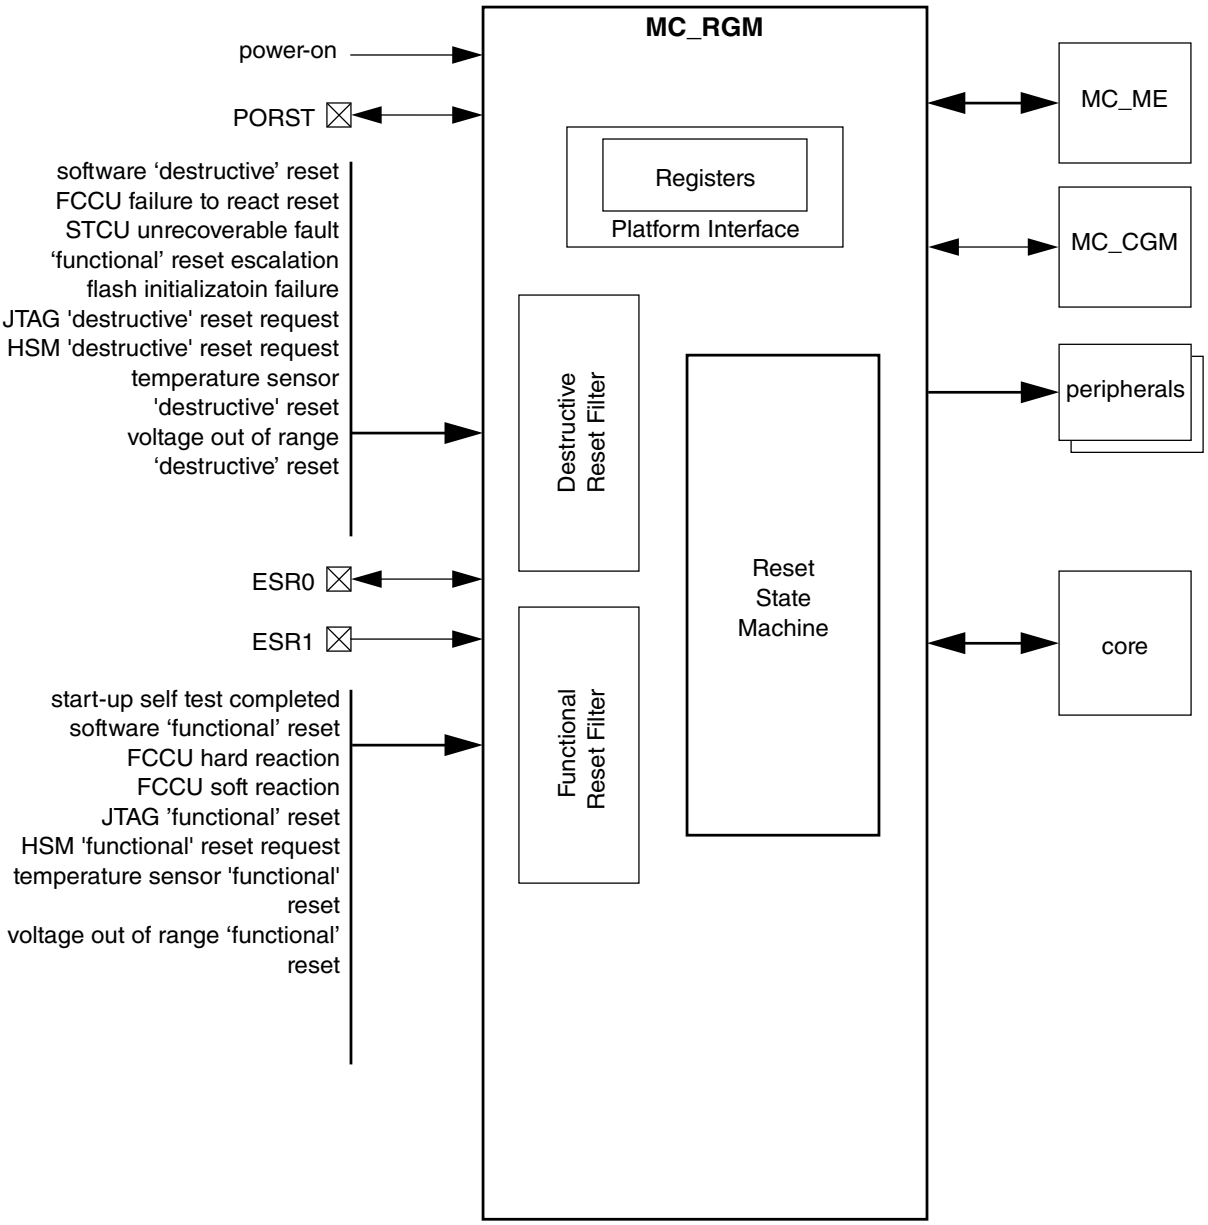

Figure 60-1. MC_RGM Block Diagram

60.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'Destructive' resets management
- 'Functional' resets management
- sSgnalling of reset events after each reset sequence (reset status flags)
- Conversion of reset events to SAFE mode or interrupt request events

- Short reset sequence configuration
- bidirectional reset behavior configuration
- configurable escalation of recurring 'functional' resets to 'destructive' reset
- configurable escalation of recurring 'destructive' resets to keep chip in reset state until next power-on reset

60.1.3 Reset sources

The different reset sources are organized into two families: 'destructive' and 'functional'.

- A 'destructive' reset source is associated with an event related to a critical - usually hardware - error or dysfunction. When a 'destructive' reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a SAFE start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software 'destructive' reset and external power-on -reset cases, which do preserve the system memory content if the chip is not configured to execute a selftest on power-on, 'destructive', and external resets. 'Destructive' resets are
  - power-on reset
  - external power-on reset
  - software 'destructive' reset
  - FCCU failure to react reset
  - STCU unrecoverable fault
  - 'functional' reset escalation
  - flash initialization failure
  - JTAG 'destructive' reset request
  - HSM 'destructive' reset request
  - temperature sensor 'destructive' reset
  - voltage out of range 'destructive' reset
- A 'functional' reset source is associated with an event related to a less-critical - usually non-hardware - error or dysfunction. When a 'functional' reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific

digital modules (e.g., debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self test on power-on, 'destructive', and external resets. 'Functional' resets are

- ESR0 external reset
- ESR1 external reset
- start-up self test completed
- software 'functional' reset
- FCCU hard reaction
- FCCU soft reaction
- JTAG 'functional' reset
- HSM 'functional' reset request
- temperature sensor 'functional' reset
- voltage out of range 'functional' reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (see 'Destructive' Event Reset Disable Register (MC_RGM_DERD) and 'Destructive' Event Alternate Request Register (MC_RGM_DEAR) for 'destructive' resets and 'Functional' Event Reset Disable Register (MC_RGM_FERD) and 'Functional' Event Alternate Request Register (MC_RGM_FEAR) for 'functional' resets).

60.2 External signal description

The MC_RGM interfaces to the bidirectional reset pin ESR0.

60.3 Memory map and register definition

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

NOTE

All registers will be accessible in "User mode" provided the access to this mode is enabled through REGPROT settings. Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error(only if SSCM_ERROR[RAE] is set)

60.3.1 'Destructive' Event Status Register (MC_RGM_DES)

This register contains the status of the 'destructive' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1'.

This register is reset only on power-on.

Address: 0h base + 0h offset = 0h

Field	Description
23 F_EDR	Flag for 'functional' reset escalation 0 No 'functional' reset escalation event has occurred since the last clear 1 A 'functional' reset escalation event has occurred
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 F_SUF	Flag for STCU unrecoverable fault 0 No STCU unrecoverable fault event has occurred since the last clear 1 A STCU unrecoverable fault event has occurred
27 F_FFRR	Flag for FCCU failure to react reset 0 No FCCU failure to react reset event has occurred since the last clear 1 A FCCU failure to react reset event has occurred
28 F_SOFT_DEST	Flag for software 'destructive' reset 0 No software 'destructive' reset event has occurred since the last clear 1 A software 'destructive' reset event has occurred
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred
31 F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

60.3.2 'Destructive' Event Reset Disable Register (MC_RGM_DERD)

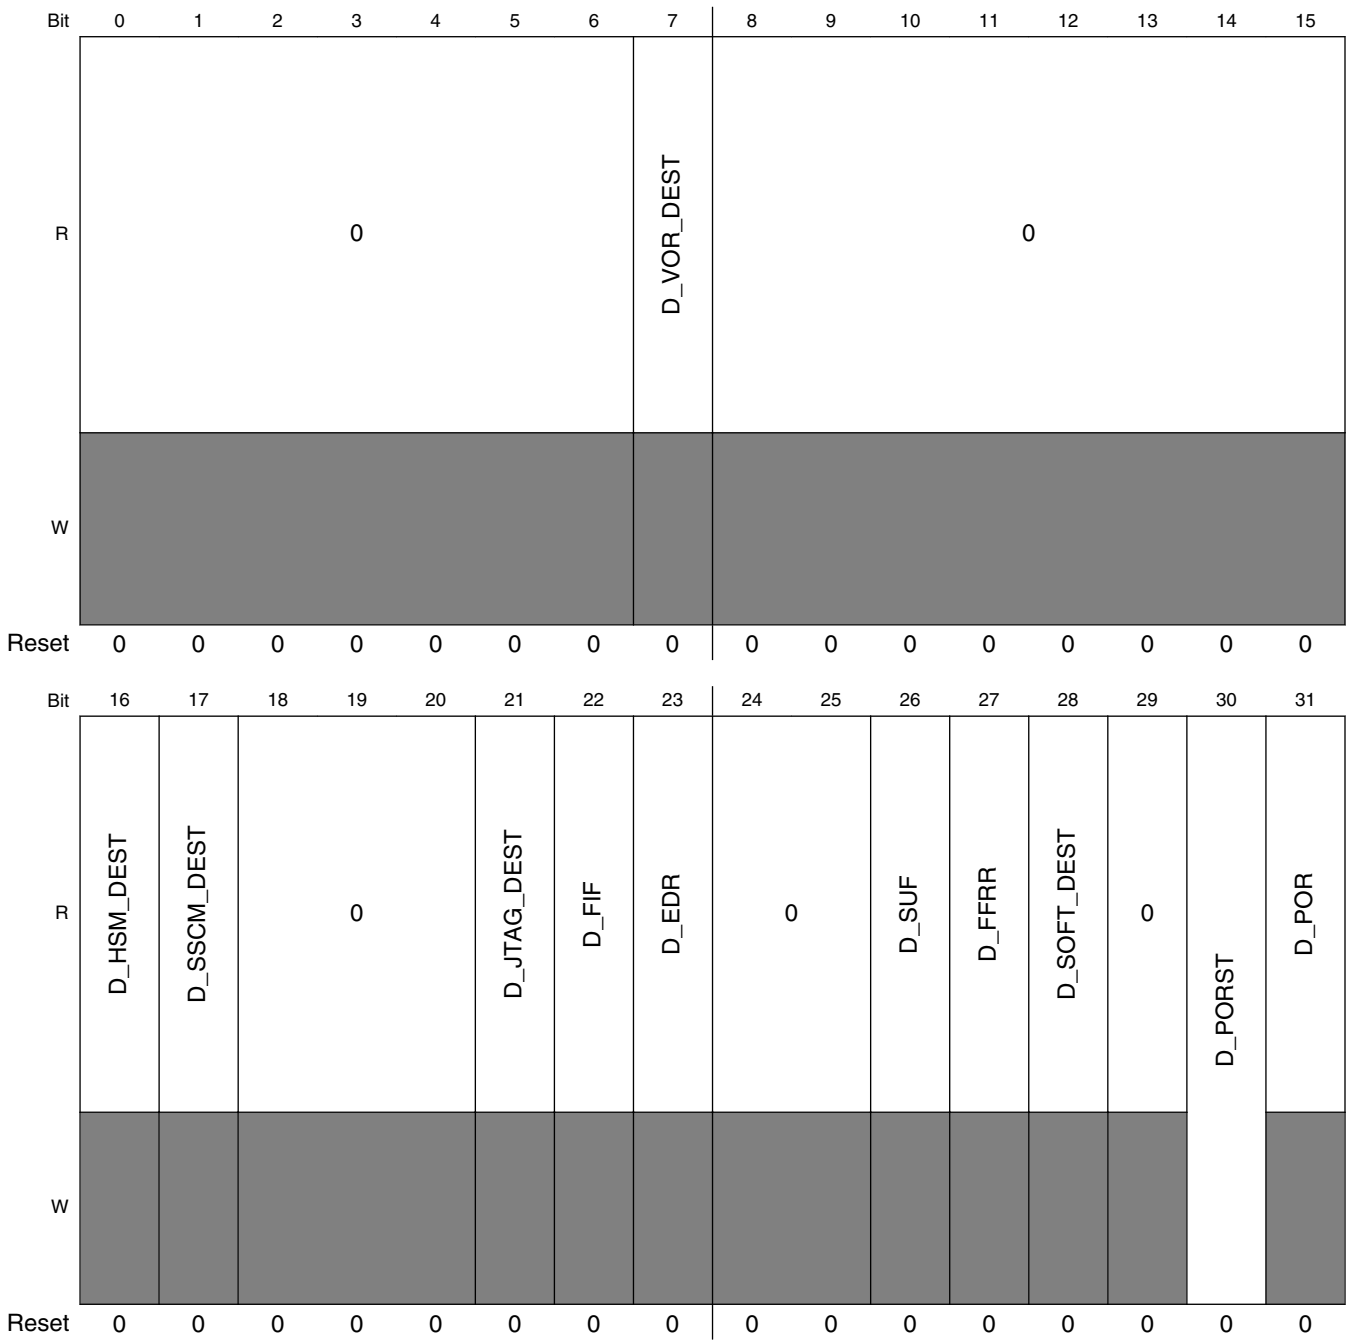
This register provides dedicated bits to disable particular 'destructive' reset sources. When a 'destructive' reset source is disabled, the associated 'destructive' event will trigger either a SAFE mode request or an interrupt request (see 'Destructive' Event Alternate Request Register (MC_RGM_DEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on.

Caution

It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0h base + 10h offset = 10h



MC_RGM_DERD field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 D_VOR_DEST	Disable voltage out of range 'destructive' reset 0 A voltage out of range 'destructive' reset event triggers a reset sequence

Table continues on the next page...

MC_RGM_DERD field descriptions (continued)

Field	Description
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 D_HSM_DEST	Disable HSM 'destructive' reset request 0 A HSM 'destructive' reset request event triggers a reset sequence
17 D_SSCM_DEST	Disable SSCM 'destructive' reset request 0 An SSCM 'destructive' reset request event triggers a reset sequence
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 D_JTAG_DEST	Disable JTAG 'destructive' reset request 0 A JTAG 'destructive' reset request event triggers a reset sequence
22 D_FIF	Disable flash initialization failure 0 A flash initialization failure event triggers a reset sequence
23 D_EDR	Disable 'functional' reset escalation 0 A 'functional' reset escalation event triggers a reset sequence
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 D_SUF	Disable STCU unrecoverable fault 0 A STCU unrecoverable fault event triggers a reset sequence
27 D_FFRR	Disable FCCU failure to react reset 0 A FCCU failure to react reset event triggers a reset sequence
28 D_SOFT_DEST	Disable software 'destructive' reset 0 A software 'destructive' reset triggers a reset sequence
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 D_PORST	Disable external power-on reset 0 An external power-on reset event triggers a reset sequence 1 An external power-on reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR
31 D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

60.3.3 'Destructive' Event Alternate Request Register (MC_RGM_DEAR)

This register defines an alternate request to be generated when a reset on a 'destructive' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0h base + 20h offset = 20h

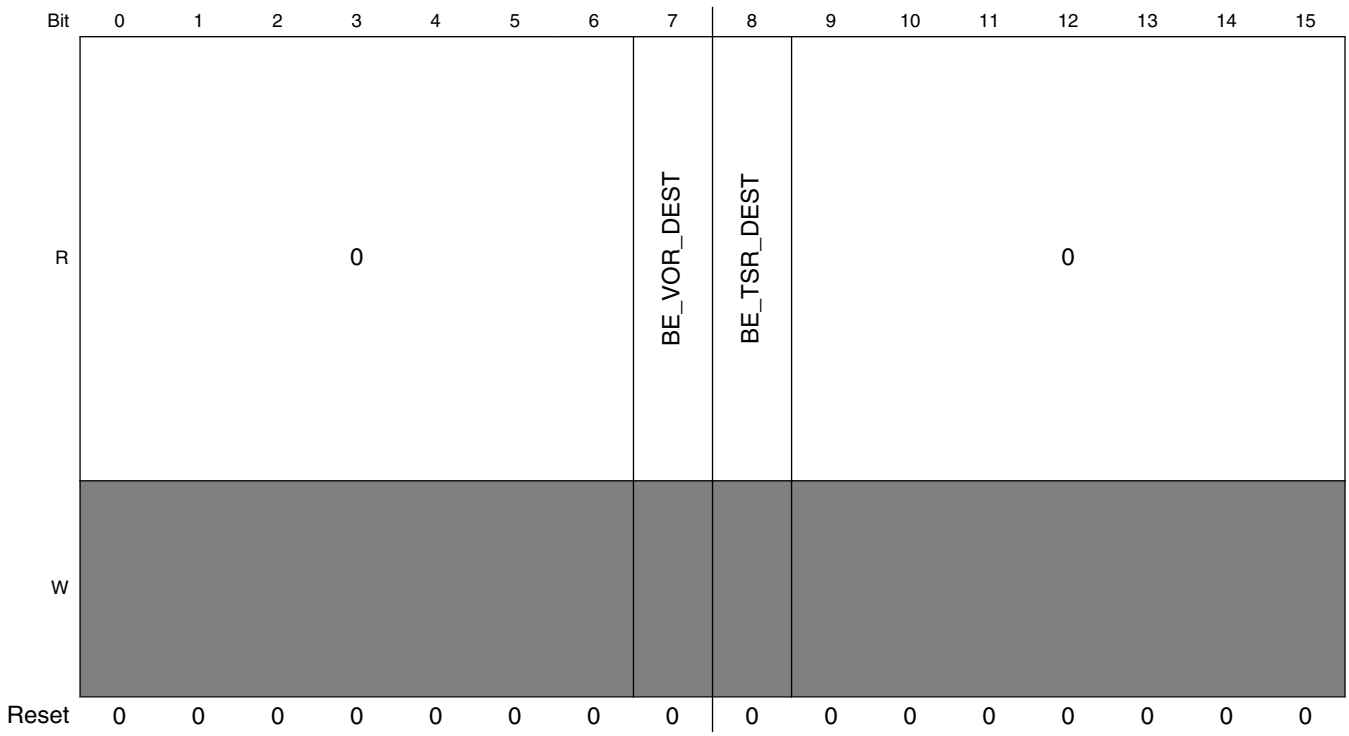
30 AR_PORST	Alternate Request for external power-on reset 0 Generate a SAFE mode request on an external power-on reset event if the reset is disabled 1 Generate an interrupt request on an external power-on reset event if the reset is disabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.3.4 'Destructive' Bidirectional Reset Enable Register (MC_RGM_DBRE)

This register enables the generation of an external reset on 'destructive' reset. It can be accessed as read only in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

Address: 0h base + 30h offset = 30h



MC_RGM_DBRE field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MC_RGM_DBRE field descriptions (continued)

Field	Description
7 BE_VOR_DEST	Bidirectional Reset Enable for voltage out of range 'destructive' reset 0 ESR0 is asserted on a voltage out of range 'destructive' reset event
8 BE_TSR_DEST	Bidirectional Reset Enable for temperature sensor 'destructive' reset 0 ESR0 is asserted on a temperature sensor 'destructive' reset event if the reset is enabled
9–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 BE_HSM_DEST	Bidirectional Reset Enable for HSM 'destructive' reset request 0 ESR0 is asserted on a HSM 'destructive' reset request event
17 BE_SSCM_ DEST	Bidirectional Reset Enable for SSCM 'destructive' reset request 0 ESR0 is asserted on a SSCM 'destructive' reset request event
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BE_JTAG_DEST	Bidirectional Reset Enable for JTAG 'destructive' reset request 0 ESR0 is asserted on a JTAG 'destructive' reset request event
22 BE_FIF	Bidirectional Reset Enable for flash initialization failure 0 ESR0 is asserted on a flash initialization failure event
23 BE_EDR	Bidirectional Reset Enable for 'functional' reset escalation 0 ESR0 is asserted on a 'functional' reset escalation event
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 BE_SUF	Bidirectional Reset Enable for STCU unrecoverable fault 0 ESR0 is asserted on a STCU unrecoverable fault event
27 BE_FFRR	Bidirectional Reset Enable for FCCU failure to react reset 0 ESR0 is asserted on a FCCU failure to react reset event
28 BE_SOFT_DEST	Bidirectional Reset Enable for software 'destructive' reset 0 ESR0 is asserted on a software 'destructive' reset event
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BE_PORST	Bidirectional Reset Enable for external power-on reset 0 ESR0 is asserted on an external power-on reset event if the reset is enabled
31 BE_POR	Bidirectional Reset Enable for Power-On reset 0 ESR0 is asserted on a Power-On reset event

60.3.5 'Functional' Event Status Register (MC_RGM_FES)

This register contains the status of the 'functional' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source.

This register is reset only on power-on.

NOTE

If a 'functional' reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.

When ESR0 gate is disabled via UTEST_Miscellaneous[ESR0_Gate] field of DCF client and ESR0 is asserted by setting the SIUL_SCR0[ESR0_ASSERT] field, and then PORST is asserted or a destructive reset occurs and the system comes up, the RGM_FES register reads a value of 0x00000001 indicating that an ESR0 reset has also occurred.

Address: 0h base + 300h offset = 300h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

28 F_SOFT_FUNC	Flag for software 'functional' reset 0 No software 'functional' reset event has occurred since either the last clear or the last power-on reset assertion 1 A software 'functional' reset event has occurred
29 F_ST_DONE	Flag for self test completed 0 No self test completed event has occurred since either the last clear or the last power-on reset assertion 1 A self test completed event has occurred
30 F_ESR1	Flag for ESR1 External Reset 0 No ESR1 external reset event has occurred since either the last clear or the last power-on reset assertion 1 An ESR1 external reset event has occurred
31 F_ESR0	Flag for ESR0 External Reset 0 No ESR0 external reset event has occurred since either the last clear or the last power-on reset assertion 1 An ESR0 external reset event has occurred

60.3.6 'Functional' Event Reset Disable Register (MC_RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources.When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see 'Functional' Event Alternate Request Register (MC_RGM_FEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any 'destructive' reset.

Caution

It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0h base + 310h offset = 310h

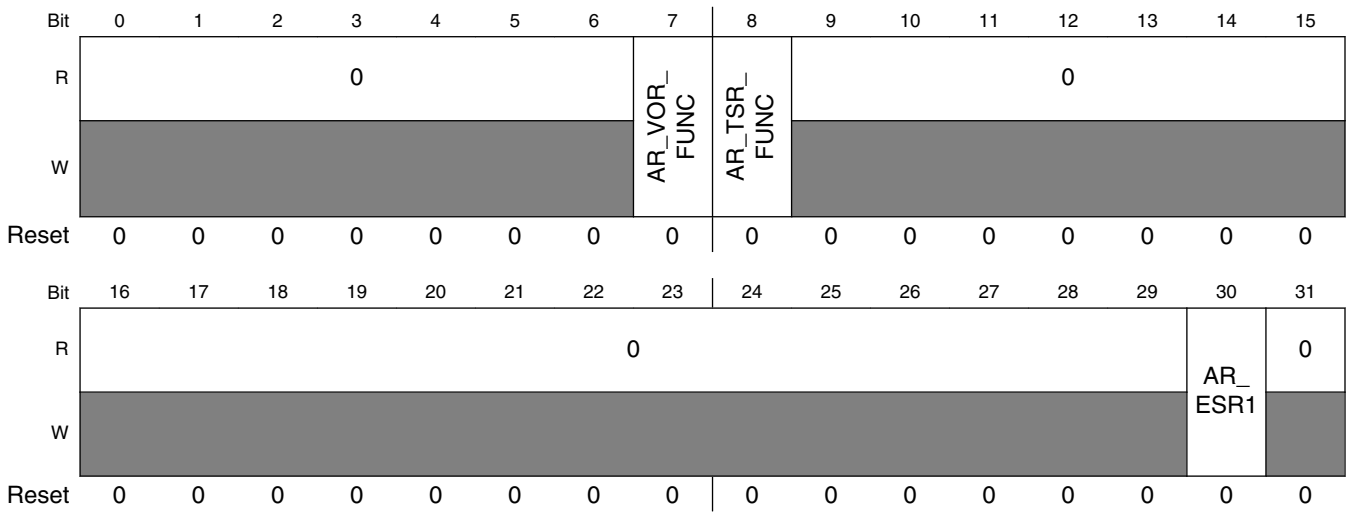
26 D_FCCU_HARD	Disable FCCU hard reaction reset 0 A FCCU hard reaction reset event triggers a reset sequence
27 D_SOFT_FUNC	software 'functional' reset 0 A software 'functional' reset triggers a reset sequence.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 D_ST_DONE	Disable self test completed 0 A self test completed event triggers a reset sequence
30 D_ESR1	Disable ESR1 External Reset 0 An ESR1 external reset event triggers a reset sequence 1 An ESR1 external reset event generates either a SAFE mode or an interrupt request depending on the value of RGM_FEAR.AR_ESR1
31 D_ESR0	Disable ESR0 External Reset 0 An ESR0 external reset event triggers a reset sequence

60.3.7 'Functional' Event Alternate Request Register (MC_RGM_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 320h offset = 320h



MC_RGM_FEAR field descriptions

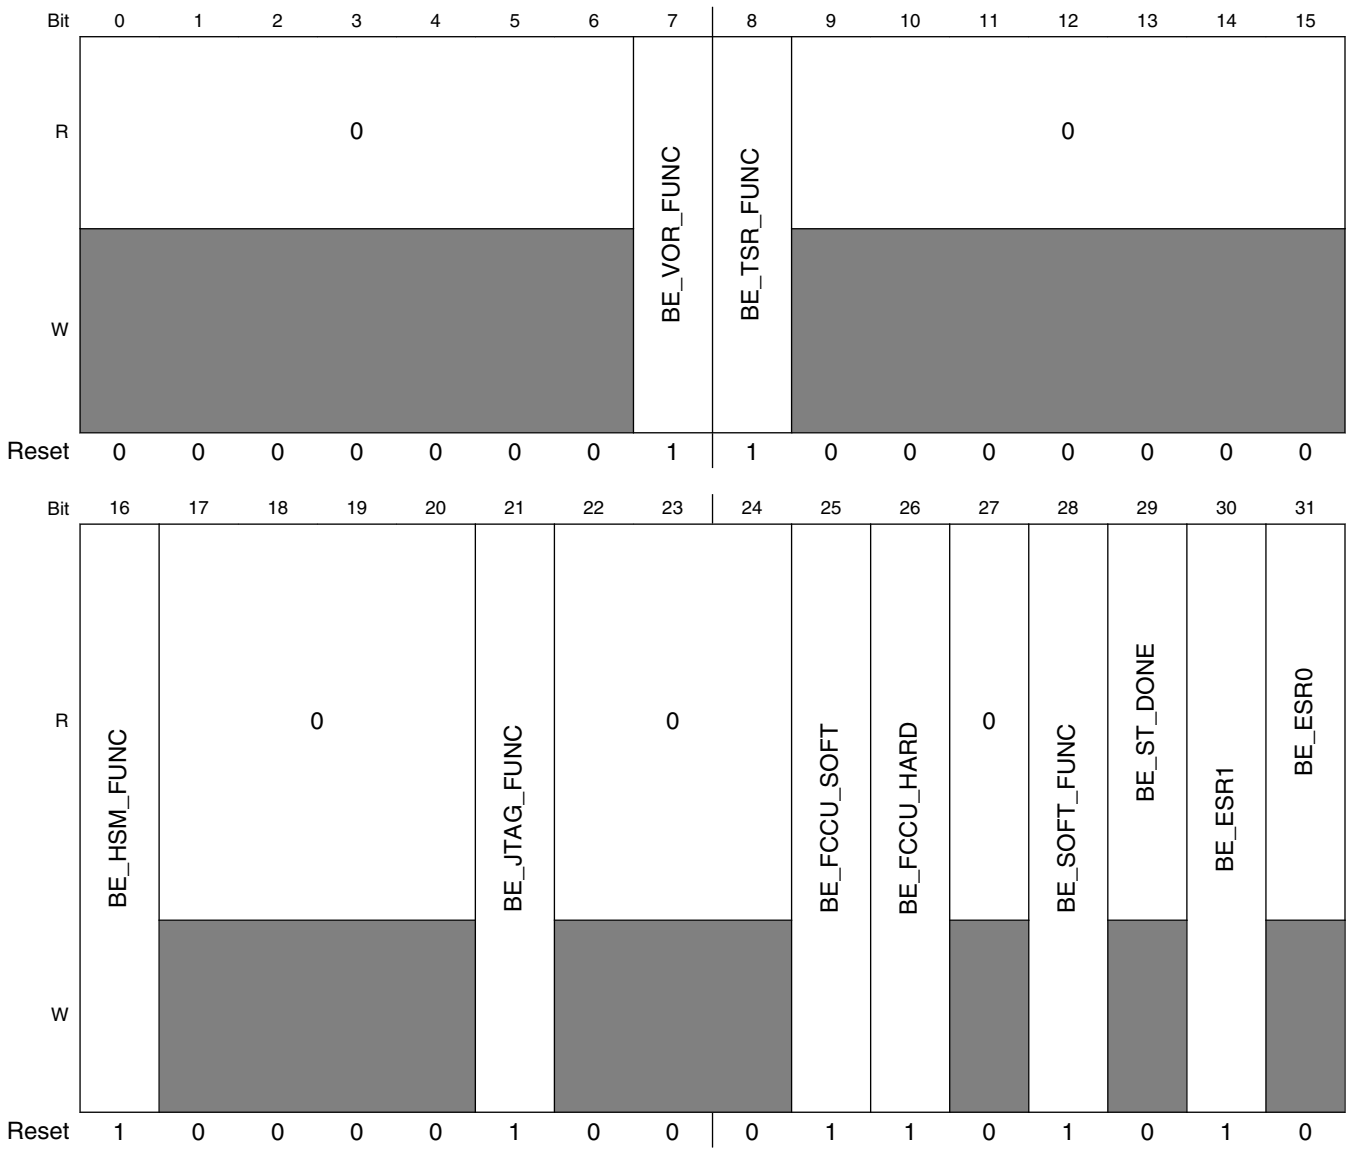
Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 AR_VOR_FUNC	Alternate Request for voltage out of range 'functional' reset 0 Generate a SAFE mode request on a voltage out of range 'functional' reset event if the reset is disabled 1 Generate an interrupt request on a voltage out of range 'functional' reset event if the reset is disabled
8 AR_TSR_FUNC	Alternate Request for temperature sensor 'functional' reset 0 Generate a SAFE mode request on a temperature sensor 'functional' reset event if the reset is disabled 1 Generate an interrupt request on a temperature sensor 'functional' reset event if the reset is disabled
9–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 AR_ESR1	Alternate Request for ESR1 External Reset 0 Generate a SAFE mode request on an ESR1 external reset event if the reset is disabled 1 Generate an interrupt request on an ESR1 external reset event if the reset is disabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.3.8 'Functional' Bidirectional Reset Enable Register (MC_RGM_FBRE)

This register enables the generation of an external reset on 'functional' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 330h offset = 330h



MC_RGM_FBRE field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 BE_VOR_FUNC	Bidirectional Reset Enable for voltage out of range 'functional' reset 0 ESR0 is asserted on a voltage out of range 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a voltage out of range 'functional' reset event
8 BE_TSR_FUNC	Bidirectional Reset Enable for temperature sensor 'functional' reset 0 ESR0 is asserted on a temperature sensor 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a temperature sensor 'functional' reset event

17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BE_JTAG_FUNC	Bidirectional Reset Enable for JTAG 'functional' reset 0 ESR0 is asserted on a JTAG 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a JTAG 'functional' reset event
22–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 BE_FCCU_SOFT	Bidirectional Reset Enable for FCCU soft reaction 0 ESR0 is asserted on a FCCU soft reaction event 1 ESR0 is not asserted on a FCCU soft reaction event
26 BE_FCCU_ HARD	Bidirectional Reset Enable for a FCCU hard reaction 0 ESR0 is asserted on a FCCU hard reaction reset event 1 ESR0 is not asserted on a FCCU hard reaction reset event
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 BE_SOFT_FUNC	Bidirectional Reset Enable for software 'functional' reset 0 ESR0 is asserted on a software 'functional' reset event if the reset is enabled 1 ESR0 is not asserted on a software 'functional' reset event
29 BE_ST_DONE	Bidirectional Reset Enable for self test completed 0 ESR0 is asserted on a self test completed event
30 BE_ESR1	Bidirectional Reset Enable for ESR1 External Reset 0 ESR0 is asserted on an ESR1 external reset event if the reset is enabled 1 ESR0 is not asserted on an ESR1 external reset event
31 BE_ESR0	Bidirectional Reset Enable for ESR0 External Reset 0 ESR0 is asserted on an ESR0 external reset event if the reset is enabled

60.3.9 'Functional' Event Short Sequence Register (MC_RGM_FESS)

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

NOTE

This could be useful for fast reset sequence, for example to skip flash reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 340h offset = 340h

22–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SS_FCCU_SOFT	Short Sequence for FCCU soft reaction 1 The reset sequence triggered by a FCCU soft reaction event will start from PHASE3, skipping PHASE1 and PHASE2
26 SS_FCCU_ HARD	Short Sequence for a FCCU hard reaction 0 The reset sequence triggered by a FCCU hard reaction reset event will start from PHASE1
27 Reserved	This field is reserved.
28 SS_SOFT_FUNC	Short Sequence for software 'functional' reset 0 The reset sequence triggered by a software 'functional' reset event will start from PHASE1 1 The reset sequence triggered by a software 'functional' reset event will start from PHASE3, skipping PHASE1 and PHASE2
29 SS_ST_DONE	Short Sequence for self test completed 0 The reset sequence triggered by a self test completed event will start from PHASE1
30 SS_ESR1	Short Sequence for ESR1 External Reset 0 The reset sequence triggered by an ESR1 external reset event will start from PHASE1 1 The reset sequence triggered by an ESR1 external reset event if the reset is enabled will start from PHASE3, skipping PHASE1 and PHASE2
31 SS_ESR0	Short Sequence for ESR0 External Reset 0 The reset sequence triggered by an ESR0 external reset event will start from PHASE1 1 The reset sequence triggered by an ESR0 external reset event if the reset is enabled will start from PHASE3, skipping PHASE1 and PHASE2

60.3.10 'Functional' Reset Escalation Threshold Register (MC_RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See 'Functional' reset escalation for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 604h offset = 604h

Bit	0	1	2	3	4	5	6	7
Read	0				FRET			
Write								
Reset	0	0	0	0	0	1	0	0

MC_RGM_FRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 FRET	'Functional' Reset Escalation Threshold - If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets which will cause a 'destructive' reset if the RGM_FRET register isn't written to beforehand.

60.3.11 'Destructive' Reset Escalation Threshold Register (MC_RGM_DRET)

This register sets the threshold for 'destructive' reset escalation topti_top.v keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the 'destructive' reset software escalation function. Writing any value to this register will reset the 'destructive' reset counter. See 'Destructive' reset escalation for details on the 'destructive' reset escalation function.

This register is reset only on power-on.

This register is reset only on power-on.

NOTE

The destructive resets which can trigger escalation are F_SOFT_DEST, F_FFRR, F_SUF, F_EDR and F_FIF. It is defined by the MC_RGM parameter DEST_ESC_INCR_TRIG.

Address: 0h base + 608h offset = 608h

Bit	0	1	2	3	4	5	6	7
Read	0				DRET			
Write								
Reset	0	0	0	0	1	0	0	0

MC_RGM_DRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 DRET	'Destructive' Reset Escalation Threshold - If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register isn't written to beforehand.

60.3.12 External Reset Output Extension Control Register (MC_RGM_EROEC)

This register controls the assertion of the ESR0 pin after the reset sequence has completed. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. The register bit is cleared on write '1'.

Clearing the EROEC bit will cause the MC_RGM to stop asserting the ESR0 pin within two 16 MHz internal RC oscillator clock cycles. The ESR0 pin cannot be asserted by writing to this register.

This register also provides the current value sampled on ESR0 via the ERIS bit. This is useful for software to poll if, for example, ESR0 is used in the system to synchronize the application software with an external event.

This register is reset only on power-on.

Address: 0h base + 60Ch offset = 60Ch

Bit	0	1	2	3	4	5	6	7
Read	0						ERIS	EROEC
Write								w1c
Reset	0	0	0	0	0	0	0	1

28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.3.15 Peripheral Reset Register 2 (MC_RGM_PRST2)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

In addition to resetting the CAN_RAM_CTR module, writing a '1' to the CAN_RAM_CTR_RST bit will also reset the MCAN_1, MCAN_2, and MCAN_3 modules and keep them in reset until a '0' is written to this bit. MCAN_1, MCAN_2, and MCAN_3 can still be reset individually via their individual bits.

Caution

Use the RGM_PRSTn registers with care. See 'Destructive' reset escalation for the proper sequence to prevent unexpected chip behavior.

Address: 0h base + 618h offset = 618h

60.4 Functional description

60.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in the following table.

Table 60-1. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion[1]	Boot Mode Capture
power-on reset	all	yes	yes
'destructive' resets	all except some clock/reset management	yes	yes
external reset	all except some clock/reset management and debug	programmable	yes
'functional' resets	all except some clock/reset management, STCU, FCCU, and debug	programmable[2]	programmable
shortened 'functional' resets	flip-flops except some clock/reset management, STCU, FCCU, and debug	programmable[2]	programmable[3]

1. 'external reset assertion' means that the ESR0 pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3
2. the assertion of the external reset is controlled via the RGM_FBRE register
3. the boot mode is captured if the external reset is asserted

Note

JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in the following figure.

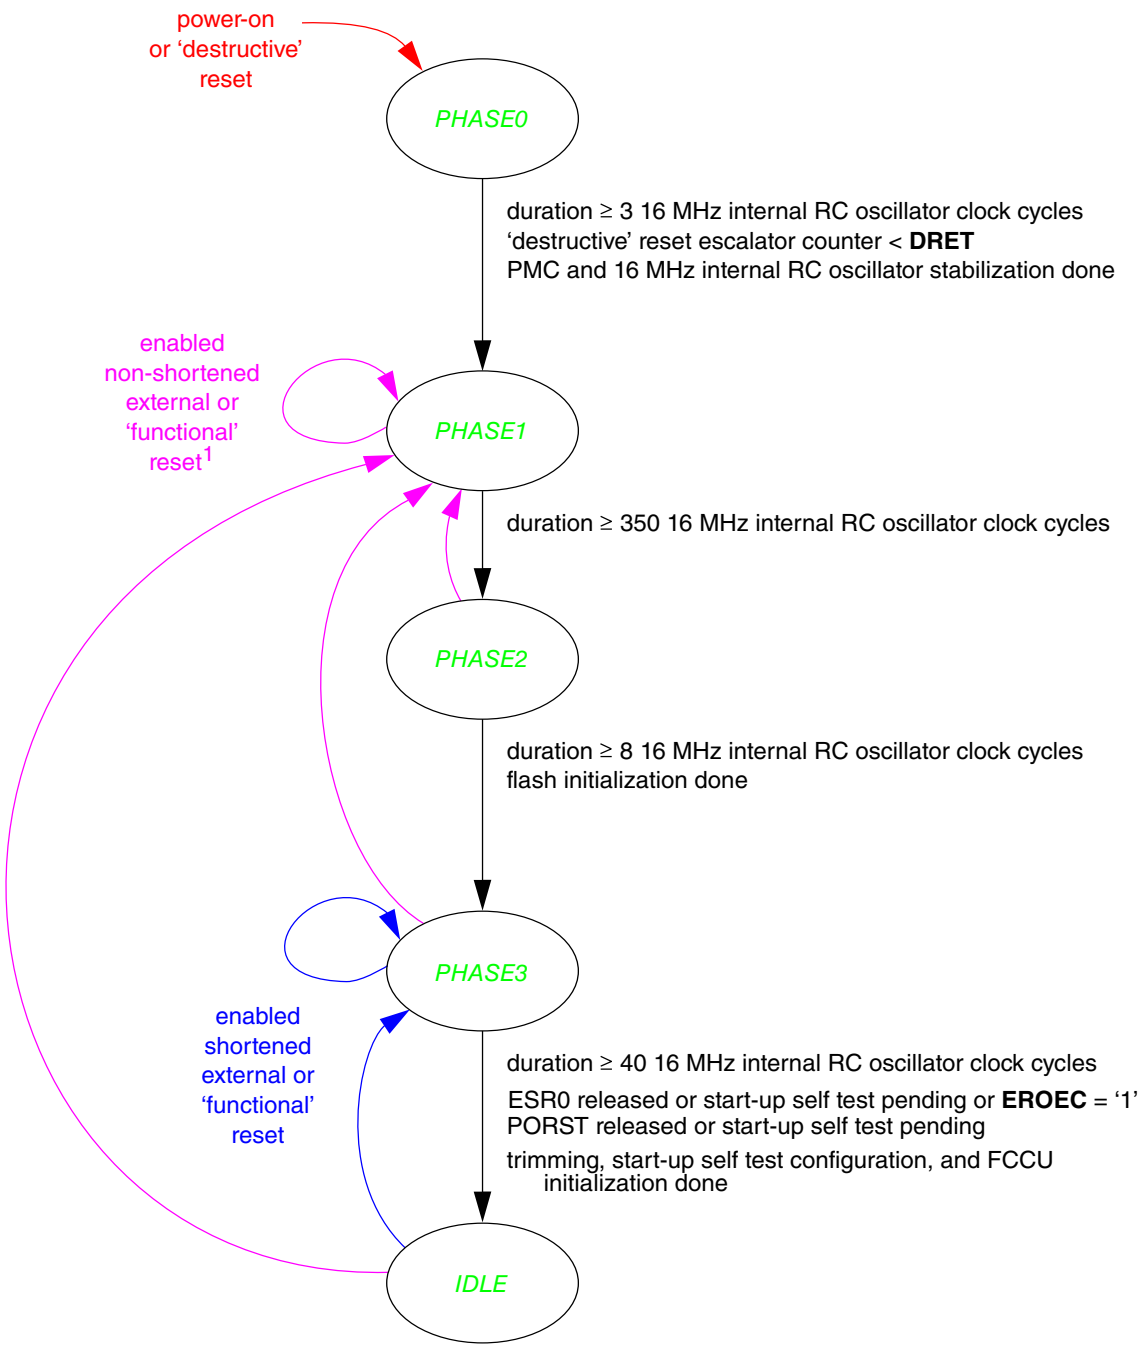

Figure 60-2. MC_RGM State Machine

60.4.1.1 PHASE0 phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled 'destructive' resets have been processed
- all processes that need to be done in PHASE0 are completed
    - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of 3 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled 'destructive' reset event
- the 'destructive' reset escalator counter has not reached the value in the DRET field of the RGM_DRET resister

60.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened 'functional' resets have been processed
- a minimum of 350 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened 'functional' reset event

60.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
    - flash initialization
- a minimum of 8 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

60.4.1.4 PHASE3 phase

This phase is a entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened 'functional' reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization
- a minimum of 40 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened 'functional' reset event
- ESR0 is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence or the EROEC bit of the RGM_EROEC register is '1'
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

60.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

60.4.2 'Destructive' resets

A 'destructive' reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exceptions to the latter are the software 'destructive' reset and the external power-on reset which do allow the memory content to be preserved if the chip is configured to not execute a self test on power-on, 'destructive', and external resets.

The status flag associated with a given 'destructive' reset event (RGM_DES.F_<destructive reset> bit) is set when the 'destructive' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'destructive' reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note

The RGM_DERD register can be written only once between two 'destructive' reset events.

The chip's low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD and/or HVD) is enabled, the supply is sufficient to have the 'destructive' event correctly propagated through the digital logic. Therefore, if a given 'destructive' reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given 'destructive' reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled 'destructive' reset will trigger a reset sequence starting from the beginning of PHASE0.

60.4.2.1 External power-on reset - PORST

The bidirectional external power-on reset pin PORST is a special case 'destructive' reset.

The detection of a falling edge on PORST will start the reset sequence.

The chip asserts PORST if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self test on power-on, 'destructive', and external resets, this is the exit of PHASE3 after self test execution has completed.

60.4.3 External reset

The MC_RGM manages the external reset coming from ESR0. The detection of a falling edge on ESR0 will start the reset sequence.

The status flag associated with the external reset falling edge event (RGM_FES.F_ESR0 bit) is set when the external reset is asserted and the power-on reset is not asserted.

The external reset can optionally be disabled by writing bit RGM_FERD.D_ESR0.

Note

The RGM_FERD register can be written only once between two 'destructive' reset events.

An enabled external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_ESR0 is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the flash.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an external reset event if configured via the RGM_FBRE register to assert the external reset
- a 'functional' reset event configured via the RGM_FBRE register to assert the external reset

In this case, ESR0 is asserted until all conditions for exiting PHASE3 have been met with the exception of the ESR0 assertion check.

If the OPT_RGM_ESR0_HW bit of the "UTEST Miscellaneous" DCF client is set to '0', the MC_RGM continues to assert ESR0 until the EROEC bit in the RGM_EROEC register has been cleared by software.

In addition, the MC_RGM asserts ESR0 while the start-up self test is being executed.

The ESR0 input is disabled immediately as of the ESR0 output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the ESR0 output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

If ESR0 is stopped being asserted by the MC_RGM and the 4 µs input mask period expires during the reset IDLE phase (e.g., due to the EROEC bit being cleared by software), and now a low value is detected on ESR0, an external reset falling edge event will not occur, and no new reset sequence will be triggered. For a new reset sequence to trigger, ESR0 must first be deasserted.

60.4.4 'Functional' resets

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (RGM_FES.F_<functional reset> bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'functional' reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note

The RGM_FERD register can be written only once between two power-on reset events.

An enabled 'functional' reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a 'functional' reset. When RGM_FESS.SS_<functional reset> is set, the associated 'functional' reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a 'functional' reset should not reset the flash module.

60.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_D/FERD and RGM_D/FEAR registers as shown in the following table.

Table 60-2. MC_RGM Alternate event selection

RGM_D/FERD Bit Value	RGM_D/FEAR Bit Value	Generated Event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (i.e., at the reset source that caused the alternate request) and also clearing the appropriate RGM_D/FES status bit.

Note

SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request isn't asserted until the system clock is re-enabled.

Note

If a masked 'destructive' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any SAFE mode/interrupt request to the MC_ME.

Note

If a masked 'functional' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any SAFE mode/interrupt request to the MC_ME.

60.4.6 'Functional' reset escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once 'functional' reset escalation has been enabled, the MC_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (i.e., entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a

write of any value to the RGM_FRET register and on any power-on or 'destructive' reset. If the counter reaches the value in the RGM_FRET register's FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

60.4.7 'Destructive' reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset which causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

60.4.8 Individual Peripheral Resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRSTn registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRSTn registers.
4. Wait at least two peripheral clock periods.
5. Clear the bit corresponding to the peripheral in the RGM_PRSTn registers.

The peripheral can be kept in reset indefinitely by not executing step 5. After the completion of step 5, the peripheral can be enabled again via the MC_ME.

Chapter 61
Boot Assist Flash (BAF)

61.1 Introduction

The MCU is booted through a collaboration of several blocks, hardware, and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, SSCM send reset vector to BAR, which sets PC to BAF start address.

The BAF code then checks the life cycle of the device. If the life cycle is FAIL_ANALYSIS, the BAF enters a loop in which it services the watchdog and CSE initialization is enabled. The BAF does not execute further since the read access to flash memory boot sectors for the core may be disabled if the device life cycle is FAIL_ANALYSIS. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD or MCAN modules. The package pins/balls used by LINFlexD are the same used by the MCAN module. Hence, the external PHY can be either LIN or CAN, allowing the ASC@CAN operation (see Serial boot configuration for configuration details).

61.2 BAF image header

BAF image contains a 256-byte header starting from the BAF version number (see table "BAF memory map" table in the "BAF Configuration" section of this chapter). The header contains important information such as BAF version and production disable flag. The BAF header is explained in Table 61-1.

Table 61-1. BAF image header

Address offset	Size (bits)	Field description
0000h	32	BAF image version
0004h	32	Reserved
0008h	32	Reserved (part of Clock Jitter Activation Constant)
000Ch	32	Clock Jitter Activation Constant
0010h – 00FFh	Reserved	

61.2.1 BAF image version

The BAF version is a 32-bit field in the image header at the BAF starting address (see the "BAF memory map" table in the "BAF Configuration" section of this chapter). The 32-bit field is explained in Table 61-2.

Table 61-2. BAF image version

Field	Description
[0:7]	Major Number: This field contains the major version number for the BAF image
[8:15]	Minor Number: This field contains the minor version number for the BAF image
[16:23]	BAF Type: This field contains customer specific information.
[24:31]	Reserved

61.2.2 Clock Jitter Activation constant

The Clock Jitter Activation constant is a 32-bit flag, but the smallest element in flash that can be programmed is 64 bits, so the first 32 bits are reserved to allow programming of this constant. This 32-bit flag can be programmed by the customer and is used to activate the Clock Jitter feature that adds clock edge jitter to the baud rate clocks of several communications modules. As part of the BAF startup procedure, the BAF copies this constant from flash to the PASS Clock Jitter Enable register.

Table 61-3. BAF Clock Jitter Activation constant

Field	Description
[0:31]	Clock Jitter Activation Constant. The initial state of the production disable flag is erased (= FFFF_FFFFh). This equates to NO clock jitter.

61.3 Functional description

A functional description of the BAF modes is contained in the following sections.

61.3.1 Boot modes

Depending on the state and the content of its flash memory the device can enter one of three different boot modes:

- Boot from internal flash – If the internal flash contains application code with a valid boot header, the application is booted. The boot header contains flags that enable/ disable individual cores and their reset vectors.
- Serial boot – If no valid boot header is found and the current life cycle phase of the device is CUST_DEL (Customer Delivery) or JDP/FSL Production, an attempt is made to download the application by a serial protocol over LINFlexD or MCAN physical interface. The downloaded code is then executed by the initial boot core.
- Static mode – The device enters power safe mode and waits for an external reset.

61.3.2 Device initialization

The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the buddy device[1] and the Hardware Security Module (HSM) in the following way:

1. Buddy device: If the device is an emulation device (buddy device present) and the calibration RAM content is valid, then this RAM is automatically remapped over the calibration flash memory. This is intended to assist with cold-start calibration.
2. HSM: If the HSM is enabled and the "wait for HSM" flag is present, then the boot core waits for the HSM to become ready. It optionally executes a random instruction sequence to create random noise on the instruction bus while waiting.
3. BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC

1. "Buddy device" refers to a companion device that is used only for system development and debug activities. It is not used in production systems.

error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module's MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.

4. BAF uses memory of the Core_2 (IOP)Main core's D-MEM area as in the 'BAF memory map' table (at the beginning of this chapter) for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.

61.3.3 Flow of control

Figure 61-1 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

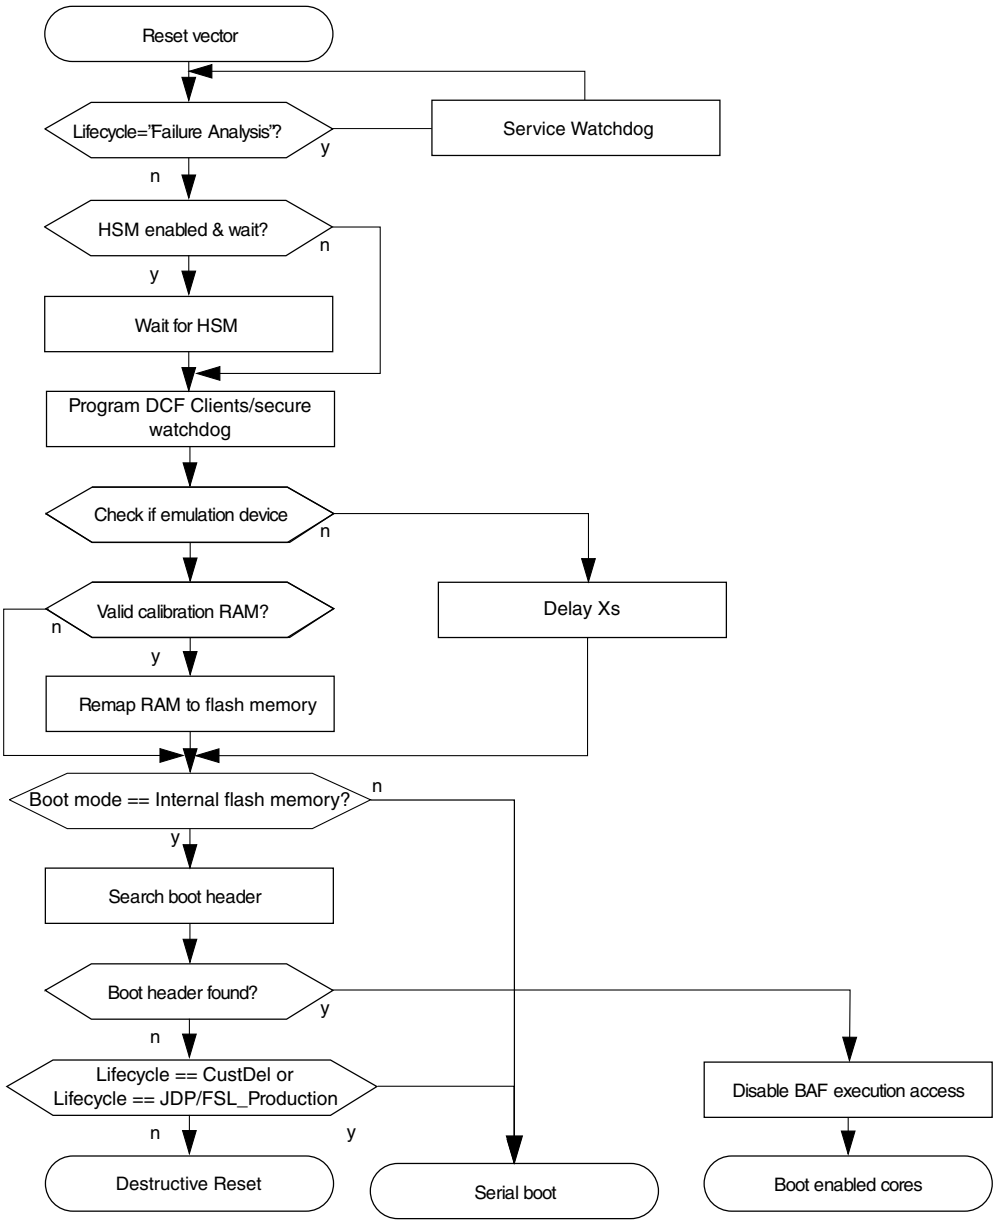

Figure 61-1. Flow of control

61.3.4 Optionally remap calibration RAM

If the device is an emulation device (buddy device present, SIUL2_MIDR1[ED] = 1), and the external overlay RAM has a valid content, then this RAM is automatically remapped over the selected flash memory regions. The details of the mapping are defined by a 400-byte configuration table at the beginning of the external overlay RAM. The layout of the table is depicted in Table 61-4.

The content of the overlay RAM is assumed valid if all of the following are true:

- The BD_INIT flag in the initialization status register of the buddy device (BD_SIUL2_ISR) is set.
- A CRC calculation over the configuration table yields the correct result.
- The version of the calibration data matches the version of the application software in flash memory (*((uint64_t*)ADDR_SWID) = DATID).

In this case, all 32 calibration remap descriptors (PFCRDs) are setup with the values contained in the configuration table. Finally, the PFCRDE field is copied to the enable register in the PFLASH controller.

Table 61-4. Remap configuration table

Address Offset	Name	Contents
00h	CRC_REF	CRC reference value
04h	ADDR_SWID	Address of 64 bit ID value in SW FLASH
08h	DATID	64 bit ID value of the calibration data
0Ch		
10h	PFCRDE	CRD enable flags
14h	LSTARTADDR0	PFCRD0 (logical start address)
18h	PSTARTADDR0	PFCRD0 (physical start address)
1Ch	CRDSize0	PFCRD0 (Master Mask, size)
20h	LSTARTADDR1	PFCRD1 (logical start address)
24h	PSTARTADDR1	PFCRD1 (physical start address)
28h	CRDSize1	PFCRD1 (Master Mask, size)
…	…	…
188h	LSTARTADDR31	PFCRD31 (logical start address)
18Ch	PSTARTADDR31	PFCRD31 (physical start address)
190h	CRDSize31	PFCRD31 (Master Mask, size)

The CRC calculation is performed using the CRC unit applying the CRC-32 (Ethernet protocol) polynomial. The calculation is initialized with a seed of 0000h. Then, the 100 32-bit words starting at table address offset 04h are moved to the CRC_INP register by the CPU. Finally, the content of the CRC_OUTP register is compared to the CRC_REF value.

61.3.5 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (if SSCM_UOPS[HSB = 1]). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls

the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

61.3.6 Initialization of BAF DCF clients

61.3.6.1 Soft DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is FFFF_FFFFh). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be an intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF are listed in Table 61-5.

The DCF clients which are used for initialization of security watchdog are explained in Security watchdog configuration.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-bit, 16-bit and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

The serial boot DCF client provides a mechanism which can configure the BAF to perform serial boot or boot from internal flash. Details can be viewed in SER_BOOT_CBACK – BAF serial boot DCF client.

Table 61-5. BAF DCF client list

Address	Name	Label	Description
0000h	Security Watchdog Control register	SEC_SWT_CR	Data to write to SWT Control Register.
0001h	Security Watchdog Timeout register	SEC_SWT_TO	Security watchdog counter value.
0002h	Security Watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0003h	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog.
0004h – 01FFh	Reserved	—	Reserved for future use
0200h	Address	ADDR	The address to which DATA*n* is written.
0201h	32-bit data	DATA32	The 32-bit data that is written to ADDR.
0202h	16-bit data	DATA16	The 16-bit data that is written to ADDR.
0203h	8-bit data	DATA8	The 8-bit data that is written to ADDR.
0204h – 020Fh	Reserved	—	Reserved for future use.
0210h	Callback Address	CALLBACK	The address of a callback function.
0211h	Serial boot Callback address	SER_BOOT_CBACK	The address of serial boot callback function.
0212h – 0213h	Reserved	–	Reserved for future use.
0214h	Enable Calibration Delay Loop	CALIBRATION_PD_DELAY_ENABLE	Enables calibration remap equivalent delay loop on PD.
0215h	IVPR2 for CPU2	IVPR2_CPU2	Programs the IVPR2 for CPU2.
0216h – 7FFFh	Reserved	—	Reserved for future use.

NOTE

BAF boots with a watchdog timeout window set to 16ms.
Parsing more and more DCF Records may increase boot time.
But it should be taken care that number of DCF records should not be very high as it can cause watchdog window timeout.

61.3.6.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. The BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then programs the security watchdog registers. BAF configures only SWT2 as security watchdog for the MainCPU2 (IOP) core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

61.3.6.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0000h while parsing, BAF programs the DCF client "Security watchdog control register" with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

61.3.6.2.2 Security Watchdog Timeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

61.3.6.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in 'fixed address execution service mode'. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record

with CS14 set and address field as 0002h while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

NOTE

To program the core IAC8 special purpose register, the ownership of this register should be with software. If Hardware has its ownership software will not be able to write to it using mtspr instruction.

61.3.6.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to the BAF which Core will use the security watchdog. The BAF parses the DCF record and if it finds a record with CS14 set and an address field of 0003h, the BAF programs this DCF client. This means that the BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. Table 61-7 and Table 61-6 shows the data layout for this client in the DCF record. This client may only be written once during reset. Subsequent writes are ignored.

NOTE

Due to the limitation that only the IAC8 on the CPU running the BAF code can be accessed, the BAF can only configure the Security Watchdog to operate on CPU2. If another CPU is selected, the Security watchdog is NOT configured.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients were not written, data is configured erroneously.

If security watchdog is assigned to CPU0 or CPU1, relevant CPU IAC8 register is programmed along with other debug configuration registers to enable IAC8 as watch point.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). If the security watchdog is assigned to CPU2 (IOP), first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). To assign the security watchdog to the Main CPU, first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

Table 61-6. Security Watchdog Core select bit configuration

Field	Description
[31:2]	Reserved
SC[1:0]	These bits select the CPU which will use the security watchdog. 00 Reserved 01 Reserved 10 CPU2 (IOP Core) 11 Reserved

NOTE

BAF programs FCCU for enabling SWT2 and SWT3 as fault source and makes them hardware recoverable. This is done to ensure that fault latched in FCCU get cleared on reset and on next SWT timeout FCCU can again trigger reset. BAF does not clear the faults latched in FCCU as they can be of interest for application.

61.3.6.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0200h while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

Table 61-8. BAF DCF ADDR client configuration

61.3.6.4 BAF DCF client - DATAX

CAUTION

While using DATAX DCF records, it should be taken in account that BAF does not take care of ECC scheme and can generate ECC, if write is performed in memory locations which are protected by ECC and are not pre-initialized as required.

61.3.6.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0201h while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2-bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

Table 61-10. DATA32 DCF client configuration

61.3.6.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0202h while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to ‘0’ (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

61.3.6.4.3 DATA8 – 8-bit data DCF client

The BAF parses the DCF records. During parsing, if the BAF finds a record with CS14 set and address field equal to 0203h, the BAF programs this 8-bit DCF client. The BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

61.3.6.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0210h while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Warning

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

61.3.6.6 SER_BOOT_CBACK – BAF serial boot DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0211h during parsing, the BAF programs this serial boot DCF client. This DCF client is written with a 32-bit start address of a function which is invoked by the BAF. The BAF code checks to see if the start address is within the UTEST or BAF flash memory blocks,

then program flow is passed to this address if it is within either of these blocks. If the address is outside the the UTEST and BAF flash memory blocks, no function call is executed. The DCF client execution is aborted, and the BAF moves to the next DCF record. The function that is called is expected to comply with Power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in the BAF.

Warning

No parameters are passed to the function invoked by the BAF.

Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a character value. The return value informs BAF if serial or normal internal flash boot should be executed (see Table 61-16 for details).

Table 61-16. Serial boot callback function return value definition

Return values	Description
00h	Boot from internal flash using standard search for boot record (see "Search boot header and boot options" at the beginning of this chapter).
01h	Serial boot using both MCAN and LINFlexD (in UART mode). See Optionally perform serial boot for details.
02h – FFh	Reserved

61.3.6.7 CALIBRATION_PD_DELAY_ENABLE – BAF calibration PD delay enable DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0214h during parsing, the BAF programs this Calibration PD delay DCF client. This DCF client is written with a 32-bit key in DATA section of this DCF record. BAF supports Calibration Remap over external overlay ram on Emulation Device. On Production Device, this feature is not present but an equivalent delay loop can be activated. This is used if same BAF boot time is required on PD and ED. This delay can be activated using this DCF Client, if key present in DATA section of DCF record is 0x000055AA. For all other values, if DCF client itself is not present then delay is not activated. This DCF record can be programmed multiple times, but only the last instance of the DCF Record will be effective.

61.3.6.8 IVPR2_CPU2 - BAF set IVPR2 for CPU2 DCF client

The BAF parses DCF records. If it finds a record with CS14 set and an address field of 0215h during parsing, the BAF programs the IVPR2 for CPU2 DCF client. This DCF client is written with a 32-bit value in DATA section of this DCF record. BAF parses this data value and programs it to IVPR2 for CPU2 just before jumping to application. If this DCF client is not present, then IVPR2 will contain address of BAF vector table. This DCF record can be programmed multiple times, but only the last instance of the DCF Record will be effective.

61.3.7 Production disable activation protocol and implementation

Module failure analysis is a standard requirement, but some OEMs have an additional requirement that upon entering failure analysis mode the MCU operation is modified in such a way that the MCU can never be used in a production ECU. The chosen operational modification for production disable is to apply clock jitters to can modules so that it prevents active communications with another can device on a can network (see the PASS chapter for details).

The BAF maintains a 64 bit flag in BAF code flash region as explained in Clock Jitter Activation constant. On every POR the BAF copies this clock jitter activation constant to the Clock Jitter Enable register in the PASS module to enable jitter on the MCAN baud clock. Default value of this flag is shown in Table 61-3. Hence, jitter on the MCAN baud clock is disabled if the default value is used. To enable jitter on CAN clock the value of this flag should be modified to FFFF_FFFEh.

The BAF flash memory is write protected and locked. To allow modification of the Clock Jitter flag and activate the production disable feature, the BAF implements production disable activation protocol as explained in Table 61-18. The BAF implements this protocol in a Power.org EABI compliant callback routine. This callback routine can be invoked by programming a callback based soft DCF client as explained in CALLBACK – BAF callback DCF client. The callback function address is show in Table 61-17.

Table 61-17. Production Disable Callback routine entry point

Description	Address
Production disable protocol callback function address	0040_40E0h
Production Disable falsh Driver SRAM area	5280_0408h - 5280_0808h

Table 61-18. Production Disable protocol description

Step	Description	Tool action or response	MCU action or response
1	After power-on tool holds the MCU in reset and writes the activation code to JDC via JTAG interface. The tool pulls hardware interlock pin high, then releases reset.	Assert hardware interlock pin Write 0xF5A0_AA55 to JDC	Starts production disable activation
2	The MCU responds by writing to the JDC an acknowledgment code and which of the 4 PASS passwords are required to unlock the BAF flash block	—	Write FA50_000*n*h to JDC if password for pass group n is required to unlock the BAF flash block. (n is either 0,1,2 or 3)
3	The tool reads the acknowledge from JDC module and writes the relevant password to the JDC module. MCU performs password comparison and writes error code to JDC module password provided by tool was incorrect.	Read JDC – Write 256 bit password for pass group n to JDC in eight 32 bit words. (n is 0,1,2 or 3)	Write FA50_F00*n*h if password does NOT match. Once the status has been read by the tool then cause reset. (n is either 0,1,2 or 3)
4	If more than one password is required to unlock the BAF flash block step 2 and step 3 are repeated until all relevant password has been supplied.	—	If password matches step 2 and step 3 are repeated for the next pass group until all pass group that lock BAF flash has been processed.
5	The MCU then attempts to program the can jitter activation constant within the BAF memory block. The can jitter activation constant flag is a write once flag. Once written it cannot be re-programed as BAF memory block is OTP. MCU write a code to JDC to signal success or failure of flash programming operation and issue reset.	—	Program can jitter activation constant in BAF flash block. If successful write FA51_0000h to JDC. If unsuccessful write FA51_F000h to JDC Issue reset.

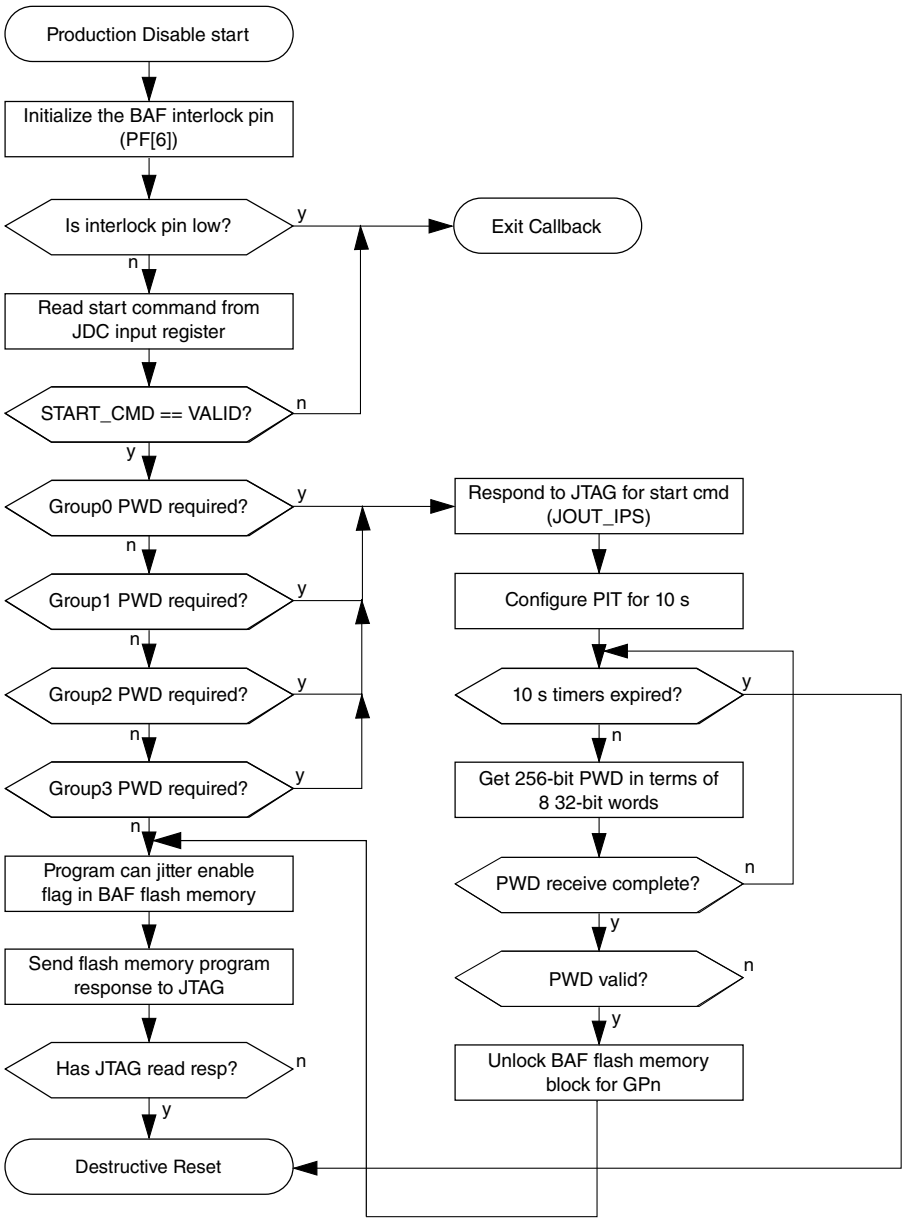

Figure 61-2. Production Disable callback function flow chart

61.3.8 TDM Diary Operation

On every reset, BAF copies the first four bytes of last record (8-byte) of every Tamper Detect Region to corresponding Software Tamper Override Key Region Registers in TDM. BAF reads the base address of TDM Diary (group of 6 continuous Tamper Detect Regions, 2k each) from DBA register in TDM. For more details on TDM please refer to corresponding section. This is done as a part of TDM Diary Override enhancement.

61.3.9 Optionally perform serial boot

If no boot header is found in any of the locations mentioned above, the BAF determines the Life Cycle status of the device. If the Life Cycle is in CUST_DELIV (Customer Delivery) or JDP/FSL Production, it attempts a serial boot. Otherwise, the boot has failed and BAF issues a destructive reset.

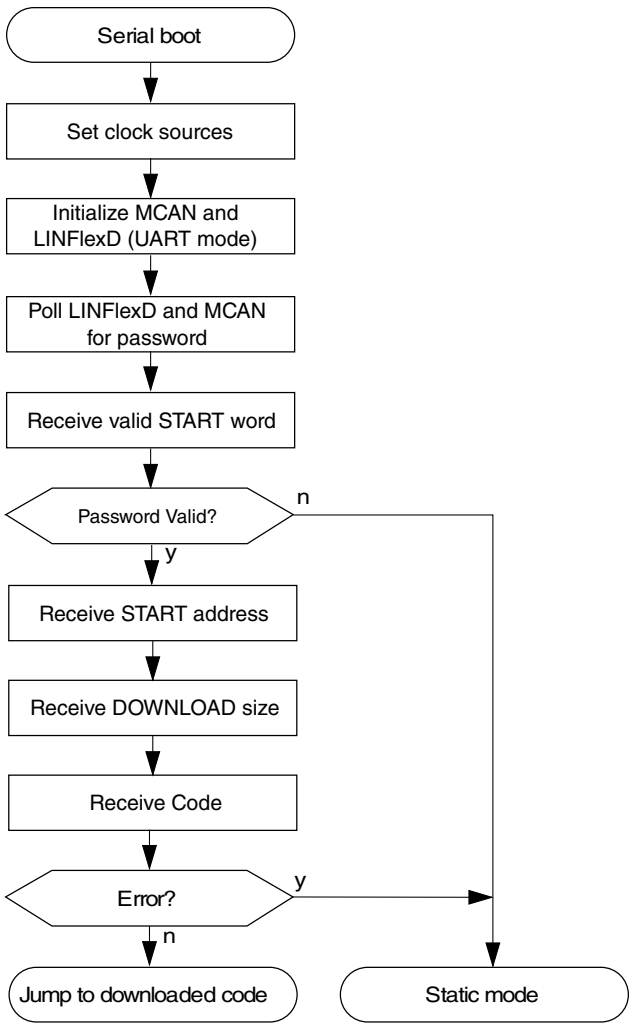

Figure 61-3. Flow of control during serial boot

The clock source in the MC_CGM module is configured and the PADs are set up for LINFlexD and MCAN signals (see Serial boot configuration for details), then the code is downloaded using LINFlexD or MCAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal SRAM via the LINFlexD or MCAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process, both LINFlexD and MCAN are configured in passive listening mode, connected to the same pair of pads. As soon as the interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The interface that is not receiving is switched back to its reset state and does not participate further in the serial boot process.

If a CAN message of 8 bytes with ID 11h is received on the or MCAN controller first, the BAF program:

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message is received that does not contain 8 bytes or does not have an ID 11h by the MCAN controller, or the MCAN controller generates a CAN error, it is probable that the tool is sending a LIN frame. Under such circumstances the BAF program:

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error.
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is FEh of the password. If not, continue polling. The data may be a valid CAN message.
- If it is first byte of the password (FEh) then disable MCAN controller and restore to its reset state.
- Configures MCAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

61.3.9.1 Serial boot mode protocol

From a high-level perspective, the download protocol over CAN and LIN interfaces follows steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes and VLE bit to MCU.
3. Host transmits a sequence of data bytes that are to be executed.
4. CPU2 executes code from start address provided in 2

Each step must be complete before the next step starts.

The exact protocol between LinFlex and MCAN differs slightly.

61.3.9.2 LINFlexD download protocol

The communication is performed in half-duplex mode, Any transmission from the host is followed by the MCU transmission:

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received data to the host.
3. The host verifies whether the echo is correct.
   - If the data is correct, the host can send the next byte of data.
   - If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded and the VLE bit.
4. x bytes of code that is downloaded to SRAM and executed, (x must match the value specified in 3).

61.3.9.3 MCAN download protocol

The MCAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 11h as the ID and 8-byte length to send the password. The MCU transmit the same message but with and ID of 1h.
2. A message with 12h as the ID and 8-byte length to send the start address, size of the code and VLE mode bit. The MCU transmit back the same data but with an ID of 2h.
3. A message with 13h as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 3h.

61.3.9.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password FEED_FACE_CAFE_BEEFh.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode(low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

61.3.9.5 Download start address, VLE bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bit and 31-bit code length as shown in Table 61-19.

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and BookE Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book-E code, the BAF puts the device into static mode.

The start address defines where the received data is stored and where the MCU branches after the download is finished. BAF ignores the three LSB bits of download address to avoid ECC on download address. But BAF does not align the address while jumping to application for executing. So, download address should be passed as 64-bit aligned for proper execution.

The Length defines how many data bytes have to be loaded.

Table 61-19. Start address, VLE bit and download size in bytes

Bytes 0-3															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
START_ADDRESS[31:16]															
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
START_ADDRESS[15:0]															
Bytes 4-7															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
VLE	CODE_LENGTH[30:16]														
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table continues on the next page...

Table 61-19. Start address, VLE bit and download size in bytes (continued)

CODE_LENGTH[15:0]

61.3.9.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until the number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-bit boundary, the BAF fills it with zero's and renders the data aligned on a 64-bit boundary. After the last data is written to SRAM, the BAF writes a dummy double-word (0000_0000_0000_0000h) to the next address location. This is written to avoid possible ECC error during core prefetch.

61.3.9.7 Execute code

The BAF program waits for the last echo message transmission being completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and MCU is controlled by new code executing from SRAM.

61.3.10 Serial boot configuration

61.3.10.1 Clock Settings

NOTE

XOSC load capacitance can be selected as internal via UTEST_MISCELLANEOUS dcf record. On such virgin device where no dcf record is programmed, XOSC may be unstable because of resulted wrong load capacitance. As CAN_CLK

should be derived from XOSC, CAN boot can not be performed on such designs. LinFlex boot can be performed on such cases because LIN_CLK can be derived from IRC.

Serial boot interfaces(LIN and MCAN) derives its clock requirements from PBRIDGE_CLK, CAN_CLK and LIN_CLK. LIN_CLK can be derived from both IRC or XOSC for successful operation. But in case of MCAN, only XOSC can be selected as CAN_CLK because of high precision requirements. Also in case of MCAN boot, module clock (PBRIDGE_CLK) should be more than Protocol Clock (CAN_CLK). For LINFlex, LIN_CLK and PBRIDGE_CLK should satisfy a relation of "2/3 × LIN_CLK ≥ PBRIDGEx_CLK > 1/3 × LINCLK". As XOSC can vary from 8 MHhz to 44 MHz, PBRIDGE also should be more than or equal to 44 MHz. To achieve the clock requirements, PLL0 is locked over IRC with a multiplying factor of 5.5 and SC_DC2 divider set to 2. PLL0_PHI is selected as system clock source via MC_ME. This makes system and PBRIDGE clock at 44 MHz. LIN_Clk is also selected as PLL0_PHI (88MHz). Also, during serial boot all peripherals are enabled. After downloading application code, clock settings are not restored and no peripheral is disabled. To change the clock source, first all peripherals must be disabled and selectors in CGM must be restored.

BAF enables XOSC via MC_ME but does not wait for M_TRANS to go low because in case of faulty XOSC, mode transition may not complete. BAF waits for 3 ms to provide enough time for XOSC to becomes stable. If XOSC is still unstable then CAN boot is not performed. Some reasons of XOSC being unstable are XOSC gets disconnected or wrong value of internal load capacitance in case of internal load capacitance option is selected in UTEST_MISCELLANEOUS dcf record.

61.3.10.2 LINFlexD configuration

Boot using UART protocol is implemented by the LINFlexD module.

NOTE

See the pin configuration table at the beginning of this chapter for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx pin is configured as an input and muxed to the LINFlexD module. The LINFlexD_Tx pin remains in a passive input state until the first byte of protocol is received. It is then configured as an output and muxed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data (such as LIN or CAN). The side effect of this is that all data transmitted on the Tx pin is also received on the Rx pin. To prevent the LINFlexD module from receiving its own transmission, the Rx pin is blocked during transmission.

The LINFlexD controller is configured to operate at a baud rate of 250 Kbps, using an 8-bit data frame with no parity bit and 1 stop bit.

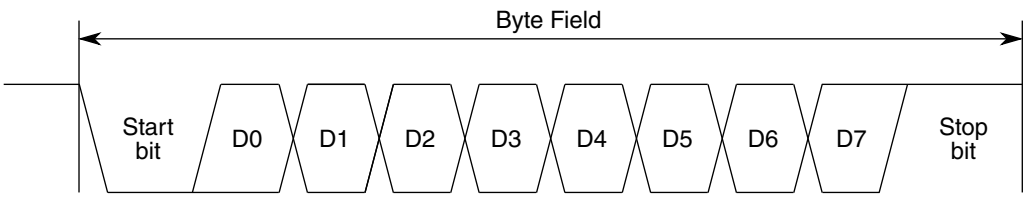

Figure 61-4. LINFlexD bit timing in UART mode

61.3.10.3 MCAN configuration

The MCAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0B specification (see Table 61-20 for baud rates).

NOTE

See the pin configuration table at the beginning of this chapter for pins used by the MCAN module.

The Bit timing is configured as shown in Figure 61-5.

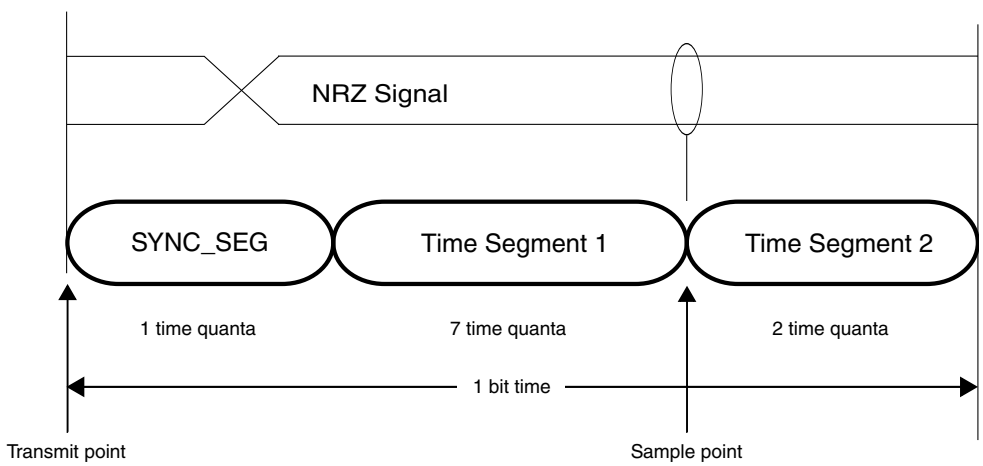

Figure 61-5. MCAN bit timing

61.3.10.4 LINFlexD and MCAN pin configuration

Please see the BAF configuration at the beginning of this chapter for pin details.

61.3.10.5 Baud rates

The LINFlexD baud rate is set to 250 Kbps. Table 61-20 shows some possible baud rates.

The MCAN baud rate is set by the frequency of the external crystal / 40.

Table 61-20. LINFLexD and MCAN baud rates

Crystal frequency	LINFlexD baud rate	MCAN baud rate
8 MHz	250 Kbps	200 Kbps
12 MHz	250 Kbps	300 Kbps
16 MHz	250 Kbps	400 Kbps
20 MHz	250 Kbps	500 Kbps
40 MHz	250 Kbps	1000 Kbps

61.3.10.6 Protocol summary

Table 61-21 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 61-21. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + 31 bits of download data size in bytes (MSB first)	VLE bit + 31 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	—	8 × 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	none	none	Branch to downloaded code

Table 61-22 shows the MCAN serial boot protocol.

Table 61-22. MCAN serial boot mode download protocol

Protocol step	Host message sent	BAF response message	Action
1	CAN ID 011h + 64-bit password	CAN ID 001h + 64-bit password	Password checked against fixed password (FEED_FACE_CAFE_BEEFh). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 012h + 32-bit store address + 32-bit (1 VLE bit, and 31 bits of download data size in bytes)	CAN ID 002h + 32-bit store address + 32-bit (1 VLE bit, and 31 bits of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 013h + 8 to 64 bits of raw binary data	CAN ID 003h + 8 to 64 bits of raw binary data	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	none	none	Branch to downloaded code

61.4 Resources

- Clocks
  - Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).
- LINFlexD and MCAN
  - The LINFlexD and MCAN modules are used if serial boot mode is entered. This can be through failing to find a valid boot header, or from the SER_BOOT_CBACK callback function. All settings are restored before the application code in system RAM is executed.
- CRC
  - The CRC module is used to validate external overlay contents, if and only if the device is an emulation device and the buddy device has been initialized.
- PFLASH
  - PFLash module is used to disable BAF execution.
- Interrupts

    - No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.
- Security watchdog
    - When SWT2 is chosen as security watchdog, SWT3 is used for task monitoring purpose.
- FCCU
    - FCCU is used to configure Fault Reaction of SWT2 and SWT3.
- TDM
    - TDM for implementing TDM Diary enhancements.

Chapter 62
System Status and Configuration Module (SSCM)

62.1 Introduction

62.1.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

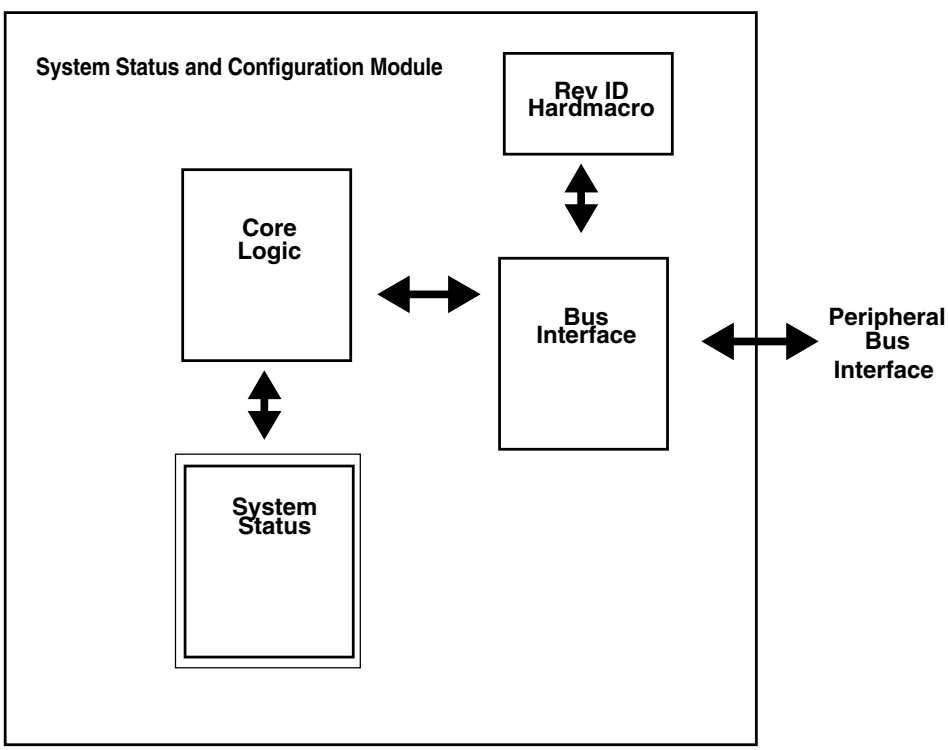

Figure 62-1. SSCM block diagram

62.1.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 62-1. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

62.1.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Determine HSM boot vector
  - Decodes the Device Life Cycle
- Bus abort enable/disable
- Peripheral abort enable/disable

62.1.4 Modes of operation

The SSCM operates identically in all system modes.

62.2 External signal description

The SSCM has no external pins.

62.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal.

NOTE

SSCM does not support transfer errors in memory holes.

SSCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SSCM System Status (SSCM_STATUS)	16	R	See section	62.3.1/3324
2	SSCM System Memory and ID Register (SSCM_MEMCONFIG)	16	R	See section	62.3.2/3325
6	SSCM Error Configuration Register (SSCM_ERROR)	16	R/W	0000h	62.3.3/3326
C	Password comparison register low word (SSCM_PWCMPH)	32	W (always reads 0)	0000_0000h	62.3.4/3327
10	Password comparison register low word (SSCM_PWCMPL)	32	W (always reads 0)	0000_0000h	62.3.5/3327
20	SSCM HSM and User Option Status Register (SSCM_UOPS)	32	R	See section	62.3.6/3328
28	Processor Start Address Register (SSCM_PSA)	32	R	See section	62.3.7/3329
30	SSCM HSM Start Address Register (SSCM_HSA)	32	R	See section	62.3.8/3329
34	Life Cycle Status Register (SSCM_LCSTAT)	32	R	See section	62.3.9/3330

62.3.1 SSCM System Status (SSCM_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0	CER	0	NXEN1	NXEN	1	Reserved	0
Write		w1c						
Reset	0	0	0	*	*	1	*	0

Bit	8	9	10	11	12	13	14	15
Read	BMODE			VLE	0	0	0	
Write								
Reset	*	*	*	*	0	0	0	0

* Notes:
- VLE field: Reset value depends on the associated option bits in flash memory.
- BMODE field: Reset value depends on the device status after leaving reset.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.
- NXEN1 field: Reset value depends on the device status after leaving reset..

SSCM_STATUS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled

Table continues on the next page...

SSCM_STATUS field descriptions (continued)

Field	Description
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6 Reserved	This field is reserved. This field is for internal use. Users should ignore read values and should not attempt to write the field.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 BMODE	Device Boot Mode This field is only updated during reset. 101 Boot from BootFlash
11 VLE	Variable Length Instruction Mode When booting in SC mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. **NOTE:** Reset value depends on the associated option bits in flash memory. 0 SC Boot Location contains standard PPC code 1 SC Boot Location contains VLE code
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	JPIN										1	MREV				0
Write																
Reset	*	*	*	*	*	*	*	*	*	*	1	*	*	*	*	0

* Notes:
- MREV field: Reset value can be found in the SSCM Configuration section.
- JPIN field: Reset value reflects the JTAG ID of the device.

SSCM_MEMCONFIG field descriptions

Field	Description
0–9 JPIN	JTAG Part ID Number **NOTE:** Reset value reflects the JTAG ID of the device.
10 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
11–14 MREV	Minor Mask Revision
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.3.3 SSCM Error Configuration Register (SSCM_ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0														PAE	RAE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SSCM_ERROR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

14
PAE
	Peripheral Bus Abort Enable.
	
	This bit enables bus aborts on:
	• any access to a peripheral slot that is not used on the device.
	  • This feature is intended to aid in debugging when developing application code.
	• illegal accesses to off-platform peripherals.
	  • On platform peripherals cannot be controlled by SSCM peripheral abort.
	
	0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception
	1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception

15 RAE	Register Bus Abort Enable. This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. This feature is intended to aid in debugging when developing application code. **NOTE:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the AIPS level). In this case, the PAE and RAE register bits have no effect on the abort.

Table continues on the next page...

SSCM_ERROR field descriptions (continued)

Field	Description
	0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception

62.3.4 Password comparison register low word (SSCM_PWCMPH)

These registers allow to unsecure the device, if the correct password is known. They are intended for device-internal operation only.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PWD_HI																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SSCM_PWCMPH field descriptions

Field	Description
0–31 PWD_HI	Upper 32 bits of the password.

62.3.5 Password comparison register low word (SSCM_PWCMPL)

These registers allow to unsecure the device, if the correct password is known. They are intended for device-internal operation only.

Address: 0h base + 10h offset = 10h

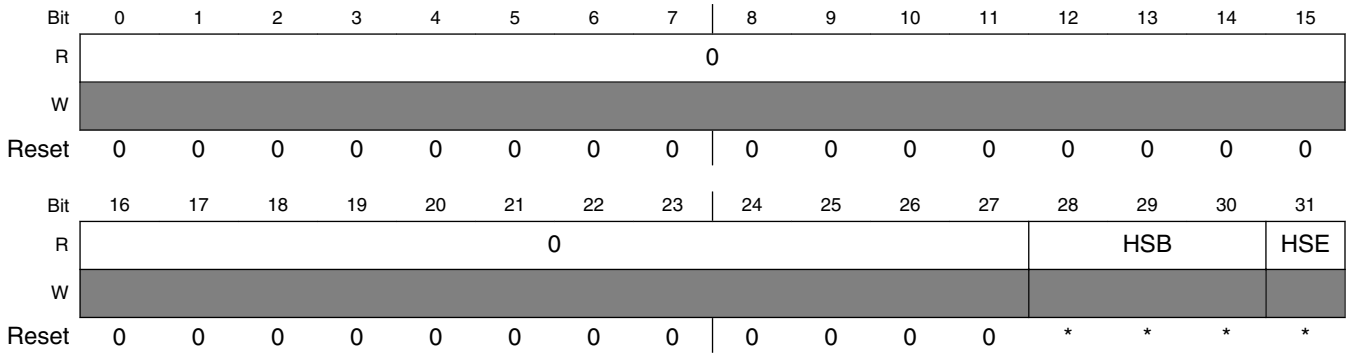
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PWD_LO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SSCM_PWCMPL field descriptions

Field	Description
0–31 PWD_LO	Lower 32 bits of the pasword

62.3.6 SSCM HSM and User Option Status Register (SSCM_UOPS)

Address: 0h base + 20h offset = 20h



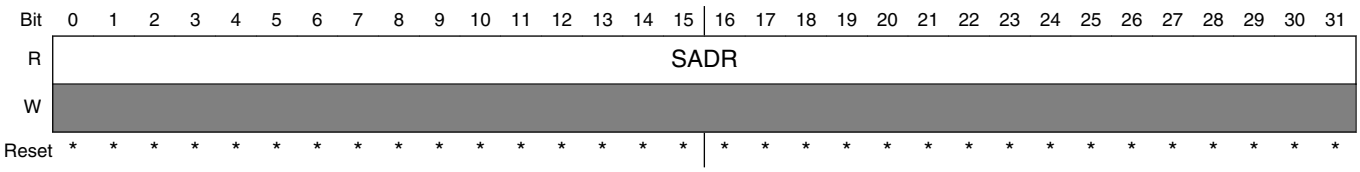
* Notes:
- HSE field: Values are determined by DCF record and life cycle - default is 0.
- HSB field: Values are determined by DCF record and life cycle - default is 0.

SSCM_UOPS field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HSB	HSM Boot Configuration These bits can be set via DCF record (see HSM documentation). All combinations not listed below are reserved. 000 When the device is in BAF mode, BAF will not wait for HSM ready flag before allowing application code to start. In SC mode the SSCM will not wait for HSM ready flag before allowing application code to start. 001 When the device is in BAF mode, BAF waits for HSM ready flag before allowing application code to start. In SC mode the SSCM waits for HSM ready flag before allowing application code to start.
31 HSE	HSM Enabled HSE is set to 1 if HSM is enabled via DCF record

62.3.7 Processor Start Address Register (SSCM_PSA)

Address: 0h base + 28h offset = 28h



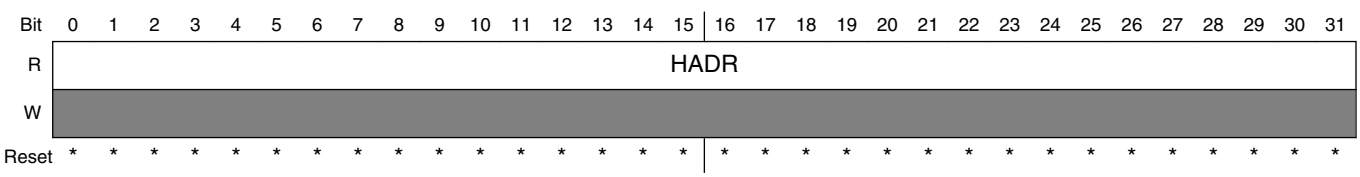
* Notes:
- SADR field: Reset value is the start address

SSCM_PSA field descriptions

Field	Description
0–31 SADR	Processor Start Address The boot processor will start executing application code from this address.In SC mode this indicates the location determined by the RCHW search. In BAF mode this will show the start address of the BAF code.

62.3.8 SSCM HSM Start Address Register (SSCM_HSA)

Address: 0h base + 30h offset = 30h



* Notes:
- HADR field: HSM Start Address

SSCM_HSA field descriptions

Field	Description
0–31 HADR	HSM Start Address HSM will start executing application code from this address. The value of this register is determined by the HSM boot header search.

62.3.9 Life Cycle Status Register (SSCM_LCSTAT)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0						Reserved		0					LC		
W																
Reset	0	0	0	0	0	0	*	*	0	0	0	0	0	*	*	*

* Notes:
- LC field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- Reserved field: Reset Value is '11' for a valid secured part.

SSCM_LCSTAT field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 Reserved	This field is reserved.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LC	Life Cycle Determined by the SSCM by reading the LC slots. The encoding is: 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 JDP Production 111 In Field

62.4 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

62.4.1 ECC error monitoring

During flash memory scanning (such as Life Cycle or DCF records), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs, the SSCM will:

- Request a destructive reset

NOTE

1. Signal the FCCU or MEMU.
2. For differential region, if any valid DCF records are programmed then there will be checked for ECC and stop record for DCF would not be checked for ECC.

62.4.2 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Boot Assisted by Flash (BAF) - The device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter static mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. HSM boot header search.

62.4.3 BAF configuration

By default the device will boot from BAF.

In BAF mode (SSCM_STATUS[BMODE]=101b), the boot core will start executing BAF code at the location shown in the configuration section of the “Boot Assist Flash (BAF)” chapter.

62.4.4 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (see the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.

The HSM Boot Header has the format as described in the table below.

Table 62-2. Boot header structure

00h	Boot Header ID	
08h	Reserved	Start Address
10h	Reserved for Configuration Bits	

A valid Boot Header ID has the value FFFF_0000_FFFF_0000h.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0000_0000_0000_0000h. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

62.4.5 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors and ECC check. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- JDP Production
- Customer Delivery
- OEM Production
- In Field
- Fail Analysis

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in Table 62-3.

Table 62-3. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

"Marked" in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh. "Erased" is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. Table 62-4 shows how the slots are arranged in memory.

Table 62-4. LC slots in memory

Offset	LC slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in Table 62-5. The priority of the entries is from top to bottom, so the first row that applies determines the resulting Life Cycle.

NOTE

"Erased" means the slot returns all 1s.

Table 62-5. LC slots

LC slot 0 JDP Production	LC slot 1 Customer Delivery	LC slot 2 OEM Production	LC slot 3 In Field	LC slot 4 Failure Analysis	Resulting life cycle
Active	Erased	Erased	Erased	Erased	JDP Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	Inactive	**Active**	Erased	Erased	OEM Production
Inactive	Inactive	Inactive	**Active**	Erased	In Field
Inactive	Inactive	Inactive	Inactive	**Active**	Failure Analysis
Erased	Erased	Erased	Erased	Erased	System Reset
Invalid[1]	Invalid	Invalid	Invalid	Erased	In Field
Invalid	Invalid	Invalid	Invalid	Not Erased	System Reset

1. Any value programmed other then shown in table above for Erased, Active and Inactive would be treated as illegal.

NOTE

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

62.5 Initialization and application information

62.5.1 Reset

The reset state of each individual bit appears in the detailed register descriptions.

62.6 Additional safety measures

62.6.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the MC_RGM. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

Chapter 63
Power Management Controller digital interface (PMC_dig)

63.1 Introduction

The power management controller (PMC) consists of two blocks: an analog block and a digital block. This chapter describes the digital block of the PMC.

The PMC_dig block contains all of the registers and digital logic to generate all of the enable signals, trim control bits, POR reset generation, and test mode logic for the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module.

In addition, the PMC digital logic contains the enable signals, trim bits, and other registers for the temperature sensor.

There are also several custom interfaces to various other blocks: The Reset Generation Module (MC_RGM) block receives the LVD/HVD values during POR to use for phase transition conditions.

There is also a custom interface to flash memory via the SSCM (and DCF client blocks) that is used to load the trim values during initial POR.

The TESTPIN must never be asserted to assure that the LVD/HVDs are active in the system.

The PMC digital block generates a transfer error event to the system if the selected address is greater than the highest address in the PMC digital memory map. A transfer error is not generated if an unused address within the PMC digital memory space is accessed.

NOTE

It is not valid to leave any of the power domains measured by an LVD or HVD unpowered. They must always be connected in such a way as to be in a valid operating range to get the device out of POR.

The following figure shows the block diagram.

63.2 Memory Map and Registers

The following table shows the PMC memory map. The PMC includes many registers for configuring, monitoring, and trimming the LVD monitors .

PMCDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Supply Gauge Status Register (PMCDIG_GR_S)	32	R	0000_0000h	63.2.1/3341
4	Pending Gauge Status Register (PMCDIG_GR_P)	32	R	0000_0000h	63.2.2/3344
8	Interrupt Enable Pending Register (PMCDIG_IE_P)	32	R/W	0000_0000h	63.2.3/3349
30	Event Pending Register (PMCDIG_EPR_VD3)	32	w1c	0000_0000h	63.2.4/3353
34	Reset Event Enable Register (PMCDIG_REE_VD3)	32	R/W	0000_00C1h	63.2.5/3355
38	Reset Event Select Register (PMCDIG_RES_VD3)	32	R/W	0000_0000h	63.2.6/3356
3C	FCCU Event Enable Register (PMCDIG_FEE_VD3)	32	R/W	0000_00C1h	63.2.7/3357
40	LVD108 Event Pending Register (PMCDIG_EPR_VD4)	32	w1c	0000_0000h	63.2.8/3359
44	Reset Event Select Register (PMCDIG_REE_VD4)	32	R/W	0000_0001h	63.2.9/3360

63.2.1 Supply Gauge Status Register (PMCDIG_GR_S)

This status register contains the gauge of the indicated supply (or temperature sensor value). This indicates the present state of the voltage (temperature) detect events for each of the supplies. Each of the voltage detect signals for a given voltage are combined to form a single bit.

Address: 0h base + 0h offset = 0h

PMCDIG_GR_S field descriptions

Field	Description
0–4 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
5 TS3	TS3 over temperature detect flag. This read-only bit is the over temperature status flag associated with the high temp sensor point (165C). It is asserted when the temperature exceeds its corresponding threshold, and clears when all the temperature falls below this threshold. 0 Currently no occurrence. 1 Temp Sensor is currently above the hot temperature threshold.

Table continues on the next page...

PMCDIG_GR_S field descriptions (continued)

Field	Description
6 TS2	TS2 over temperature detect flag. This read-only bit is the over temperature status flag associated with the high temp sensor point (150C). It is asserted when the temperature exceeds its corresponding threshold, and clears when all the temperature falls below this threshold. 0 Currently no occurrence. 1 Temp Sensor is currently above the temp threshold.
7 TS0	TS0 under temperature detect flag. This read-only bit is the undertemperature status flag associated with the cold temp sensor point. It is asserted when the temperature goes below its corresponding threshold, and clears when all the temperature rises above this threshold. 0 Currently no occurrence. 1 Temp Sensor is currently below the cold temp threshold.
8–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 VD15	VD15 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 6.00 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 6.00 V supply.
17 VD14	VD14 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold. All the 4.00 V supplies are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 4.00 V supplies.
18 VD13	VD13 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3.6 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold.All the 3.6 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 3.6V supply.
19 VD12	VD12 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 6.00 V HVDs are combined to form this bit.

Table continues on the next page...

PMCDIG_GR_S field descriptions (continued)

Field	Description
	0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 3.60 V supply.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 VD10	HVD occurrence detected on the high voltage 3.60 V supply. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 3.00 V supply.
22 VD9	VD9 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold. All of the 2.8 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.8 V supplies.
23 VD8	VD8 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 1.45 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 1.45 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage 1.45 V supplies.
24 VD7	VD7 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 1.40 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 1.40 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage 1.40 V supplies.
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 VD4	VD4 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detects for the low voltage 1.14 V supply associated with the PLL, Flash, and hot point. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 1.14 V point supply.
28 VD3	VD3 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V supply associated with the core logic. It is asserted when any of the VD3 supplies fall below the

PMCDIG_GR_S field descriptions (continued)

Field	Description
	corresponding LVD threshold, and clears when the supplies rise above the corresponding LVD threshold. All the 1.14 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on any of the low voltage 1.14 V supplies.
29–31 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

63.2.2 Pending Gauge Status Register (PMCDIG_GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

Address: 0h base + 4h offset = 4h

PMCDIG_GR_P field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 VD15_A	VD15_A high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V ADC supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD15[HVD15_A] is cleared. 0 No occurrence has happened, or EPR_VD15[HVD15_A] has been cleared. 1 HVD occurrence detected on the high voltage ADC supply.
7 VD15_C	VD15_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD15[HVD15_C] is cleared. 0 No occurrence has happened, or EPR_VD15[HVD15_C] has been cleared. 1 HVD occurrence detected on the high voltage cold point supply.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 VD14_A	VD14_A low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V ADC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD14[LVD14_A] is cleared. 0 No occurrence has happened, or EPR_VD14[LVD14_A] has been cleared. 1 LVD occurrence detected on the high voltage ADC supply.
10 VD14_IM	VD14_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD14[LVD14_IM] is cleared.

Table continues on the next page...

PMCDIG_GR_P field descriptions (continued)

Field	Description
	0 No occurrence has happened, or EPR_VD14[LVD14_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
11–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 VD13_IM	VD13_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3.6 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD13[LVD13_IM] is cleared. 0 No occurrence has happened, or EPR_VD13[LVD13_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
14 VD12_F	VD12_F high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 3.6 V flash supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD12[HVD12_F] is cleared. 0 No occurrence has happened, or EPR_VD12[HVD12_F] has been cleared. 1 HVD occurrence detected on the high voltage flash supply.
15 VD10_A	VD10_A low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V ADC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD10[LVD10_A] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD10[LVD10_A] = 1. 0 No occurrence has happened, or EPR_VD10[LVD10_A] has been cleared. 1 LVD occurrence detected on the high voltage ADC supply.
16 VD10_F	VD10_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD10[LVD10_F] is cleared. 0 No occurrence has happened, or EPR_VD10[LVD10_F] has been cleared. 1 LVD occurrence detected on the high voltage flash supply.
17 VD9_O	VD9_O low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V OSC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_O] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_O] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_O] has been cleared. 1 LVD occurrence detected on the high voltage OSC supply.
18 VD9_IF2	VD9_IF2 low-voltage detect flag.

Table continues on the next page...

PMCDIG_GR_P field descriptions (continued)

Field	Description
	This read-only bit is the low-voltage status flag associated with the voltage level detect for the second high voltage 2.8 V I/O Flexray supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IF2] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_IF] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_IF2] has been cleared. 1 LVD occurrence detected on the second high voltage I/O Flexray supply.
19 VD9_IF	VD9_IF low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O Flexray supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IF] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_IF] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_IF] has been cleared. 1 LVD occurrence detected on the high voltage I/O Flexray supply.
20 VD9_IJ	VD9_IJ low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O JTAG supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IJ] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_IJ] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_IJ] has been cleared. 1 LVD occurrence detected on the high voltage I/O JTAG supply.
21 VD9_IM	VD9_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IM] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_IM] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
22 VD9_F	VD9_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_F] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_F] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_F] has been cleared. 1 LVD occurrence detected on the high voltage flash supply.
23 VD9_EBI	VD9_EBI low-voltage detect flag.

Table continues on the next page...

PMCDIG_GR_P field descriptions (continued)

Field	Description
	This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O External Bus Interface (EBI) supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_EBI] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_EBI] has been cleared. 1 LVD occurrence detected on the high voltage I/O External Bus Interface supply.
24 VD9_C	VD9_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V cold point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_C] is cleared. This bit is indeterminate after reset, so it must be cleared during initialization by writing PMCDIG_EPR_VD9[LVD9_C] = 1. 0 No occurrence has happened, or EPR_VD9[LVD9_C has been cleared. 1 LVD occurrence detected on the high voltage cold point supply.
25 VD8_C	VD8_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD8[HVD8_C] is cleared. 0 No occurrence has happened, or EPR_VD8[HVD8_C] has been cleared. 1 LVD occurrence detected on the low voltage cold point supply.
26 VD8_F	VD8_F high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V flash supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD8[HVD8_F] is cleared. 0 No occurrence has happened, or EPR_VD7[HVD7_F] has been cleared. 1 HVD occurrence detected on the low voltage flash supply.
27 VD7_C	VD7_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.4 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD7[HVD7_C] is cleared. 0 No occurrence has happened, or EPR_VD7[HVD7_C] has been cleared. 1 HVD occurrence detected on the low voltage cold point supply.
28 VD4_C	VD4_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V cold point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD4[LVD4_C] is cleared. 0 No occurrence has happened, or EPR_VD4[LVD4_C] has been cleared. 1 LVD occurrence detected on the low voltage cold point supply.
29 VD3_P	VD3_P low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V PLL supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_P] is cleared.

Table continues on the next page...

PMCDIG_GR_P field descriptions (continued)

Field	Description
	0 No occurrence has happened, or EPR_VD3[LVD3_P] has been cleared. 1 LVD occurrence detected on the low voltage PLL supply.
30 VD3_F	VD3_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_F] is cleared. 0 No occurrence has happened, or EPR_VD3[LVD3_F] has been cleared. 1 LVD occurrence detected on the low voltage flash supply.
31 VD3_C	VD3_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V hot point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_C] is cleared. 0 No occurrence has happened, or EPR_VD3[LVD3_C] has been cleared. 1 LVD occurrence detected on the low voltage hot point supply.

63.2.3 Interrupt Enable Pending Register (PMCDIG_IE_P)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt occurs when the voltage event is seen. A ‘0’ indicates that no interrupt is to be sent, and a ‘1’ indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

NOTE

Special care must be taken with the EPR_VD9, EPR_VD10 and the interrupt enables of the IE_P reguster. EPR_VD9 and EPR_VD10 must be cleared before enabling the interrupts for VD9IE and VD10IE voltage detection.

Address: 0h base + 8h offset = 8h

PMCDIG_IE_P field descriptions

Field	Description
0 IE_EN	IE_EN. Interrupt Enable. This bit determines whether any of the Interrupt Enable bits can be written. 0 No interrupt enables can be written. 1 Any interrupt enable can be written.
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 VD15IE_A	VD15IE_A Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
7 VD15IE_C	VD15IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 VD14IE_A	VD14IE_A Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
10 VD14IE_IM	VD14IE_IM Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
11–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 VD13IE_IM	VD13IE_IM Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
14 VD12IE_F	VD12IE_F Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.

Table continues on the next page...

Field	Description
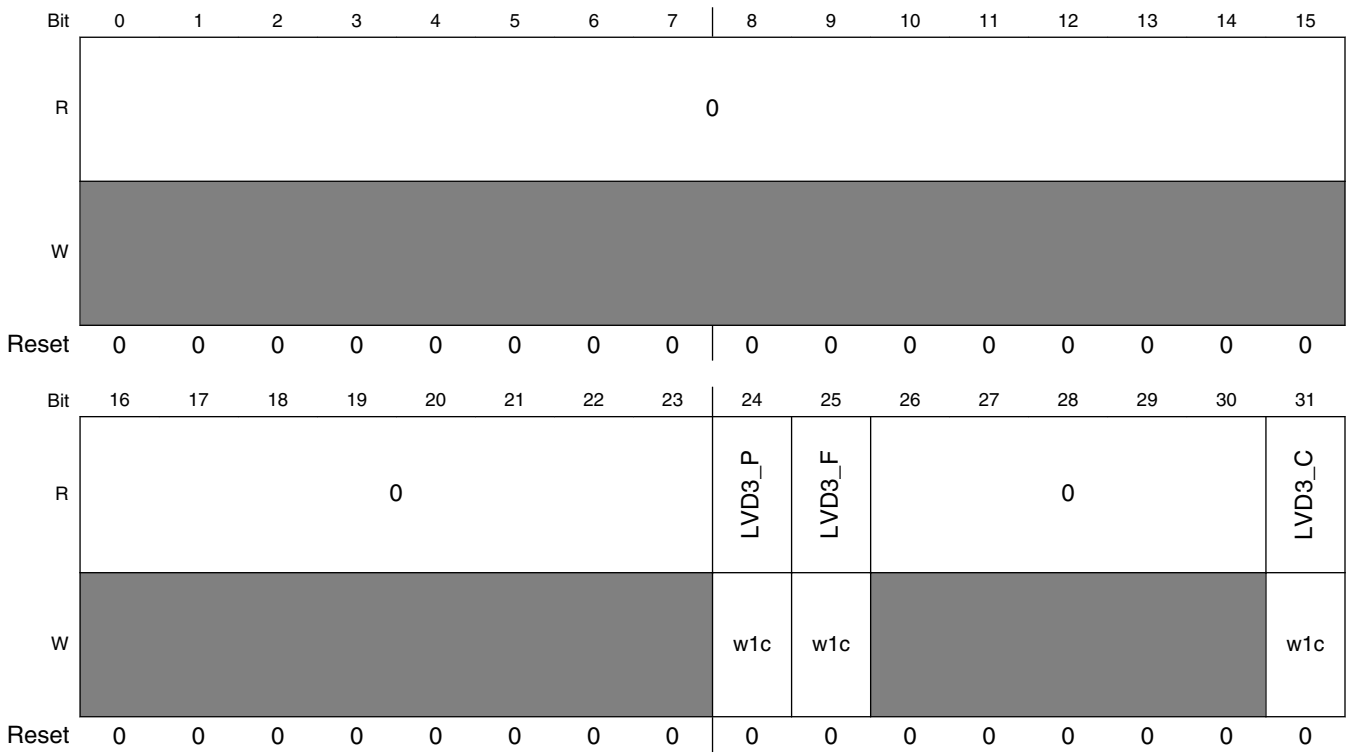
25 VD8IE_C	VD8IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
26 VD8IE_F	VD8IE_F Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
27 VD7IE_C	VD7IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
28 VD4IE_C	VD4IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. VD3IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
29 VD3IE_P	VD3IE_P Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
30 VD3IE_F	VD3IE_F Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
31 VD3IE_C	VD3IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.

63.2.4 Event Pending Register (PMCDIG_EPR_VD3)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set asynchronously. To clear the flag, a one must be written to the flag bit that needs to be cleared.

Address: 0h base + 30h offset = 30h



PMCDIG_EPR_VD3 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 LVD3_P	LVD3_P flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V PLL supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD3IE_P bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD3[LVD3_P] is also asserted, a system reset is generated, which clears VD3IE_P and negates the interrupt request. If REE_VD3[LVD3_P] is asserted and a destructive reset is selected (via RES_VD3[LVD3_P] being 0), then a destructive reset is generated. If RES_VD3[LVD3_P] is set, then a functional reset is generated.

Table continues on the next page...

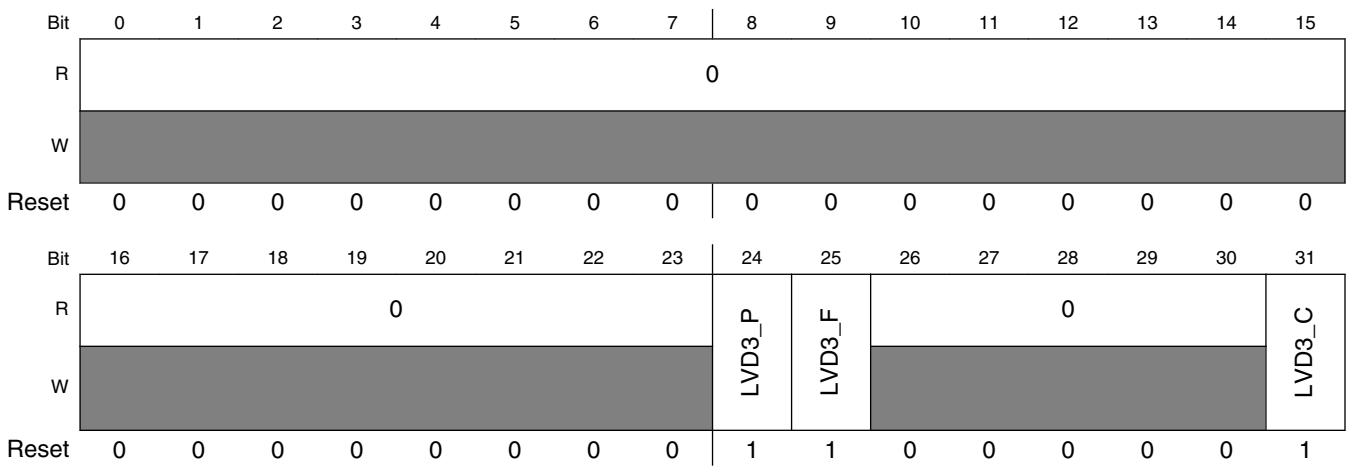
PMCDIG_EPR_VD3 field descriptions (continued)

Field	Description
	0 Currently no occurrence. 1 LVD occurrence detected on the low voltage PLL supply.
25 LVD3_F	LVD3_F flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V flash supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD3IE_F bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD3[LVD3_F] is also asserted, a system reset is generated, which clears VD3IE_F and negatse the interrupt request. If REE_VD3[LVD3_F] is asserted and a destructive reset is selected (via RES_VD3[LVD3_F] being 0), then a destructive reset is generated. If RES_VD3[LVD3_F] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage flash supply.
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD3_C	LVD3_C flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V hot point supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD3IE_C bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD3[LVD3_C] is also asserted, a system reset is generated, which clears VD3IE_C and negates the interrupt request. If REE_VD3[LVD3_C] is asserted and a destructive reset is selected (via RES_VD3[LVD3_C] being 0), then a destructive reset is generated. If RES_VD3[LVD3_C] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 1.14 V hot point supply.

63.2.5 Reset Event Enable Register (PMCDIG_REE_VD3)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared) .

Address: 0h base + 34h offset = 34h



PMCDIG_REE_VD3 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 LVD3_P	LVD3_P reset enable. This bit defines whether an LVD assertion on the supply of the PLL generates a system reset. The RES_VD3[LVD3_P] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the PLL does not cause system reset. 1 Enabled. LVD assertion on the supply of the PLL causes system reset.
25 LVD3_F	LVD3_F reset enable. This bit defines whether an LVD assertion on the supply of the flash generates a system reset. The RES_VD3[LVD3_F] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the flash does not cause system reset. 1 Enabled. LVD assertion on the supply of the flash causes system reset.
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD3_C	LVD3_C reset enable.

Table continues on the next page...

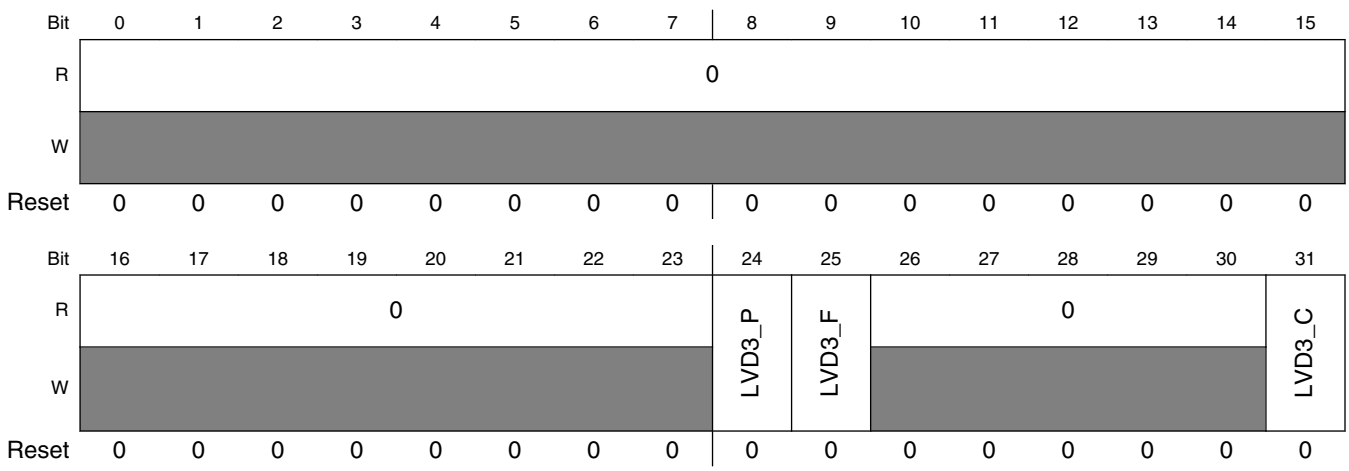
PMCDIG_REE_VD3 field descriptions (continued)

Field	Description
	This bit defines whether an LVD assertion on the supply of the cold point generates a system reset. The RES_VD3[LVD3_C] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

63.2.6 Reset Event Select Register (PMCDIG_RES_VD3)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

Address: 0h base + 38h offset = 38h



PMCDIG_RES_VD3 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 LVD3_P	LVD3_P reset event select. This bit defines whether an LVD assertion on the supply of the PLL generates a destructive reset or a functional reset. The REE_VD3[LVD3_P] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the PLL causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the PLL causes a functional system reset.

Table continues on the next page...

PMCDIG_RES_VD3 field descriptions (continued)

Field	Description
25 LVD3_F	LVD3_F reset event select. This bit defines whether an LVD assertion on the supply of the flash generates a destructive reset or a functional reset. The REE_VD3[LVD3_F] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the flash causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the flash causes a functional system reset.
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD3_C	LVD3_C reset event select. This bit defines whether an LVD assertion on the supply of the cold point generates a destructive reset or a functional reset. The REE_VD3[LVD3_C] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

63.2.7 FCCU Event Enable Register (PMCDIG_FEE_VD3)

This FCCU Event Enable Register controls whether the voltage detect signal event causes an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Address: 0h base + 3Ch offset = 3Ch

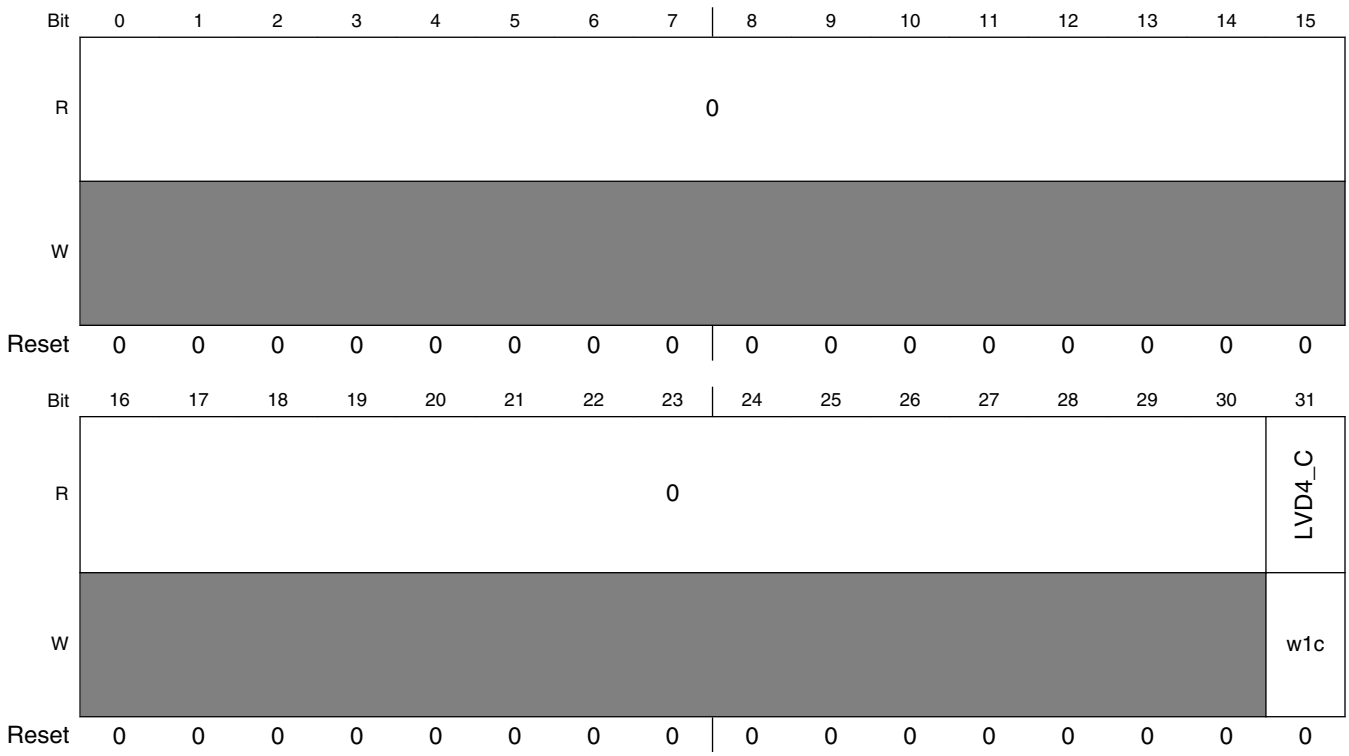
Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 FEE3_P	FEE3_P FCCU event enable. This bit defines whether an LVD assertion on the supply of the PLL generates an FCCU event. 0 Disabled. LVD assertion on the supply of the PLL does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the PLL causes an FCCU event.
25 FEE3_F	FEE3_F FCCU event enable. This bit defines whether an LVD assertion on the supply of the flash generates an FCCU event. 0 Disabled. LVD assertion on the supply of the flash does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the flash causes an FCCU event.
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FEE3_C	FEE3_C FCCU event enable. This bit defines whether an LVD assertion on the supply of the cold point generates an FCCU event. 0 Disabled. LVD assertion on the supply of the cold point does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the cold point causes an FCCU event.

63.2.8 LVD108 Event Pending Register (PMCDIG_EPR_VD4)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set asynchronously. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Address: 0h base + 40h offset = 40h



PMCDIG_EPR_VD4 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD4_C	LVD4_C flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V cold point supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD4IE_C bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD4[LVD4_C] is also asserted, a system reset is generated, which clears VD4IE_C and negates the interrupt request. If REE_VD4[LVD4_C] is asserted and a destructive reset is selected (via RES_VD4[LVD4_C] being 0), then a destructive reset is generated. If RES_VD4[LVD4_C] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage cold point supply.

63.2.9 Reset Event Select Register (PMCDIG_REE_VD4)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared) .

Address: 0h base + 44h offset = 44h

Field	Description
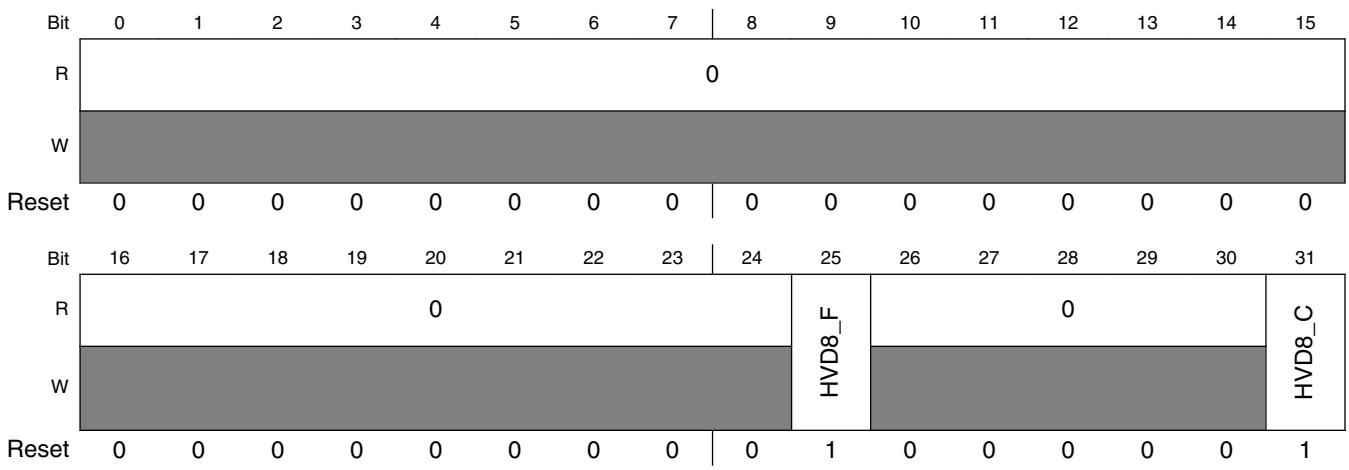
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 HVD8_F	HVD8_F flag. This bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V Flash supply. It is asserted asynchronously when the supply rises above its corresponding HVD threshold, and clears when a one is written to this bit location. If the VD8IE_F bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD8[HVD8_F] is also asserted, a system reset is generated, which clears VD8IE_F and negates the interrupt request. If REE_VD8[HVD8_F] is asserted and a destructive reset is selected (via RES_VD8[HVD8_F] being 0), then a destructive reset is generated. If RES_VD8[HVD8_F] is set, then a functional reset is generated. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage Flash supply.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 HVD8_C	HVD8_C flag. This bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V cold point supply. It is asserted asynchronously when the supply rises above its corresponding HVD threshold, and clears when a one is written to this bit location. If the VD8IE_C bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD8[HVD8_C] is also asserted, a system reset is generated, which clears VD8IE_C and negates the interrupt request. If REE_VD8[HVD8_C] is asserted and a destructive reset is selected (via RES_VD8[HVD8_C] being 0), then a destructive reset is generated. If RES_VD8[HVD8_C] is set, then a functional reset is generated. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage cold point supply.

63.2.17 Reset Event Enable Register (PMCDIG_REE_VD8)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared) unless in test mode.

Address: 0h base + 84h offset = 84h



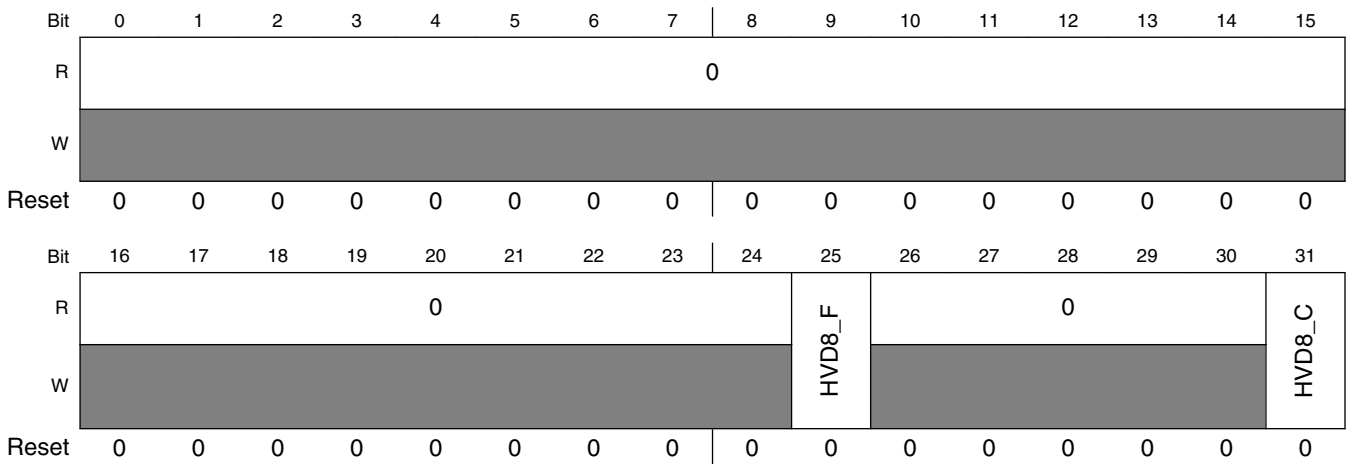
PMCDIG_REE_VD8 field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 HVD8_F	HVD8_F reset enable. This bit defines whether an HVD assertion on the supply of the Flash generates a system reset. The RES_VD8[HVD8_F] bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the Flash does not cause system reset. 1 Enabled. HVD assertion on the supply of the Flash causes system reset.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 HVD8_C	HVD8_C reset enable. This bit defines whether an HVD assertion on the supply of the cold point generates a system reset. The RES_VD8[HVD8_C] bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. HVD assertion on the supply of the cold point causes system reset.

63.2.18 Reset Event Select Registerr (PMCDIG_RES_VD8)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

Address: 0h base + 88h offset = 88h



PMCDIG_RES_VD8 field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 HVD8_F	HVD8_F reset event select This bit defines whether an HVD assertion on the supply of the Flash generates a destructive reset or a functional reset. The REE_VD8[HVD8_F] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. HVD assertion on the supply of the Flash causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the Flash causes a functional system reset.
26–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 HVD8_C	HVD8_C reset event select. This bit defines whether an HVD assertion on the supply of the cold point generates a destructive reset or a functional reset. The REE_VD8[HVD8_C] bit determines whether the reset event is enabled.

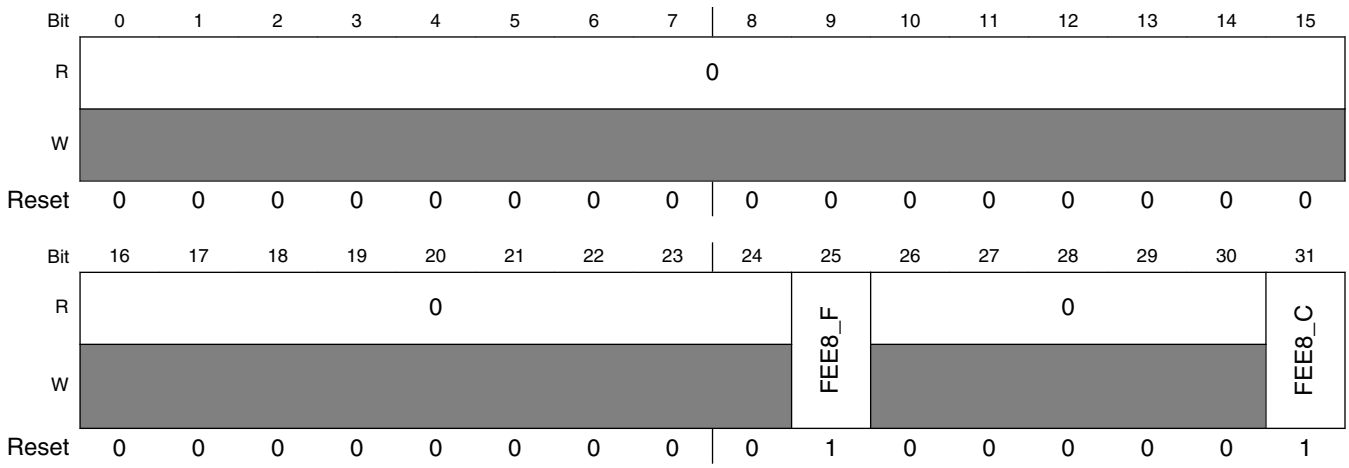
Field	Description
	0 Destructive Reset Generated. HVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. HVD assertion on the supply of the cold point causes a functional system reset.

63.2.19 FCCU Event Enable Register (PMCDIG_FEE_VD8)

This FCCU Event Enable Register controls whether the voltage detect signal event causes an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Address: 0h base + 8Ch offset = 8Ch



PMCDIG_FEE_VD8 field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FEE8_F	FEE8_F FCCU event enable. This bit defines whether an HVD assertion on the supply of the Flash generates an FCCU event. 0 Disabled. HVD assertion on the supply of the Flash does not cause an FCCU event. 1 Enabled. HVD assertion on the supply of the Flash causes an FCCU event.
26–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FEE8_C	FEE8_C FCCU event enable. This bit defines whether an HVD assertion on the supply of the cold point generates an FCCU event.

Table continues on the next page...

PMCDIG_FEE_VD8 field descriptions (continued)

Field	Description
	0 Disabled. HVD assertion on the supply of the cold point does not cause an FCCU event. 1 Enabled. HVD assertion on the supply of the cold point causes an FCCU event.

63.2.20 LVD270 Event Pending Register (PMCDIG_EPR_VD9)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set asynchronously. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

NOTE

These bits are cleared out of initial power up POR, but are not reset during other LVD, HVD, and POR events. They must be cleared by software during initialization by writing 1 to the EPR_VD9 field. The field values are retained until the core voltage is less than 0.8V).

Address: 0h base + 90h offset = 90h

PMCDIG_EPR_VD9 field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 LVD9_O	LVD9_O flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V OSC supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. If the VD9IE_O bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVDn_O] is also asserted, a system reset is generated, which clears VD9IE_O and negates the interrupt request. If REE_VD9[LVD9_O] is asserted, a POR reset is generated. This field is indeterminate after reset, so it must be cleared during initialization by writing 1 to this location. This field may be cleared if the LV supply is below 0.9 V. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage OSC supply.
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 LVD9_IF2	LVD9_IF2 flag. This bit is the low-voltage status flag associated with the voltage level detect for the second high voltage 2.8 V I/O Flexray supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD9IE_IF2 bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_IF2] is also asserted, a system reset is generated, which clears VD9IE_IF2 and negate the interrupt request. If REE_VD9[LVD9_IF2] is asserted and a destructive reset is selected (via RES_VD9[LVD9_IF2] being 0), then a destructive reset is generated. If RES_VD9[LVD9_IF2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the second high voltage I/O Flexray supply.
21 LVD9_IF	LVD9_IF flag. This bit is the low-voltage status flag associated with the voltage level detect for the first high voltage 2.8 V I/O Flexray supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. If the VD9IE_IF bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_IF] is also asserted, a system reset is generated, which clears VD9IE_IF and negates the interrupt request. If REE_VD9[LVD9_IF] is asserted and a destructive reset is selected (via RES_VD9[LVD9_IF] being 0), then a destructive reset is generated. If RES_VD9[LVD9_IF] is set, then a functional reset is generated. This field is indeterminate after reset, so it must be cleared during initialization by writing 1 to this location. This field may be cleared if the LV supply is below 0.9 V. 0 Currently no occurrence. 1 LVD occurrence detected on the first high voltage I/O Flexray supply.
22 LVD9_IJ	LVD9_IJ flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O JTAG supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. If the VD9IE_IJ bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_IJ] is also asserted, a system reset is generated, which clears VD9IE_IJ and negates the interrupt request. If REE_VD9[LVD9_IJ] is asserted, a POR reset is generated.

Table continues on the next page...

PMCDIG_EPR_VD9 field descriptions (continued)

Field	Description
	This field is indeterminate after reset, so it must be cleared during initialization by writing 1 to this location. This field may be cleared if the LV supply is below 0.9 V. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage I/O JTAG supply.
23 LVD9_IM	LVD9_IM flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O main supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. If the VD9IE_IM bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_IM] is also asserted, a system reset is generated, which clears VD9IE_IM and negates the interrupt request. If REE_VD9[LVD9_A] is asserted, a POR reset is generated. This field is indeterminate after reset, so it must be cleared during initialization by writing 1 to this location. This field may be cleared if the LV supply is below 0.9 V. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage I/O main supply.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 LVD9_F	LVD9_F flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V flash supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. If the VD9IE_F bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_F] is also asserted, a system reset is generated, which clears VD9IE_F and negates the interrupt request. If REE_VD9[LVD9_F] is asserted, a POR reset is generated. This field is indeterminate after reset, so it must be cleared during initialization by writing 1 to this location. This field may be cleared if the LV supply is below 0.9 V. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage flash supply.
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LVD9_EBI	LVD9_EBI flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V External Bus Interface (EBI) supply. It is asserted asynchronously when the supply falls below its corresponding LVD threshold, and clears when a one is written to this bit location. If the VD9IE_EBI bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_EBI] is also asserted, a system reset is generated, which clears VD9IE_EBI and negates the interrupt request. If REE_VD9[LVD9_EBI] is asserted, a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage External Bus Interface supply.
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD9_C	LVD9_C flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V cold point supply. It is asserted asynchronously when the supply falls below its corresponding LVD

Field	Description
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 LVD9_IF2	LVD9_IF2 reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the second set of Flexray pins generates a system reset. The RES_VD9[LVD9_IF2] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the second set of Flexray pins does not cause system reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the second set of Flexray pins causes system reset.
21 LVD9_IF	LVD9_IF reset enable. This bit defines whether an LVD assertion on the supply of the first I/O segment that contains the Flexray pins generates a system reset. The RES_VD9[LVD9_IF] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the first Flexray pins does not cause system reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the first Flexray pins causes system reset.
22 LVD9_IJ	LVD9_IJ reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the JTAG pins generates a POR reset. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the JTAG pins does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the JTAG pins causes a POR reset.
23 LVD9_IM	LVD9_IM reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the main pins generates a POR reset. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the main pins does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the main pins causes a POR reset.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 LVD9_F	LVD9_F reset enable. This bit defines whether an LVD assertion on the supply of the flash generates a POR reset. 0 Disabled. LVD assertion on the supply of the flash does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the flash causes a POR reset.
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LVD9_EBI	LVD9_EBI reset enable.

Table continues on the next page...

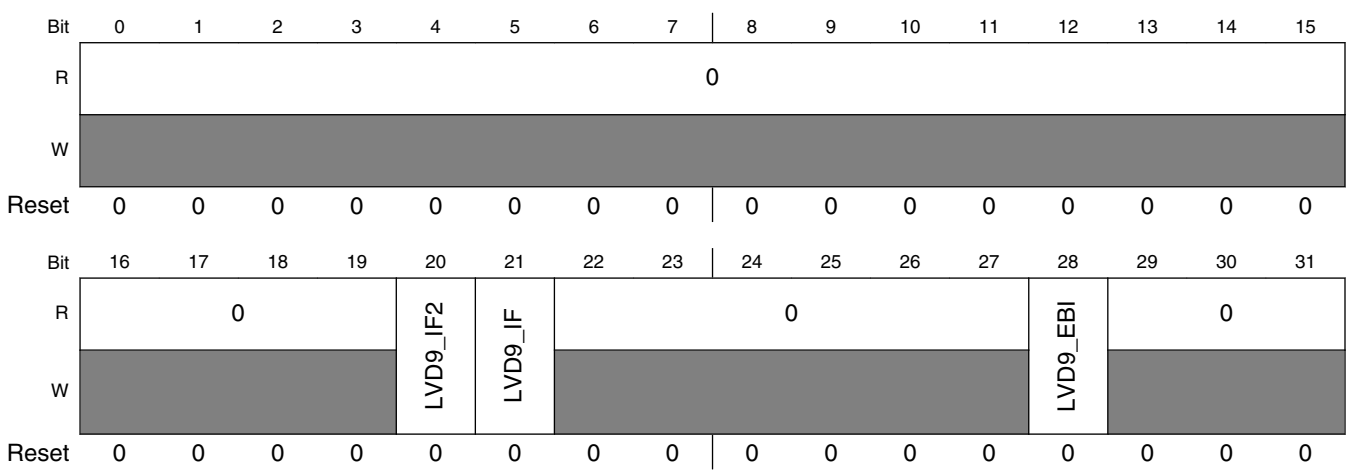
PMCDIG_REE_VD9 field descriptions (continued)

Field	Description
	This bit defines whether an LVD assertion on the supply of the External Bus Interface (EBI) generates a POR reset. 0 Disabled. LVD assertion on the supply of the External Bus Interface does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the External Bus Interface causes a POR reset.
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 LVD9_C	LVD9_C reset enable. This bit defines whether an LVD assertion on the supply of the cold point generates a POR reset. 0 Disabled. LVD assertion on the supply of the cold point does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the cold point causes a POR reset.

63.2.22 Reset Event Select Register (PMCDIG_RES_VD9)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. All of the LVD9 signals are used to generate a POR except for LVD9_IF, LVD9_IF2, and LVD9_EBI. The LVD9_IF, LVD9_IF2, and LVD9_EBI are the only events at this voltage level that can cause a functional or destructive reset. All the others cause a POR (if enabled via the corresponding REE bit) or do not cause a reset.

Address: 0h base + 98h offset = 98h



PMCDIG_RES_VD9 field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 LVD9_IF2	LVD9_IF2 reset event select. This bit defines whether an LVD assertion on the supply of the second I/O segment that contains the Flexray pins generates a destructive reset or a functional reset. The REE_VD9[LVD9_IF2] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the second I/O segment that contains the Flexray pins causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the second I/O segment that contains the Flexray pins causes a functional system reset.
21 LVD9_IF	LVD9_IF reset event select. This bit defines whether an LVD assertion on the supply of the first I/O segment that contains the Flexray pins generates a destructive reset or a functional reset. The REE_VD9[LVD9_IF] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the first I/O segment that contains the Flexray pins causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the first I/O segment that contains the Flexray pins causes a functional system reset.
22–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 VSIO_IF2	VSIO_IF2 control. This bit is used to control the supply levels used by the second Flexray I/O segment. 0 The I/O segment uses a 3.3V supply. 1 The I/O segment uses a 5.0V supply.
21 VSIO_IF	VSIO_IF control. This bit is used to control the supply levels used by the Flexray I/O segment. 0 The I/O segment uses a 3.3V supply. 1 The I/O segment uses a 5.0V supply.
22 VSIO_IJ	VSIO_IJ control. This bit is used to control the supply levels used by the JTAG I/O segment. 0 The I/O segment uses a 3.3V supply. 1 The I/O segment uses a 5.0V supply.
23 VSIO_IM	VSIO_IM control. This bit is used to control the supply levels used by the Main I/O segment.

Table continues on the next page...

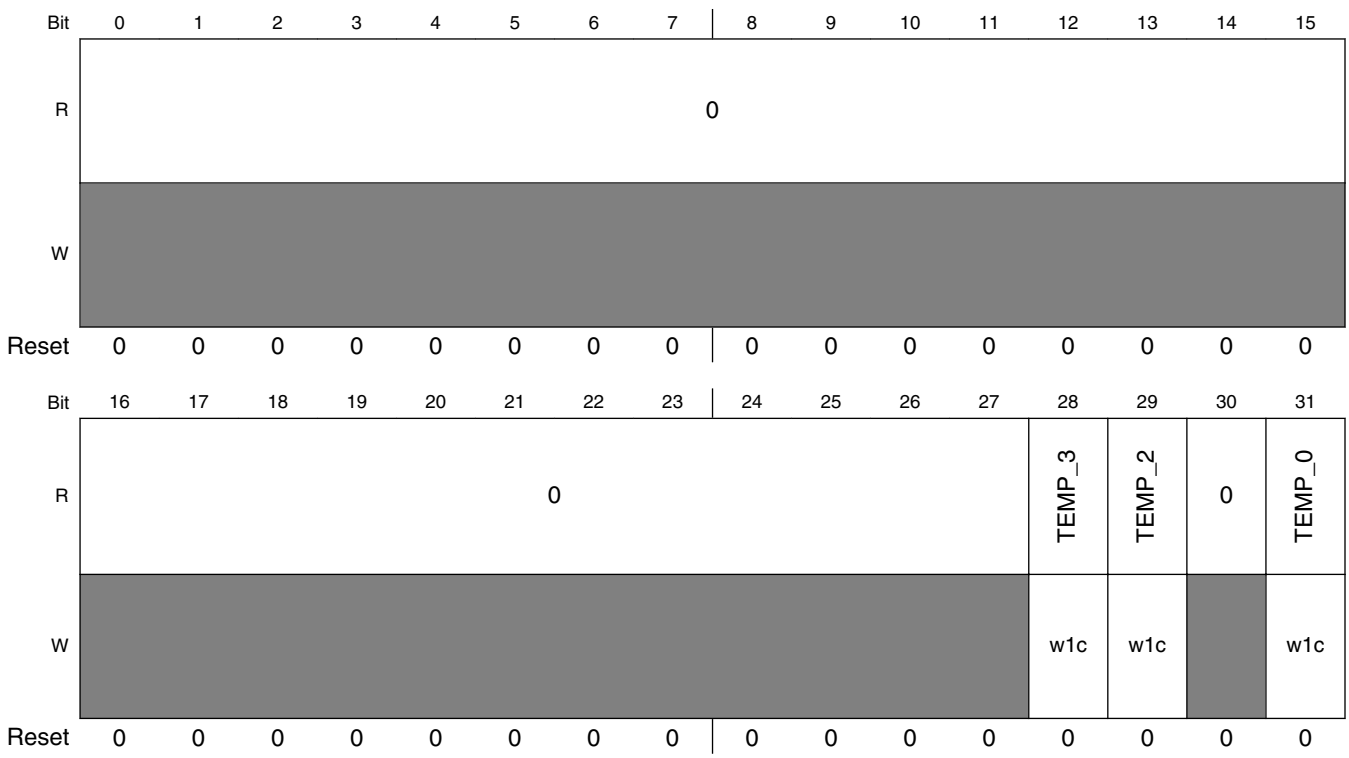
PMCDIG_VSIO field descriptions (continued)

Field	Description
	0 The I/O segment uses a 3.3V supply. 1 The I/O segment uses a 5.0V supply.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

63.2.44 Event Pending Register (PMCDIG_EPR_TD)

This Event Pending Register indicates the present and past state of the temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Address: 0h base + 300h offset = 300h



PMCDIG_EPR_TD field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PMCDIG_EPR_TD field descriptions (continued)

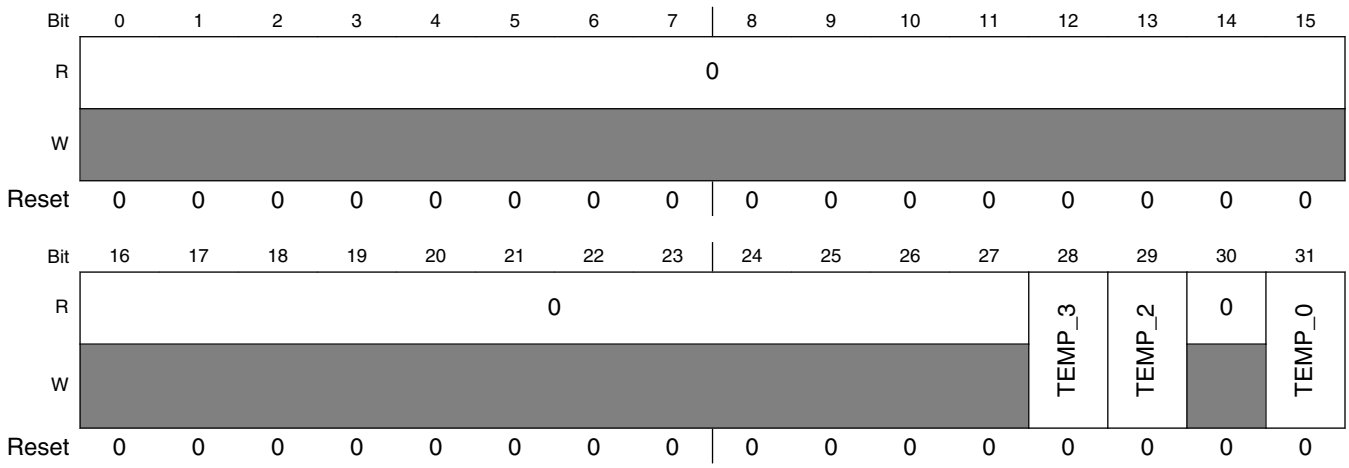
Field	Description
28 TEMP_3	TEMP_3 flag. This bit is the temperature status flag associated with the temperature for the high temperature sensor point (165C). It is asserted when the temperature exceeds its corresponding threshold, and clears when a one is written to this bit location. If the IETD_3 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP_3] is also asserted, a system reset is generated, which clears IETD_3 and negates the interrupt request. If REE_TD[TEMP_3] is asserted and a destructive reset is selected (via RES_TD[TEMP_3] being 0), then a destructive reset is generated. If RES_TD[TEMP_3] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
29 TEMP_2	TEMP_2 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150C). It is asserted when the temperature exceeds its corresponding threshold, and clears when a one is written to this bit location. If the IETD_2 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP_2 is also asserted, a system reset is generated, which clears IETD_2 and negates the interrupt request. If REE_TD[TEMP_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TEMP_0	TEMP_0 flag. This bit is the temperature status flag associated with the temperature for the cold temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold, and clears when a one is written to this bit location. If the IETD_0 bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP_0] is also asserted, a system reset is generated, which clears IETD_0 and negates the interrupt request. If REE_TD[TEMP_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.

63.2.45 Reset Event Enable Register (PMCDIG_REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Address: 0h base + 304h offset = 304h



PMCDIG_REE_TD field descriptions

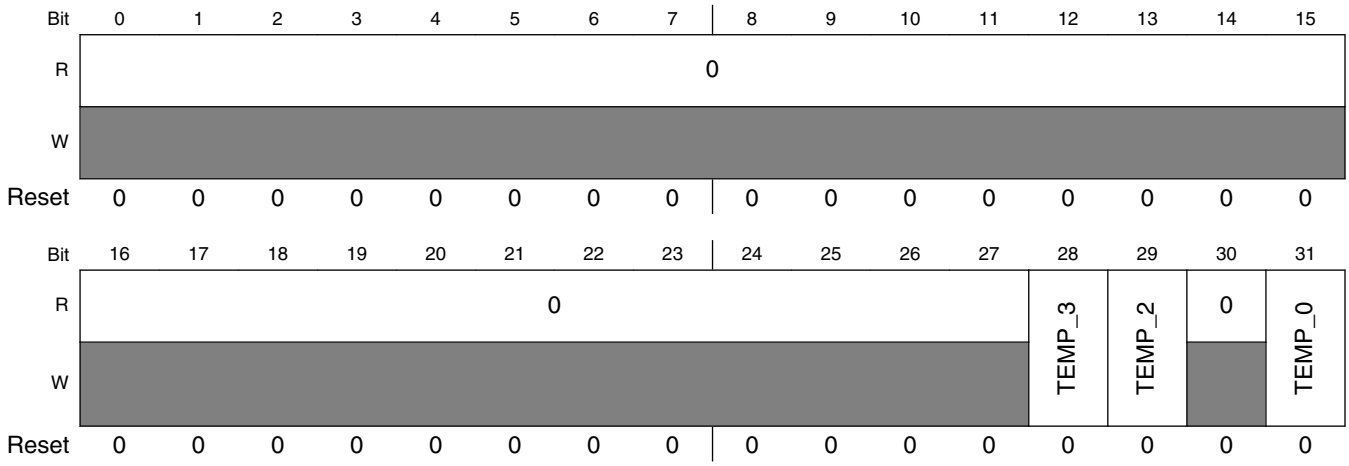
Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 TEMP_3	TEMP_3 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_2] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
29 TEMP_2	TEMP_2 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_1] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TEMP_0	TEMP_0 reset enable. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP_0] bit determines whether the reset is functional or destructive. 0 Disabled. Temperature Sensor detect does not cause system reset. 1 Enabled. Temperature Sensor detect causes system reset.

63.2.46 Reset Event Select Register (PMCDIG_RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Address: 0h base + 308h offset = 308h



PMCDIG_RES_TD field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 TEMP_3	TEMP_3 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_3] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
29 TEMP_2	TEMP_2 reset event select. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_2] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TEMP_0	TEMP_0 reset event select. This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.

63.2.47 Temperature Sensor Configuration Register (PMCDIG_CTL_TD)

The Temperature Sensor register (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to operate. It also includes two 4-bit signed trim adjustment register fields that are used to modify both TS trim values (one bus for overtemperature and one bus for undertemperature). Finally, this register includes Interrupt Enables (IE) for each of the Temperature Sensor EPR bits.

The use case for the TRIM_ADJ_OVER and TRIM_ADJ_UNDER fields would be to introduce additional hysteresis into the Temperature Sensor events. For instance, 1111b (-7) could be written to the TRIM_ADJ_OVER field and the Temperature Sensor event configured for an interrupt. When this interrupt occurs, the TRIM_ADJ_OVER bits could be updated to 0111b (+7), the interrupt cleared, and the Temperature Sensor event configured for a reset. In this way, a "warning" event (like an interrupt) could be detected as well as a "shutdown" event (at a higher temperature).

NOTE

Care must be taken to include a timeout during the clearing of the interrupt described in the example above. The Temperature Sensor has hysteresis and a timeout may be necessary to indicate if the interrupt flag has not cleared in a reasonable amount of time. If this is the case, then an error should be indicated.

PMCDIG_CTL_TD field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TS3IE	TS3IE Temperature Sensor input 3 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. **NOTE:** The MSB in IE_P must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
17 TS2IE	TS2IE Temperature Sensor input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. **NOTE:** The MSB in IE_P must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
18 TS0IE	TS0IE Temperature Sensor input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. The MSB in IE_P must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 TRIM_ADJ_ OVER[3:0]	Customer adjustable over trim register. These bits are a signed binary number that is added to the over temperature trim (NT_TD2)value. The TRIM value is protected from overflows and underflows due to this addition.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–29 TRIM_ADJ_ UNDER[3:0]	Customer adjustable trim register. These bits are a signed binary number that is added to the Under temperature trim value (NT_TD0). The TRIM value is protected from overflows and underflows due to this addition.
30 DOUT_EN	Digital Output Enable. This signal behavior has changed. The analog block now uses a 5 V signal for this input (and this field is not used) (see the Temperature Sensor Analog Chapter for details). 0 Disable 1 Enable
31 AOUT_EN	Analog Output Enable. 0 Disable 1 Enable

63.2.48 Temp Sensor FCCU Event Enable Register (PMCDIG_FEE_TD)

This Temp Sensor FCCU Event Enable Register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

Address: 0h base + 318h offset = 318h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 FEE_TS3	FEE_TS3 Temp Sensor FCCU event enable. This bit defines whether a temperature detect assertion generates an FCCU event.. 0 Disabled. Temp Sensor detect does not cause an FCCU event. 1 Enabled. Temp Sensor detect causes an FCCU event.
29 FEE_TS2	FEE_TS2 Temp Sensor FCCU event enable. This bit defines whether a temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_2] bit determines whether the reset event is enabled. 0 Disabled. Temp Sensor detect does not cause an FCCU event. 1 Enabled. Temp Sensor detect causes an FCCU event.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FEE_TS0	FEE_TS0 Temp Sensor FCCU event enable. This bit defines whether a temperature detect assertion generates an FCCU event. 0 Disabled. Temp Sensor detect does not cause an FCCU event. 1 Enabled. Temp Sensor detect causes an FCCU event.

63.2.49 Voltage Detect User Mode Test Register (PMCDIG_VD_UTST)

This register is used for testing of the LVDs and HVDs during user mode.

Before using the User Self-Test register field, the LVDs, HVDs, and PORs must be deasserted. If they are not deasserted, the self-test can cause an error. Check that all the LVDs, HVDs, and PORs are deasserted before starting this test.

Address: 0h base + 340h offset = 340h

PMCDIG_VD_UTST field descriptions

Field	Description
0–3 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
4 VOLT4_EN	VOLT4 enable. This bit defines whether internal voltage VOLT4 can generate a system reset. 0 Disabled. Only disable during Self Test process for VOLT4 1 Enabled. Normal resets are enabled.
5 VOLT3_EN	VOLT3 enable. This bit defines whether internal voltage VOLT4 can generate a system reset. 0 Disabled. Only disable during Self Test process for VOLT4 1 Enabled. Normal resets are enabled.
6 VOLT2_EN	VOLT2 enable. This bit defines whether internal voltage VOLT4 can generate a system reset. 0 Disabled. Only disable during Self Test process for VOLT4 1 Enabled. Normal resets are enabled.
7 VOLT1_EN	VOLT1 enable.

Table continues on the next page...

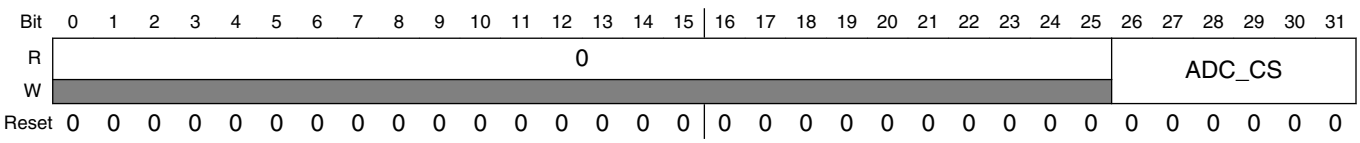
PMCDIG_VD_UTST field descriptions (continued)

Field	Description
	This bit defines whether internal voltage VOLT4 can generate a system reset. 0 Disabled. Only disable during Self Test process for VOLT4 1 Enabled. Normal resets are enabled.
8–11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 VOLT4	VOLT4 flag. This bit is the status flag associated with VOLT4. It is asserted asynchronously when the appropriate Self Test Mode bus is selected, and clears when a one is written to this bit location. 0 Currently no occurrence. 1 Voltage event occurrence detected.
13 VOLT3	VOLT3 flag. This bit is the status flag associated with VOLT3. It is asserted asynchronously when the appropriate Self Test Mode bus is selected, and clears when a one is written to this bit location. 0 Currently no occurrence. 1 Voltage event occurrence detected.
14 VOLT2	VOLT2 flag. This bit is the status flag associated with VOLT2. It is asserted asynchronously when the appropriate Self Test Mode bus is selected, and clears when a one is written to this bit location. 0 Currently no occurrence. 1 Voltage event occurrence detected.
15 VOLT1	VOLT1 flag. This bit is the status flag associated with VOLT1. It is asserted asynchronously when the appropriate Self Test Mode bus is selected, and clears when a one is written to this bit location. 0 Currently no occurrence. 1 Voltage event occurrence detected.
16–25 Reserved	This field is reserved.
26–31 VD_UTST[5:0]	Voltage Detect: User Test. User mode Test bits for testing of LVDs and HVDs.

63.2.50 ADC Channel Select Register (PMCDIG_ADC_CH)

This register configures the analog channel select mux of the PMC module.

Address: 0h base + 344h offset = 344h



PMCDIG_ADC_CH field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ADC_CS	ADC_CS Channel Select. These bits are used to control the analog PMC's test mux going to the ADC.

63.2.51 Voltage Regulator 1.2V Control Register (PMCDIG_VREG1P2_CTRL)

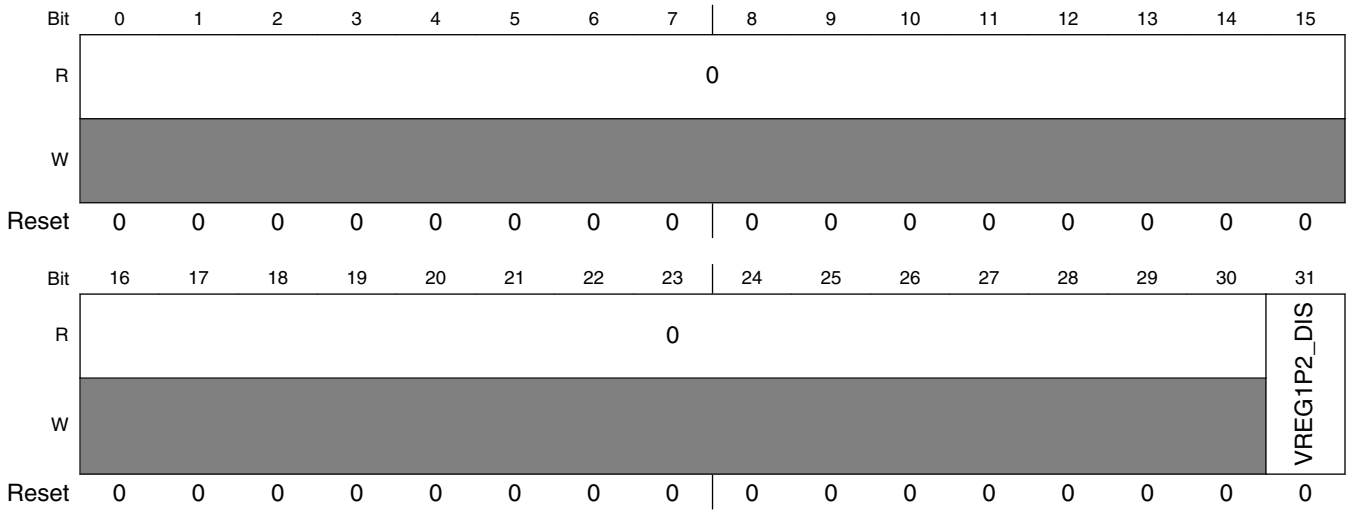
This register is used to disable the Auxiliary Regulator (also known as Spike or VREG1P2 Regulator) during an intentional power down event. The LSB of this register is a bit that is OR'd with the DCF control for the PMC_VREG1P2_ENB. If either the DCF loaded bit or the LSB of VREG1P2_CTRL is a 1, then the Auxiliary Regulator is disabled.

This bit is loaded during reset to match the value of the DCF location, and it is also only reset during a POR event.

This bit (VREG1P2_DIS) can only be used to turn off the Auxilliary Regulator, not turn it on.

This bit should be written high before any expected power down events.

Address: 0h base + 34Ch offset = 34Ch



PMCDIG_VREG1P2_CTRL field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 VREG1P2_DIS	This bit controls if the AUX Regulator (Vreg1p2) is disabled. During Power Down, this bit should be written to a 1 so that the AUX regulator is disabled. By default, the DCF loaded value (PMC_VREG1P2_ENB) is used to control the AUX regulator. 0 The enable of the VREG1P2 follows the DCF loaded bit. 1 VREG1P2 is disabled.

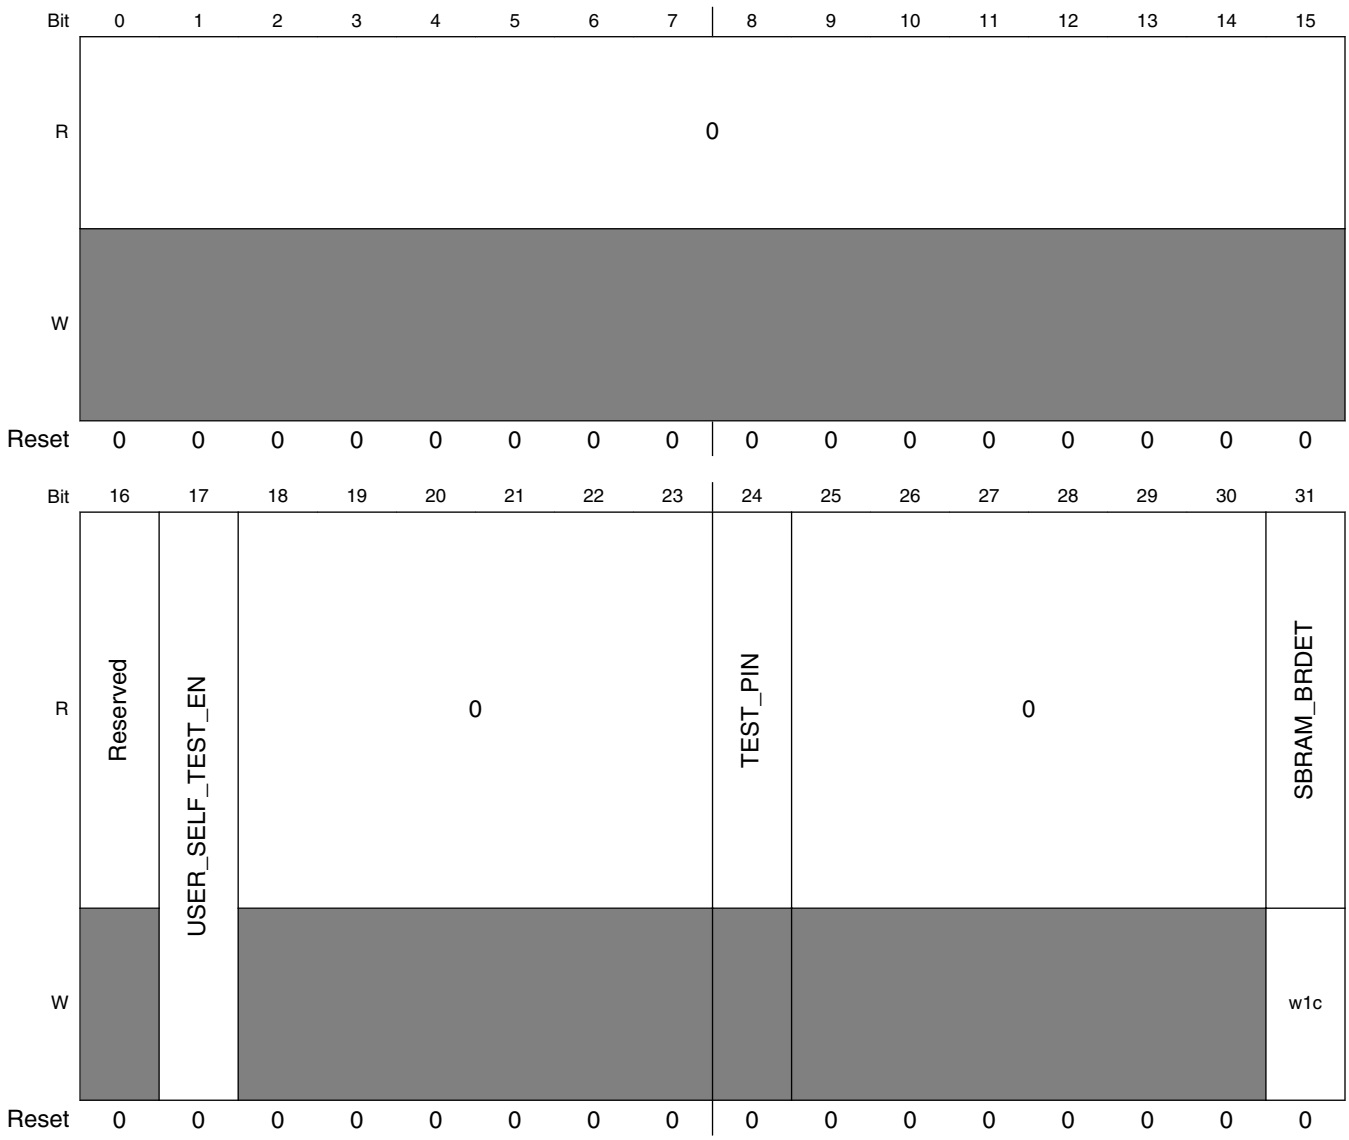
63.2.52 Module Control Register (PMCDIG_MCR)

This register contains several status and control bits. First, it the bit that is used to detect the status and to clear the Brown Out Detection logic for the Standby RAM module.

This register also contains the enable that is needed for the use of the PMC analog block User Self Test feature (USER_SELF_TEST_EN).

The proper procedure to enable these busses would be to write the value to the register containing the bus, then write this enable high, evaluate the test associated with this bus, and then write this bus enable bit low. After that, any further tests can be continued.

Address: 0h base + 350h offset = 350h



PMCDIG_MCR field descriptions

Field	Description
0–15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved.
17 USER_SELF_ TEST_EN	This bit allows the VD_UTST bits int he VD_UTST register to be enabled. This bit should be set after the VD_UTST bus has been updated, and cleared after the test has completed. The VD_UTST bus should not be updated while the USER_SELF_TEST_EN is enabled (high). 0 The VD_UTST bus is not enabled in the PMC analog. 1 The VD_UTST bus is enabled in the PMC analog.

Table continues on the next page...

PMCDIG_MCR field descriptions (continued)

Field	Description
18–23 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
24 TEST_PIN	This bit is indicates the current value of the Test Pin. 0 Test Pin is not asserted. 1 Test Pin is asserted.
25–30 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
31 SBRAM_BRDET	SBRAM_BRDET. This bit is the detection status flag for the Standby RAM Brown Out Detection circuit. When a brown out event is detected in the Standby RAM logic, this signal asserts. In order to clear this flag, the brown out detection logic must no longer be detecting an event, and a one must be written to this bit location. 0 Currently no occurrence. 1 Standby RAM Brown Out occurrence detected.

63.3 Functional description

63.3.1 Analog PMC interface

The outputs from the PMC digital to the PMC analog circuit consists of trim registers for each LVD circuit, an enable for each LVD (tied to the enabled state), and ADC channel select controls. The ADC channel select controls are described in more detail in the ADC interface section of this chapter, and in the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

The signals from the PMC analog to the PMC digital logic consists of simply POR and LVD event indication signals. These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There is a settling time for the analog voltage detect circuits specified at 5 µsec. The PMC digital counts clock edges after the loading of new flash trim values to verify that this time has passed. This time can be ≥ 5 µsec.

After a POR, some of the EPR registers may be set due to slow supply ramps or noisy supplies duirng power up. Clear these flags during initialization after a POR."

63.3.2 Temperature Sensor interface logic

The Temperature Sensor interface consists of two enables: an analog and digital enable, a set of mode registers, two 7-bit trim registers (sometimes referenced as one 14-bit trim register), and an overtemperature threshold select control.

The Temperature Sensor simply outputs three signals to the PMC digital logic: over_temp1, over_temp2, and under_temp signals. These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There are two 4-bit signed registers (TRIM_ADJ_OVER[3:0] and TRIM_ADJ_UNDER[3:0]) that can be used by software to adjust the value of the Temp Sensor Trim values. The fourth bit of these registers indicates the sign.

TRIM_ADJ_OVER is added to TS2_TRIM and TRIM_ADJ_UNDER is added to TS0_TRIM. This addition is protected from overflow and underflow (the TRIM value will simply stay at max or min value).

Before changing either of the TRIM_ADJ registers, the Temp Sensor resets and interrupts should be disabled via the TEMP bits in the PMCDIG_REE_TD register and TSIE bits in the PMCDIG_CTL_TD register. Resets and interrupts for the Temp Sensor should not be enabled until the Temp Sensor Status bits (TS bits in GR_S register) indicate that there is no longer a temperature event occurring.

For more information regarding the Temperature Sensor function, please refer to the Temperature Sensor chapter in this Reference Manual chapter.

NOTE

When the temperature exceeds the defined threshold, the bits of PMCDIG_EPR_TD register are set. These bits are cleared when a "1" is written to the bit location. The current status of the Temperature Status can be determined with PMCDIG_GR_S[TS3], PMCDIG_GR_S[TS2] and PMCDIG_GR_S[TS0] bits of the PMCDIG_GR_S register. These bits also indicate if the temperature threshold has been exceeded previously.

63.3.3 Standby RAM regulator interface logic

The Standby RAM Regulator interface consists of one bit that indicates that a Standby RAM Brown-out event has occurred, and a method to clear this indication (by writing a one to the flag bit).

For more information regarding the Standby RAM Regulator function, please refer to the Standby RAM Regulator Analog Chapter.

63.3.4 Power On Reset (MC_RGM phase gates)

The PMC digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMC and Temperature Sensor Analog blocks.

There are two signals for each the PMC and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMC digital logic also indicates when is OK to for the RGM to allow transition to the next POR phase.

The digital PMC also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMC digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled HVD/LVDs have become deasserted and the time for the LVD/HVD circuits to adjust to new trim values (Tlvdtrim (and other system time counts): see PMC analog block guide) has elapsed, the signal is then sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

There are nine POR signals:

- POR_VDDREG
- POR_VDDC
- POR081_C
- POR085_C
- POR085_F
- POR098_C
- POR098_F
- POR250_F
- POR260_C

63.3.5 Flash memory interface (DCF client usage)

The PMC digital is updated during POR from flash memory via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMC, Temperature Sensor, and ADC Bandgap).

The trim bits that are loaded from flash memory are not readable. These trim values loaded via the DCF client are compacted (they are written several at a time).

A DCF client is used to interface to flash memory for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips. If any issues occur during any of the DCF data loads (like a second write of different data), the DCF client will indicate an error to the FCCU.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES registers.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset values of the REE DCF bits are all low (thus to allow the bits to be rewriteable), but the reset value of the REE register fields are high (to enable the resets normally out of POR).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the destructive reset signal (see the "Device Configuration Format (DCF) Records" chapter for details).

Trim data is read from the flash memory's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the flash memory indicates read completion to PMC_dig via the SSCM module (see the flash memory chapter for details on differential reads and required voltage levels).

Once the PMC trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the flash memory to indicate that the voltage is high enough for faster single access reads.

All of the LVD/HVD signals must indicate that a valid voltage has been reached before the voltage indication will be sent to the flash memory.

63.3.6 Other module interfaces

The FCCU block receives several signals to indicate a fault has occurred. The first is a safety error from the DCF interface indicating that some error has happened during the load of the trim data from the flash during POR. All of the DCF client safety error signals are combined in the PMC digital logic and then sent to the FCCU.

The second set of signals indicate that an HVD, LVD, or temperature event has occurred.

- The LVDs that are sent to the FCCU are:
  - LVD108_C
  - LVD108_F
  - LVD108_P
  - LVD112_C
  - LVD270_C
  - LVD270_F
  - LVD270_IF
  - LVD270_IJ
  - LVD270_IM
  - LVD270_O
  - LVD295_F
  - LVD295_A
  - LVD360_IM
  - LVD400_IM
  - LVD400_A
- The HVDs that are sent to the FCCU are:
  - HVD140_C
  - HVD145_F
  - HVD145_C
  - HVD360_F
  - HVD600_C
  - HVD600_A

The Temp Sensor outputs tmpsns3, tmpsns2, and tmpsns0 are all combined and sent to the FCCU.

For more information regarding the FCCU block and these signals, please refer to the FCCU chapter.

The HSM module receives four signals from the PMC digital. There are two signals that are sent to the HSM that includes both over_temp1 and over_temp2 values. The under_temp signal is also sent to the HSM as well. The last signal indicates that the PMC has detected a voltage higher than 1.4V on the internal cold detection point.

For more information regarding the HSM block and these signals, please refer to the HSM chapter of the MPC5700 Family Microcontroller Security Reference Manual.

Chapter 64
Power Control Unit (MC_PCU)

64.1 Introduction

64.1.1 Overview

The power control unit (MC_PCU) acts as a bridge for mapping the PMC peripheral to the MC_PCU address space.

The following figure depicts the MC_PCU block diagram.

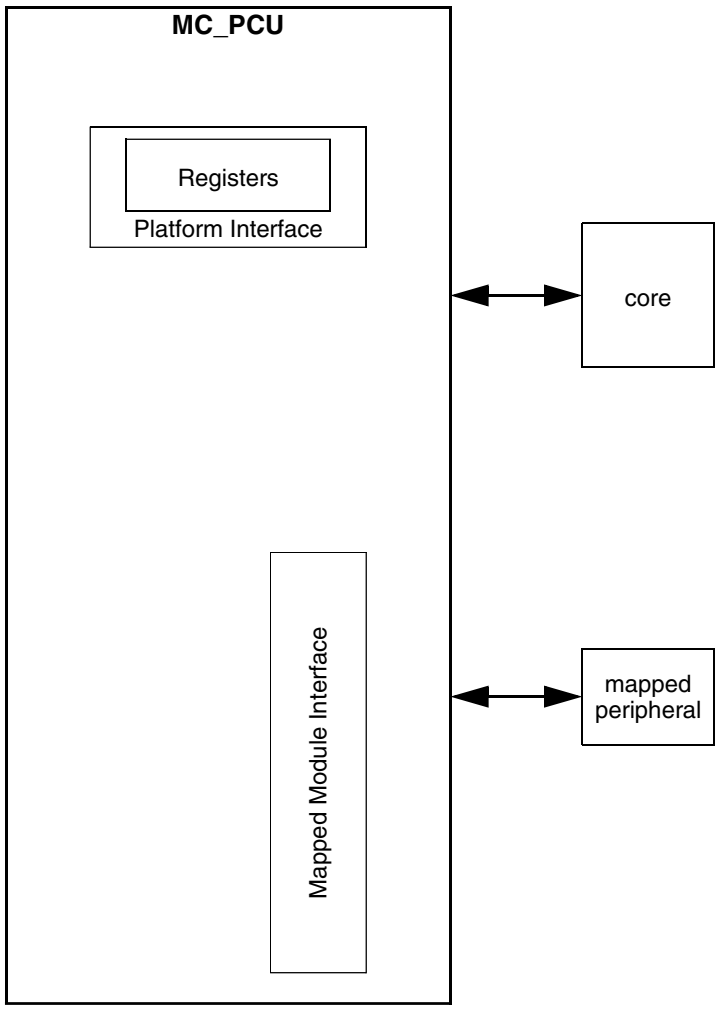


Figure 64-1. MC_PCU block diagram

64.1.2 Features

The MC_PCU includes the following features:

- maps the PMC registers to the MC_PCU address space

64.2 Memory Map and Register Definition

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at address 0x0040, as a half-word at address 0x0042, or as a byte at address 0x0043.

NOTE

All registers will be accessible in "User mode" provided the access to this mode is enabled through REGPROT settings. Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error(only if SSCM_ERROR[RAE] is set)

MC_PCU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
40	Power Domain Status Register (MC_PCU_PSTAT)	32	R	0000_0001h	64.2.1/3425

64.2.1 Power Domain Status Register (MC_PCU_PSTAT)

This register reflects the power status of all available power domains.

Address: FFFA_0000h base + 40h offset = FFFA_0040h

Field	Description

64.3 Functional Description

Please see the PMC_dig chapter for specific details on the PMC control registers.

Chapter 65
Mode Entry Module (MC_ME)

65.1 Introduction

65.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

The following figure shows the MC_ME block diagram.

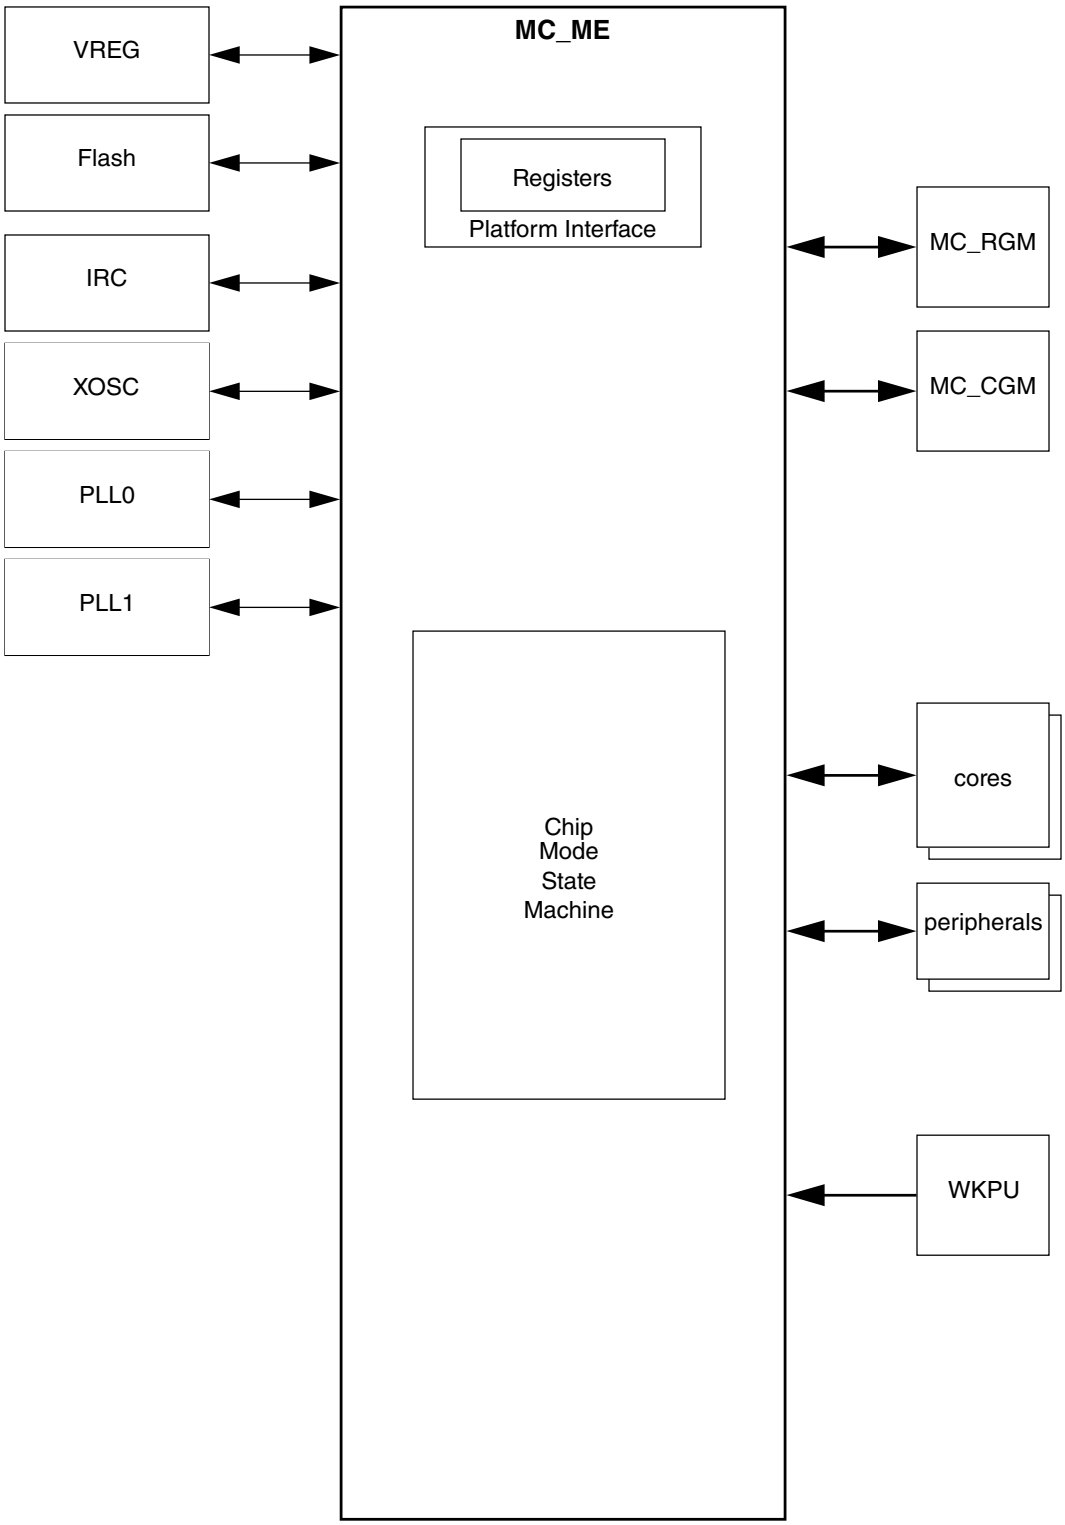

Figure 65-1. MC_ME Block Diagram

65.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers
- additional core clock gating and boot address control based on the ME_CCTLn and ME_CADDRn registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

65.1.3 Modes of operation

- The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0…3, HALT0, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0…3 are the chip software running modes.

The following table describes the MC_ME modes.

Table 65-1. MC_ME Mode Descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAF when present is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0…3	system reset assertion, RUN0…3, TEST via software, SAFE via software or hardware failure.
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0…3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0…3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0…3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0…3 modes, HALT0, STOP0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals like clock sources, flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.	software request from RUN0…3	system reset assertion, SAFE on hardware failure, RUN0…3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0…3	system reset assertion, SAFE on hardware failure, RUN0…3 on interrupt event[1] or wakeup event

1. If the user does not want the part to be woken up from certain Interrupt events, then the user needs to explicitly disable those interrupts in the respective peripherals. Disabling the respective interrupt channels in the Interrupt Controller will not suffice.

65.2 External signal description

The MC_ME has no connections to any external pins.

65.3 Memory map and register definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

NOTE

All registers will be accessible in "User mode" provided the access to this mode is enabled through REGPROT settings. Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error(only if SSCM_ERROR[RAE] is set)

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
6–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 S_PDO	Output power-down status - This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In STOP0 mode, the slew rate control mechanism of the output pads is disabled to reduce power consumption, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 S_FLA	Flash availability status 00 Flash is not available 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode and available for use
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 S_PLL1	secondary PLL status 0 secondary PLL is not stable 1 secondary PLL is providing a stable clock
25 S_PLL0	primary PLL status 0 primary PLL is not stable 1 primary PLL is providing a stable clock
26 S_XOSC	external crystal oscillator status

Table continues on the next page...

MC_ME_GS field descriptions (continued)

Field	Description
	0 external crystal oscillator is not stable 1 external crystal oscillator is providing a stable clock
27 S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
28–31 S_SYSCLK	System clock switch status - These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

65.3.2 Mode Control Register (MC_ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

NOTE

Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TARGET_MODE				0																											
W																	KEY															
Reset	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1

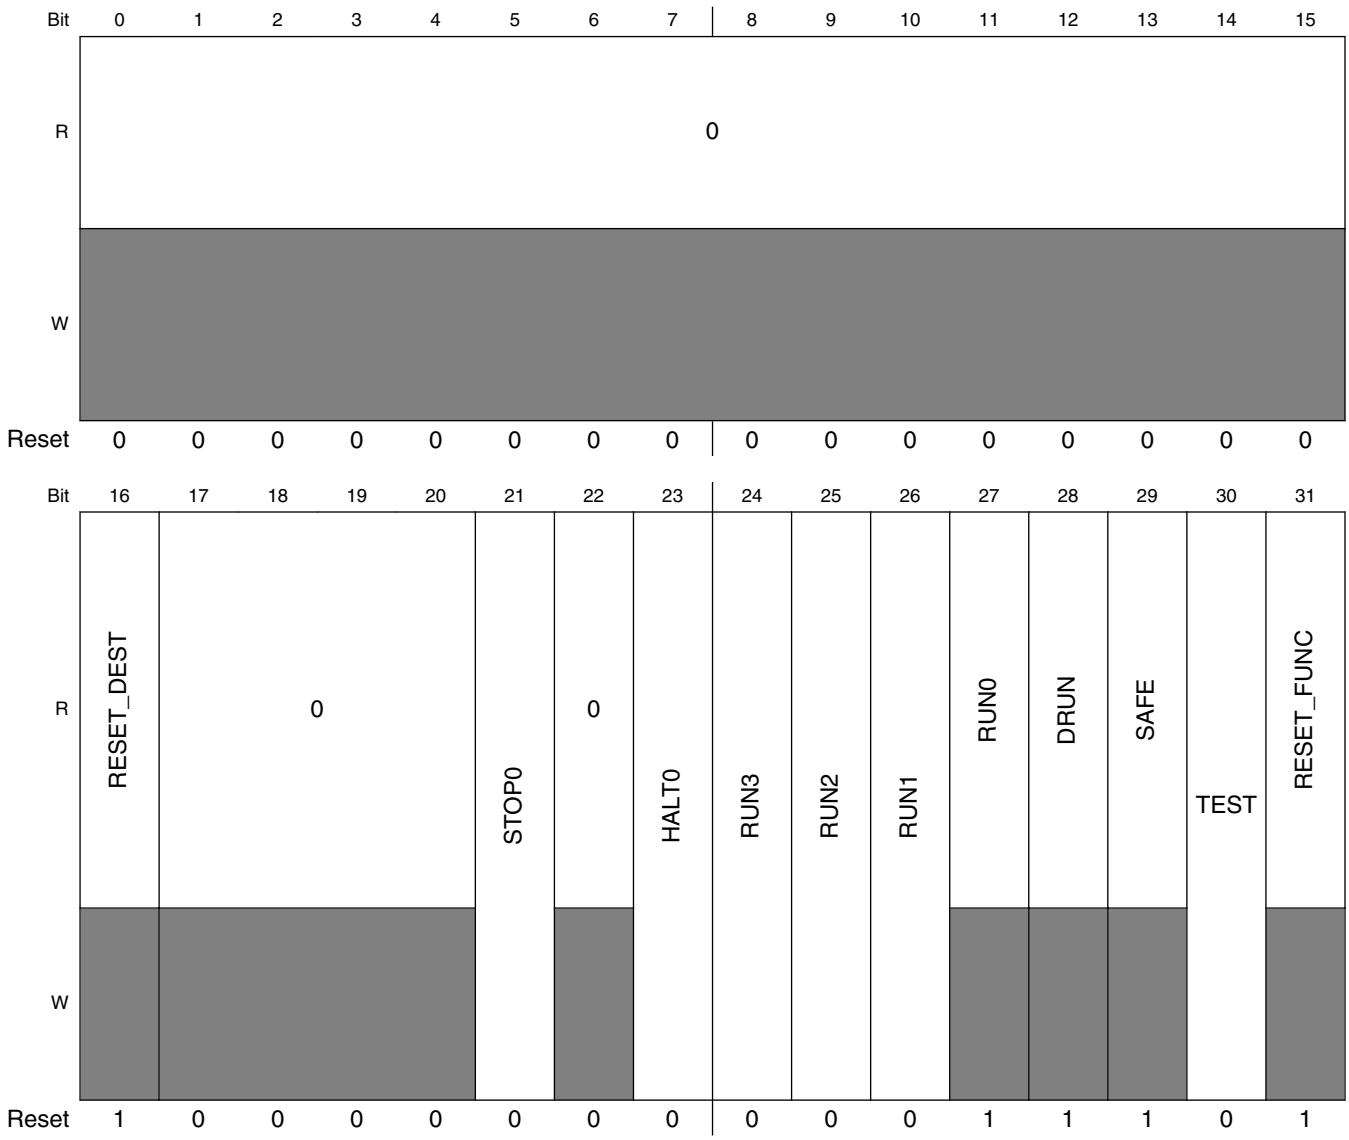
MC_ME_MCTL field descriptions

Field	Description
0–3 TARGET_MODE	Target chip mode - These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0…3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 KEY	Control key - These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101101011110000 (0x5AF0) INVERTED KEY: 1010010100001111 (0xA50F)

65.3.3 Mode Enable Register (MC_ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET_FUNC, SAFE, DRUN, RUN0, and RESET_DEST modes are always enabled.

Address: 0h base + 8h offset = 8h



MC_ME_ME field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

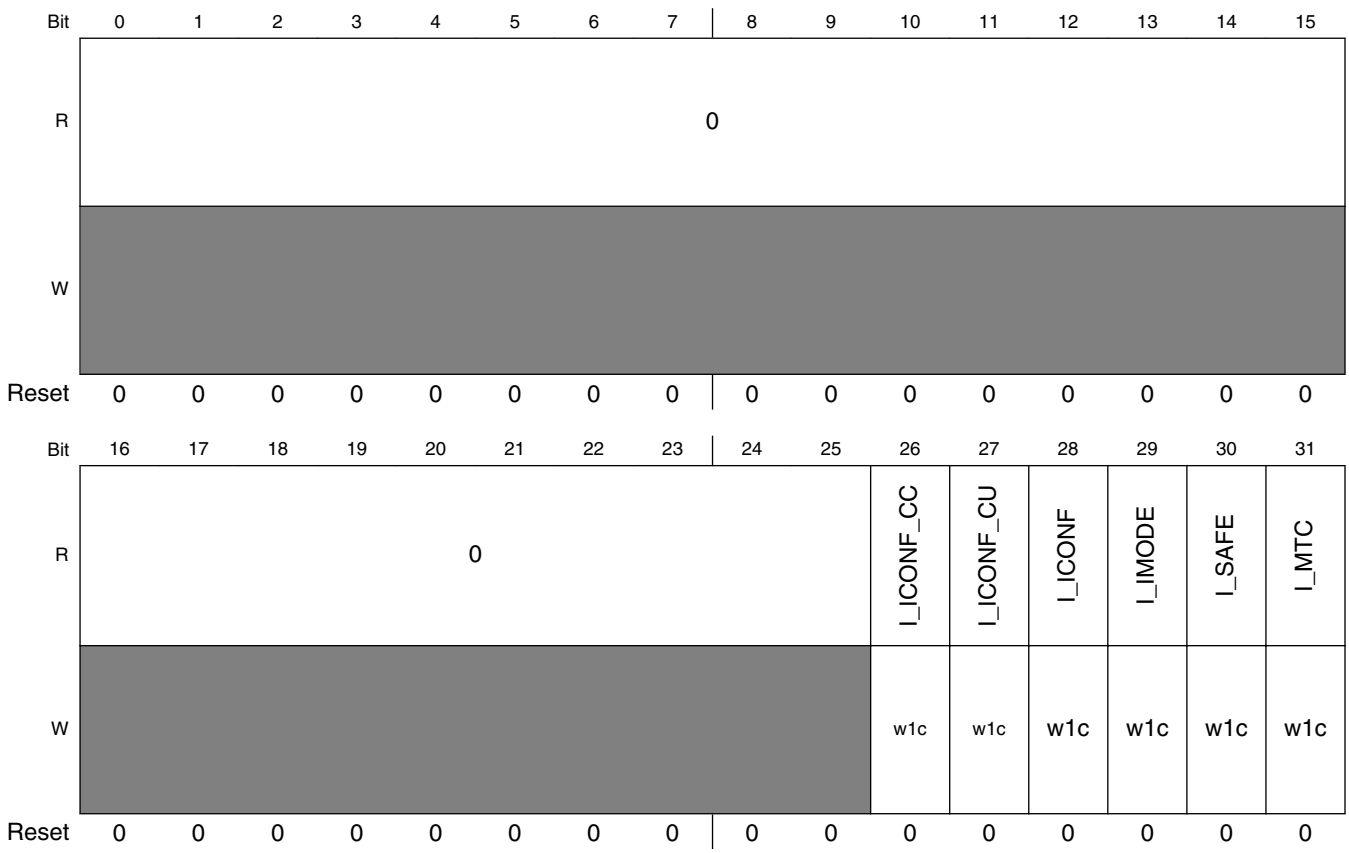
MC_ME_ME field descriptions (continued)

Field	Description
16 RESET_DEST	'destructive' RESET mode enable 1 'destructive' RESET mode is enabled
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	STOP0 mode enable 0 STOP0 mode is disabled 1 STOP0 mode is enabled
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HALT0	HALT0 mode enable 0 HALT0 mode is disabled 1 HALT0 mode is enabled
24 RUN3	RUN3 mode enable 0 RUN3 mode is disabled 1 RUN3 mode is enabled
25 RUN2	RUN2 mode enable 0 RUN2 mode is disabled 1 RUN2 mode is enabled
26 RUN1	RUN1 mode enable 0 RUN1 mode is disabled 1 RUN1 mode is enabled
27 RUN0	RUN0 mode enable 1 RUN0 mode is enabled
28 DRUN	DRUN mode enable 1 DRUN mode is enabled
29 SAFE	SAFE mode enable 1 SAFE mode is enabled
30 TEST	TEST mode enable 0 TEST mode is disabled 1 TEST mode is enabled
31 RESET_FUNC	'functional' RESET mode enable 1 'functional' RESET mode is enabled

65.3.4 Interrupt Status Register (MC_ME_IS)

This register provides the current interrupt status.

Address: 0h base + Ch offset = Ch



MC_ME_IS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) - This bit is set if a write access to one of the ME_CCTLn registers is attempted while a mode transition is in progress. 0 No write to an ME_CCTLn register was attempted during an ongoing mode transition 1 A write to an ME_CCTLn register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) - This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending

Table continues on the next page...

MC_ME_IS field descriptions (continued)

Field	Description
28 I_ICONF	Invalid mode configuration interrupt - This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt - This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt - This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt - This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

65.3.5 Interrupt Mask Register (MC_ME_IM)

This register controls whether an event generates an interrupt or not.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

R	0										M_ICONF_CC	M_ICONF_CU	M_ICONF	M_IMODE	M_SAFE	M_MTC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

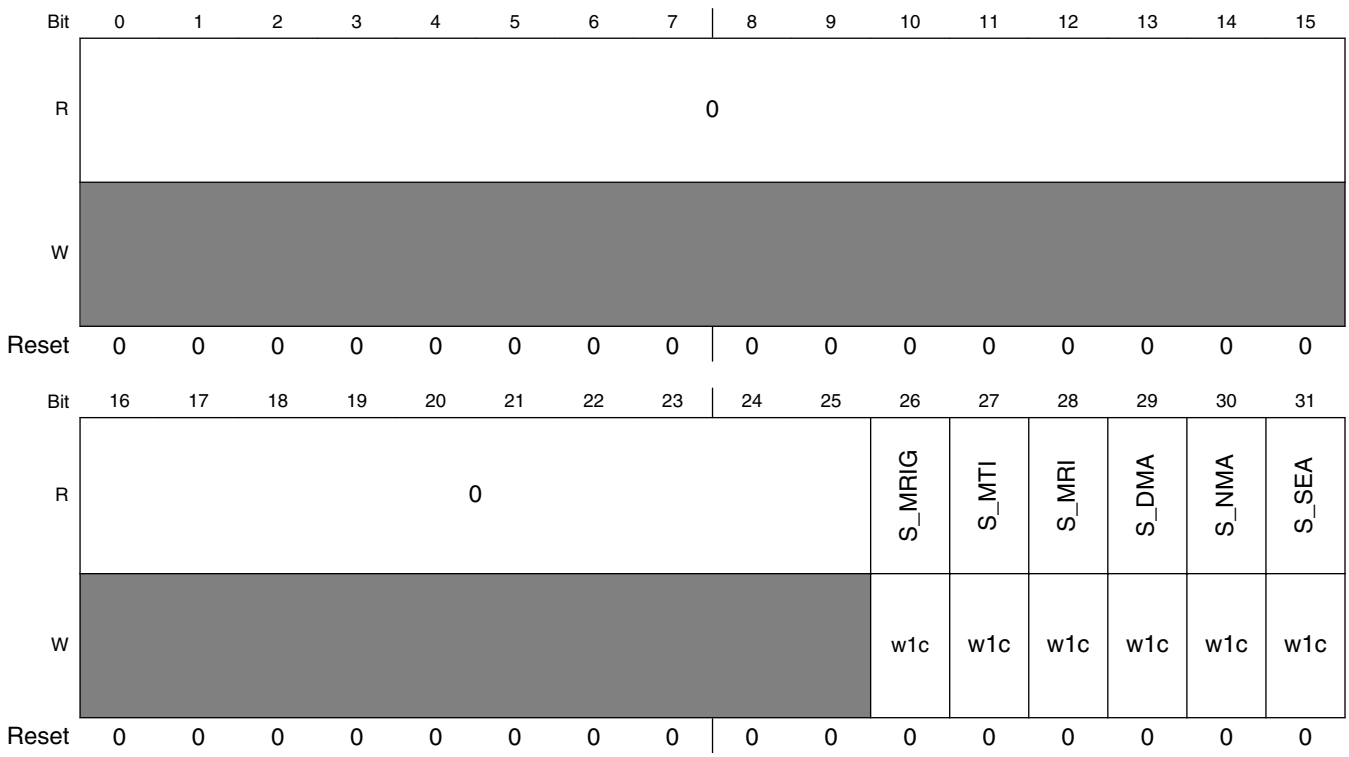
MC_ME_IM field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 M_ICONF_CC	Invalid mode configuration (core configuration) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
27 M_ICONF_CU	Invalid mode configuration (clock usage) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
28 M_ICONF	Invalid mode configuration interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
29 M_IMODE	Invalid mode interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
30 M_SAFE	SAFE mode interrupt mask 0 SAFE mode interrupt is masked 1 SAFE mode interrupt is enabled
31 M_MTC	Mode transition complete interrupt mask 0 Mode transition complete interrupt is masked 1 Mode transition complete interrupt is enabled

65.3.6 Invalid Mode Transition Status Register (MC_ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Address: 0h base + 14h offset = 14h



MC_ME_IMTS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_MRIG	Mode Request Ignored Status - This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress. This bit is also set if a transition to STOP/HALT mode is requested when a wakeup is active. It is cleared by writing 1 to this bit. 0 Mode transition requested is not ignored 1 Mode transition requested is ignored
27 S_MTI	Mode Transition Illegal status - This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is '1'). Please refer to Mode transition interrupts for the exceptions to this behavior. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
28 S_MRI	Mode Request Illegal status - This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a '1' to this bit.

Table continues on the next page...

MC_ME_IMTS field descriptions (continued)

Field	Description
	0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
29 S_DMA	Disabled Mode Access status - This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status - This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status - This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

65.3.7 Debug Mode Transition Status Register (MC_ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

NOTE

The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MC_ME_DMTS field descriptions

Field	Description
0–3 PREVIOUS_ MODE	Previous chip mode - These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator - This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has power-up/down sequencing. 0 Handshake is not busy 1 Handshake is busy
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PMC_PROG	MC_PCU Mode Change in Progress indicator - This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator - This bit reads 0.
13 CCKL_PROG	Core Clock Enable/Disable in Progress - This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress - This bit is set while the progressive system clock switching process is in progress, or the peripheral clock switching is ongoing, or core clock switching is ongoing, or a power sequence process is ongoing (provided the target mode is not STANDB0). 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator - This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared.

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
	0 A SAFE mode request is not active 1 A SAFE mode request is active
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
19 IRC_SC	IRC State Change during mode transition indicator - This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator - This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A 'secondary clock source' is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status - 0 No system clock source switching is pending 1 A system clock source switching is pending
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FLASH_SC	FLASH State Change during mode transition indicator - This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224…255 - This bit is set when any peripheral has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
25 CDP_PRPH_ 192_223	Clock Disable Process Pending status for Peripherals 192…223 - This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
26 CDP_PRPH_ 160_191	Clock Disable Process Pending status for Peripherals 160…191 - This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
27 CDP_PRPH_ 128_159	Clock Disable Process Pending status for Peripherals 128…159 - This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_ 127	Clock Disable Process Pending status for Peripherals 96…127 - This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_ 95	Clock Disable Process Pending status for Peripherals 64…95 - This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
	0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32…63- This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0…31 - This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. **NOTE:** Peripheral n corresponds to the ME_PCTLn register. See the memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

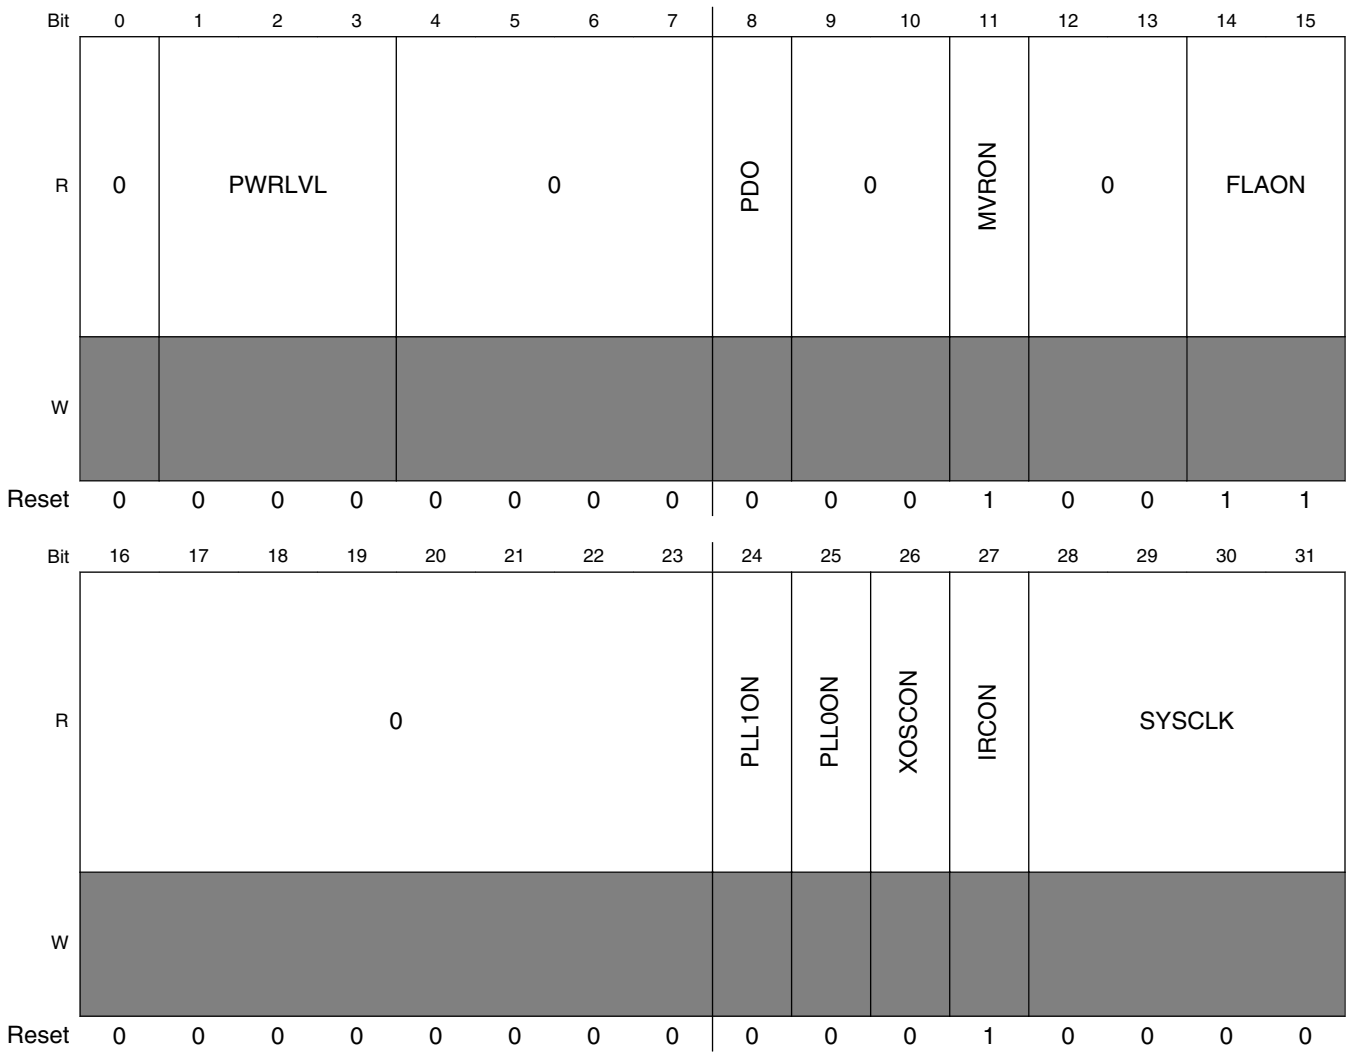
65.3.8 RESET Mode Configuration Register (MC_ME_RESET_MC)

This register configures system behavior during RESET mode.

NOTE

The following configuration values are set according to the chip configuration: XOSCON

Address: 0h base + 20h offset = 20h



MC_ME_RESET_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control - This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled **NOTE:** Power-sequence drivers control pad slopes during run mode and are disabled in certain System or User modes to further reduce power consumption. 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.

Table continues on the next page...

MC_ME_RESET_MC field descriptions (continued)

Field	Description
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control - This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 FLAON	Flash power-down control - This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on
26 XOSCON	external crystal oscillator control **NOTE:** For a loss of oscillator clock, there is a dedicated monitor (CMU0) on the device. If a S/W programmable minimum frequency threshold is violated, an interrupt to the FCCU is generated and the device is safe-stated (switch to backup clock - internal RCOSC). At that point, S/W can re-enter normal mode through the MC_ME, and the oscillator is restarted. No full power down of the device is required to restart the oscillator. 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28–31 SYSCLK	System clock switch control - These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved

MC_ME_SAFE_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control - This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control - This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 FLAON	Flash power-down control - This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PLL1ON	secondary PLL control

Table continues on the next page...

MC_ME_SAFE_MC field descriptions (continued)

Field	Description
	0 secondary PLL is switched off 1 secondary PLL is switched on
25 PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on
26 XOSCON	external crystal oscillator control[1] 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on
27 IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
28–31 SYSCLK	System clock switch control - These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

1. For a loss of oscillator clock, there is a dedicated monitor (CMU0) on the device. If a S/W programmable minimum frequency threshold is violated, an interrupt to the FCCU is generated and the device is safe-stated (switch to backup clock - internal RCOSC). At that point, S/W can re-enter normal mode through the MC_ME, and the oscillator is restarted. No full power down of the device is required to restart the oscillator.

65.3.11 DRUN Mode Configuration Register (MC_ME_DRUN_MC)

This register configures system behavior during DRUN mode.

NOTE

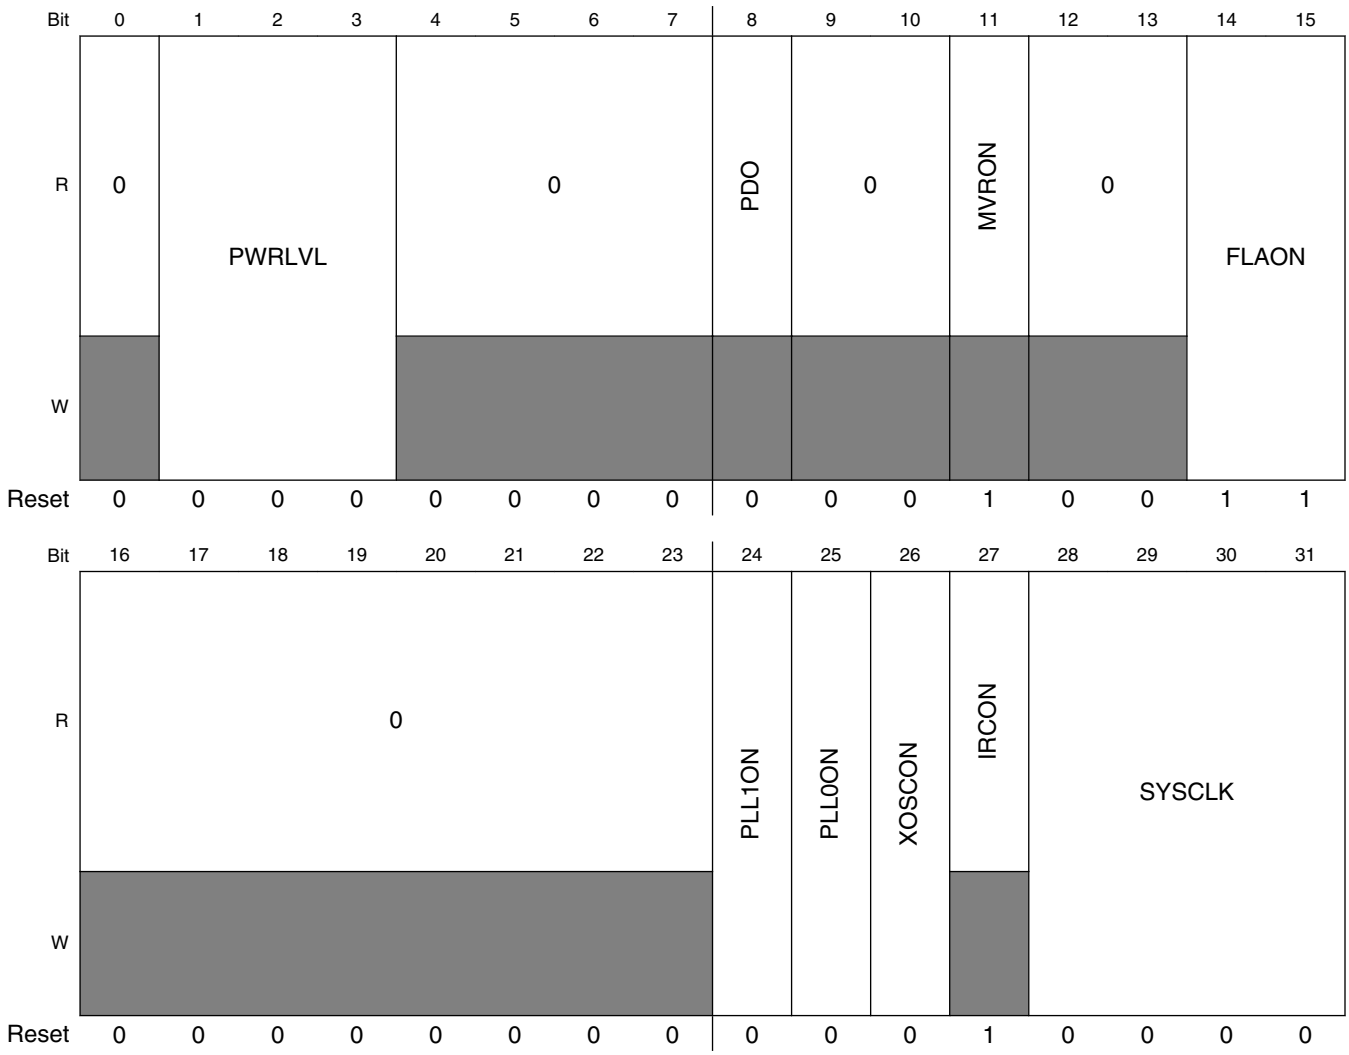
Byte write accesses are not allowed to this register.

NOTE

The following configuration values are set according to the chip configuration: XOSCON. The XOSCON bit is set according to

the DCF UTEST MISC register, XOSC_EN bit, described in the DCF chapter.

Address: 0h base + 2Ch offset = 2Ch



MC_ME_DRUN_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

MC_ME_PS0 field descriptions

Field	Description
0 S_PIT_RTC_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
1 S_PIT_RTC_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
2–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 S_SIUL	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 0 Peripheral is active
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 S_SIPI_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 S_LFAST_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
23–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_EBI_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.19 Peripheral Status Register 1 (MC_ME_PS1)

This register provides the status of the peripherals.

Address: 0h base + 64h offset = 64h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0			S_ADCSD_0	S_ADCSD_2	S_ADCSD_4	S_ADCSD_6	S_ADCSD_8	0

MC_ME_PS1 field descriptions

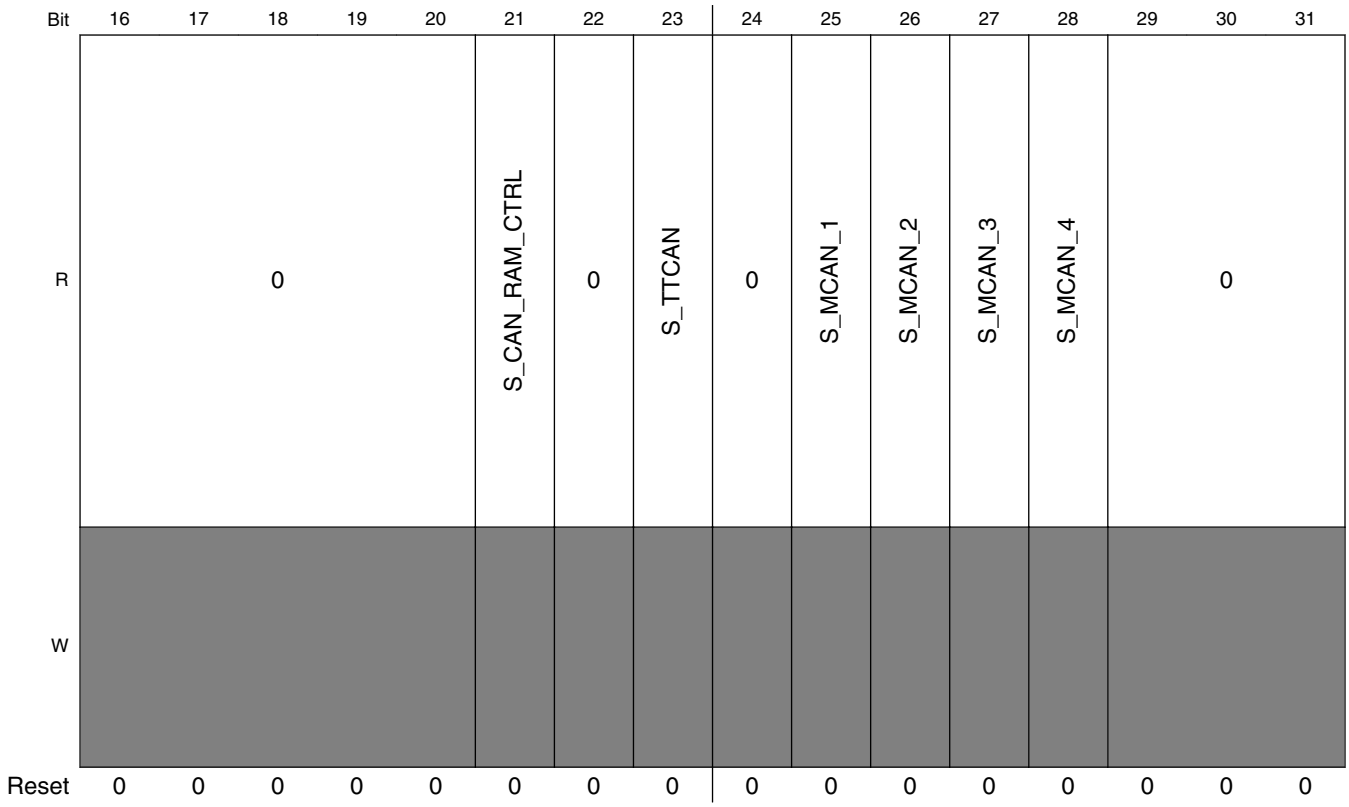
Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 S_ADCSD_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
4 S_ADCSD_2	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
5 S_ADCSD_4	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
6 S_ADCSD_6	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
7 S_ADCSD_8	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
8–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 S_CRC_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 S_DMAMUX_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.20 Peripheral Status Register 2 (MC_ME_PS2)

This register provides the status of the peripherals.

Address: 0h base + 68h offset = 68h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0		S_DSPI_12	S_LINFlexD_0	S_LINFlexD_1	0					S_LINFlexD_14	S_LINFlexD_16	0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



MC_ME_PS2 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 S_DSPI_12	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
3 S_LINFlexD_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
4 S_LINFlexD_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
5–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 S_LINFlexD_14	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active

Table continues on the next page...

MC_ME_PS2 field descriptions (continued)

Field	Description
11 S_LINFlexD_16	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
12–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 S_CAN_RAM_CTRL	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_TTCAN	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 S_MCAN_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
26 S_MCAN_2	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
27 S_MCAN_3	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
28 S_MCAN_4	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.21 Peripheral Status Register 3 (MC_ME_PS3)

This register provides the status of the peripherals.

Address: 0h base + 6Ch offset = 6Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	S_ADCSAR_0	0			S_ADCSAR_4	0			0							S_ADCSAR_b

MC_ME_PS3 field descriptions

Field	Description
0 S_ADCSAR_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 S_ADCSAR_4	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
5–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 S_ADCSAR_b	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
16 S_PSI5_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 S_FLEXRAY_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_SENT_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_IIC_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_DSPI_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME.

Table continues on the next page...

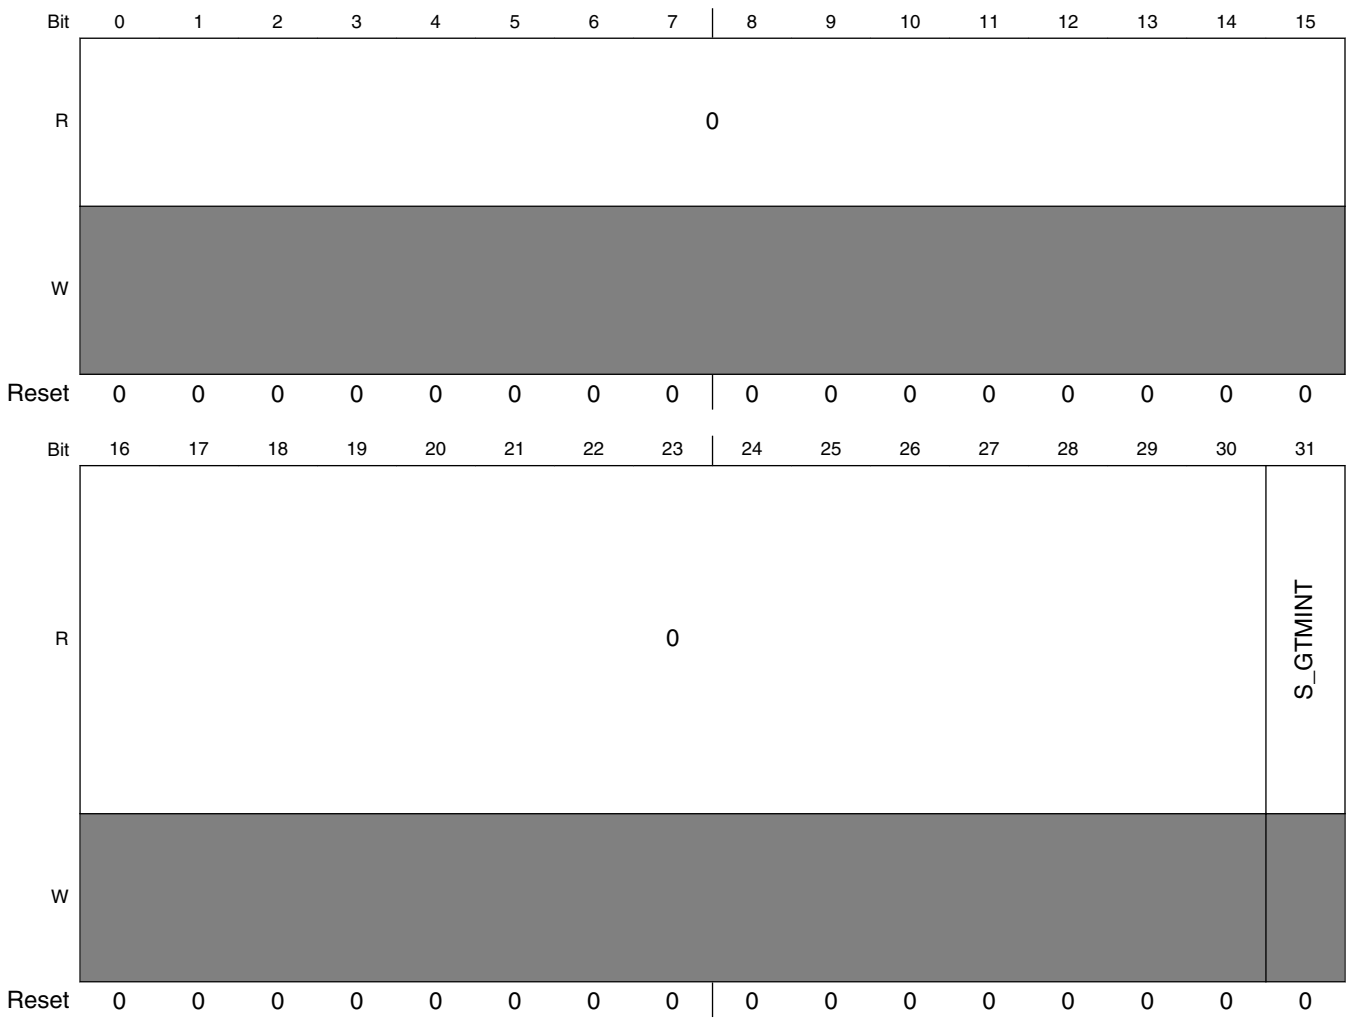
MC_ME_PS3 field descriptions (continued)

Field	Description
	0 Peripheral is frozen 1 Peripheral is active
29 S_DSPI_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
30 S_DSPI_4	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
31 S_DSPI_6	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active

65.3.22 Peripheral Status Register 4 (MC_ME_PS4)

This register provides the status of the peripherals.

Address: 0h base + 70h offset = 70h



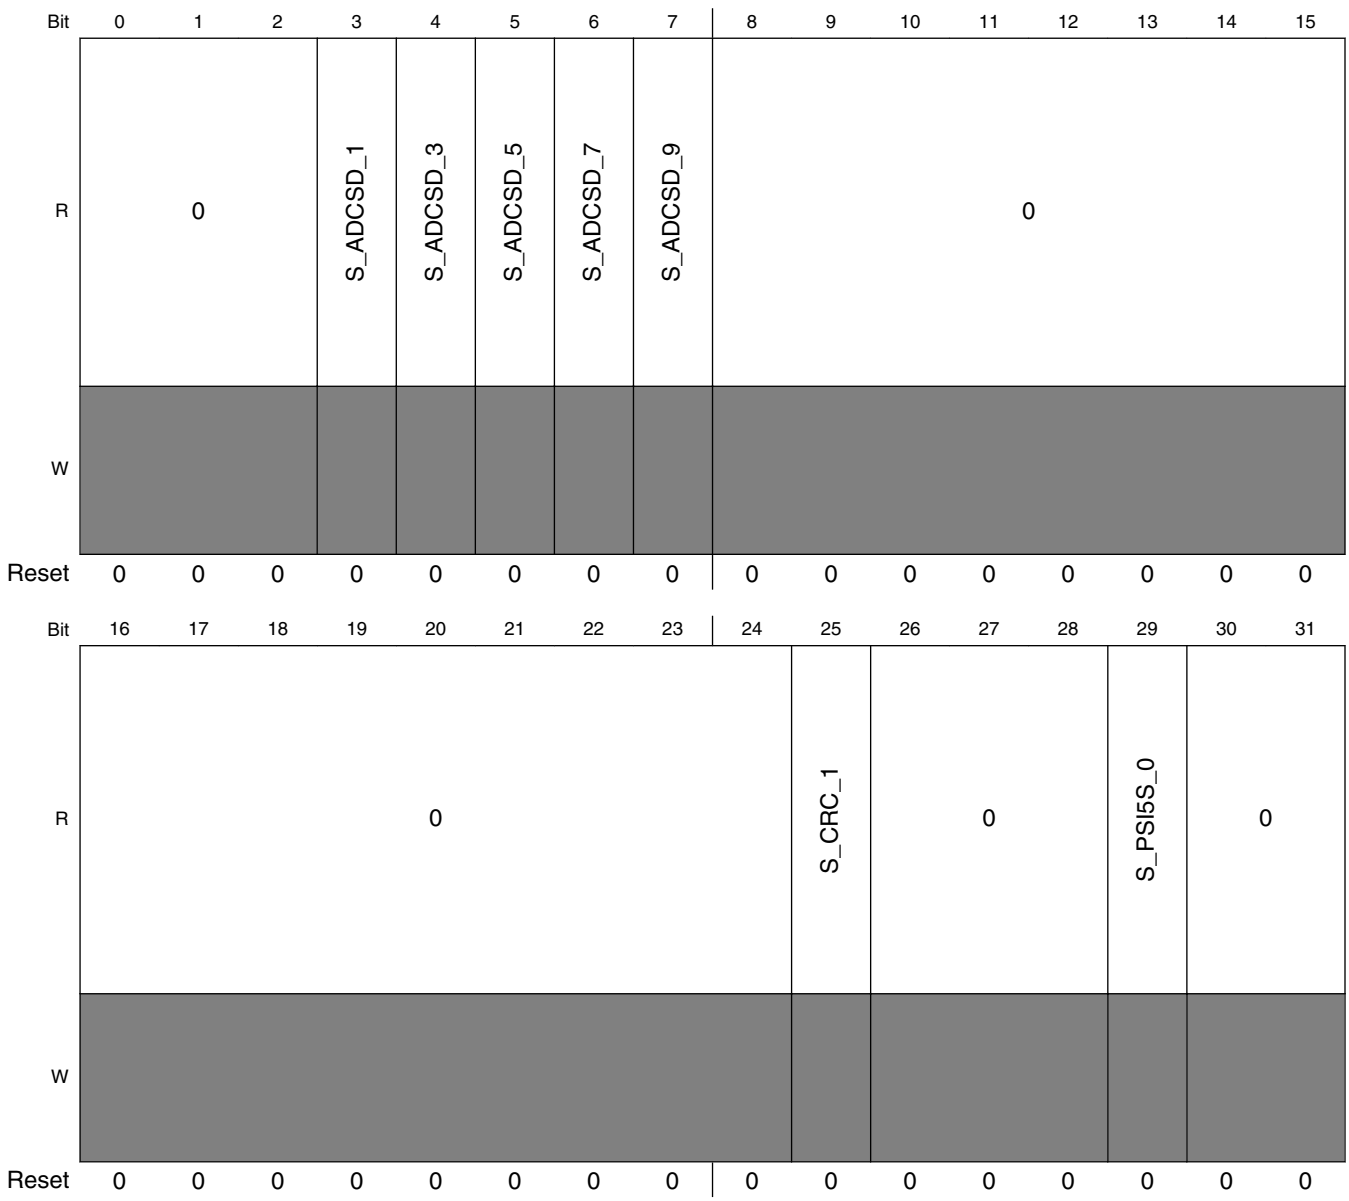
MC_ME_PS4 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 S_GTMINT	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active

65.3.23 Peripheral Status Register 5 (MC_ME_PS5)

This register provides the status of the peripherals.

Address: 0h base + 74h offset = 74h



MC_ME_PS5 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

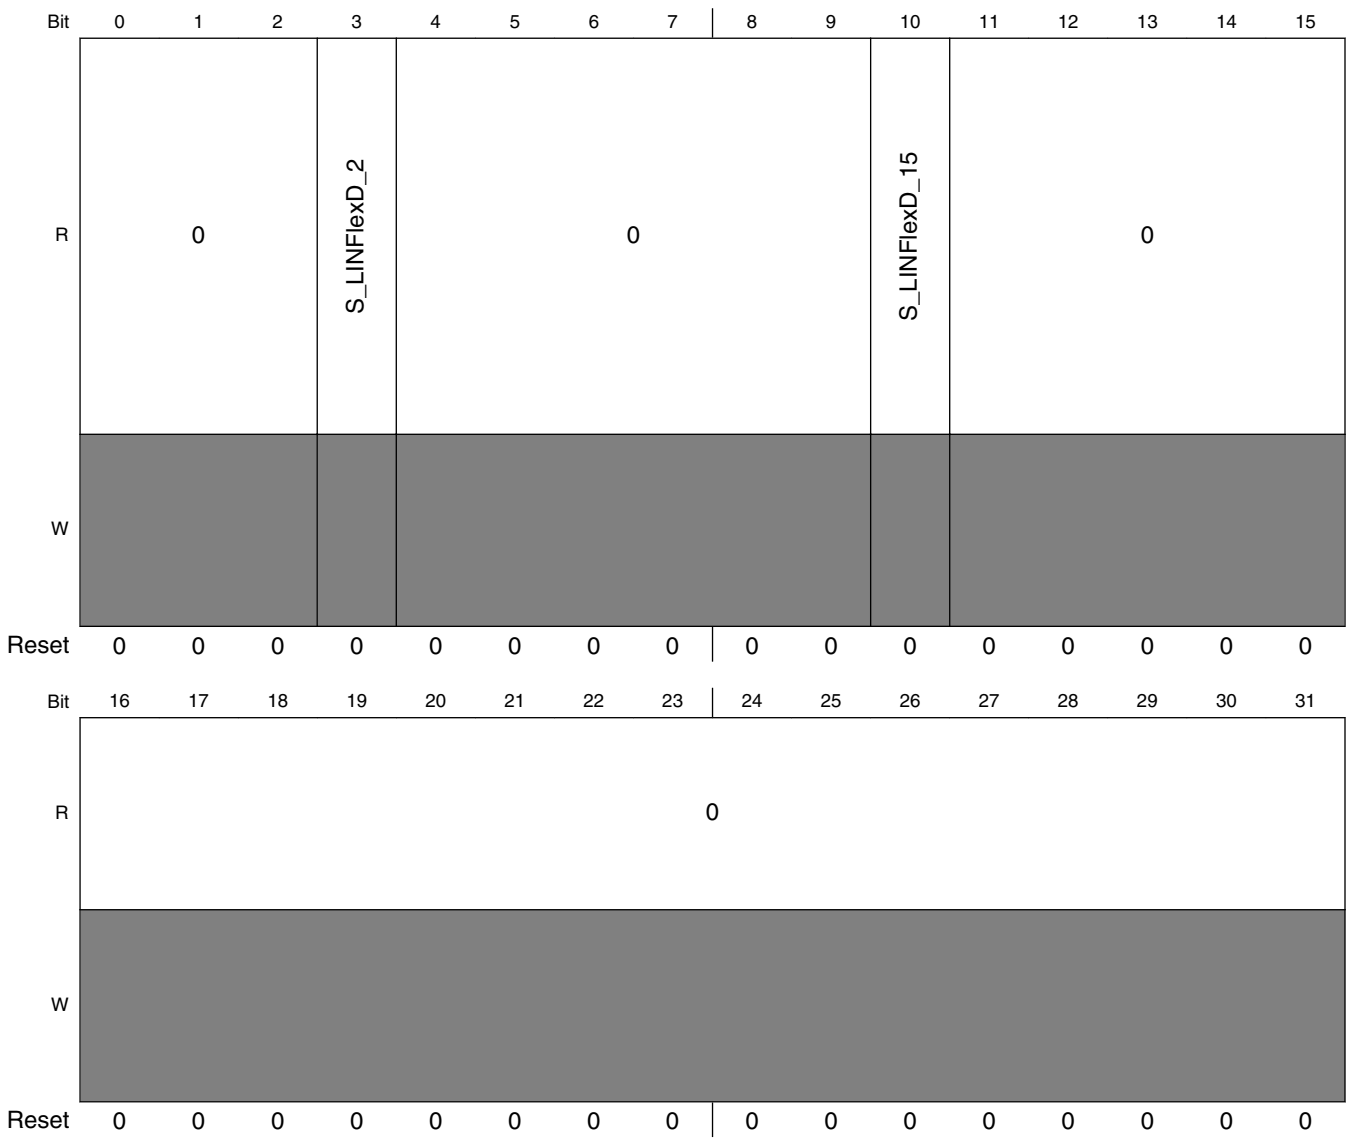
MC_ME_PS5 field descriptions (continued)

Field	Description
3 S_ADCSD_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
4 S_ADCSD_3	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
5 S_ADCSD_5	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
6 S_ADCSD_7	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
7 S_ADCSD_9	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
8–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 S_CRC_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
26–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 S_PSI5S_0	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.24 Peripheral Status Register 6 (MC_ME_PS6)

This register provides the status of the peripherals.

Address: 0h base + 78h offset = 78h



MC_ME_PS6 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 S_LINFlexD_2	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME.

Table continues on the next page...

MC_ME_PS6 field descriptions (continued)

Field	Description
	0 Peripheral is frozen 1 Peripheral is active
4–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 S_LINFlexD_15	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
11–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.25 Peripheral Status Register 7 (MC_ME_PS7)

This register provides the status of the peripherals.

Address: 0h base + 7Ch offset = 7Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MC_ME_PS7 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 S_ADCSAR_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
2 S_ADCSAR_2	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
3 S_ADCSAR_3	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 S_ADCSAR_5	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
6 S_ADCSAR_6	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
7 S_ADCSAR_7	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
8 S_ADCSAR_8	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
9 S_ADCSAR_9	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
10 S_ADCSAR_10	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active

Table continues on the next page...

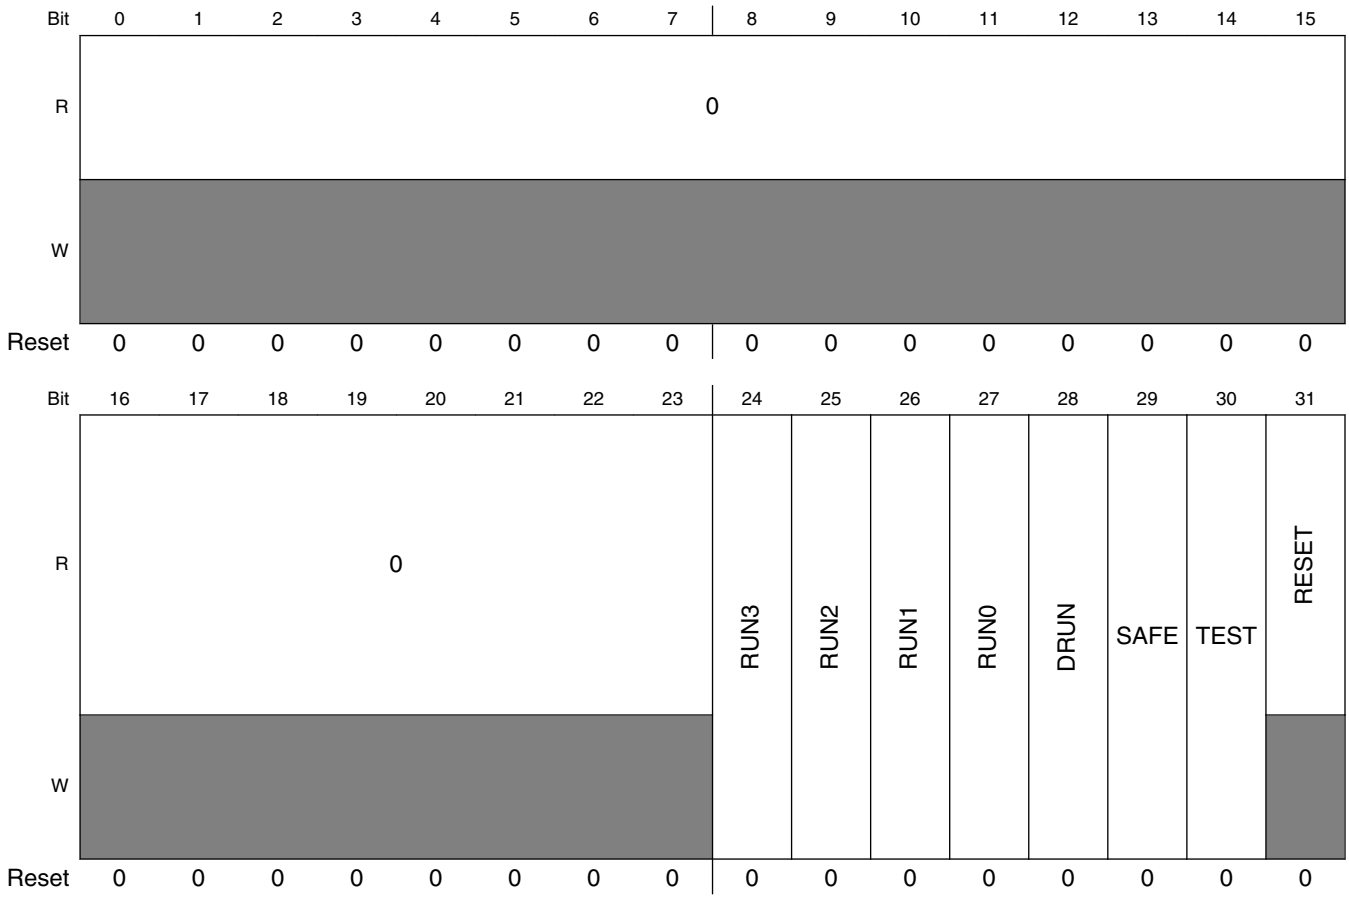
MC_ME_PS7 field descriptions (continued)

Field	Description
11–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 S_PSI5_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
17–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 S_FLEXRAY_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_SENT_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_IIC_1	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_DSPI_2	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
29 S_DSPI_3	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
30 S_DSPI_5	Peripheral status - These bits specify the current status of each peripheral which is controlled by the MC_ME. 0 Peripheral is frozen 1 Peripheral is active
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.26 Run Peripheral Configuration Register (MC_ME_RUN_PC*n*)

These registers configure eight different types of peripheral behavior during run modes.

Address: 0h base + 80h offset + (4d × i), where i=0d to 7d



MC_ME_RUN_PC*n* field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RUN3	Peripheral control during RUN3 0 Peripheral is frozen with clock gated 1 Peripheral is active
25 RUN2	Peripheral control during RUN2 0 Peripheral is frozen with clock gated 1 Peripheral is active
26 RUN1	Peripheral control during RUN1

Table continues on the next page...

MC_ME_RUN_PC*n* field descriptions (continued)

Field	Description
	0 Peripheral is frozen with clock gated 1 Peripheral is active
27 RUN0	Peripheral control during RUN0 0 Peripheral is frozen with clock gated 1 Peripheral is active
28 DRUN	Peripheral control during DRUN 0 Peripheral is frozen with clock gated 1 Peripheral is active
29 SAFE	Peripheral control during SAFE 0 Peripheral is frozen with clock gated 1 Peripheral is active
30 TEST	Peripheral control during TEST 0 Peripheral is frozen with clock gated 1 Peripheral is active
31 RESET	Peripheral control during RESET 0 Peripheral is frozen with clock gated 1 Peripheral is active

65.3.27 Low-Power Peripheral Configuration Register (MC_ME_LP_PC*n*)

These registers configure eight different types of peripheral behavior during non-run modes.

Address: 0h base + A0h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_ME_LP_PC*n* field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	Peripheral control during STOP0 0 Peripheral is frozen with clock gated 1 Peripheral is active
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HALT0	Peripheral control during HALT0 0 Peripheral is frozen with clock gated 1 Peripheral is active
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

65.3.28 EBI_0 Peripheral Control Register (MC_ME_PCTL3)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + C3h offset = C3h

Bit	0	1	2	3	4	5	6	7
Read	0	0	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL3 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0. 0 1
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration

Table continues on the next page...

MC_ME_PCTL3 field descriptions (continued)

Field	Description
	100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes - These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

65.3.29 LFAST_0 Peripheral Control Register (MC_ME_PCTL9)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + C9h offset = C9h

Bit	0	1	2	3	4	5	6	7
Read	0	0	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL9 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration

Table continues on the next page...

MC_ME_PCTL9 field descriptions (continued)

Field	Description
	110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes - These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

65.3.30 SIPI_0 Peripheral Control Register (MC_ME_PCTL11)

This register selects the configurations during run and non-run modes for the associated peripheral.

Address: 0h base + CBh offset = CBh

Bit	0	1	2	3	4	5	6	7
Read	0	0	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL11 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration

1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration 011 Selects ME_LP_PC3 configuration 100 Selects ME_LP_PC4 configuration 101 Selects ME_LP_PC5 configuration 110 Selects ME_LP_PC6 configuration 111 Selects ME_LP_PC7 configuration
5–7 RUN_CFG	Peripheral configuration select for run modes - These bits associate a configuration as defined in the ME_RUN_PC0…7 registers to the peripheral. 000 Selects ME_RUN_PC0 configuration 001 Selects ME_RUN_PC1 configuration 010 Selects ME_RUN_PC2 configuration 011 Selects ME_RUN_PC3 configuration 100 Selects ME_RUN_PC4 configuration 101 Selects ME_RUN_PC5 configuration 110 Selects ME_RUN_PC6 configuration 111 Selects ME_RUN_PC7 configuration

65.3.83 ADCSAR_7 Peripheral Control Register (MC_ME_PCTL248)

This register selects the configurations during run and non-run modes for the associated peripheral.

NOTE

After modifying any of the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers, software must request a mode change and wait for the mode change to be completed before entering debug mode in order to have consistent behavior between the peripheral clock control process and the clock status reporting in the ME_PSn registers.

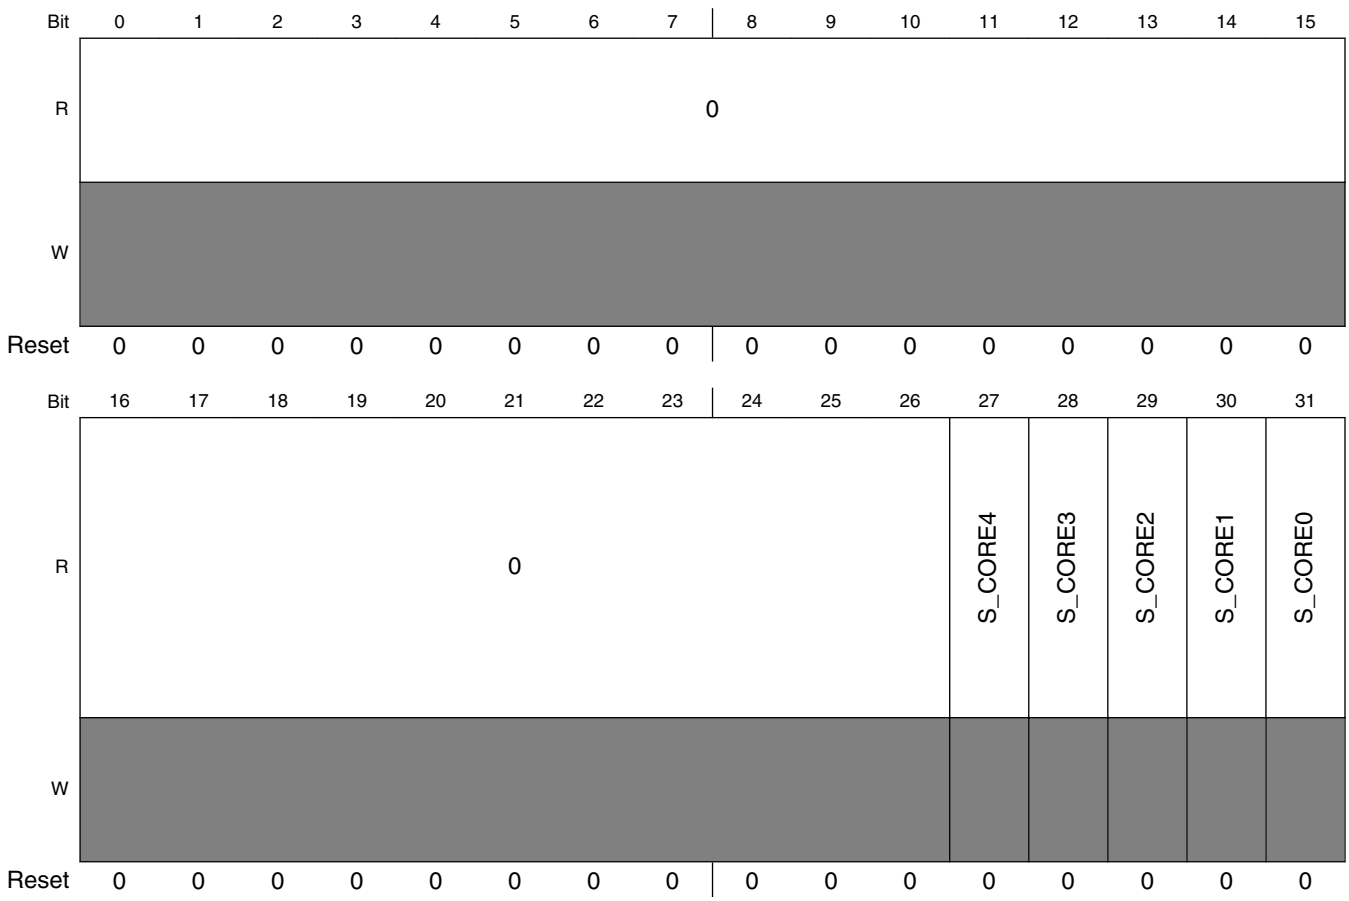
65.3.89 Core Status Register (MC_ME_CS)

This register provides the status of each core.

Address: 0h base + 1C0h offset = 1C0h



MC_ME_CS field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 S_CORE4	Core 4 status - This bits specifies the current status of the HSM which is controlled by the ME_CCTL4 register. 0 the HSM is disabled 1 the HSM is running
28 S_CORE3	Core 3 status - This bits specifies the current status of main core_1 which is controlled by the ME_CCTL3 register. 0 main core_1 is disabled 1 main core_1 is running

Table continues on the next page...

MC_ME_CS field descriptions (continued)

Field	Description
29 S_CORE2	Core 2 status - This bits specifies the current status of checker core_0s which is controlled by the ME_CCTL2 register. 0 checker core_0s is disabled 1 checker core_0s is running
30 S_CORE1	Core 1 status - This bits specifies the current status of main core_0 which is controlled by the ME_CCTL1 register. 0 main core_0 is disabled 1 main core_0 is running
31 S_CORE0	Core 0 status - This bits specifies the current status of peripheral core_2 which is controlled by the ME_CCTL0 register. 0 peripheral core_2 is disabled 1 peripheral core_2 is running

65.3.90 CORE0 Core Control Register (MC_ME_CCTL0)

This register controls whether peripheral core_2 is disabled or running during run modes.

This register cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1'). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

Address: 0h base + 1C4h offset = 1C4h

Bit	0	1	2	3	4	5	6	7
Read	0					STOP0	0	HALT0

13 SAFE	Core control during SAFE 0 peripheral core_2 is frozen with clock gated 1 peripheral core_2 is running
14 TEST	Core control during TEST 0 peripheral core_2 is frozen with clock gated 1 peripheral core_2 is running
15 RESET	Core control during RESET - peripheral core_2 is always disabled during RESET.

65.3.91 CORE1 Core Control Register (MC_ME_CCTL1)

This register controls whether main core_0 is disabled or running during run modes.

This register cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1'). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

NOTE

It is possible to turn off Master Core in any RUN mode transition. It is software responsibility that at least 1 core should be on in that RUN mode and all software routines are configured, such that all requests to the master core are now routed to new assigned master core.

Address: 0h base + 1C6h offset = 1C6h

7 HALT0	Core control during HALT0 - the HSM is always disabled during HALT0.
8 RUN3	Core control during RUN3 0 the HSM is disabled with clock gated 1 the HSM is running
9 RUN2	Core control during RUN2 0 the HSM is disabled with clock gated 1 the HSM is running

Table continues on the next page...

MC_ME_CCTL4 field descriptions (continued)

Field	Description
10 RUN1	Core control during RUN1 0 the HSM is disabled with clock gated 1 the HSM is running
11 RUN0	Core control during RUN0 0 the HSM is frozen with clock gated 1 the HSM is running
12 DRUN	Core control during DRUN 0 the HSM is frozen with clock gated 1 the HSM is running
13 SAFE	Core control during SAFE 0 the HSM is frozen with clock gated 1 the HSM is running
14 TEST	Core control during TEST 0 the HSM is frozen with clock gated 1 the HSM is running
15 RESET	Core control during RESET - the HSM is always disabled during RESET.

65.3.95 CORE0 Core Address Register (MC_ME_CADDR0)

This registers gives the boot address for peripheral core_2 and a bit for controlling whether peripheral core_2 is to be reset on the next mode change that has peripheral core_2 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1').

NOTE

The reset value of the ADDR field of the ME_CADDR0 is determined by the chip configuration and boot mode.

Address: 0h base + 1E0h offset = 1E0h

MC_ME_CADDR1 field descriptions

Field	Description
0–29 ADDR	Core Address - This field is used by main core_0 as the boot address (32-bit word aligned) when main core_0 next exits reset.

Table continues on the next page...

MC_ME_CADDR1 field descriptions (continued)

Field	Description
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change - main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode. 0 main core_0 will not be reset on the next mode change 1 main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode

65.3.97 CORE2 Core Address Register (MC_ME_CADDR2)

This registers contains a bit for controlling whether checker core_0s is to be reset on the next mode change that has checker core_0s configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1').

Address: 0h base + 1E8h offset = 1E8h

MC_ME_CADDR2 field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change — checker core_0s will be reset on the next mode change that has checker core_0s configured to be running in the target mode. 0 checker core_0s will not be reset on the next mode change 1 checker core_0s will be reset on the next mode change that has checker core_0s configured to be running in the target mode

65.3.98 CORE3 Core Address Register (MC_ME_CADDR3)

This registers gives the boot address for main core_1 and a bit for controlling whether main core_1 is to be reset on the next mode change that has main core_1 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1').

Address: 0h base + 1ECh offset = 1ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MC_ME_CADDR3 field descriptions

Field	Description
0–29 ADDR	Core Address - This field is used by main core_1 as the boot address (32-bit word aligned) when main core_1 next exits reset.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RMC	Reset on Mode Change - main core_1 will be reset on the next mode change that has main core_1 configured to be running in the target mode. 0 main core_1 will not be reset on the next mode change 1 main core_1 will be reset on the next mode change that has main core_1 configured to be running in the target mode

65.3.99 CORE4 Core Address Register (MC_ME_CADDR4)

This registers gives the boot address for the HSM and a bit for controlling whether the HSM is to be reset on the next mode change that has the HSM configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1').

NOTE

The reset value of the ADDR field of the ME_CADDR4 is determined by the chip configuration.

NOTE

Before setting the RMC bit and issuing a Mode Change to reset the HSM Core, make sure that all the HSM-HOST Bridge registers, on the HOST side are moved to the RESET state.

Address: 0h base + 1F0h offset = 1F0h

65.4 Functional description

65.4.1 Mode transition request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register.The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to Mode transition interrupts.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as RUN0…3 → RUN0…3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set until the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note

It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0 or STOP0 modes.

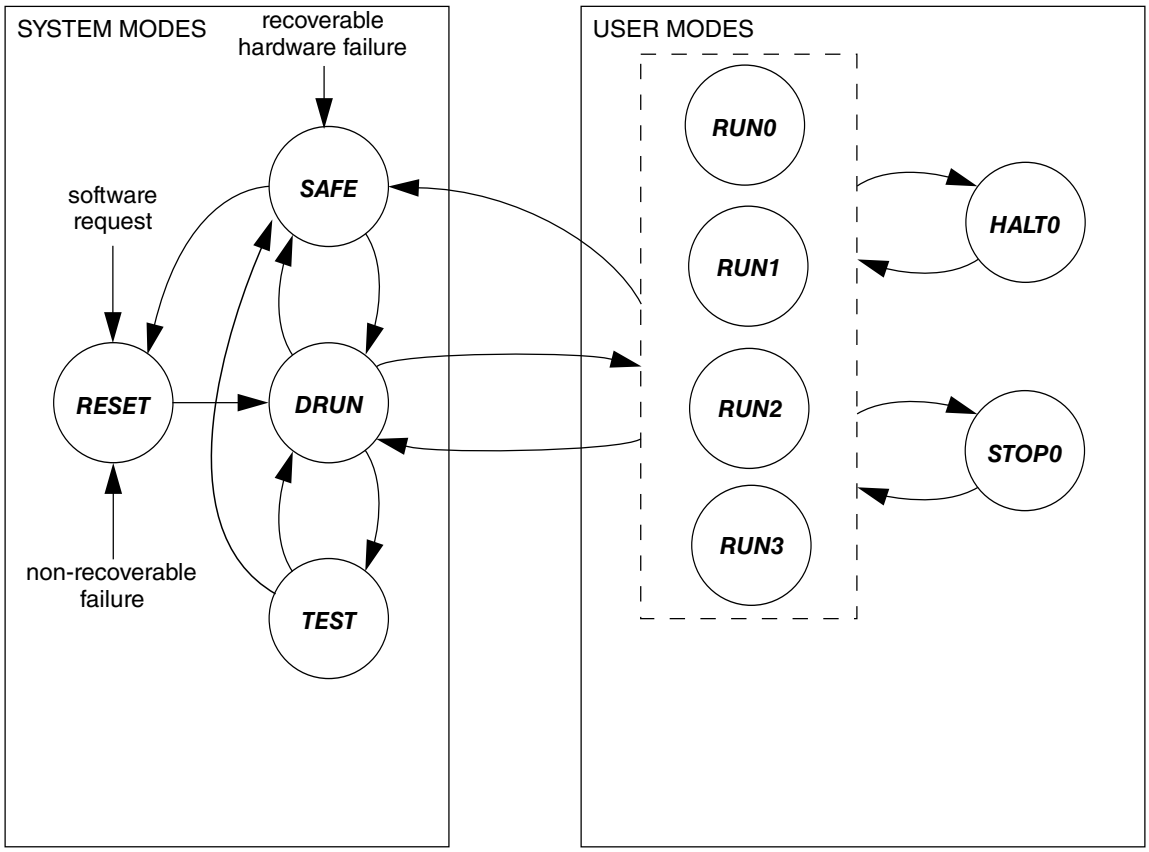

Figure 65-2. MC_ME Mode Diagram

65.4.2 Modes details

65.4.2.1 RESET Mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0…3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

65.4.2.2 DRUN Mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0…3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0011"

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.3 SAFE Mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with "0010"
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see the Reset Generation Module (MC_RGM) chapter for details)

Note

If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note

If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged.

65.4.2.4 TEST Mode

The chip enters this mode on the following events:

- from the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0001"

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to "1111", and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.5 RUN0…3 Modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0…3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0100…0111"
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0…3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0…3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

65.4.2.6 HALT0 Mode

The chip enters this mode on the following events:

- from one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1000".

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (i.e., within a few system clock cycles of an interrupt event)

Note

It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0…3 mode configuration has been fully restored before executing critical code.

65.4.2.7 STOP0 Mode

The chip enters this mode on the following events:

- from one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1010".

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the primary PLL
- the secondary PLL

The flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the ***STOP0*** mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note

It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0…3 mode configuration has been fully restored before executing critical code.

65.4.3 Mode transition process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

65.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to Mode transition interrupts for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

65.4.3.2 Target mode configuration loading

On completion of the Target mode request step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in . A '√' indicates that a given resource is configurable for a given mode.

Table 65-2. MC_ME Resource Control Overview (continued)

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0…3	HALT0	STOP0
IRC	on	√ on	on	on	on	on	on
XOSC	off	√ off	off	√ off	√ off	√ off	√ off
PLL0	off	√ off	off	√ off	√ off	√ off	off
PLL1	off	√ off	off	√ off	√ off	√ off	√ off
FLASH	normal	√ normal	normal	√ normal	√ normal	√ low-power	√ power-down
MVREG	on	on	on	on	on	on	on
PDO	off	√ off	√ on	off	off	off	√ off

65.4.3.3 Peripheral clocks disable

On completion of the Target mode request step and the system clock frequency ramp-down of the System clock switching step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0…7 and ME_LP_PC0…7, and the peripheral control registers ME_PCTLn

Note

The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to Peripheral clock gating for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

65.4.3.4 Processor low-power mode entry

If, on completion of the Peripheral clocks disable step, the mode transition is to the HALT0,STOP0 mode, the MC_ME requests each processor to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the Peripheral clocks disable step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC_ME requests each processor which is configured in the ME_CCTLn registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

65.4.3.5 Processor Clocks Disable

If, on completion of the Processor low-power mode entry step, and all processors which are configured in the ME_CCTLn registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

warning

Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

65.4.3.6 System clock disable

If, on completion of the Processor Clocks Disable step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

65.4.3.7 Clock sources switch-on

On completion of the Processor low-power mode entry step, the MC_ME switches on all clock sources based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

65.4.3.8 Flash module switch-on

On completion of the step, if the flash needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the flash to exit from its low-power/power-down mode. When the flash is available for access, the S_FLA bit field of the ME_GS register is updated to "11" by hardware.

warning

It is illegal to switch the FLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

65.4.3.9 Pad outputs-on

On completion of the step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- the slew rate control mechanism is switched on

65.4.3.10 Peripheral clocks enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0…7, ME_LP_PC0…7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. This step is executed only after the process is completed, and if the value of the PWRLVL field of the ME_<target mode>_MC register is process is completed.

65.4.3.11 System and processor clocks enable

On completion of the Flash module switch-on step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTLn registers to be running in the target mode and which have their RMC bits in the ME_CADDRn registers set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the MW_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the System clock switching process is completed.

65.4.3.12 Processor low-power mode exit

On completion of the System and processor clocks enable step, the MC_ME requests all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

65.4.3.13 System clock switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the external crystal osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (i.e., the external crystal oscillator has stabilized).
- The target clock configuration for the secondary PLL takes effect only after the S_PLL0 bit of the ME_GS register is set by hardware (i.e., the primary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with "1111". This is possible only in the TEST mode.

If the value of the PWRLVL field of the ME_<target mode>_MC register not equal to that of the ME_<current mode>_MC register's, a progressive clock switching is performed.

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the Clock sources switch-on process has completed if the target system clock source is one of the following:
  - the 16 MHz internal RC oscillator

- the external crystal oscillator
- the primary PLL

- the Peripheral clocks disable process has completed in order not to change the system clock frequency before peripherals close their internal activitiesthe Peripheral clocks enable process has completed

An overview of system clock source selection possibilities for each mode is shown in the following table. A '√' indicates that a given clock source is selectable for a given mode.

Table 65-3. MC_ME System Clock Selection Overview

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
16 MHz int. RC osc.	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)
external crystal osc.		√		√	√	√	√
primary PLL (PHI)		√		√	√	√	√
secondary PLL		√		√	√		
system clock is disabled		√[1]					

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

65.4.3.14 Pad switch-off

If the PDO bit of the ME_<target mode>_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the Peripheral clocks disable process has completed.

65.4.3.15 Clock sources switch-off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources switched off at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the System clock switching process has completed.

- the 16 MHz internal RC oscillator

65.4.3.16 Flash switch-off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the flash is to be put in its low-power or power-down mode, the MC_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the Processor Clocks Disable and System clock disable processes have completed.

65.4.3.17 Current mode update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :

- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

Note

SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

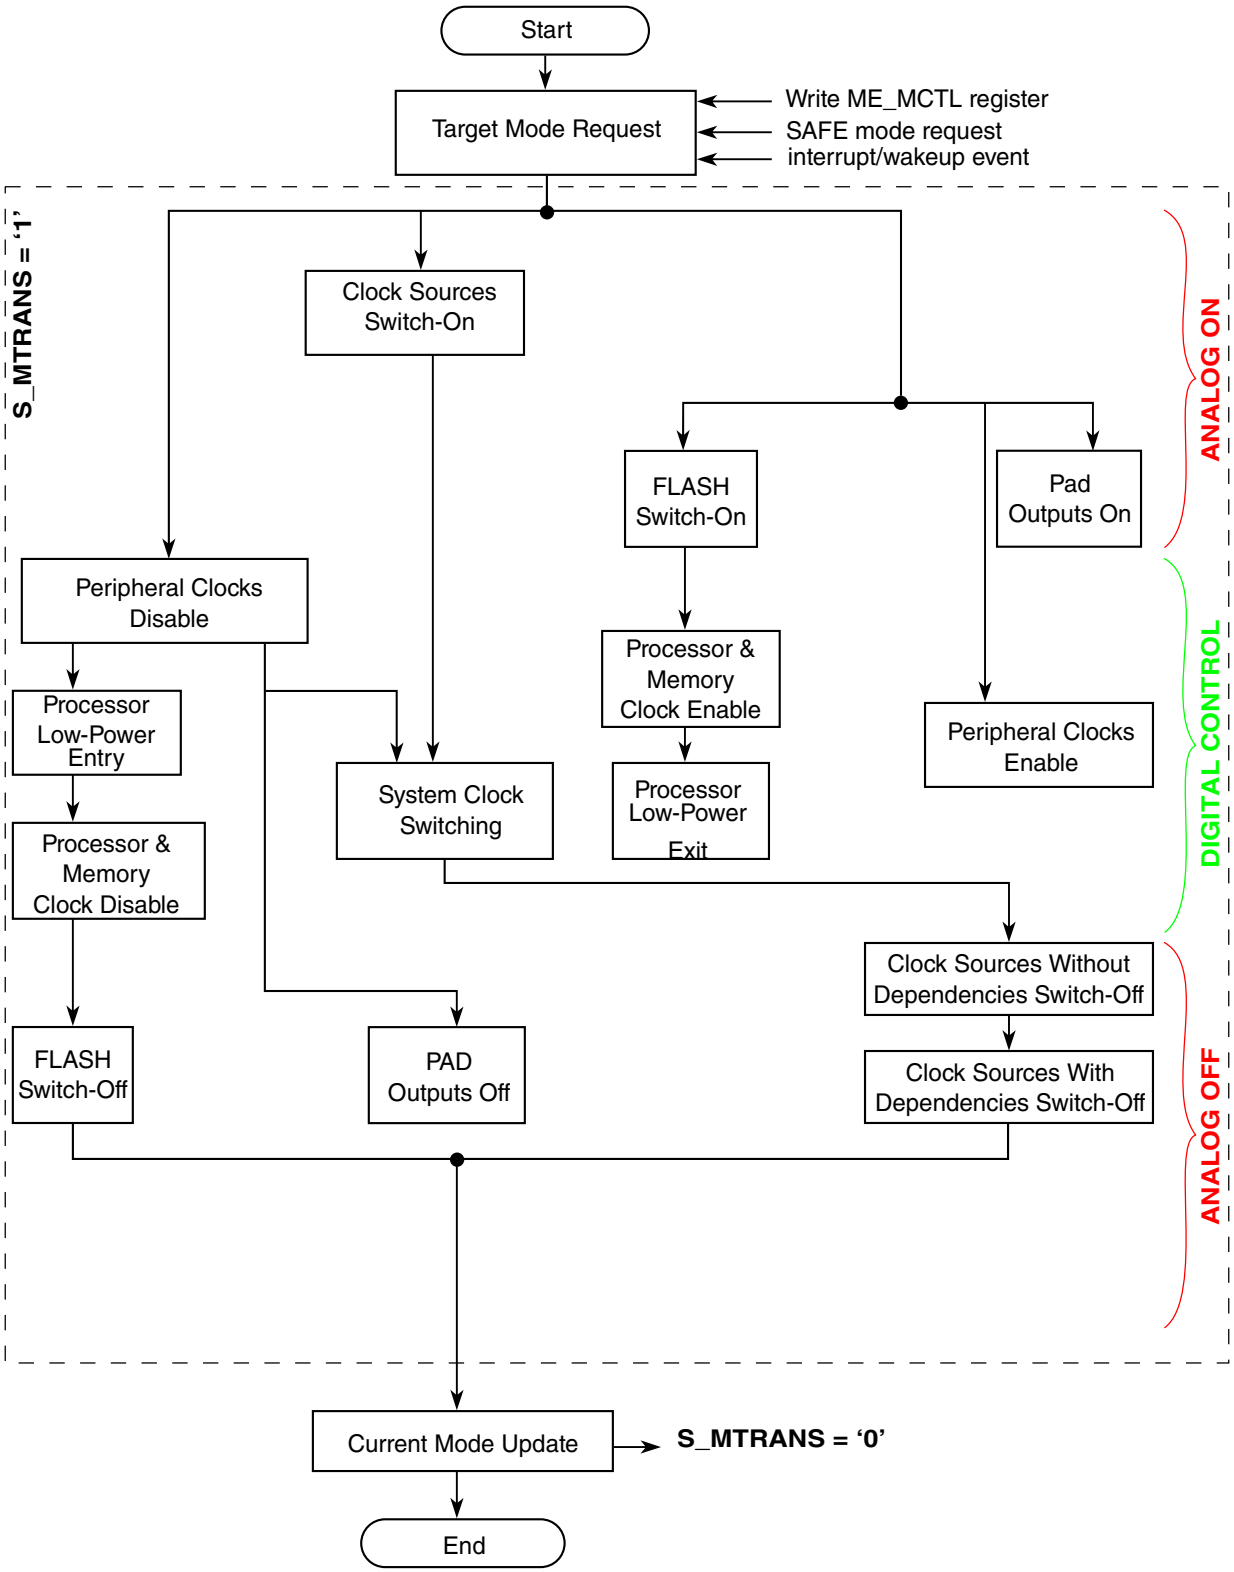

Figure 65-3. MC_ME Transition Diagram

65.4.4 Protection of mode configuration registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz int. RC osc. is selected as the system clock, IRC must be on.
- If the external crystal osc. clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note

Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration "00" for the FLAON bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration "1111" for the SYSCLK bit field is allowed only for theTEST mode, and only in this case may all system clock sources be turned off.

warning

If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

65.4.5 Mode transition interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

65.4.5.1 Invalid mode configuration interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in the Protection of mode configuration registers, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is '1'.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0…7/ME_LP_PC0…7 and ME_PCTLn registers, the interrupt pending bit I_ICONF_CU of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CU of the ME_IM register is '1'.

If an attempt to write to one of the ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_MCTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is '1'.

65.4.5.2 Invalid mode transition interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.
- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.

- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition is in progress (the S_MTRANS bit of the ME_GS register is '1'), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note

As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0…3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.
- Self-transition requests (e.g., RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (i.e., S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0…3 mode properly (i.e., all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'.

65.4.5.3 SAFE mode transition interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1' .

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (i.e., programming of ME_MCTL register).

65.4.5.4 Mode transition complete interrupt

Whenever the system fully completes a mode transition (i.e., the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

65.4.6 Peripheral clock gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0…7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0…3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTLn registers.

The low-power peripheral configuration registers ME_LP_PC0…7 are chosen only during the low-power modes HALT0 and STOP0. All configurations are programmable by software according to the needs of the application. Each configuration register

contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTLn registers.

Any modifications to the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTLn register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits.

65.4.7 Application example

The following figure shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

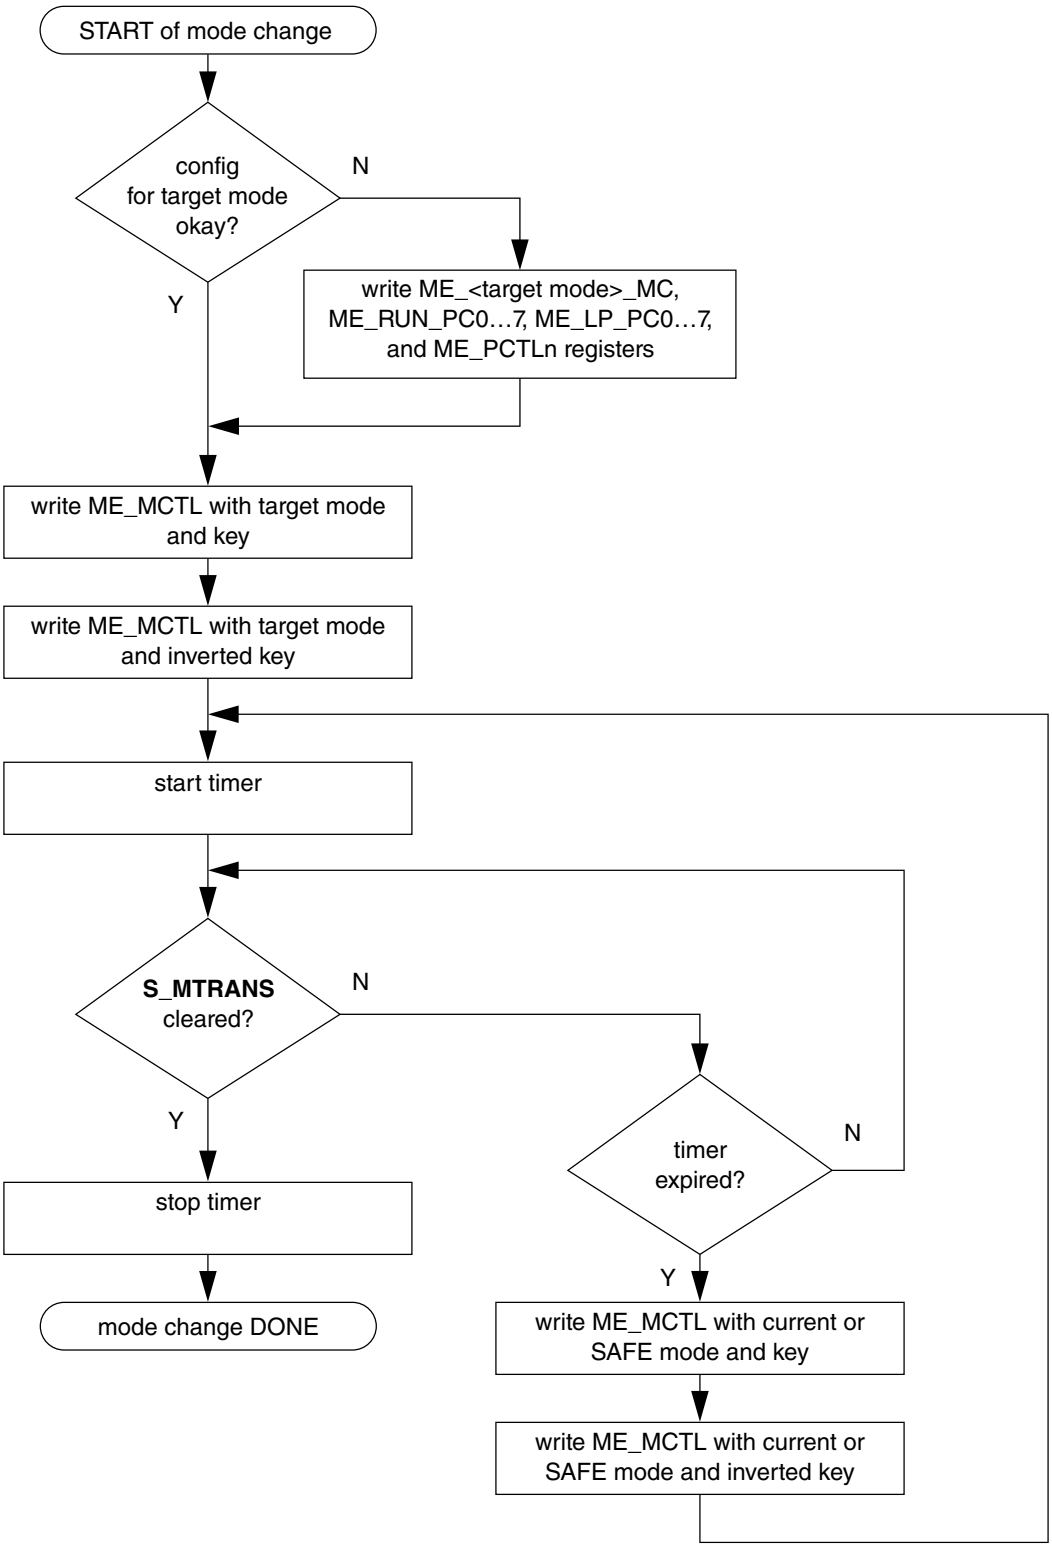

Figure 65-4. MC_ME Application Example Flow Diagram

Chapter 66
Core Debug Support

66.1 Overview

Internal debug support in the e200z425Bn3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z425Bn3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z425Bn3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

66.1.1 Software Debug Facilities

e200z425Bn3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

66.1.1.1 *PowerISA 2.06* Compatibility

The e200z425Bn3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

66.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z425Bn3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

66.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z425Bn3 core. This port provides information corresponding to each read or write access

completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z425Bn3) Nexus 3 Module chapter. The data trace port will report aligned accesses, and most misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0. Also, for accesses generated by a LSP load/store instruction using circular addressing mode which crosses a buffer boundary, the two portions of the misaligned access will be reported separately, since otherwise it is not possible to correctly correlate the data with the initial access address.

66.1.3 Hardware Debug Facilities

The e200z425Bn3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z425Bn3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

66.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

66.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z425Bn3 debug resources.

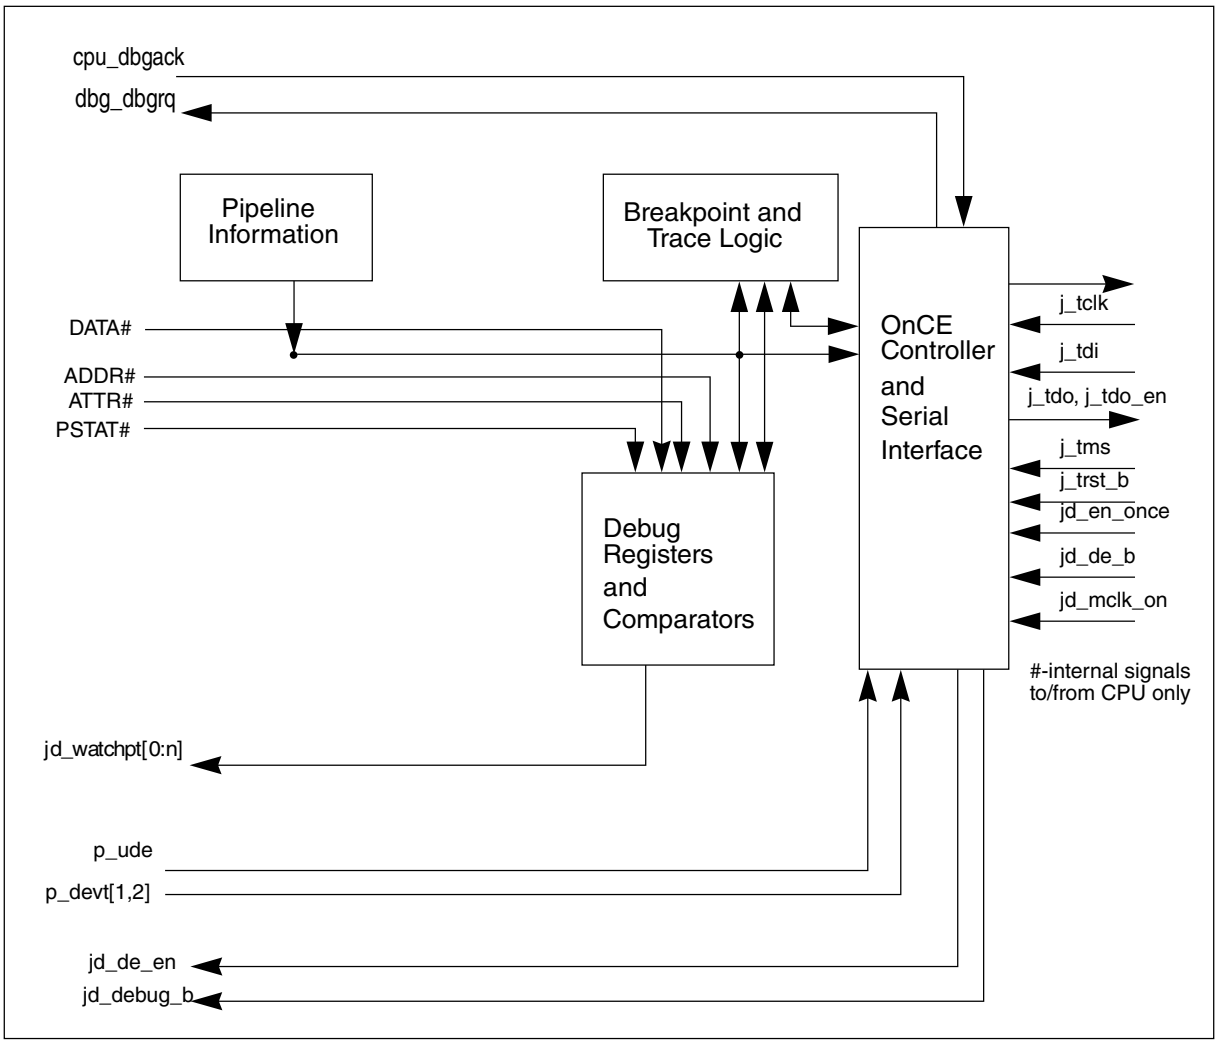

Figure 66-1. e200z425Bn3 Debug Resources

66.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z425Bn3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z425Bn3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

66.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

66.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load or store operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *PowerISA 2.06* definition, Data Address Compare events on e200z425Bn3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC\_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer

however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

66.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC\_OFST}$ field when the DVC DAC status is recorded.

Table 66-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in Table 66-1, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 66-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

Table continues on the next page...

Table 66-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 66-2 through Table 66-5 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 66-2. DAC events and Resultant Updates, Dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.

Table continues on the next page...

Table 66-2. DAC events and Resultant Updates, Dual-issue case 1 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5):	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

66.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

66.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

66.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

66.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

66.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

66.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

66.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

66.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

66.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

66.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

66.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

66.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

66.3.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z425Bn3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

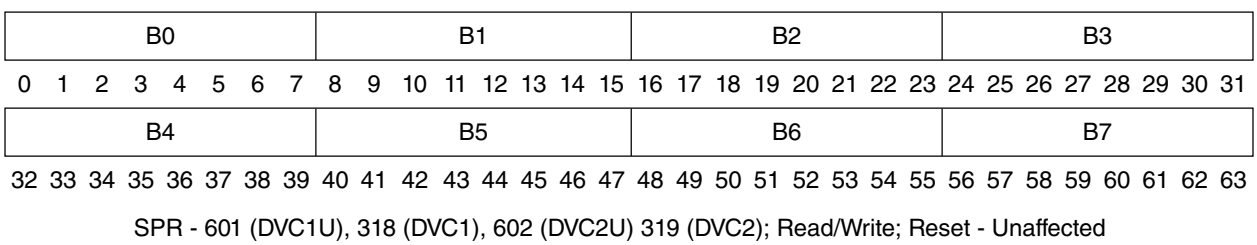

Figure 66-2. DVC1, DVC2 registers

66.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z425Bn3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

66.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z425Bn3 adds some implementation specific bits to this register, as seen in the following figure.

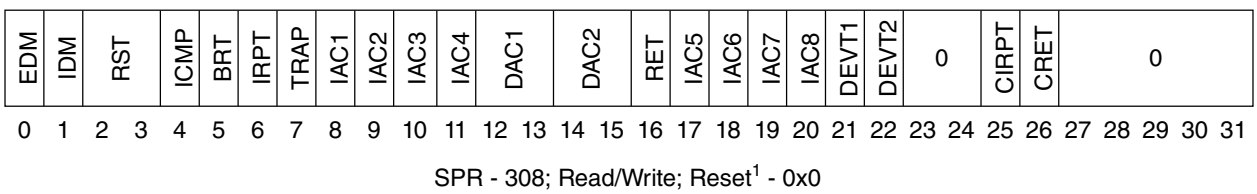

Figure 66-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 66-6. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled

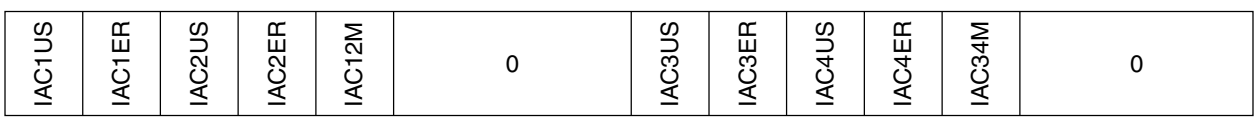
66.3.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.



SPR - 309; Read/Write; Reset[1] - 0x0

Figure 66-4. DBCR1 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 1.

Table 66-7. DBCR1 field descriptions

Bit	Name	Description

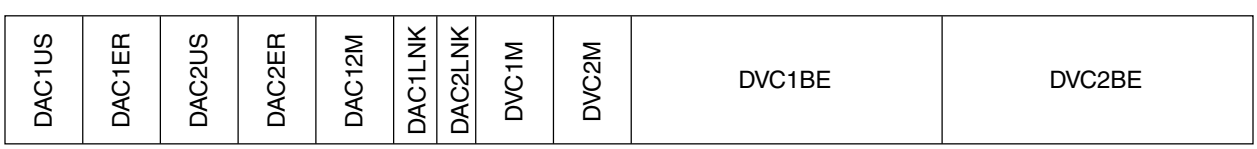
66.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.



SPR - 310; Read/Write; Reset[1] - 0x0

Figure 66-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 66-8. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table continues on the next page...

Table 66-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access.

Table continues on the next page...

Table 66-8. DBCR2 Bit Definitions (continued)

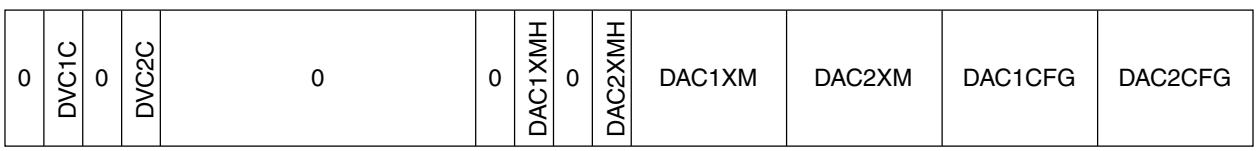
Bit	Name	Description
		10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2.

Table 66-8. DBCR2 Bit Definitions

Bit	Name	Description
		xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

66.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.



SPR - 563; Read/Write; Reset[1] - 0x0

Figure 66-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 66-9. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation.

Table continues on the next page...

Table 66-9. DBCR4 field description (continued)

Bit	Name	Description
		1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 - DAC1XM masks 0–15 low-order address bits 1 - DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint).

Table continues on the next page...

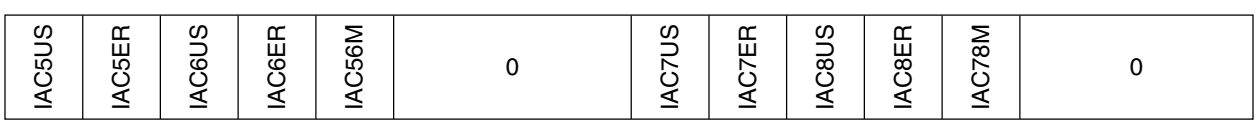
Table 66-9. DBCR4 field description (continued)

Bit	Name	Description
		NOTE: unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

66.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.



SPR - 564; Read/Write; Reset[1] - 0x0

Figure 66-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 66-10. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)

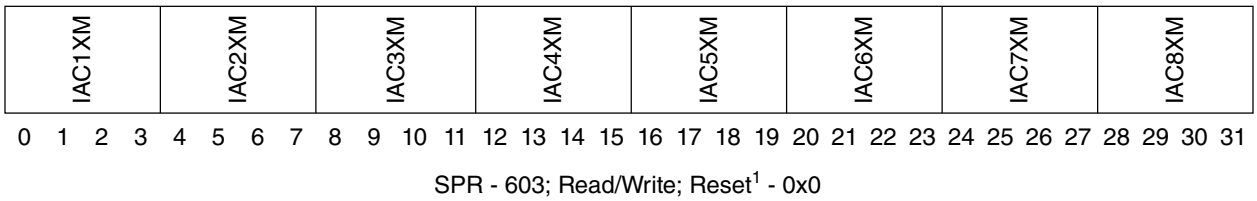
18:19	IAC7ER	Instruction Address Compare 7 Effective/Real Mode 00 IAC7 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC7 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC7 debug events are based on effective address and can only occur if MSR_{IS}=1
20:21	IAC8US	Instruction Address Compare 8 User/Supervisor Mode 00 IAC8 debug events not affected by MSR_{PR} 01 Reserved 10 IAC8 debug events can only occur if MSR_{PR}=0 (Supervisor mode). 11 IAC8 debug events can only occur if MSR_{PR}=1. (User mode)
22:23	IAC8ER	Instruction Address Compare 8 Effective/Real Mode 00 IAC8 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC8 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC8 debug events are based on effective address and can only occur if MSR_{IS}=1
24:25	IAC78M	Instruction Address Compare 7/8 Mode 00 Exact address compare. IAC7 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC7. IAC8 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC8. 01 Address bit match. IAC7 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC8 are equal to the contents of IAC7, also ANDed with the contents of IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used. 10 Inclusive address range compare. IAC7 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC7 and less than the value specified in IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used. 11 Exclusive address range compare. IAC7 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC7 or is greater than or equal to the value specified in IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used.
26:31	—	Reserved

66.3.2.6 Debug Control Register 6 (DBCR6)

Debug Control Register 6 is used to extend instruction address compare matching functionality. DBCR6 is shown in the following figure.



SPR - 603; Read/Write; Reset[1] - 0x0

Figure 66-8. DBCR6 Register

Note

[1] DBCR6 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 6.

Table 66-11. DBCR6 field descriptions

Bit	Name	Description
0:3	IAC1XM	Instruction Address Compare 1 Extended Mask Control. IAC1XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC1 when comparing the storage address with the value in IAC1 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
4:7	IAC2XM	Instruction Address Compare 2 Extended Mask Control. IAC2XM allows for binary power of 2 address range compares for IAC2 without requiring the use of IAC1. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC2 when comparing the storage address with the value in IAC2 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
8:11	IAC3XM	Instruction Address Compare 3 Extended Mask Control. IAC3XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC3 when comparing the storage address with the value in IAC3 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
12:15	IAC4XM	Instruction Address Compare 4 Extended Mask Controll. IAC4XM allows for binary power of 2 address range compares for IAC4 without requiring the use of IAC3. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC4 when comparing the storage address with the value in IAC4 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported.

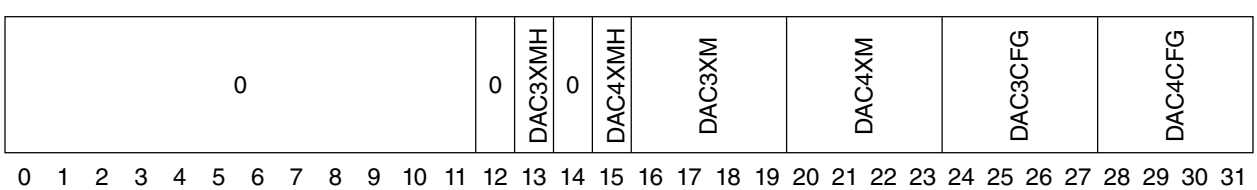
Table 66-11. DBCR6 field descriptions (continued)

Bit	Name	Description
		1101 - 1111 Reserved
16:19	IAC5XM	Instruction Address Compare 5 Extended Mask Control. IAC5XM allows for binary power of 2 address range compares for IAC5 without requiring the use of IAC6. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC5 when comparing the storage address with the value in IAC5 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
20:23	IAC6XM	Instruction Address Compare 6 Extended Mask Control. IAC6XM allows for binary power of 2 address range compares for IAC6 without requiring the use of IAC5. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC6 when comparing the storage address with the value in IAC6 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
24:27	IAC7XM	Instruction Address Compare 7 Extended Mask Control. IAC7XM allows for binary power of 2 address range compares for IAC7 without requiring the use of IAC8. 0000 No additional masking when DBCR5[IAC78M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC7 when comparing the storage address with the value in IAC7 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
28:31	IAC8XM	Instruction Address Compare 8 Extended Mask Control. IAC8XM allows for binary power of 2 address range compares for IAC8 without requiring the use of IAC7. 0000 No additional masking when DBCR5[IAC78M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC8 when comparing the storage address with the value in IAC8 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved

66.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.



SPR - 596; Read/Write; Reset[1] - 0x0

Figure 66-9. DBCR7 Register

Note

[1] DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 7.

Table 66-12. DBCR7 Field Descriptions

Bit	Name	Description
0:12	—	Reserved
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High .DAC3XMH extends the range of the DAC3XM field 0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. . DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses

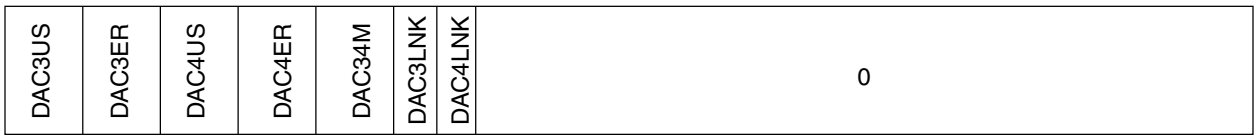
Table continues on the next page...

Table 66-12. DBCR7 Field Descriptions (continued)

Bit	Name	Description
		0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

66.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.



SPR - 597; Read/Write; Reset[1] - 0x0

Figure 66-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 66-13. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0

Table continues on the next page...

Table 66-13. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

66.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no

effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

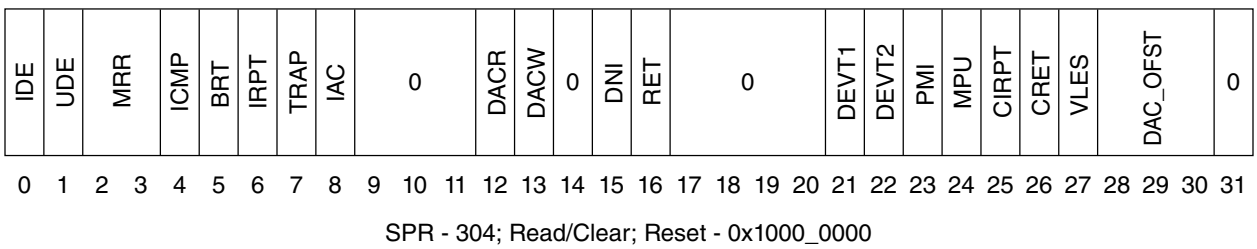


Figure 66-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 66-14. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event

Table continues on the next page...

Table 66-14. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

66.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load or store operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

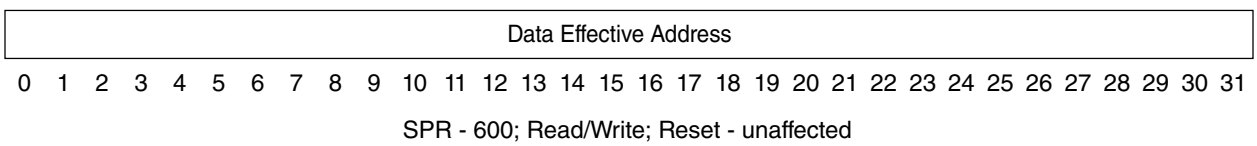

Figure 66-12. DDEAR Register

66.3.3 External Debug Resource Allocation Control Register (EDBRAC0)
