The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

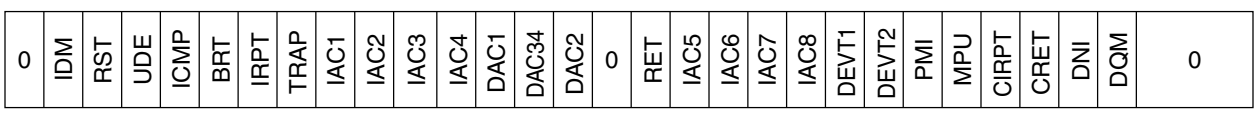
The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.



SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 66-13. EDBRAC0 Register

Table 66-14 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 66-15. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.

Table continues on the next page...

Table 66-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields.

Table continues on the next page...

Table 66-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event

Table continues on the next page...

Table 66-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 - Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 - Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** this bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 66-16 shows which resources are controlled by EDBRAC0 settings.

1	-[1]	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	1	$DEVENT_{DQTAG}$, DDAM

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 66-16 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

66.3.4 Debug Event Select Register (DEVENT)

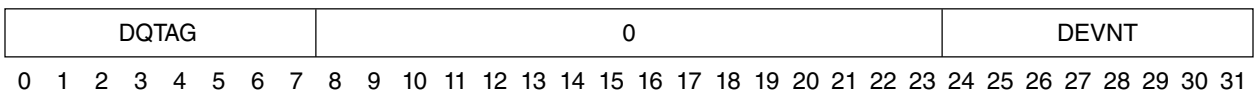
The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has

occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z425Bn3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.



SPR - 975; Reset[1] - 0x0

Figure 66-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 66-17. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 - No signal is asserted xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock xxx1xxxx - **p_devnt_out[4]** is asserted for one clock xx1xxxxx - **p_devnt_out[5]** is asserted for one clock

Table 66-17. DEVENT Bit Definitions

Bit(s)	Name	Description
		x1xxxxxx - **p_devnt_out[6]** is asserted for one clock 1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

66.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z425Bn3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

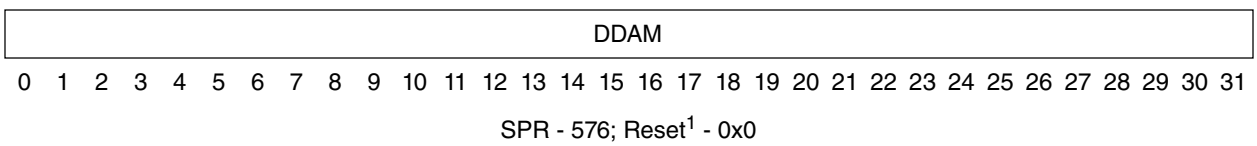


Figure 66-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 66-18. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

66.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 66-9. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses,

an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 66-9 and Table 66-12 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

66.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

66.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

66.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

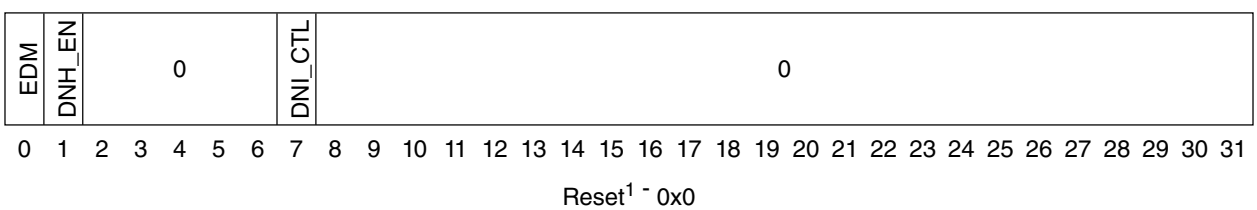

Figure 66-16. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

The following table provides bit definitions for External Debug Control Register 0.

Table 66-19. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

66.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9 10 11	12	13	14	15	16	17 18 19 20	21	22	23	24	25	26	27	28 29 30	31

Read/Write; Reset[1] - 0x0000_0000

Figure 66-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 66-20. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved

Table continues on the next page...

Table 66-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

66.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

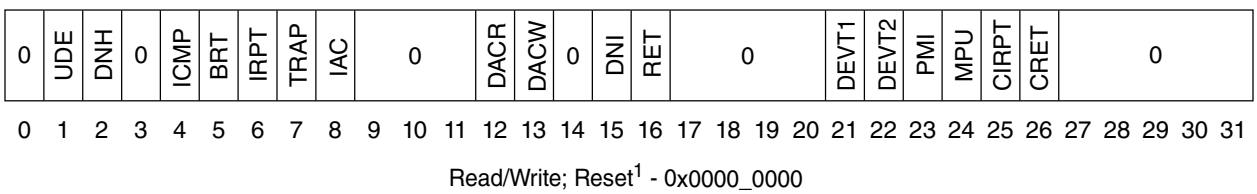

Figure 66-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 66-21. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$

Table continues on the next page...

Table 66-21. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

66.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load or store operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent

hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

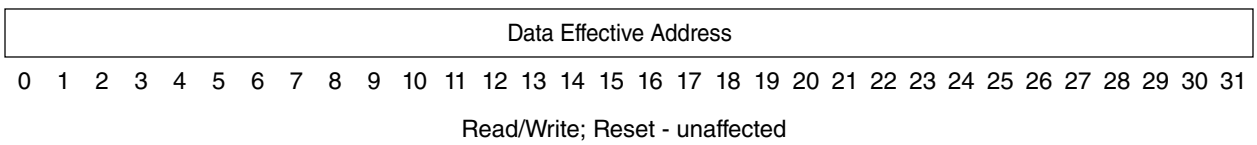

Figure 66-19. EDDEAR Register

66.5.2 OnCE Introduction

The e200z425Bn3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z425Bn3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/ software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

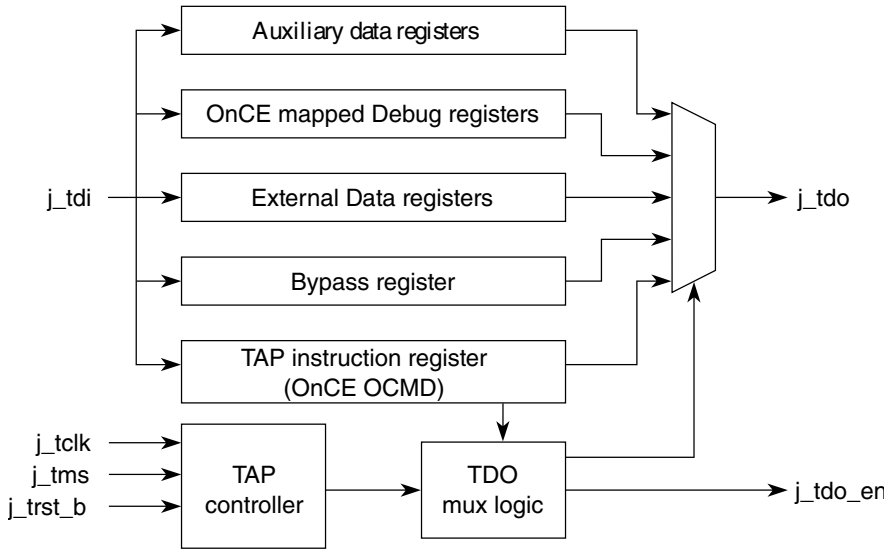

Figure 66-20. OnCE TAP Controller and Registers

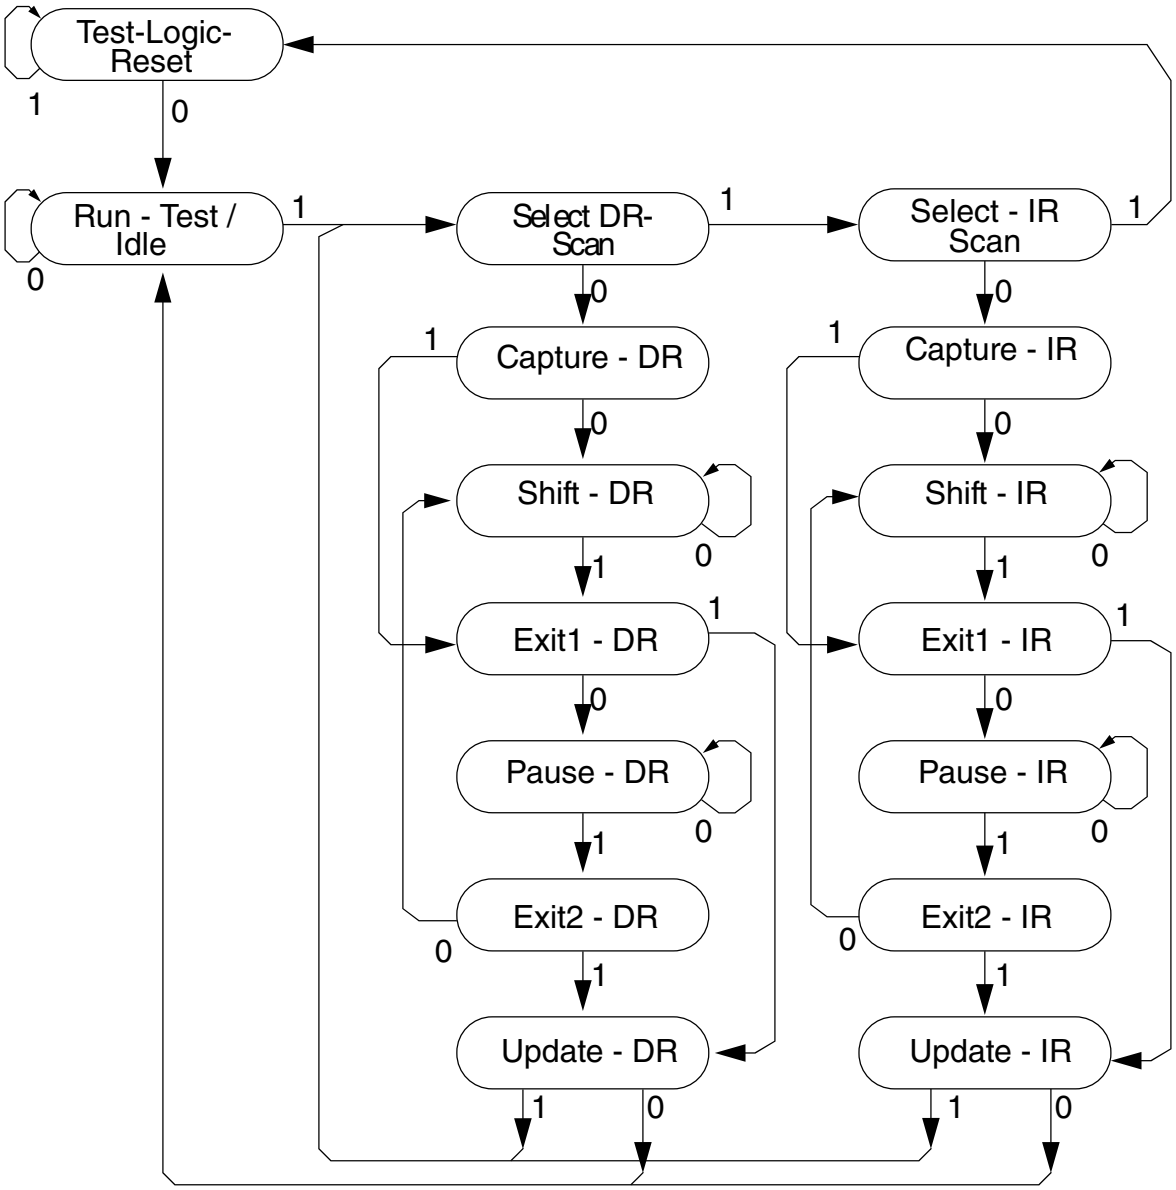
The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.



Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

66.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 66-22. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z425Bn3) Core Complex Overview.

66.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

66.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

66.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

66.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

66.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

66.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

66.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

66.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z425Bn3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

66.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

66.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z425Bn3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

66.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

66.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

66.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

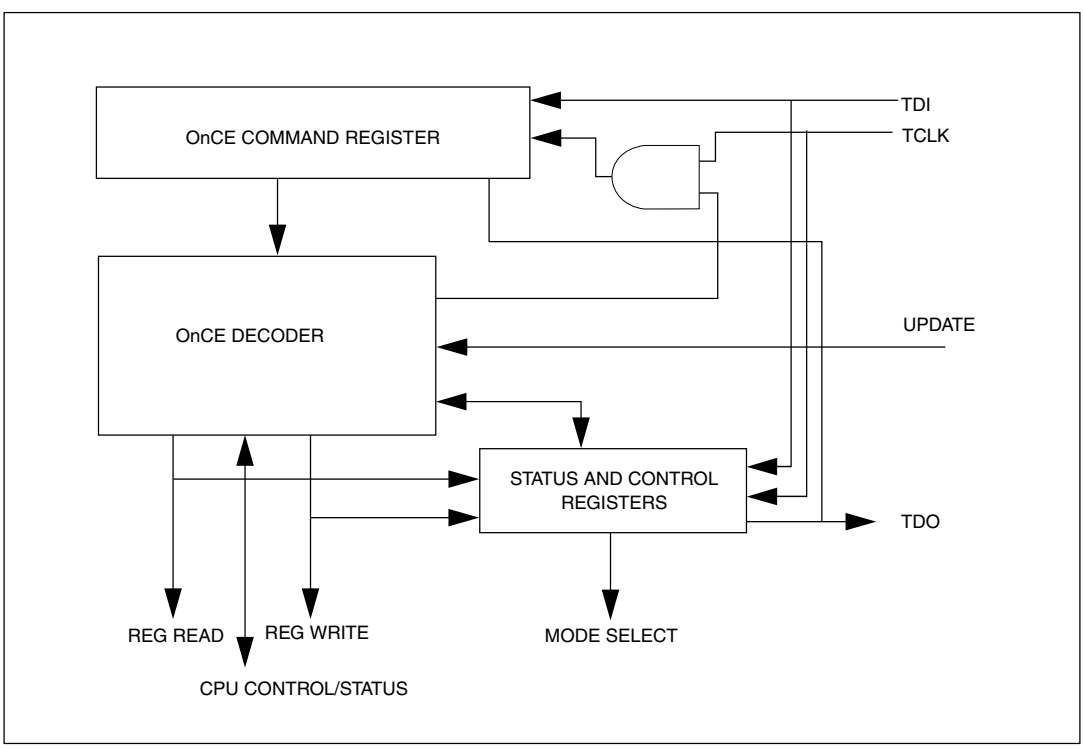


Figure 66-21. OnCE Controller and Serial Interface

66.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 66-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 66-23. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.

Table continues on the next page...

Table 66-23. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

66.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 66-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 66-23. OnCE Command Register

Table 66-24 provides bit definitions for the Once Command Register.

Table 66-24. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6]

Table continues on the next page...

Table 66-24. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 66-25 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 66-25 indicates the OnCE register addresses.

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

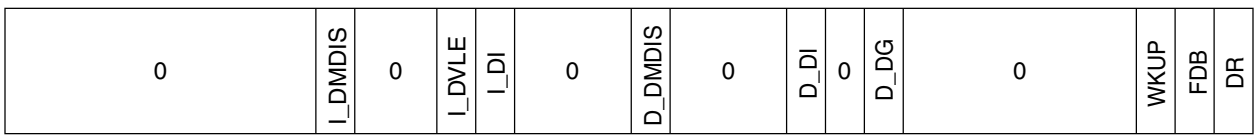
Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

66.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z425Bn3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see MPU Operation During Debug). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.



Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 66-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 66-26. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit (I_DVLE) This bit is used to provide the 'VLE' attribute bit to be used during a debug session. Note: this bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug 'I' Attribute Bit (I_DI) This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions

Table continues on the next page...

Table 66-26. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
		This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

66.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z425Bn3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z425Bn3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z425Bn3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 66-27. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*	
DBCR0	Y	Y	Y	N	*[1]	*EDBCR0$_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	

Table continues on the next page...

Table 66-27. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.

66.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

66.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z425Bn3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z425Bn3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

66.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

66.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

66.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled

along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

66.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z425Bn3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

66.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH\_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z425Bn3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

66.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

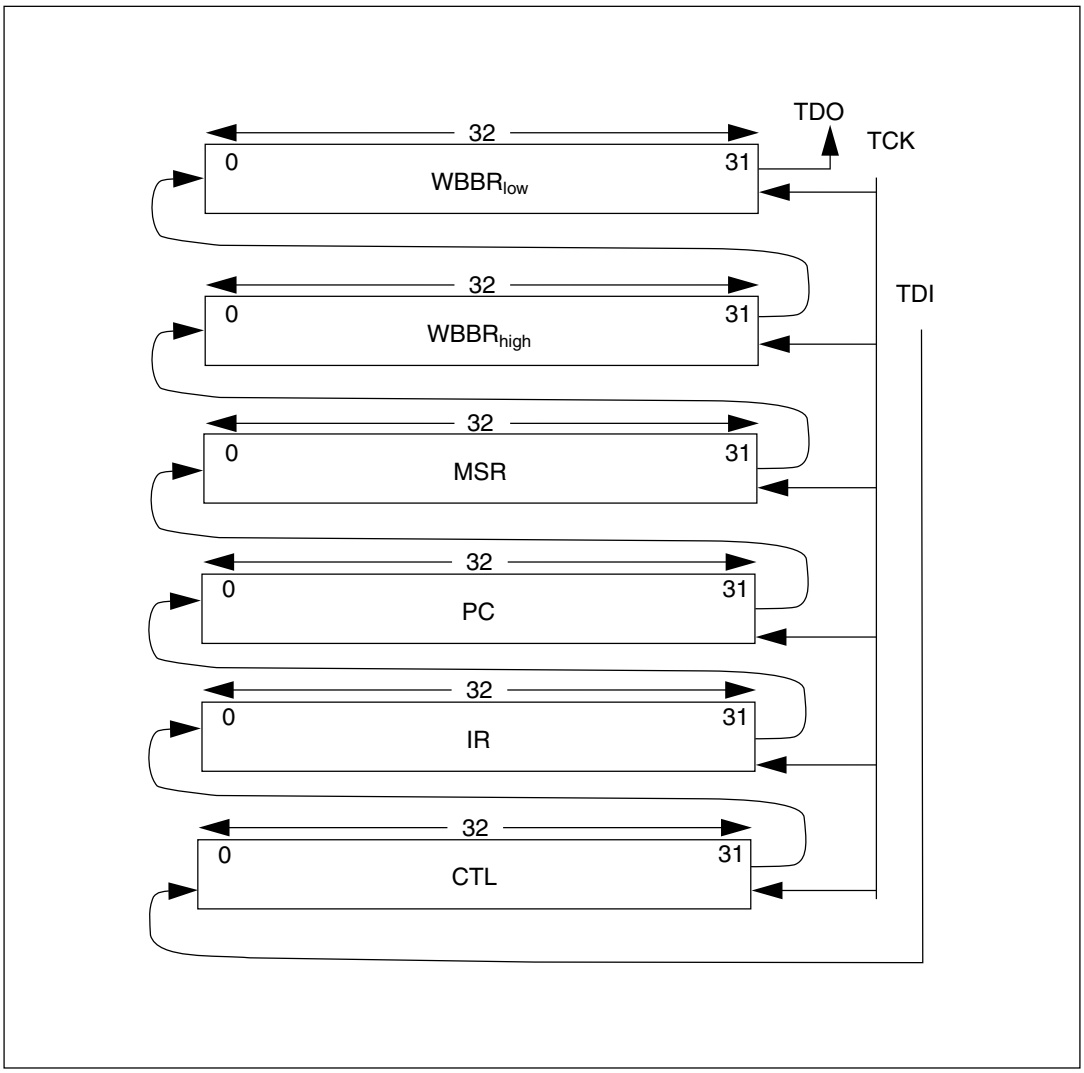


Figure 66-25. CPU Scan Chain Register (CPUSCR)

66.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

66.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

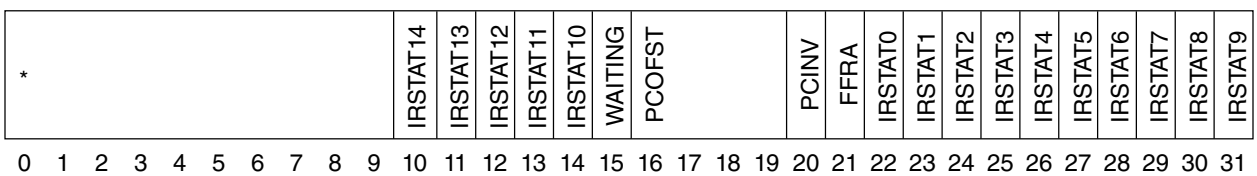

Figure 66-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, $WBBR_{hi, lo}$ is used to supply the 64-bit source value.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$or $WBBR_{hi,lo}$used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the PowerISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

66.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

66.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. For LSP instructions which generate 64-bit results, $WBBR_{low}$ holds the low-order 32 bits of the result. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. For LSP instructions which generate 64-bit results, $WBBR_{high}$ holds the high-order 32 bits of the result. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

66.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

66.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

66.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

66.6 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

66.7 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

66.8 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode.
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should re-write the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 67
Core Debug Support

67.1 Overview

Internal debug support in the e200z710n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *Power ISA 2.06*. e200z710n3 supports a subset of these defined facilities. In addition to the facilities defined in *Power ISA 2.06*, e200z710n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

67.1.1 Software Debug Facilities

e200z710n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

67.1.1.1 *Power ISA 2.06* Compatibility

The e200z710n3 core implements a subset of the *Power ISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

67.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *Power ISA 2.06*, e200z710n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

67.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z710n3 core. This port provides information corresponding to each read or write access

completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z710n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

67.1.3 Hardware Debug Facilities

The e200z710n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard IEEE 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z710n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

67.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

67.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z710n3 debug resources.

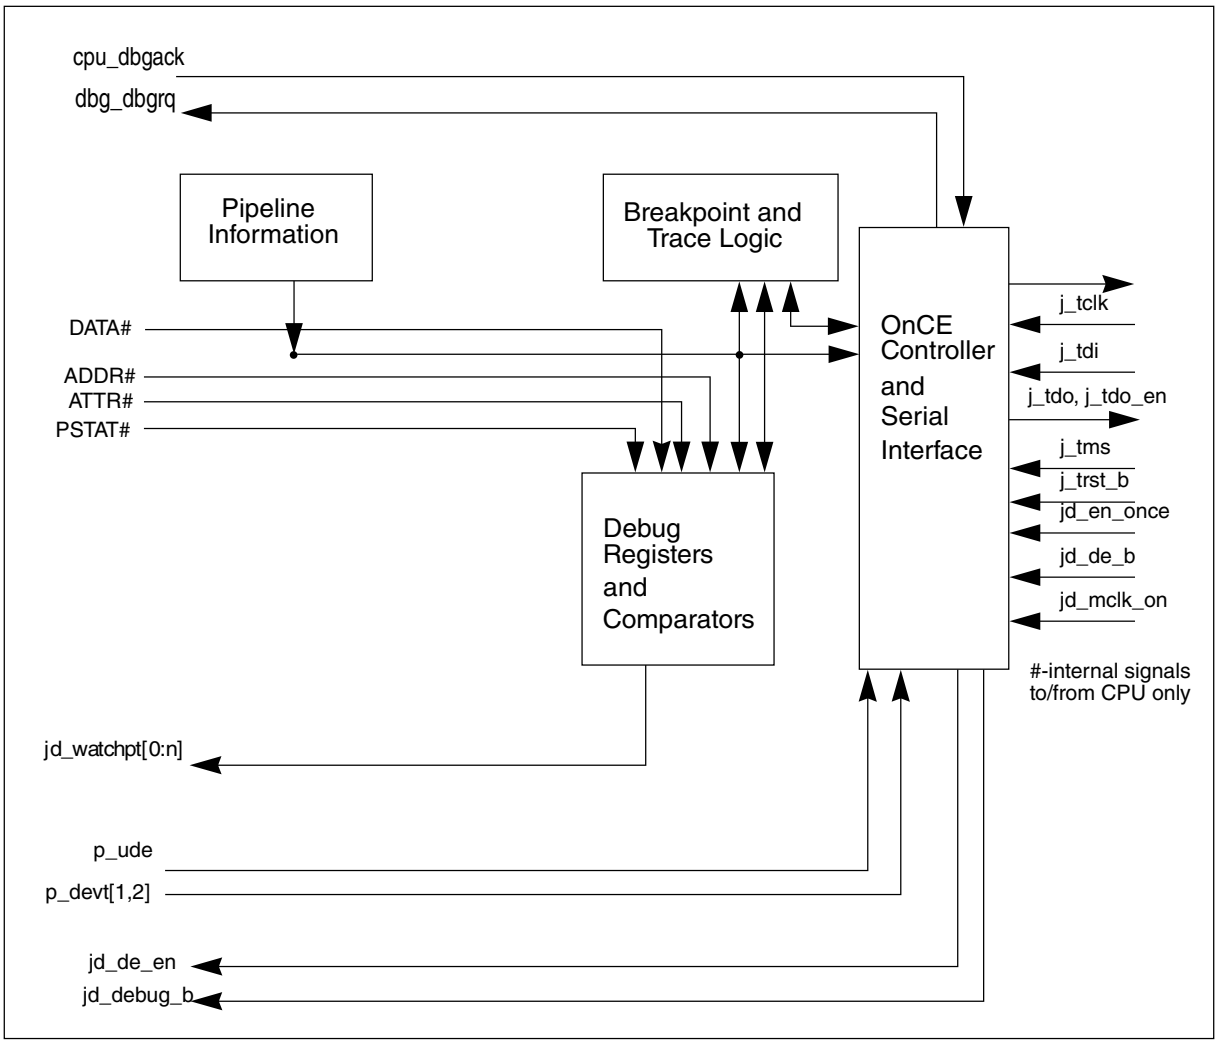

Figure 67-1. e200z710n3 Debug Resources

67.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *Power ISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z710n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z710n3 debug configuration supports most of these event types. Unsupported *Power ISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

67.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

67.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *Power ISA 2.06* definition, Data Address Compare events on e200z710n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC\_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/ EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

67.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/ store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC\_OFST}$ field when the DVC DAC status is recorded.

Table 67-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to

this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0.

Table 67-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction.

Table continues on the next page...

Table 67-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
			Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

67.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

67.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

67.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

67.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

67.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

67.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

67.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

67.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

67.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

67.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

67.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

67.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction

targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

67.3.1 Debug Address and Value Registers

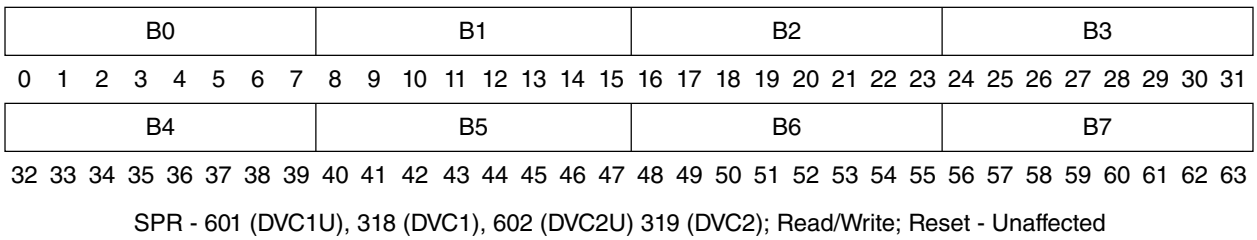
Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z710n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned

access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.



SPR - 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset - Unaffected

Figure 67-2. DVC1, DVC2 registers

67.3.2 Debug Control and Status registers

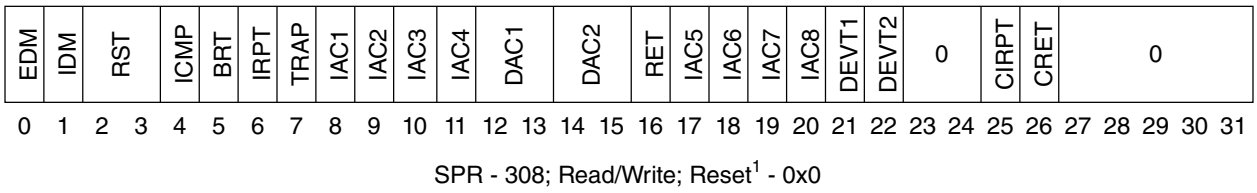
Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z710n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

67.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z710n3 adds some implementation specific bits to this register, as seen in the following figure.



SPR - 308; Read/Write; Reset[1] - 0x0

Figure 67-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 67-2. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control

Table continues on the next page...

Table 67-2. DBCR0 field descriptions (continued)

Bit	Name	Description
		00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved

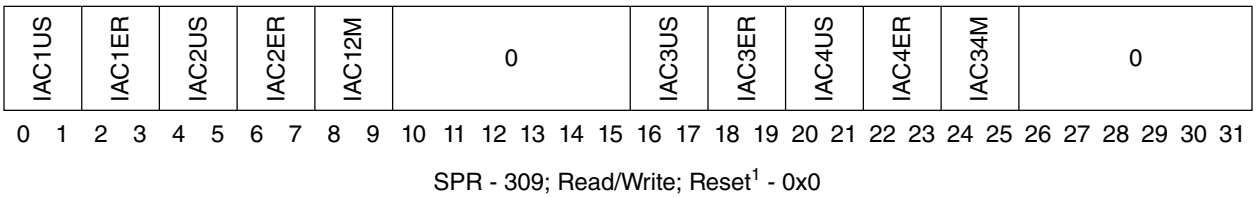
67.3.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.



SPR - 309; Read/Write; Reset[1] - 0x0

Figure 67-4. DBCR1 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 1.

Table 67-3. DBCR1 field descriptions

Bit	Name	Description
0:1	IAC1US	Instruction Address Compare 1 User/Supervisor Mode 00 IAC1 debug events not affected by MSR_{PR} 01 Reserved 10 IAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC1 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC1ER	Instruction Address Compare 1 Effective/Real Mode 00 IAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC2US	Instruction Address Compare 2 User/Supervisor Mode 00 IAC2 debug events not affected by MSR_{PR} 01 Reserved 10 IAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC2 debug events can only occur if MSR_{PR}=1. (User mode)

		10 Inclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.
26:31	—	Reserved

67.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.

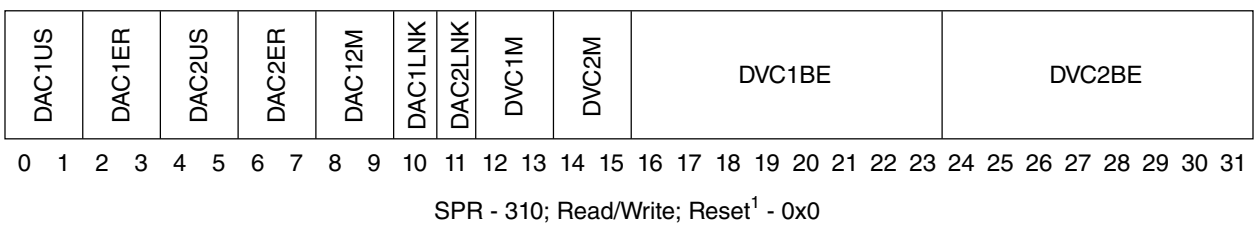

Figure 67-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 67-4. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode

Table continues on the next page...

Table 67-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0:

Table continues on the next page...

Table 67-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables

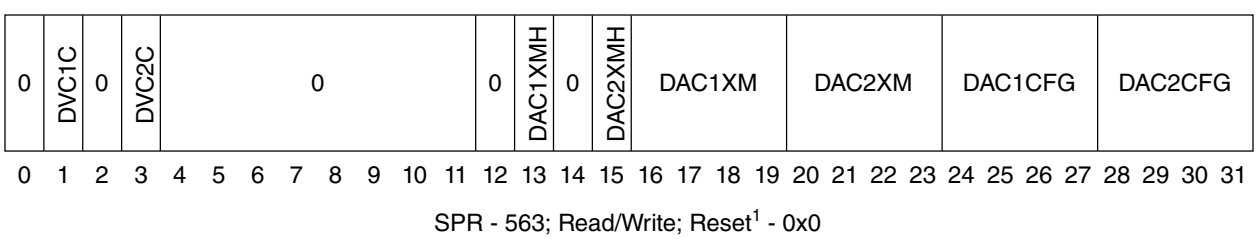
Table continues on the next page...

Table 67-4. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

67.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.



SPR - 563; Read/Write; Reset[1] - 0x0

Figure 67-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 67-5. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM:

Table continues on the next page...

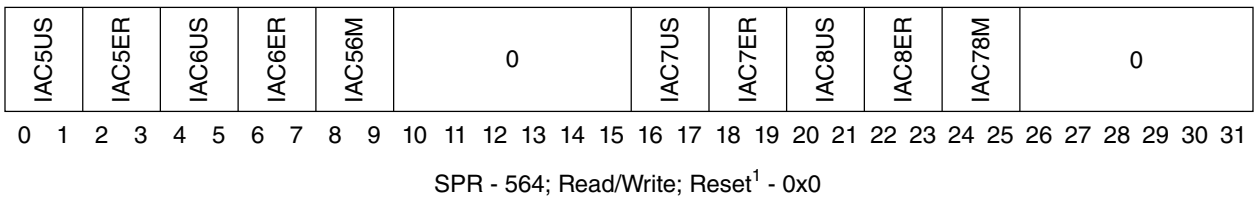
Table 67-5. DBCR4 field description (continued)

Bit	Name	Description
		00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **NOTE:** unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

67.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.



SPR - 564; Read/Write; Reset[1] - 0x0

Figure 67-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 67-6. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)

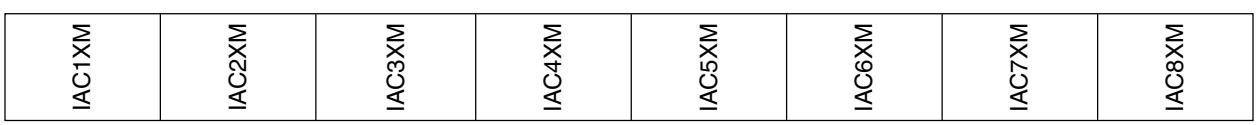
67.3.2.6 Debug Control Register 6 (DBCR6)

Debug Control Register 6 is used to extend instruction address compare matching functionality. DBCR6 is shown in the following figure.



SPR - 603; Read/Write; Reset[1] - 0x0

Figure 67-8. DBCR6 Register

Note

[1] DBCR6 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 6.

Table 67-7. DBCR6 field descriptions

Bit	Name	Description
0:3	IAC1XM	Instruction Address Compare 1 Extended Mask Control. IAC1XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC1 when comparing the storage address with the value in IAC1 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
4:7	IAC2XM	Instruction Address Compare 2 Extended Mask Control. IAC2XM allows for binary power of 2 address range compares for IAC2 without requiring the use of IAC1. 0000 No additional masking when DBCR1[IAC12M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC2 when comparing the storage address with the value in IAC2 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
8:11	IAC3XM	Instruction Address Compare 3 Extended Mask Control. IAC3XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC3 when comparing the storage address with the value in IAC3 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
12:15	IAC4XM	Instruction Address Compare 4 Extended Mask Controll. IAC4XM allows for binary power of 2 address range compares for IAC4 without requiring the use of IAC3. 0000 No additional masking when DBCR1[IAC34M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC4 when comparing the storage address with the value in IAC4 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
16:19	IAC5XM	Instruction Address Compare 5 Extended Mask Control. IAC5XM allows for binary power of 2 address range compares for IAC5 without requiring the use of IAC6. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC5 when comparing the storage address with the value in IAC5 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
20:23	IAC6XM	Instruction Address Compare 6 Extended Mask Control. IAC6XM allows for binary power of 2 address range compares for IAC6 without requiring the use of IAC5. 0000 No additional masking when DBCR5[IAC56M]=00 0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC6 when comparing the storage address with the value in IAC6 for exact address compare (DBCR5[IAC56M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved
24:27	IAC7XM	Instruction Address Compare 7 Extended Mask Control. IAC7XM allows for binary power of 2 address range compares for IAC7 without requiring the use of IAC8.

67.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.

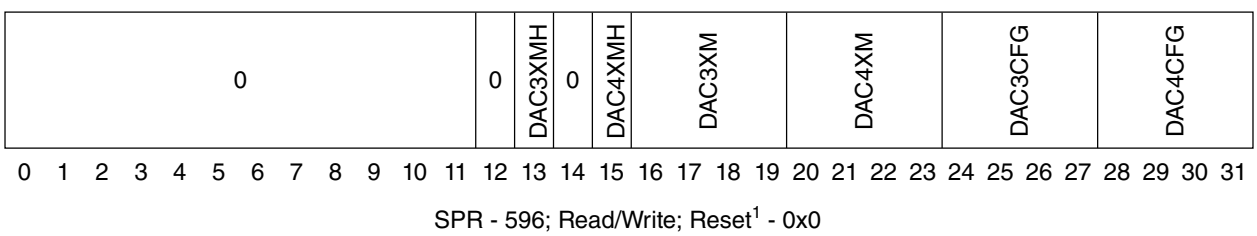

Figure 67-9. DBCR7 Register

Note

[1] DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 7.

Table 67-8. DBCR7 Field Descriptions

Bit	Name	Description
0:12	—	Reserved

Table continues on the next page...

Table 67-8. DBCR7 Field Descriptions (continued)

Bit	Name	Description
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High .DAC3XMH extends the range of the DAC3XM field 0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. . DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses

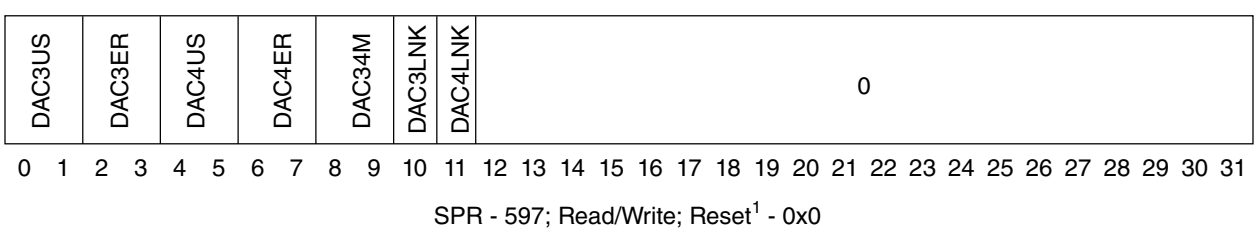
Table continues on the next page...

Table 67-8. DBCR7 Field Descriptions (continued)

Bit	Name	Description
		1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

67.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.



SPR - 597; Read/Write; Reset[1] - 0x0

Figure 67-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 67-9. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4.

Table continues on the next page...

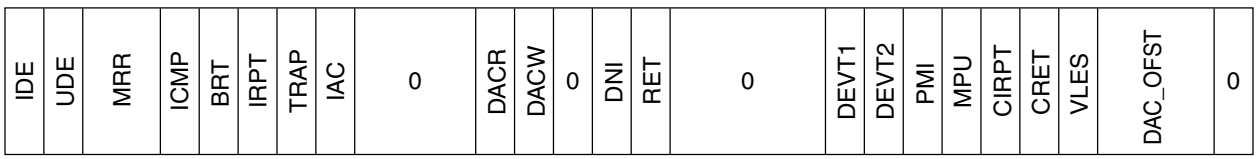
Table 67-9. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

67.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource

sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.



SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 67-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 67-10. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred

Table continues on the next page...

Table 67-10. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

67.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

Data Effective Address																														
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 600; Read/Write; Reset - unaffected

Figure 67-12. DDEAR Register

67.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 67-13. EDBRAC0 Register

Table 67-10 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 67-11. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.

Table continues on the next page...

Table 67-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields.

Table continues on the next page...

Table 67-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event

Table continues on the next page...

Table 67-11. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 - Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 - Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** this bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 67-12 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

67.3.4 Debug Event Select Register (DEVENT)

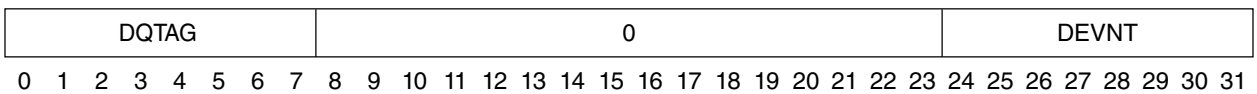
The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has

occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z710n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.



SPR - 975; Reset[1] - 0x0

Figure 67-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 67-13. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 - No signal is asserted xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock xxx1xxxx - **p_devnt_out[4]** is asserted for one clock xx1xxxxx - **p_devnt_out[5]** is asserted for one clock

Table 67-13. DEVENT Bit Definitions

Bit(s)	Name	Description
		x1xxxxxx - **p_devnt_out[6]** is asserted for one clock 1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

67.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z710n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

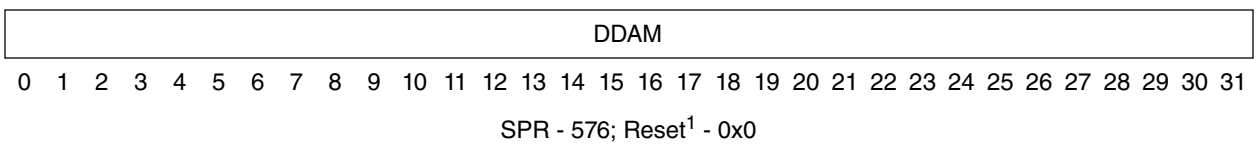


Figure 67-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 67-14. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

67.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 67-5. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0

pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 67-5 and Table 67-8 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

67.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

67.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

67.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

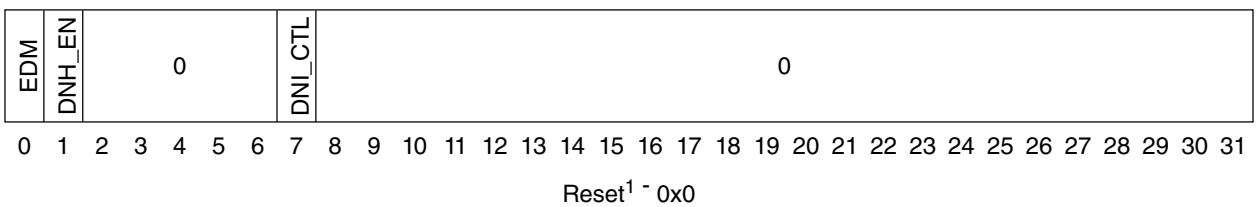

Figure 67-16. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

The following table provides bit definitions for External Debug Control Register 0.

Table 67-15. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

67.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

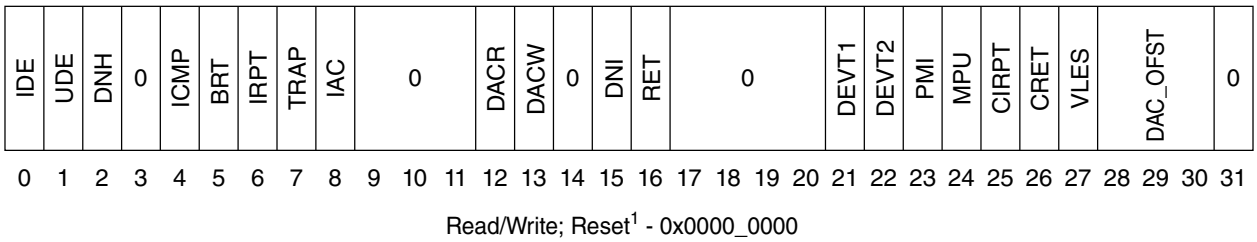

Figure 67-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 67-16. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved

Table continues on the next page...

Table 67-16. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

67.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

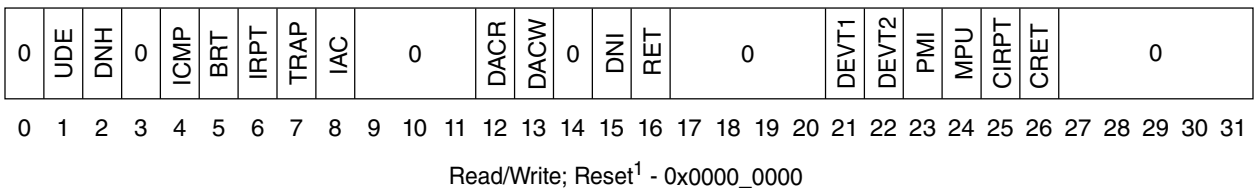

Figure 67-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 67-17. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$

Table continues on the next page...

Table 67-17. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

67.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR

hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

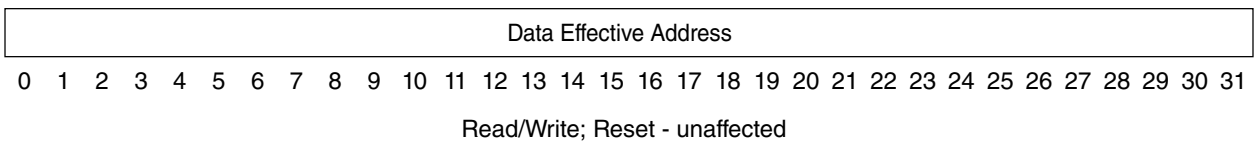

Figure 67-19. EDDEAR Register

67.5.2 OnCE Introduction

The e200z710n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z710n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

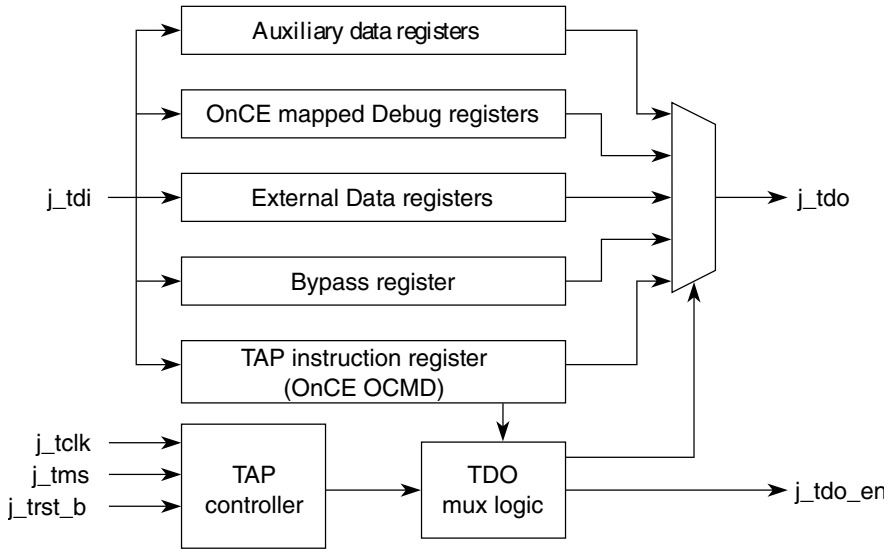

Figure 67-20. OnCE TAP Controller and Registers

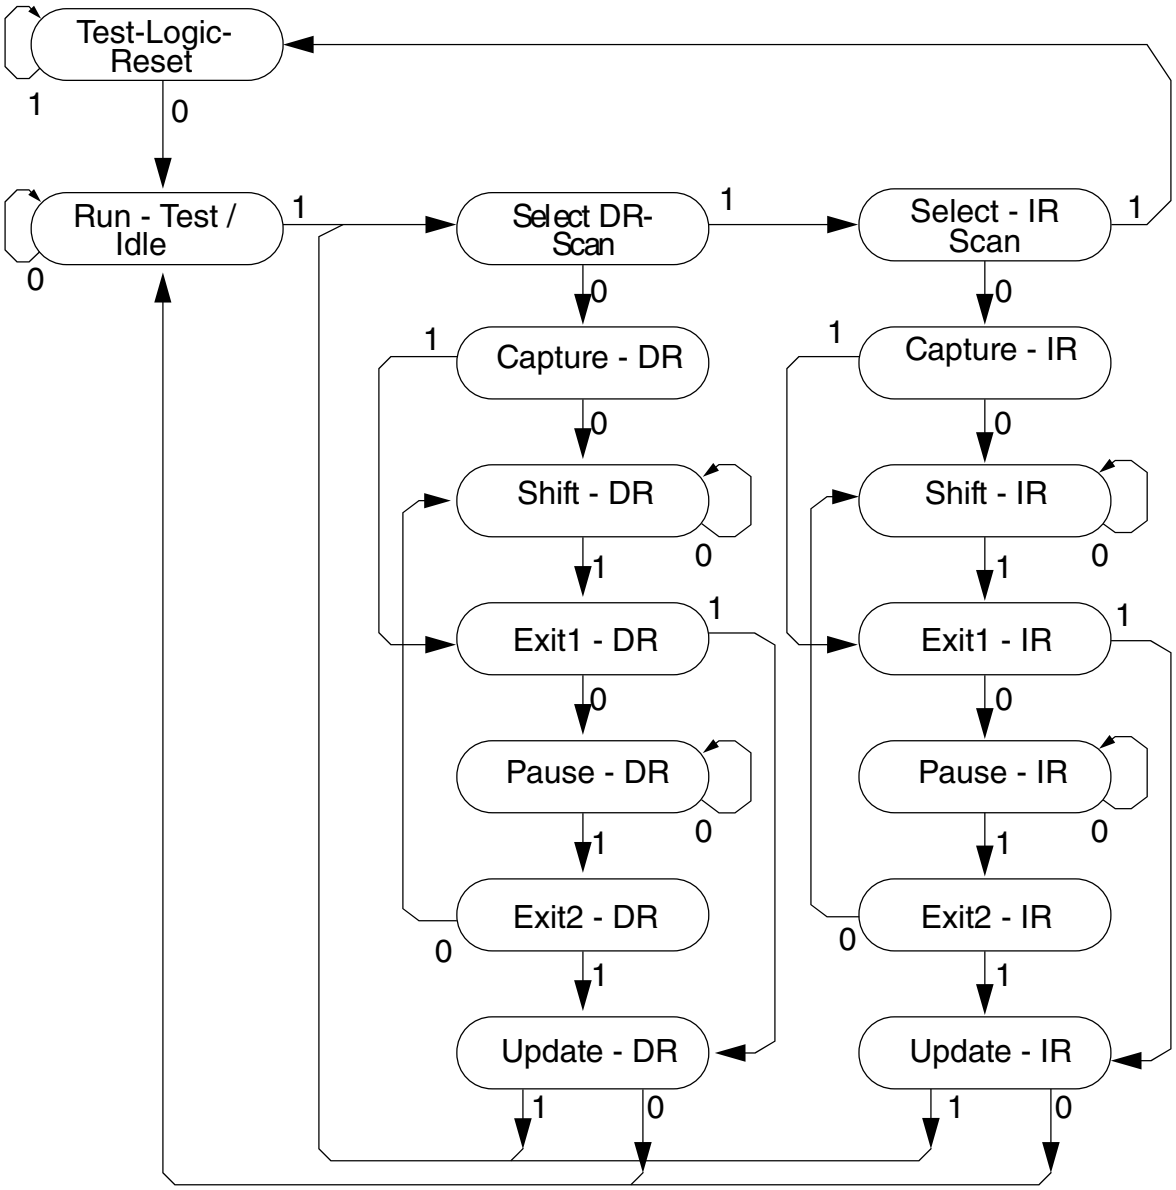
The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.



Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

67.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 67-18. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z710n3) Core Complex Overview.

67.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

67.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

67.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

67.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

67.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

67.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

67.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

67.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z710n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

67.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

67.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z710n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

67.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

67.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

67.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

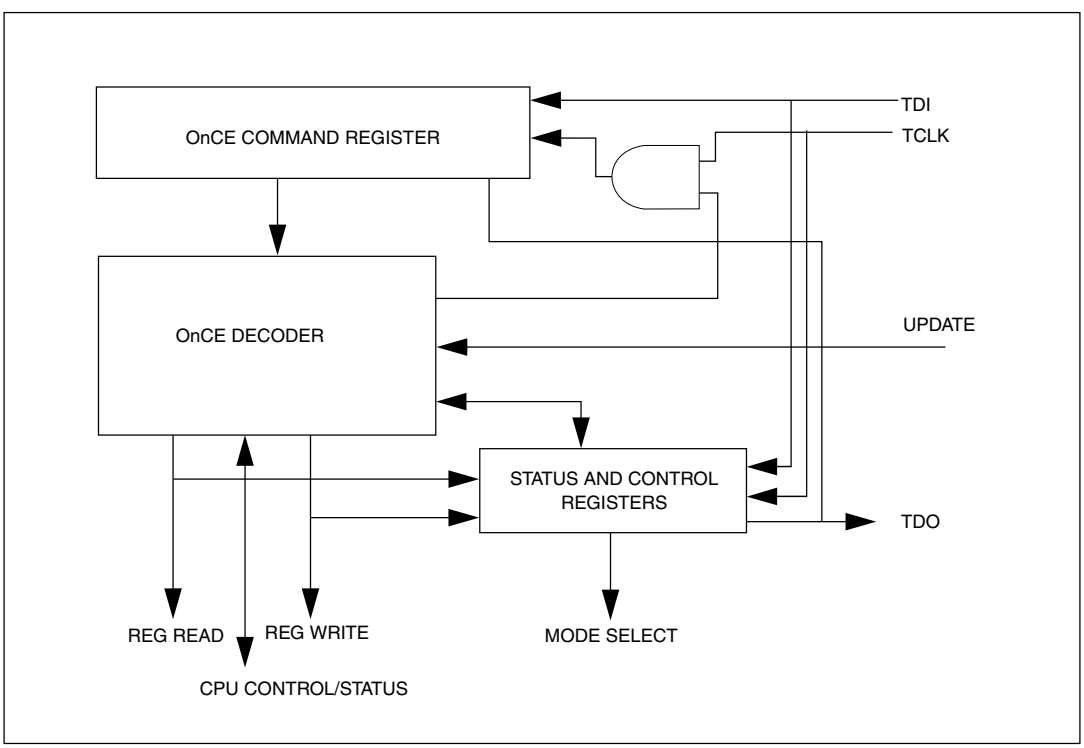


Figure 67-21. OnCE Controller and Serial Interface

67.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 67-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 67-19. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.

Table continues on the next page...

Table 67-19. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

67.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 67-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 67-23. OnCE Command Register

Table 67-20 provides bit definitions for the Once Command Register.

Table 67-20. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6]

Table continues on the next page...

Table 67-20. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 67-21 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 67-21 indicates the OnCE register addresses.

Table 67-21. OnCE Register Addressing

RS[0:6]	Register Selected
000 0000	Reserved

Table continues on the next page...

Table 67-21. OnCE Register Addressing (continued)

RS[0:6]	Register Selected
000 0001	Reserved
000 0010	JTAG ID (read-only)

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

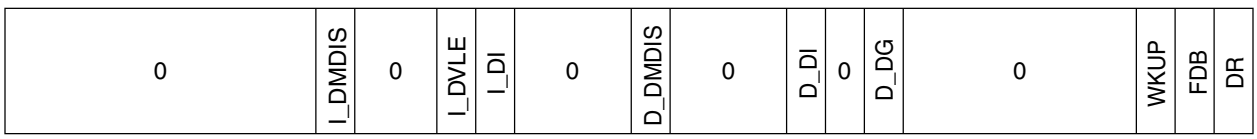
Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

67.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z710n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see MPU Operation During Debug). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.



Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 67-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 67-22. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit (I_DVLE) This bit is used to provide the 'VLE' attribute bit to be used during a debug session. Note: this bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug 'I' Attribute Bit (I_DI) This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions

Table continues on the next page...

Table 67-22. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
		This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

67.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z710n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z710n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z710n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 67-23. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1]	
DBCR0	Y	Y	Y	N	*[1]	*$EDBCR0_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	

Table continues on the next page...

Table 67-23. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

67.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

67.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z710n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z710n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

67.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

67.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

67.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled

along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

67.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z710n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

67.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH\_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z710n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

67.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

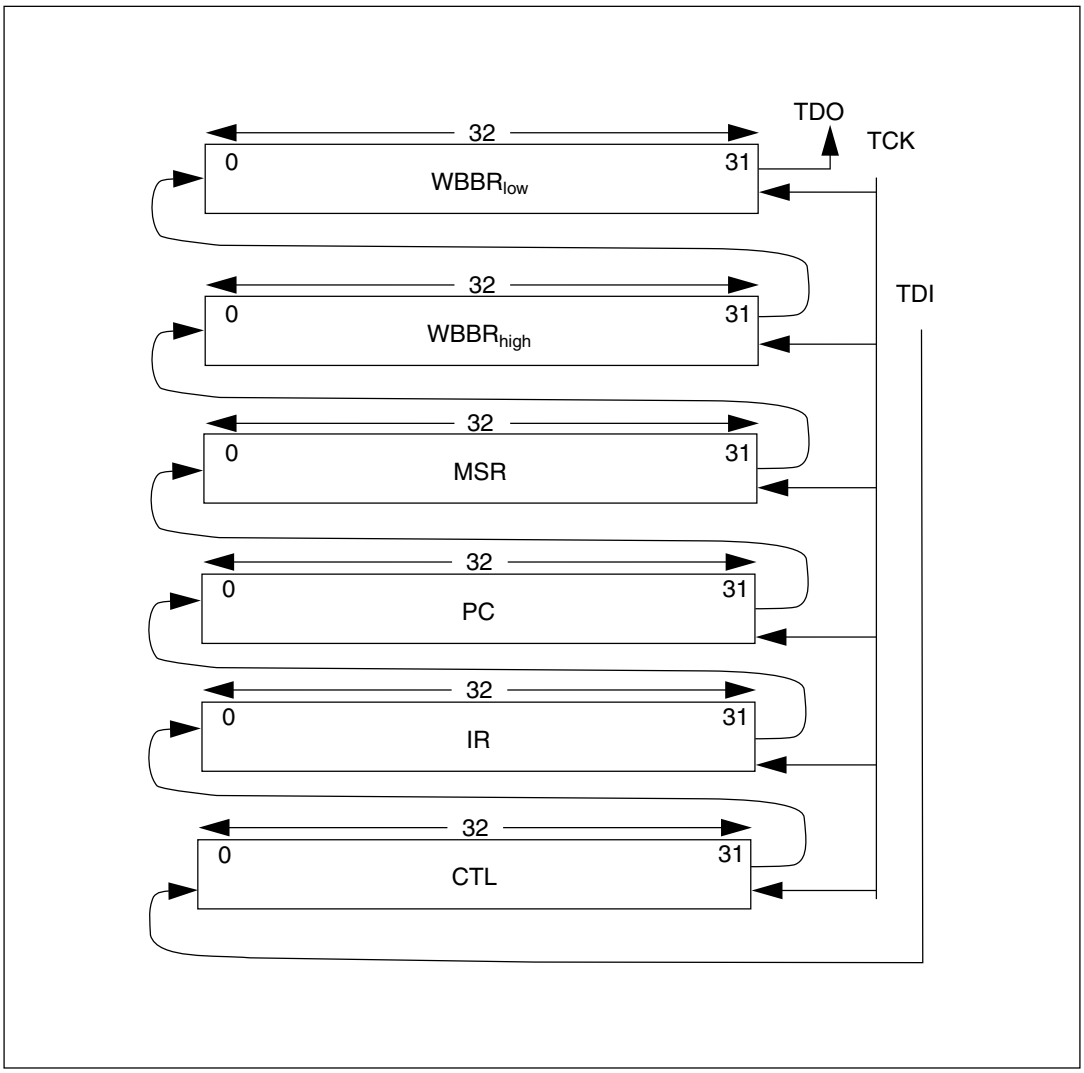


Figure 67-25. CPU Scan Chain Register (CPUSCR)

67.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

67.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

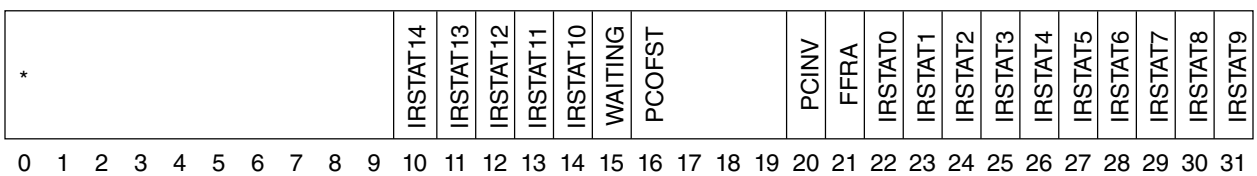

Figure 67-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the Power ISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a Power ISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

67.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

67.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

67.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

67.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

67.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

67.6 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

67.7 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

67.8 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode.
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should re-write the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 68
Debug and Calibration Interface (DCI)

68.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard IEEE 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

68.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and IEEE 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for CPU(s) when exiting debug mode
- Tool hot plug capability

- Security access control
- Debug reset control

68.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
    - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
    - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as timers/ SPU, etc. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

This figure shows the DCI block diagram.

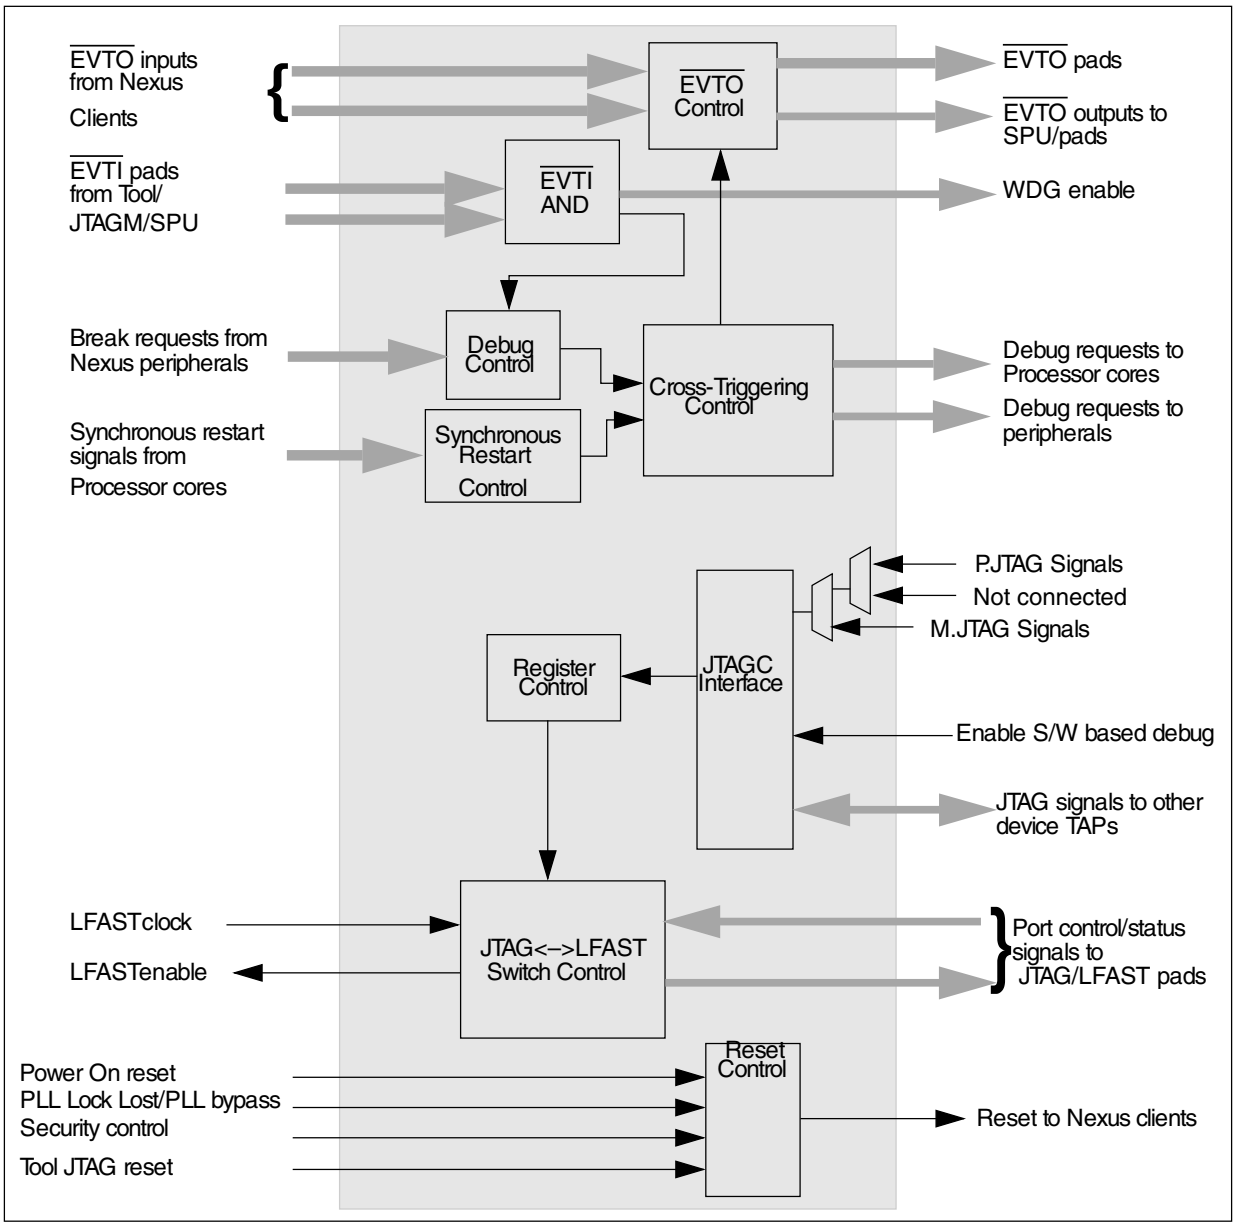

Figure 68-1. DCI block diagram

This figure shows the DCI configuration for the standard production package.

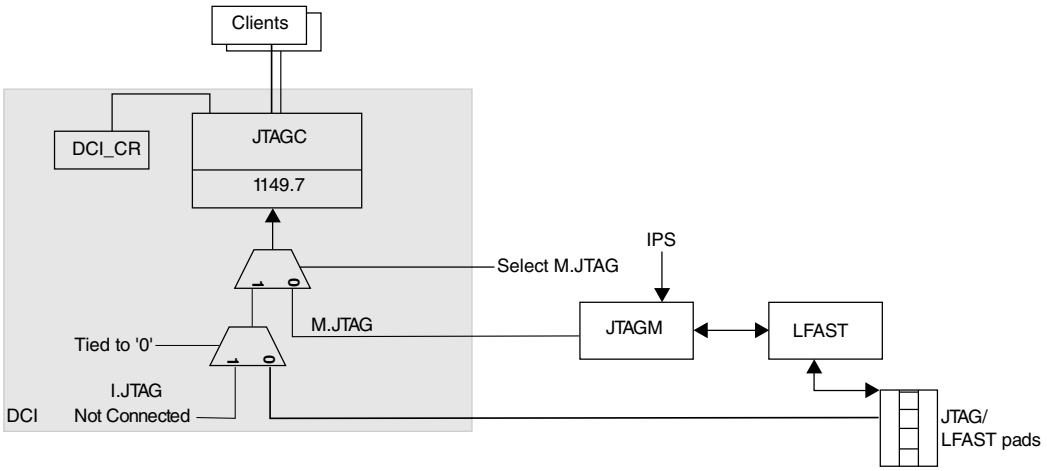

Figure 68-2. DCI in a standard configuration

68.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

This table shows a summary of the configuration options.

Table 68-1. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed. Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in Port sharing between JTAG and LFAST modes. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. Table 68-2 shows the port mapping.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 68-2. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

This figure shows the DCI mode switching operation.

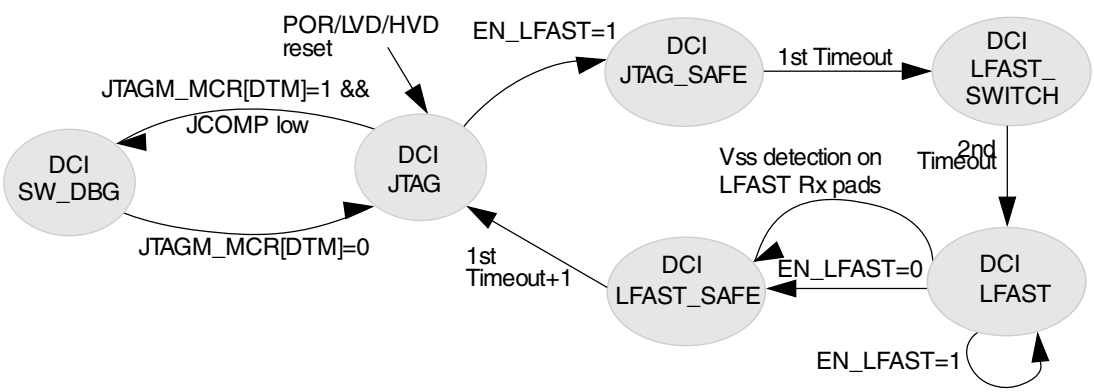

Figure 68-3. DCI operating modes state diagram

Note

JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

This table contains the operating mode descriptions.

Table 68-3. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: • JCOMP is latched inside to control until switching gets completed • The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state • An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

This figure shows a block diagram of the JTAG/LFAST connections.

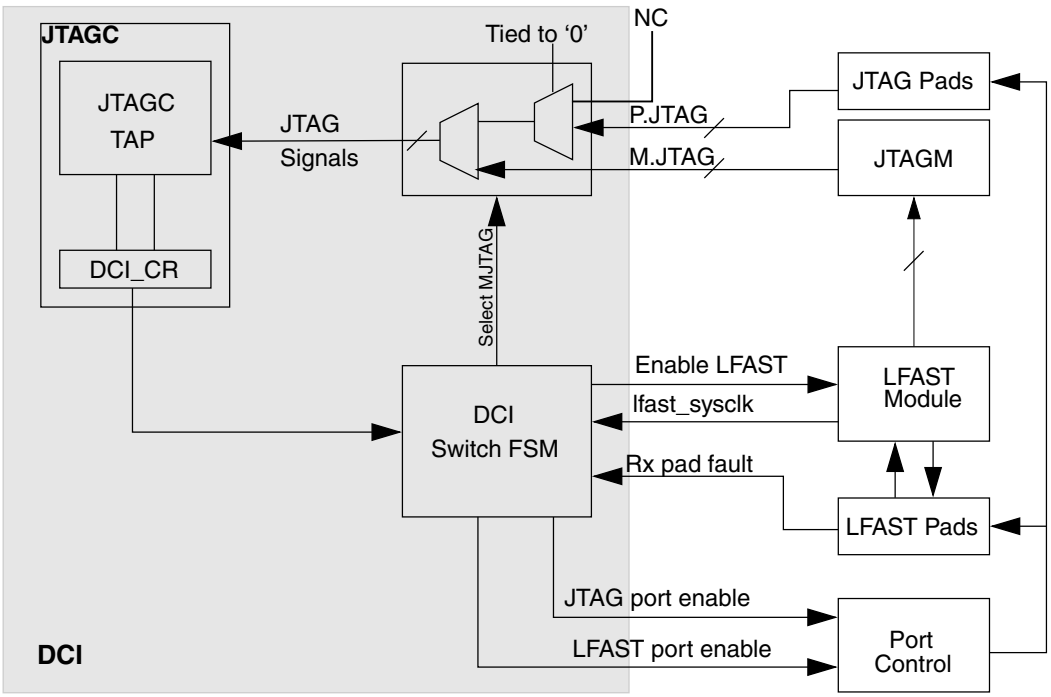

Figure 68-4. DCI JTAG/LFAST switch integration

68.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in Figure 68-5.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

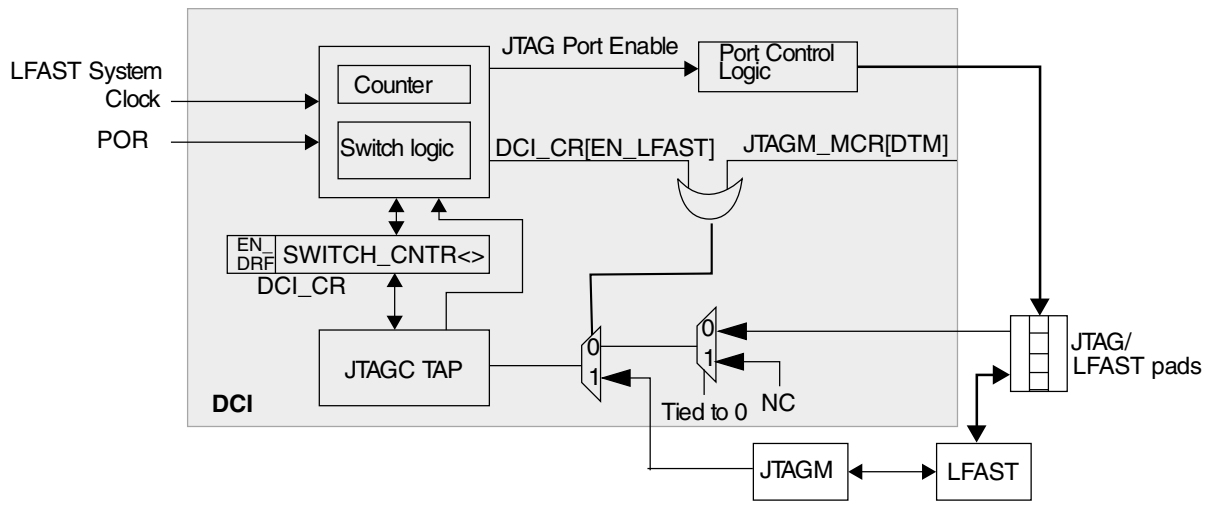

Figure 68-5. DCI switching between JTAG and LFAST modes

68.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.

5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

This figure shows the timing sequence.

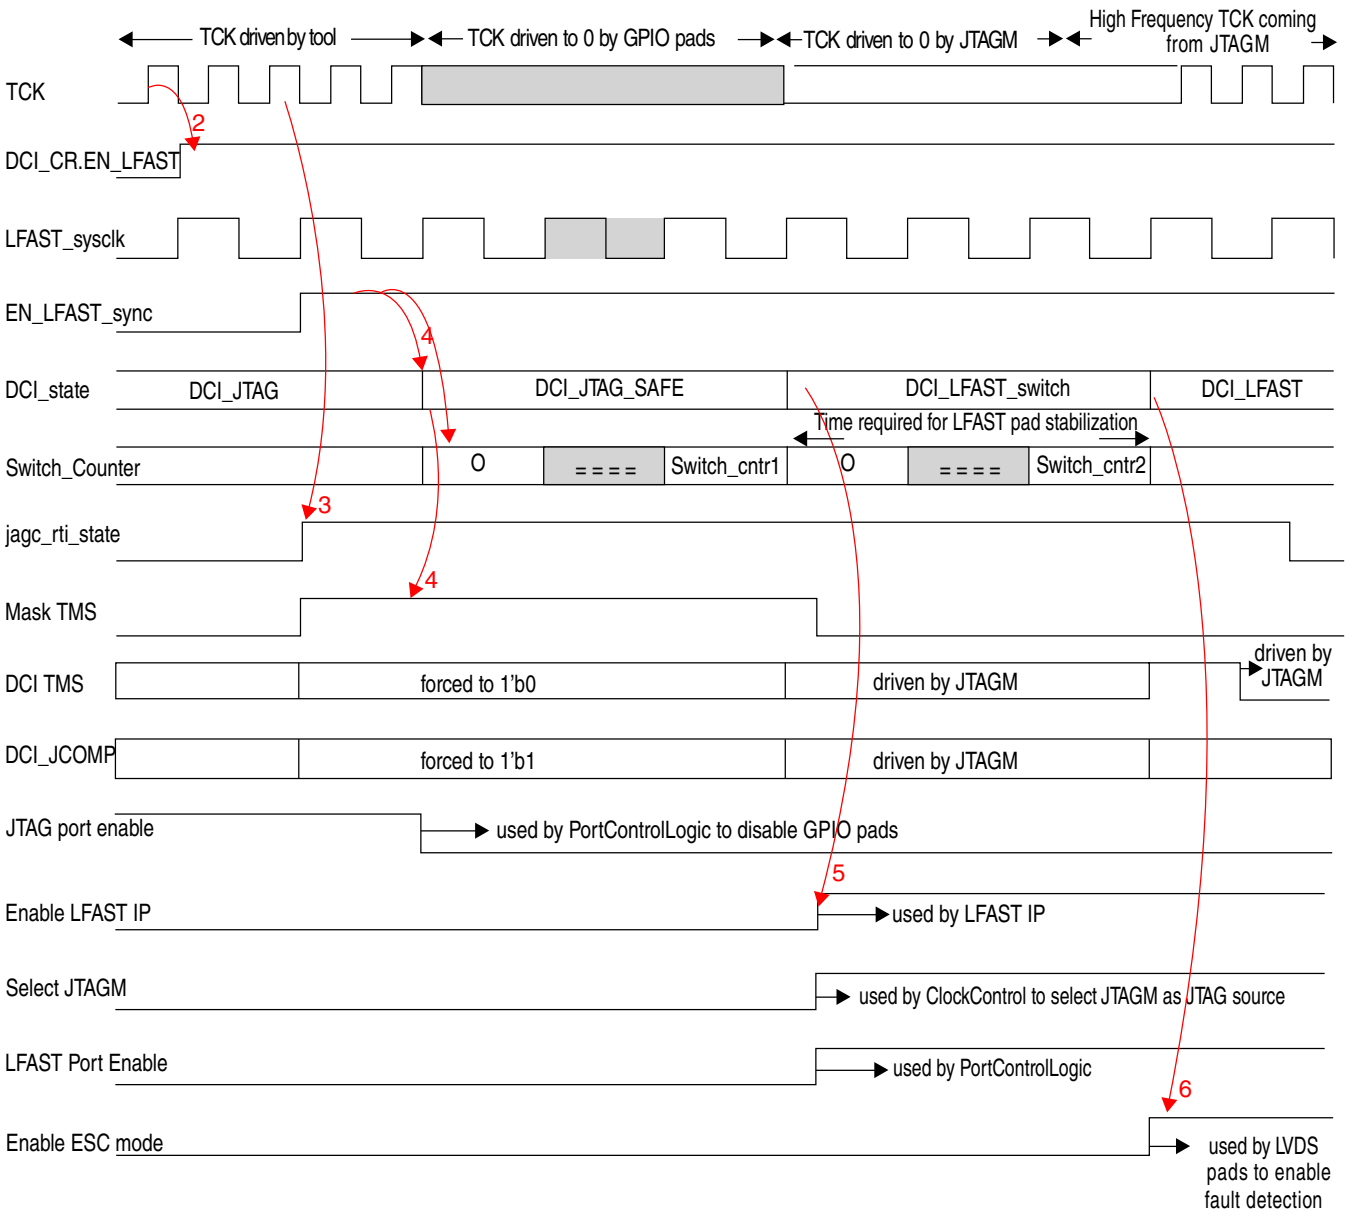

Figure 68-6. DCI JTAG to LFAST switching diagram

68.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.

3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 68-7 and Table 68-9 summarize the MCU and tool behaviors. The following figure shows the timing sequence.

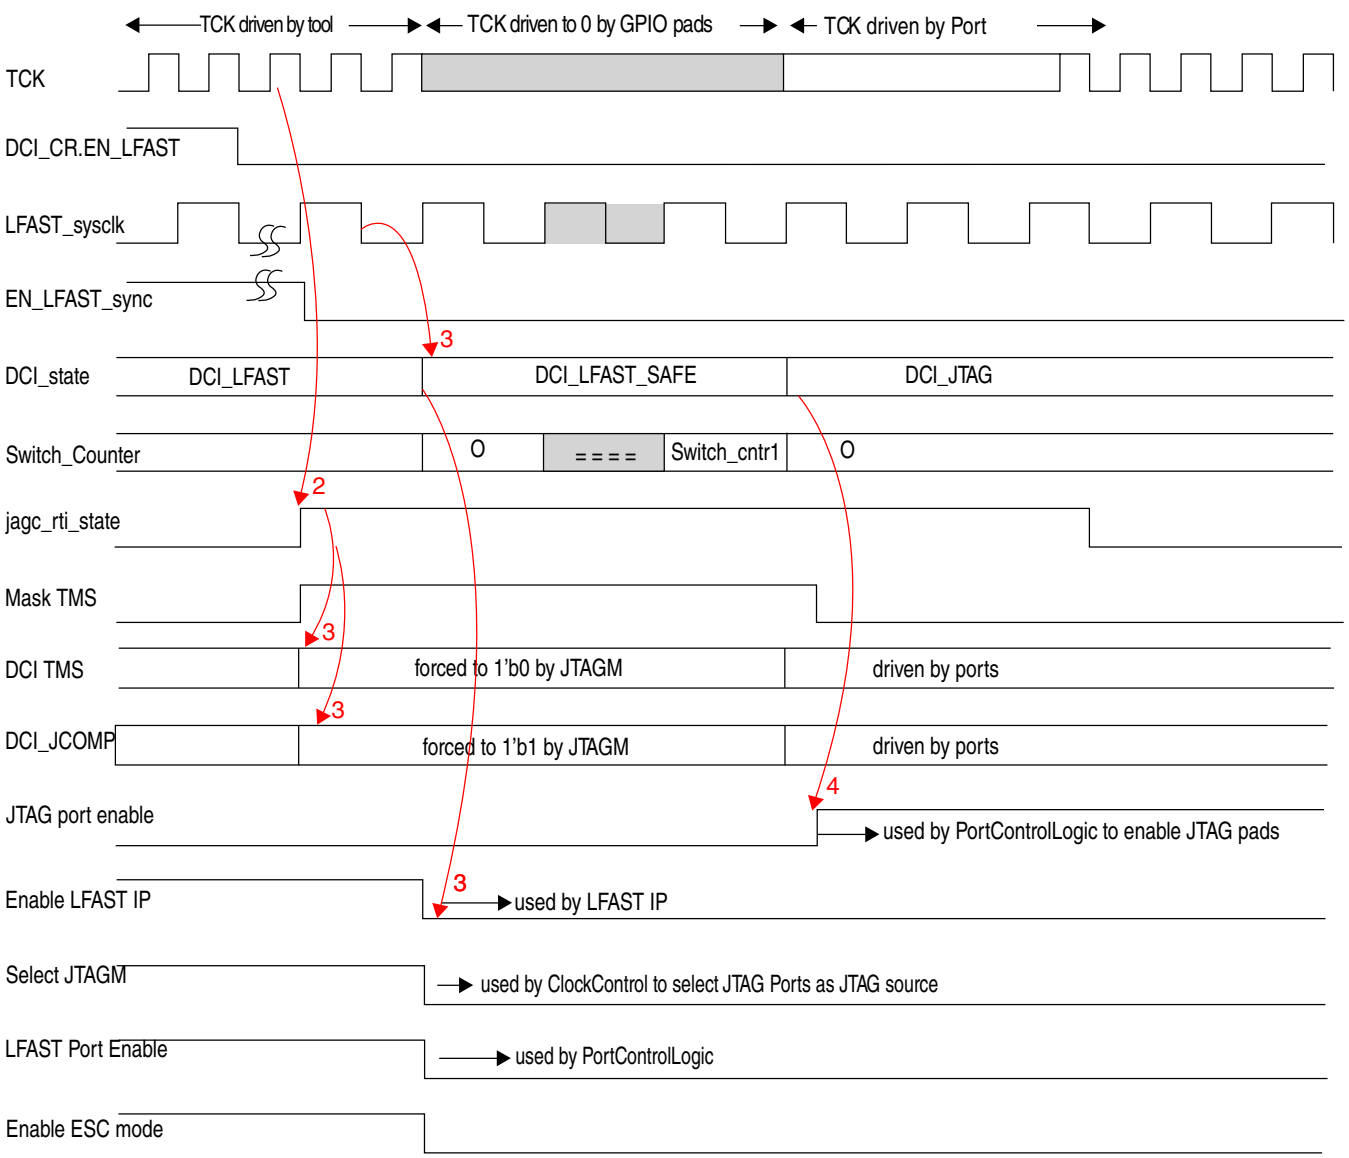

Figure 68-7. DCI LFAST to JTAG switching diagram

68.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

68.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

NOTE

It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

68.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 68-4. Nexus Reset Truth Table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

68.1.3.5 System watchdog control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

68.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as timers, DMA, Watchdog and other peripherals.

There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[1:0] signals from EVTI pads
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

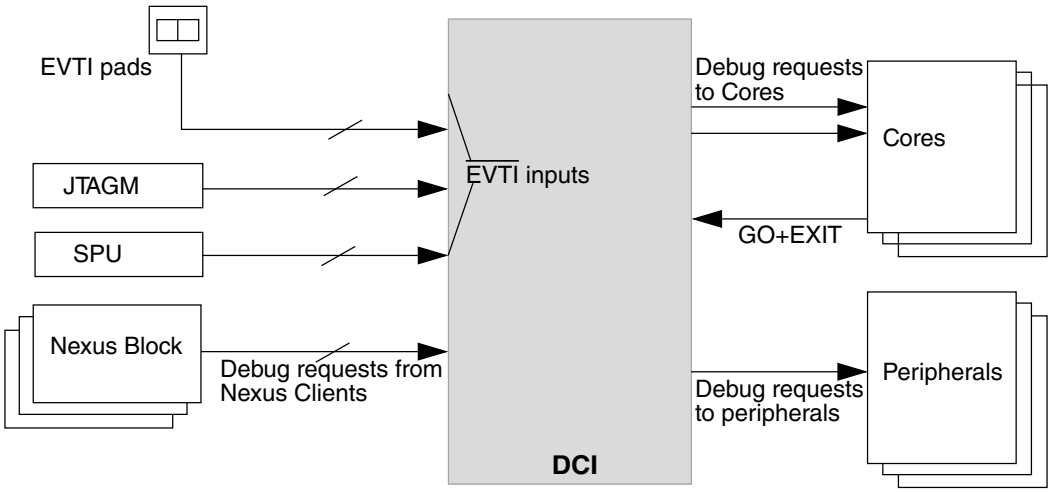

Figure 68-8. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}$[1:0] inputs are synchronized and logically ANDed in the DCI to generate two debug requests $\overline{\text{DCI\_EVTI}}$[1:0] for the processor cores and non-CPU peripherals. Of these two inputs, $\overline{\text{EVTI}}$[0] is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\overline{\text{EVTI}}$[1], is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted. The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command. The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

This figure shows the timing sequence.

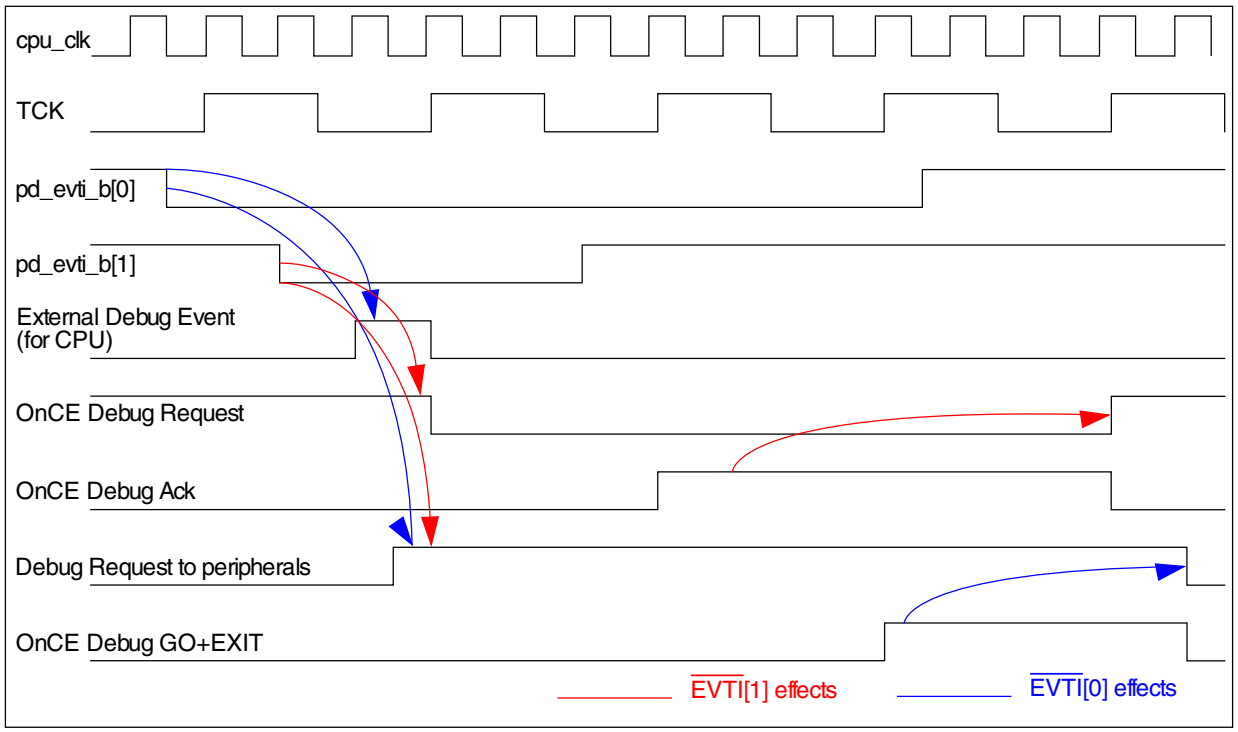

Figure 68-9. DCI debug signal generation

68.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

68.1.3.8 Synchronous restart control

The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

68.1.3.9 EVTO management

The EVTO management block diagram is presented in the following figure.

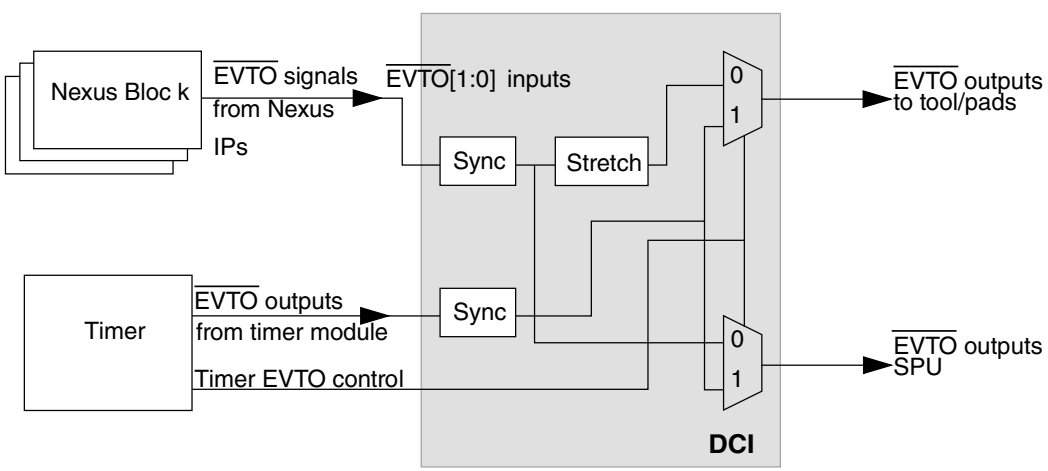

Figure 68-10. DCI EVTO management

The DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce $\overline{\text{EVTO}}$[1:0] signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted $\overline{\text{EVTO}}$[1:0] signals from any Nexus client, the DCI immediately asserts $\overline{\text{EVTO}}$[1:0] outputs and stretches it for a minimum of one output clock period for the output to the

tool(Figure 68-11). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the timer to take control of the EVTO outputs by controlling a timer register. If these fields are programmed to HALT/TIM/TOM/ATOM EVTO value, the timer EVTO outputs are directly available on the ports bypassing the stretch logic.

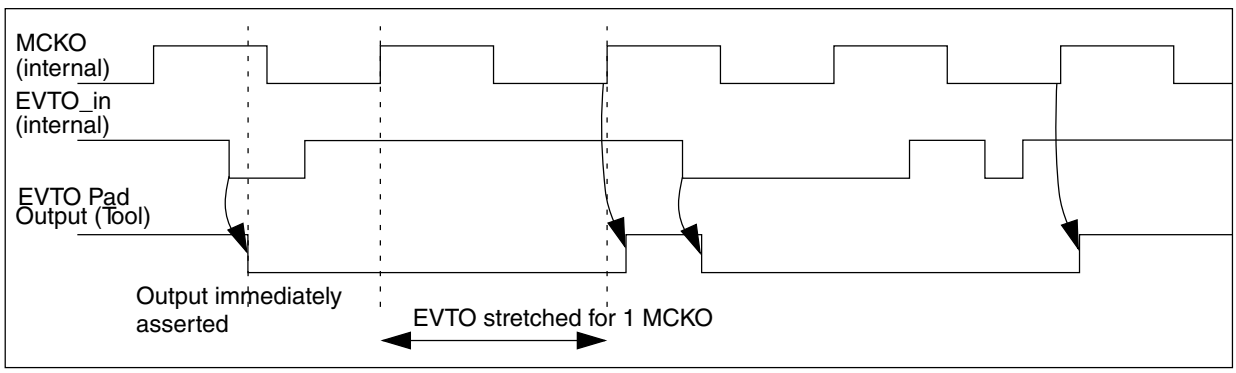

Figure 68-11. DCI EVTO timing diagram

68.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

68.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

68.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

68.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

68.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. The following table shows the format of the DCI_CR.

	31	30	29	28	27	26	25	24
R W	SWITCH_CNTR2							
Reset	1	1	1	1	1	1	1	1
	23	22	21	20	19	18	17	16
R W	SWITCH_CNTR2							
Reset	1	1	1	1	1	1	1	1
	15	14	13	12	11	10	9	8
R W	SWITCH_CNTR1					FLVDS_PAD_FLT	FPD_FUNC	FPD_DEST
Reset	1	1	1	1	1	0	0	0
	7	6	5	4	3	2	1	0
R W	Reserved	FORCE_LFAST	EVTI1_PAD_EN	EVTI0_PAD_EN	EVTO1_PAD_EN	EVTO0_PAD_EN	EN_ESC_MODE	EN_LFAST
Reset	0	0	0	0	0	0	0	0

The DCI_CR is described in this table.

Table 68-5. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2. Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force destructive reset 0 Do not force destructive reset 1 Force destructive reset

Table continues on the next page...

Table 68-5. DCI_CR field descriptions (continued)

Field	Description
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN[1]	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}$[1] pad 0 $\overline{\text{EVTO}}$[1] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[1] pad output enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST[2]	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

68.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

68.4 Functional description

This section describes the functional description of the DCI.

68.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. Table 68-6 and Table 68-7 show the steps and expected states for the MCU and tool for JTAG to LFAST switching. Table 68-8 and Table 68-9 contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 68-6. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN
TMS	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxP

Table 68-9. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

68.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode.Table 68-10 and Table 68-11 contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 68-10. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input

JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don't Care

Chapter 69
JTAG Controller (JTAGC)

69.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

69.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

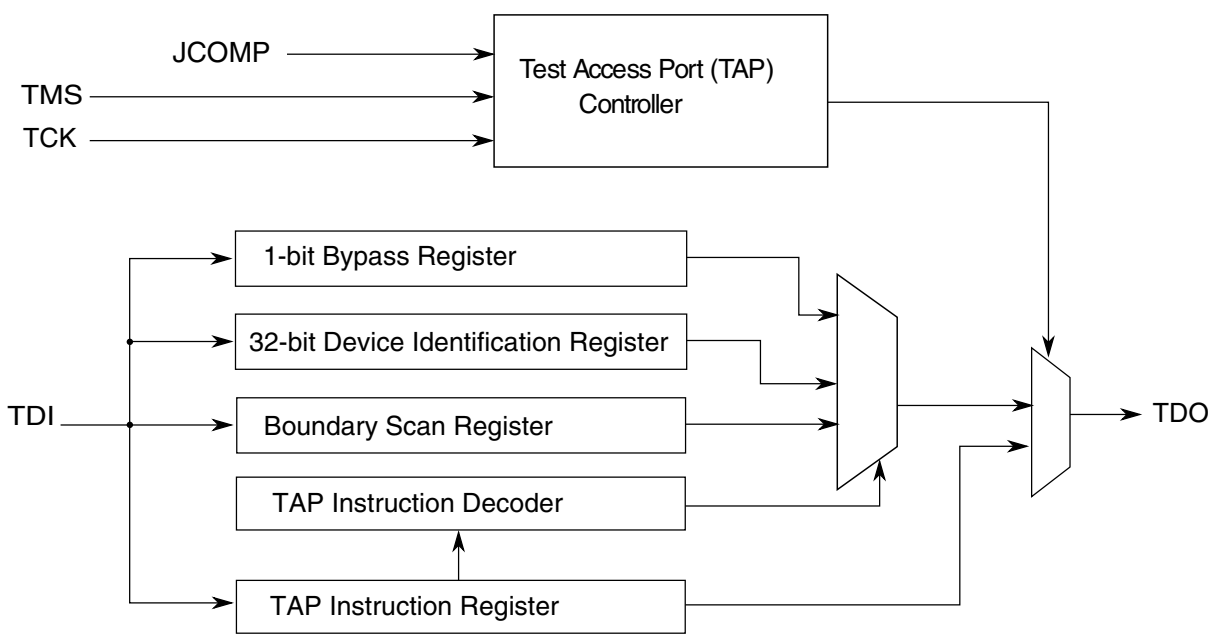

Figure 69-1. JTAG (IEEE 1149.1) block diagram

69.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 69-4 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Bypass register, boundary scan register, data registers, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

69.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

69.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

69.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

69.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

69.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 69-1. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down

Table continues on the next page...

Table 69-1. JTAG signal properties (continued)

Name	I/O	Function	Reset State	Pull
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z[1]	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

69.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

69.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

69.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

69.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

69.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

69.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

69.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

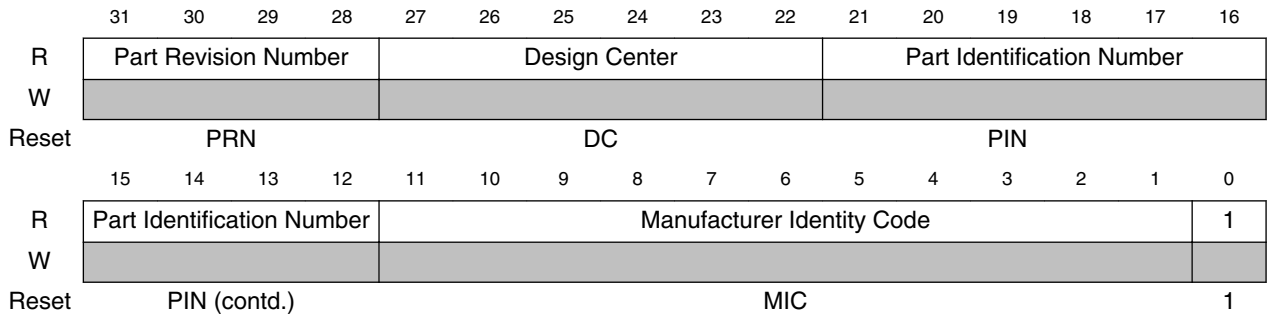
Figure 69-2. Instruction register

69.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

69.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.



The following table describes the device identification register functions.

Table 69-2. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. 0x30E.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

69.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

	255	...	2	1	0
R	JTAG_PASSWORD				
W					
Reset:	*[1]	*	*	*	*

1. The reset value of JTAG_PASSWORD is 256 'b0.
1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 69-3. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

69.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

69.4 Functional description

This section explains the JTAGC functional description.

69.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

69.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

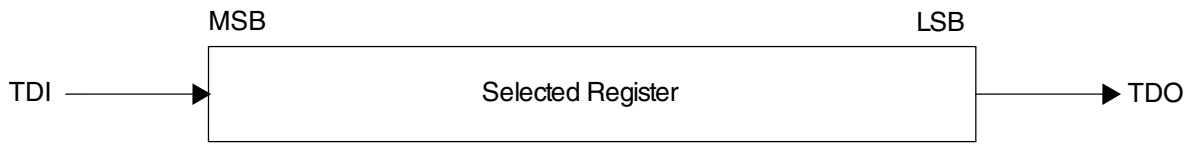


Figure 69-3. Shifting data through a register

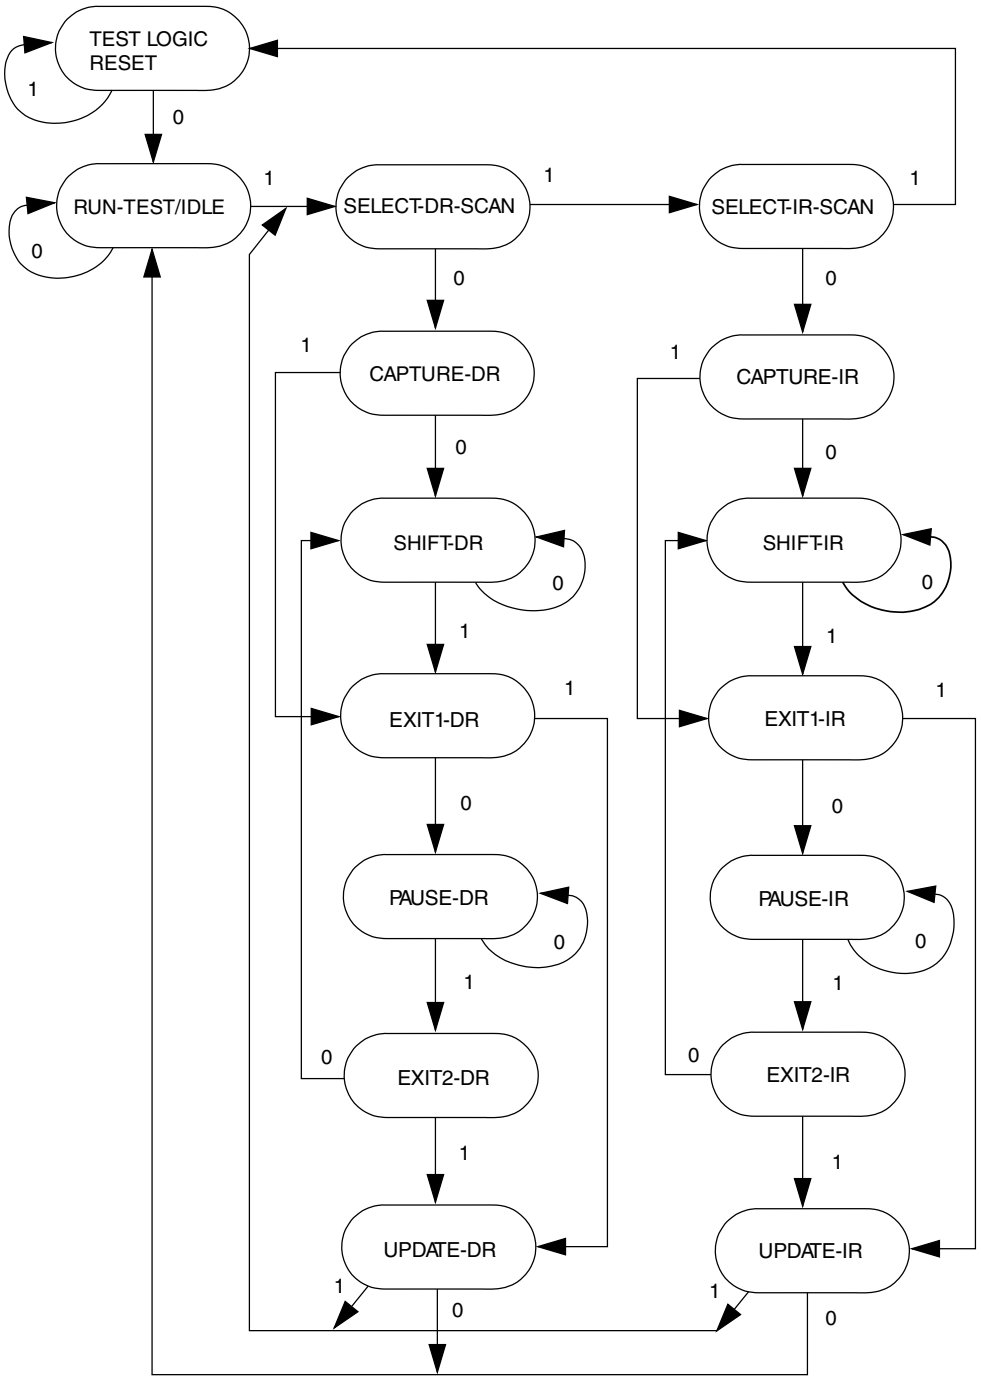
69.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 69-4. IEEE 1149.1-2001 TAP controller finite state machine

69.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

69.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

69.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 69-4. General 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.

Table continues on the next page...

Table 69-4. General 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

69.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

69.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

69.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

69.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

69.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

69.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

69.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

69.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

69.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

69.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

69.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

TAP	Test Access Port
TAP.1	An IEEE 1149.1 Test Access Port
TAP.7	An IEEE 1149.7 Test Access Port
TCA	Tap Controller Address
TCK	Test Clock
TCKC	Test Clock Compact
TDI	Test Data Input
TDIC	Test Data Input Compact
TDO	Test Data Output
TDOC	Test Data Output Compact
TMS	Test Mode Select
TMSC	Test Mode Select Compact
TS	Target System
ZBS	Zero Bit Scan

70.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

70.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- **Advanced**
  - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

70.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

70.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC and nTRST pins.

Table 70-2. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M

Table continues on the next page...

Table 70-2. TAP.7 signal list (continued)

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4

70.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

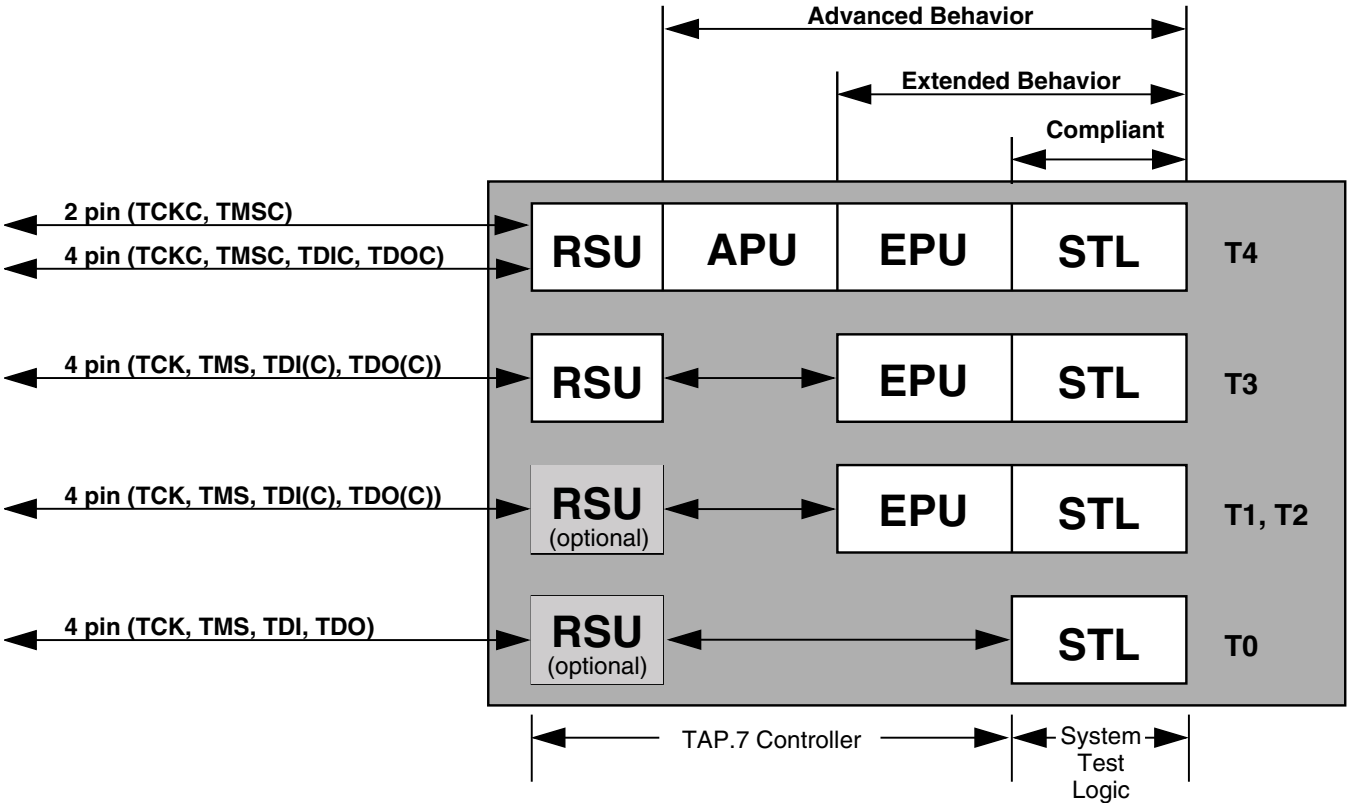

Figure 70-1. TAP.7 Controller Architecture

70.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

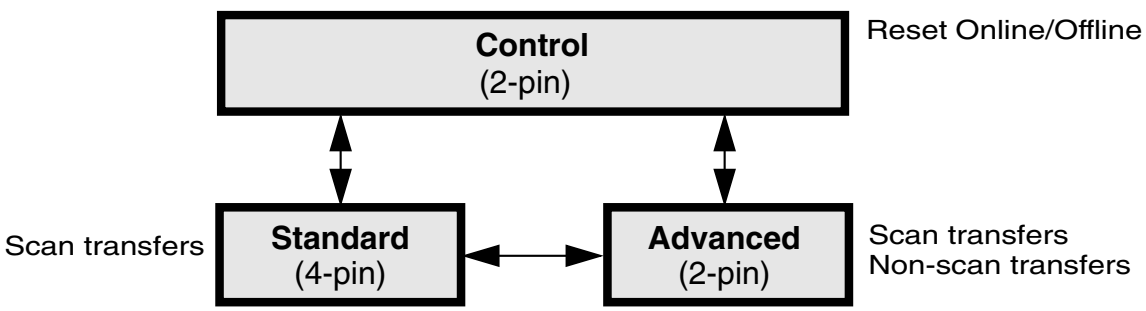

Figure 70-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

Table 70-3. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

70.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

70.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

70.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

70.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

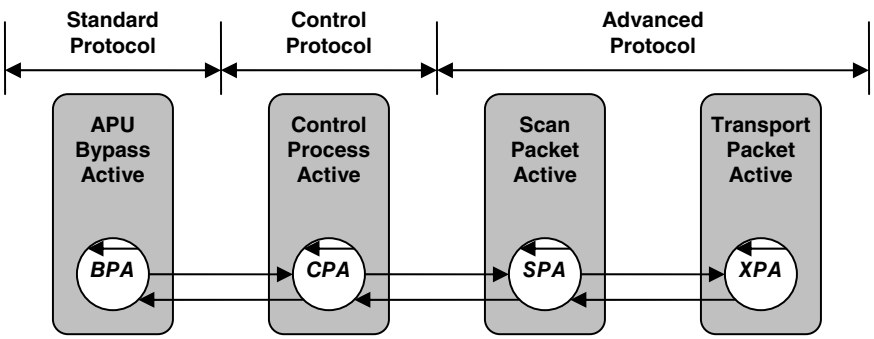

Figure 70-3. CJTAG operating model

70.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

70.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

70.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

70.5.3 T2 functions

- "Super Bypass" function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

70.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

70.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

70.6 Ancillary services

70.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

70.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

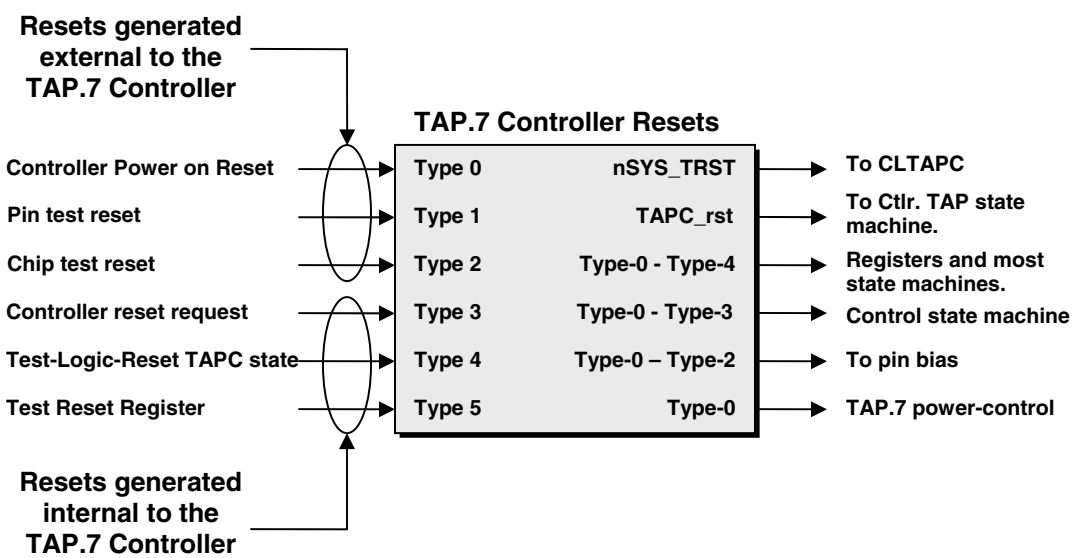

Figure 70-4. Conceptual view of the EPU reset logic and state machines

70.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

70.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

70.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

70.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

70.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

70.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

70.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

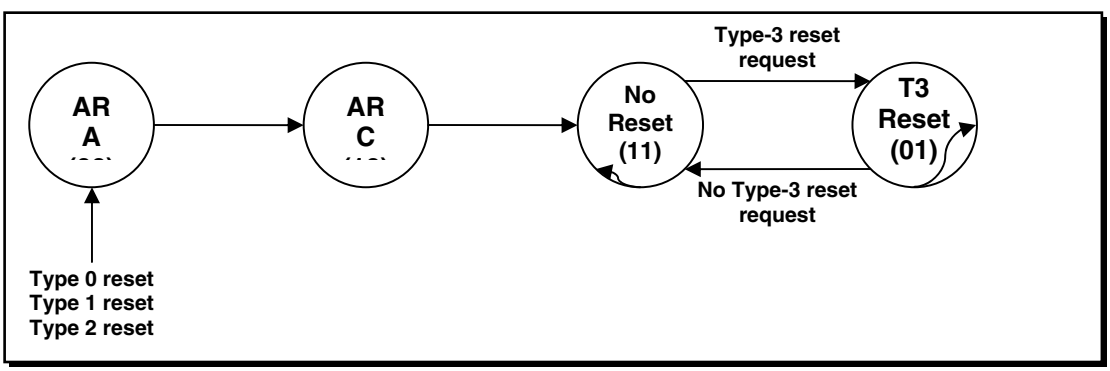

Figure 70-5. Reset state machine

Table 70-4. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

Table 70-5. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

70.6.3 Start-up Options

70.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 70-6. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled

Table continues on the next page...

Table 70-6. Start-up Options (continued)

Start-up Option	Description
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

70.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 70-7. Reset values for TAP.7 startup options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

70.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

70.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP. 7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

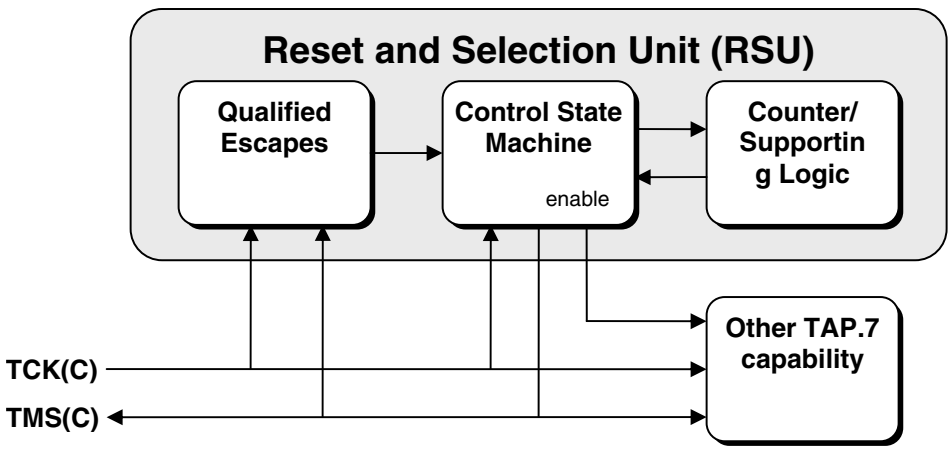

Figure 70-6. Conceptual view of technology selection mechanism

70.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

70.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

70.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

70.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

70.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

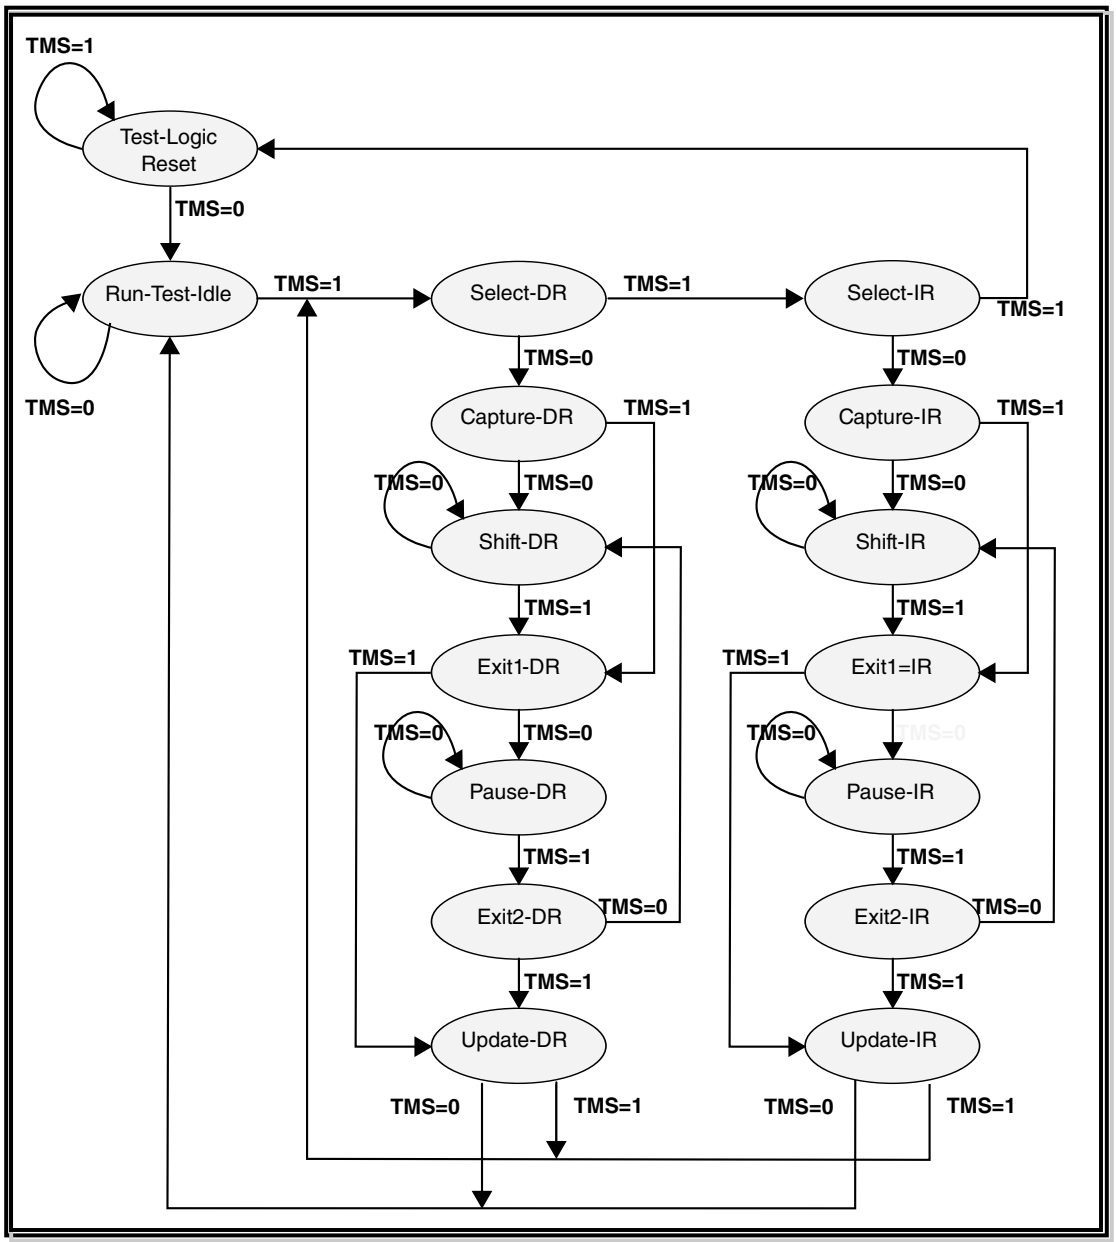

Figure 70-7. Falling edge TAP controller state machine

70.7 EPU (Extended Protocol Unit) Operation

70.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

70.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

70.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

70.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

70.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

70.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

70.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

70.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP. 7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

70.7.2 EPU Registers

70.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

70.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 70-8. TAP.7 controller register list (managed with commands)

Register type	Global/local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	RDBACK1	Read-back 1
		32	CNFG0	Configuration Register 0

M = Mandatory register

O = Optional register

70.7.2.3 Register Descriptions

70.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

70.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

1 – Suspend use of control levels. Enables "System Path."

0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

70.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

1 – Inhibit ZBS detection.

0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

70.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 70-9. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	**JScan0:** • 1149.1 Compliant Operation. • Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	**JScan1:** • 1149.1 Compatible Operation • Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	**JScan2:** • 1149.1 Compatible Operation. • Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	**JScan3:**

Table continues on the next page...

Table 70-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
		• Non-compatible 1149.1 Operation • Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. • Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. • Enables the use of SSDs
T4	01000	**OScan0** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01001	**OScan1** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01010	**OScan2** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01011	**OScan3** • TAP.1 components • No TDI in non-shift states • No TDO in any state
T4	01100	**OScan4** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01101	**OScan5** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01110	**OScan6** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications

Table continues on the next page...

Table 70-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
	01111	**OScan7** • TAP.1 components • No TDI in non-shift states • No TDO in any state
	10000	**MScan** • Data rate dependent components • Multi TAP.7 communication • Directed CID assignment • Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	**Reserved**

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

70.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

0 – Scan selection directives are not enabled.

1 – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

70.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

70.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

70.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

0 – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.

1 – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

70.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

0x – TDI and TDO have JTAG function.

1x – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

70.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

70.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

70.7.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

70.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

70.7.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

70.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

70.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

70.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

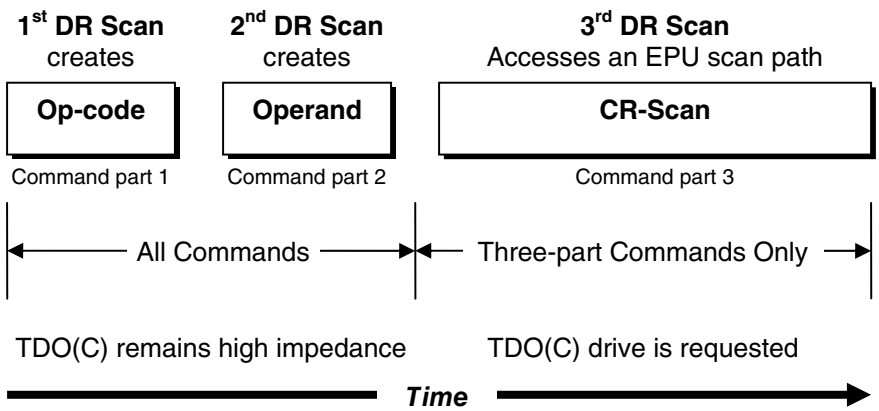

Figure 70-8. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

70.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

Table 70-13. – TAP.7 controller command list

Command class	Opcode count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate[1]	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

70.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

70.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

70.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

70.7.3.5 Command Definitions

70.7.3.5.1 Store Commands

70.7.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 70-14. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	Operand	bbb		x	y	Description
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	-	SGC = y
				1	-	CGM = y

Table continues on the next page...

			10	1	APFC = vv
			11	1	Reserved

70.7.3.5.1.4 Store Scan Format (STFMT)

Table 70-17. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

70.7.3.5.2 Select Commands

This section describes the select commands with their operands.

70.7.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 70-18. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

70.7.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 70-19. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

70.7.3.5.3 Scan Commands

70.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 70-20. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

70.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 70-21. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only

Table continues on the next page...

Table 70-21. Scan String (SCNS) (continued)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

70.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

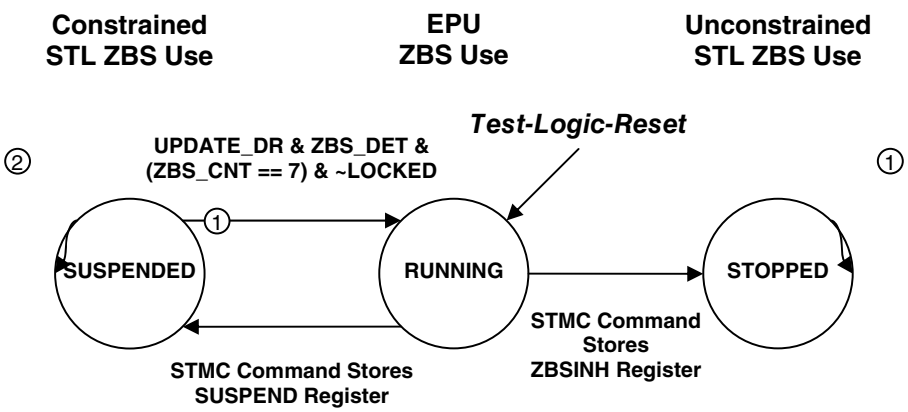

Figure 70-9. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 70-22. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL

Table continues on the next page...

Table 70-22. ZBS use state characteristics with both TAP.7 and other ZBS use (continued)

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

70.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

70.8 APU (Advanced Protocol Unit) Operation

70.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

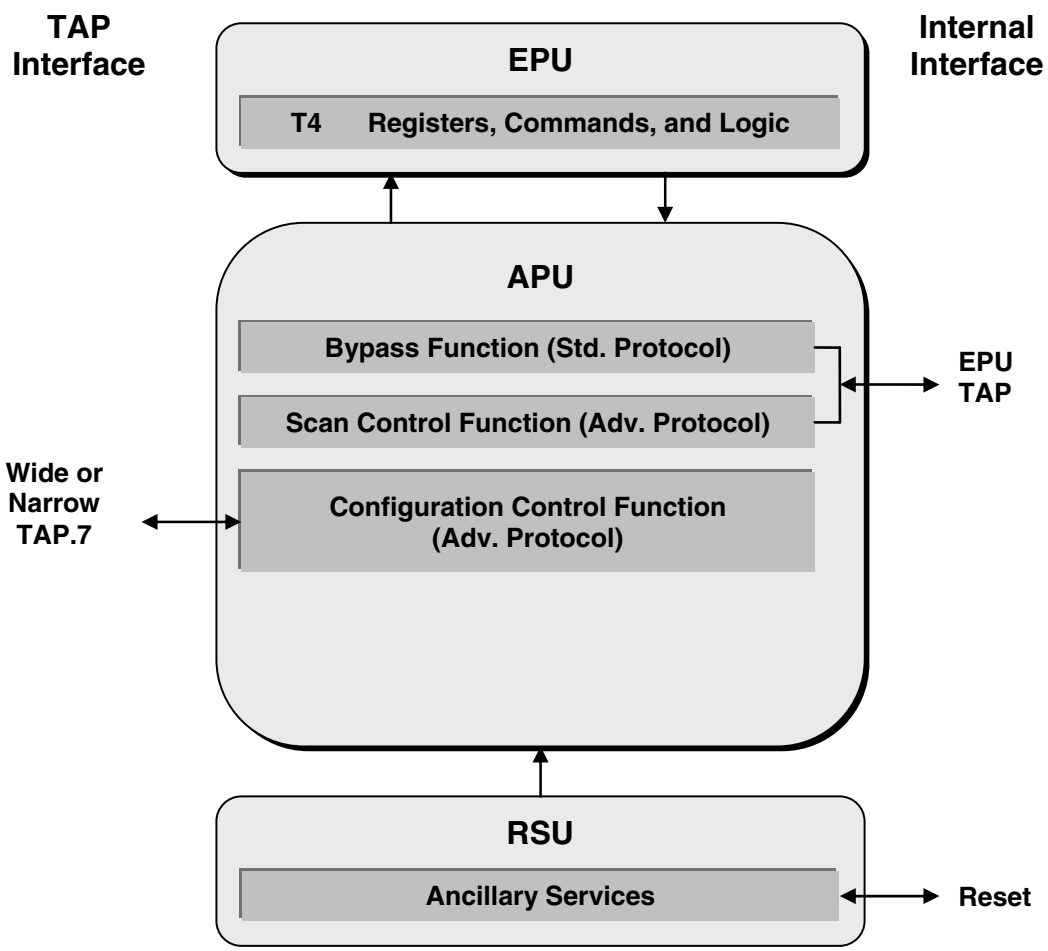

Figure 70-10. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

70.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

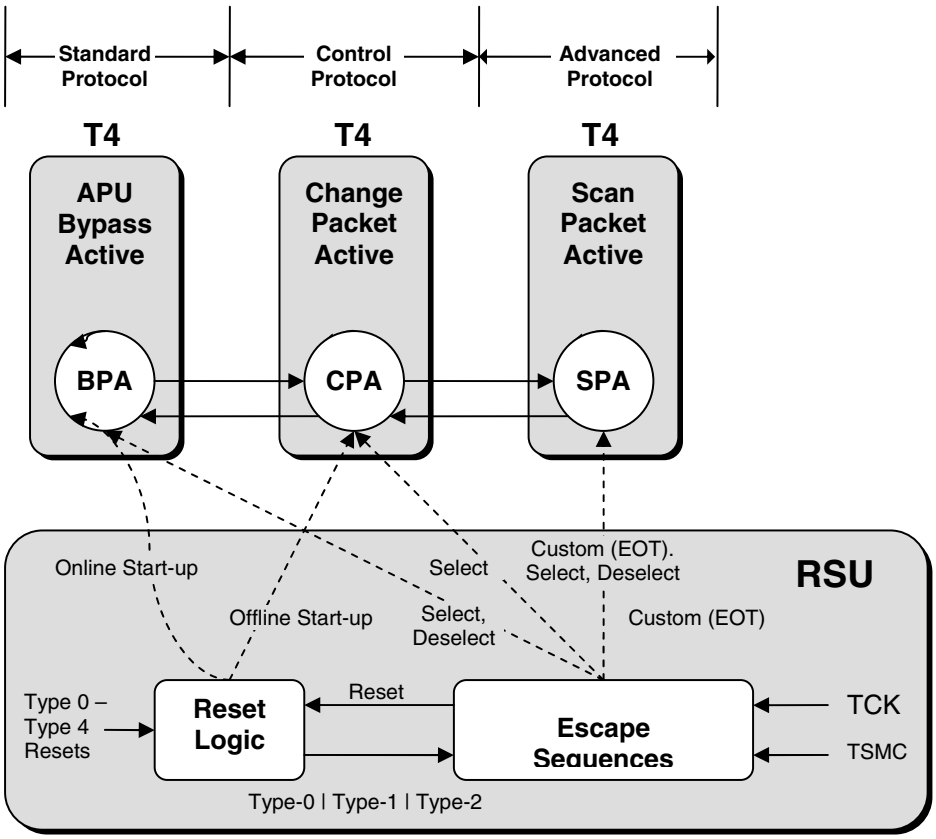

Figure 70-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

70.8.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

70.8.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

70.8.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

70.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

70.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

70.8.5 APU Functions

70.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

70.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

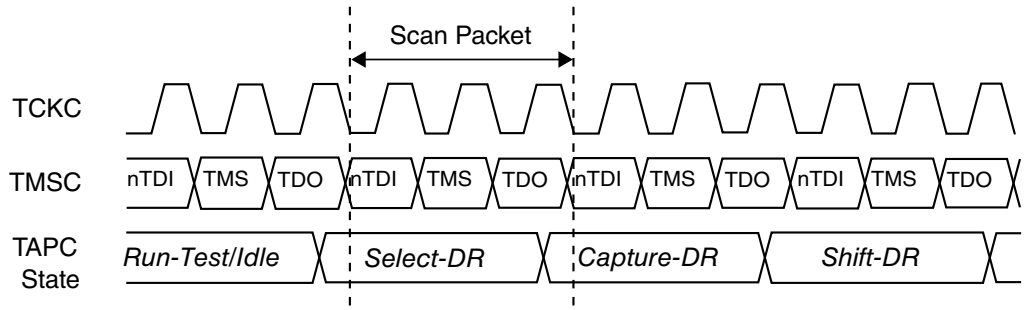

Figure 70-12. Scan Packet Sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

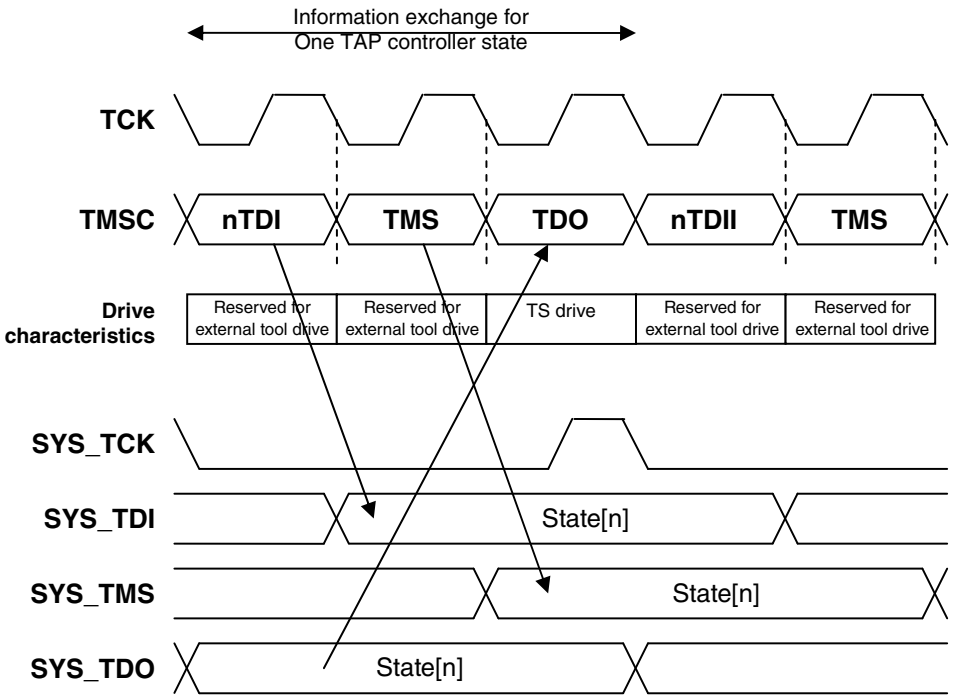

Figure 70-13. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

70.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

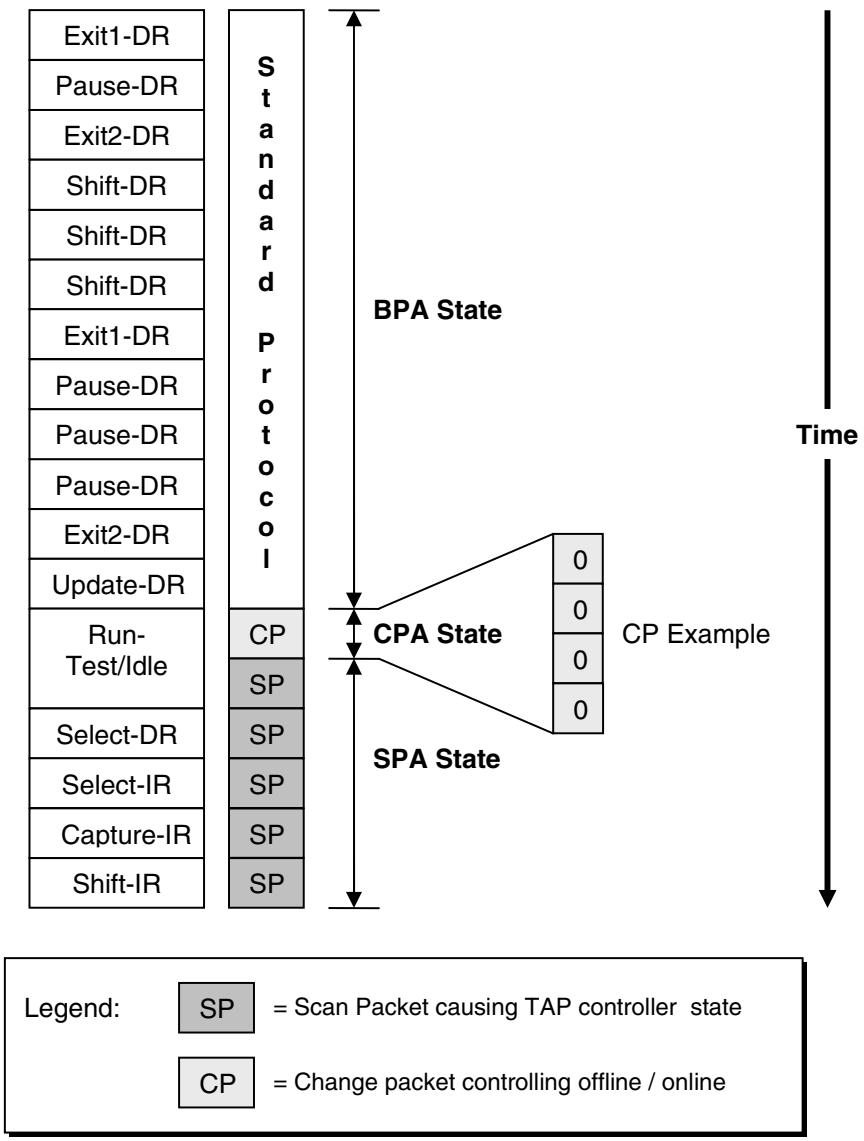

Figure 70-14. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

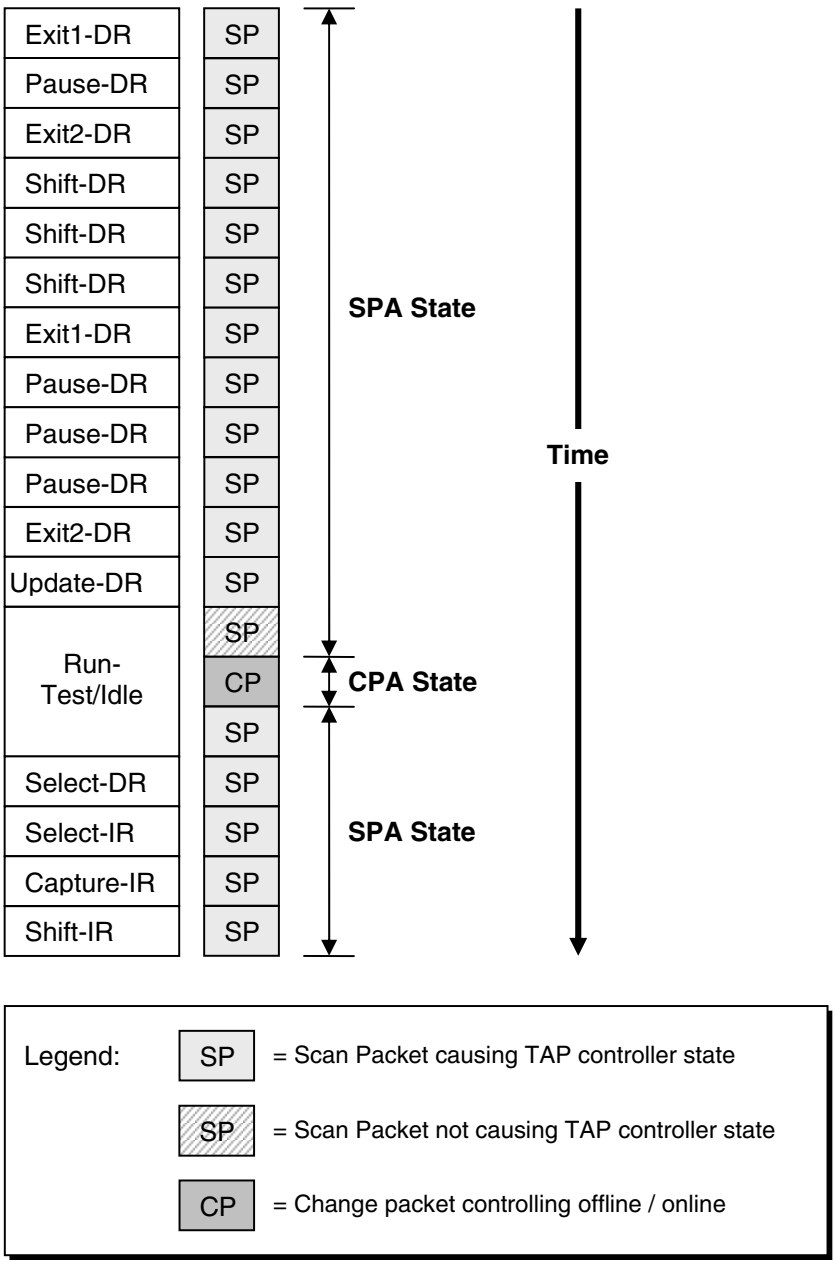

Figure 70-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

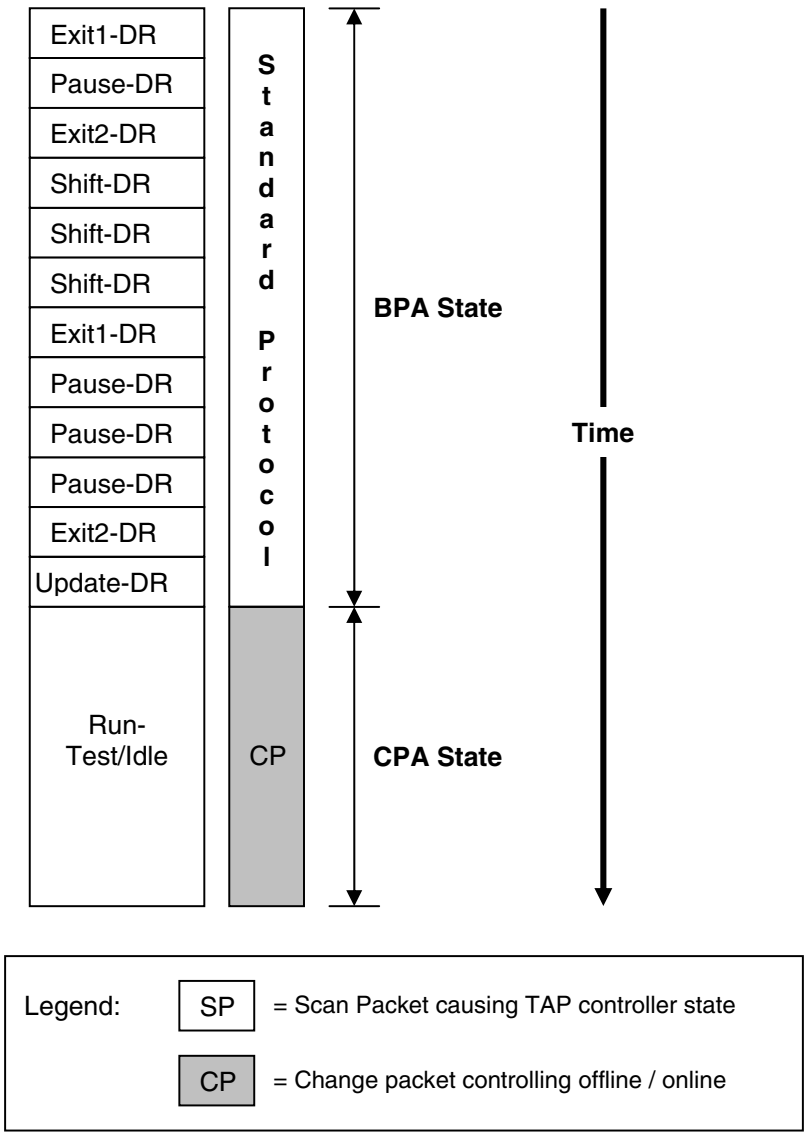

Figure 70-16. CPA State Entry from the BPA State with Offline Operation

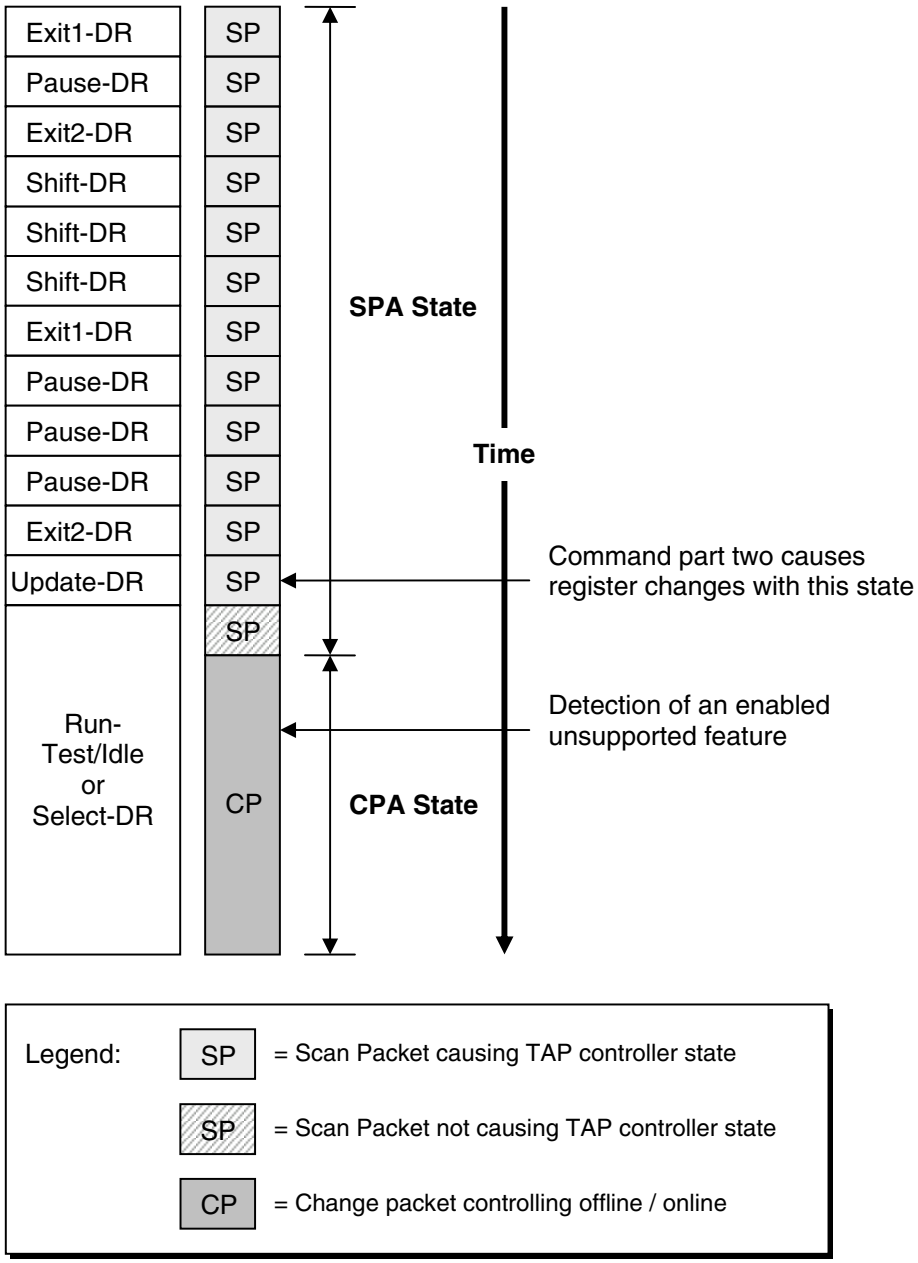

Figure 70-17. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

70.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

70.8.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

70.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

70.8.8.1 Payload Element Content

70.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain and input bit frame, an output bit frame, or both. When an input bet frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

70.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

Table 70-23. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

70.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

70.8.8.3 Scan Formats

70.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in Table 70-24 and Table 70-26. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

70.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 70-24. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP

MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

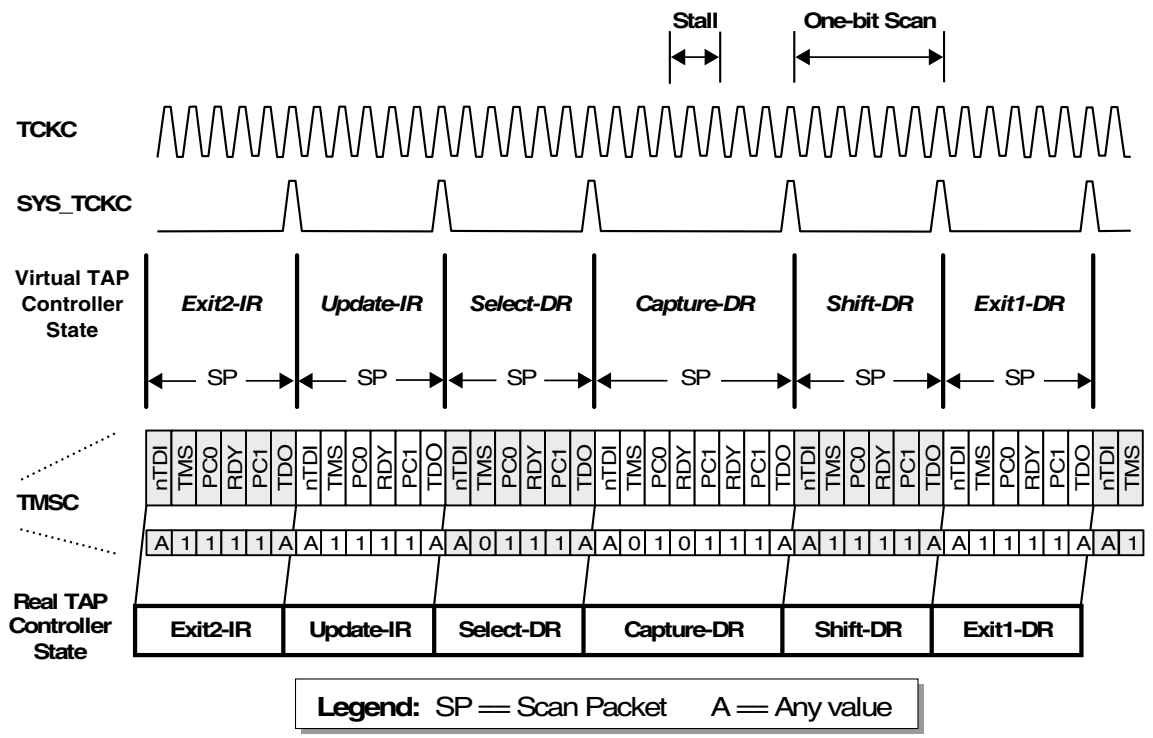

Figure 70-18. MScan Transaction

70.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

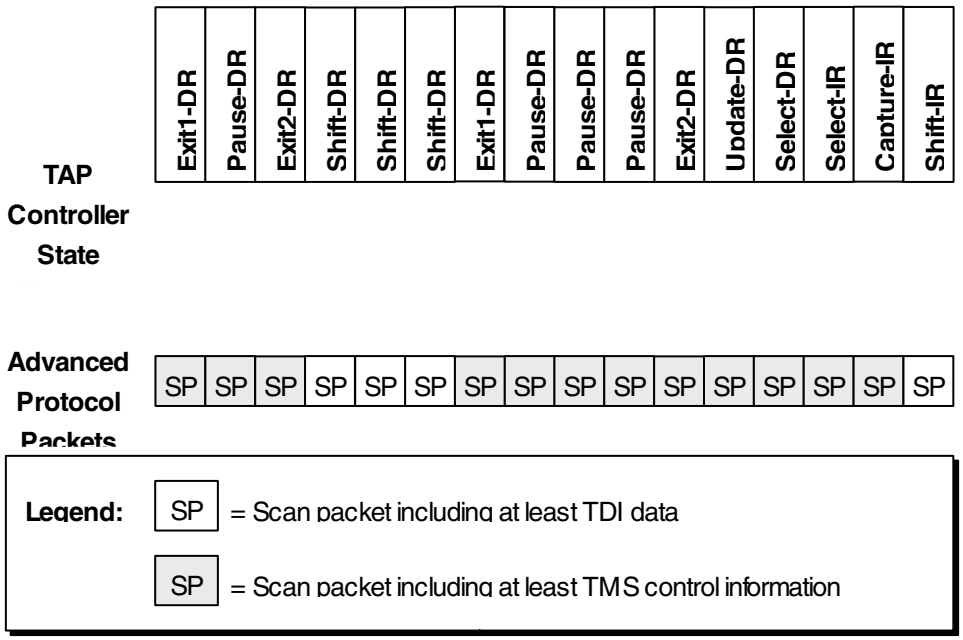

Figure 70-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

Table 70-26. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 70-27. OScan Scan Format "Payload"

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO
OScan1	nTDI	TMS	–	TDO		nTDI	TMS	–	TDO

Note 2: Following Shift-xR Scan Packet

70.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

70.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in Control levels.

After the control level is set tocontrol level 2, TAP.7 commands can be executed as described in EPU Commands. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in Control Process Active (CPA) Function and Configuration Change Packets (CP). Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in Store Conditional 2-bit (STC2).

Chapter 71
JTAG Data Communication (JDC)

71.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

71.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN_IPS register, and when new data has been written to the JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

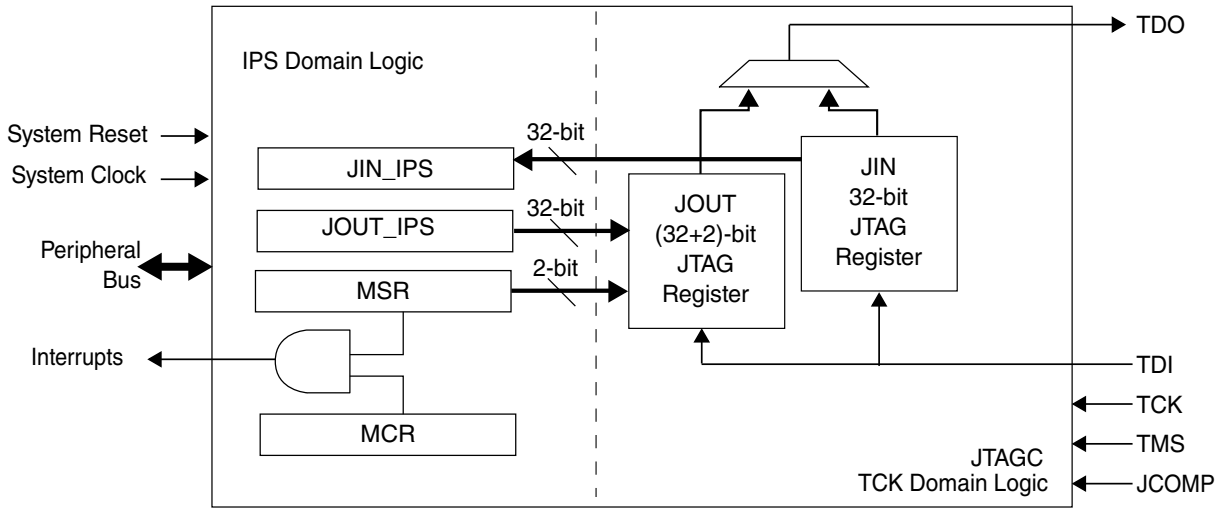

Figure 71-1. JDC block diagram

71.3 Memory mapped registers

Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

JDC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JDC_MCR)	32	R/W	0000_0000h	71.3.1/3877
4	Module Status Register (JDC_MSR)	32	R/W	0000_0000h	71.3.2/3878
8	JTAG Output Data Register (JDC_JOUT_IPS)	32	R/W	0000_0000h	71.3.3/3879
C	JTAG Input Data Register (JDC_JIN_IPS)	32	R	0000_0000h	71.3.4/3880

71.3.1 Module Configuration Register (JDC_MCR)

The MCR is used to enable the interrupt outputs of the JDC. This register is reset by system destructive reset.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

31 JOUT_INT	JOUT Interrupt. 0 Cleared by writing logic 1 1 Set when JOUT_RDY bit is cleared by tool reading JOUT register

71.3.3 JTAG Output Data Register (JDC_JOUT_IPS)

The JOUT_IPS register holds data written via IPS. The JOUT_IPS contents are ported out and captured into the JOUT register to be read via the JTAG port. This register is reset by system destructive reset.

Address: 0h base + 8h offset = 8h

Field	Description
0–31 Data	JIN_IPS data.

71.4 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register and ready status from the MSR to be shifted out via the JTAG port.

71.4.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JOUT register.

	33	…	2	1	0
R W	JOUT_IPS Data			JIN_RDY	JOUT_RDY
Reset	*[1]	*	*	*	*

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in the following table.

Table 71-1. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from MSR
JOUT_RDY	State of JOUT_RDY bit from MSR

71.4.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The following figure shows the format of the JIN register.

	31	…	0
R W	JIN Data		
Reset	*[1]	*	*

1. The reset value of the JIN register is 32'b0.

The JIN register is described in the following table.

Table 71-2. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

71.5 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ

instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.

- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JIN_IPS register upon exit of the Update-DR state. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

71.5.1 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

71.5.1.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 71-3. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

71.6 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

Chapter 72
Sequence Processing Unit (SPU)

72.1 Introduction

The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores, GTM, or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on) The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

72.1.1 SPU block diagram

The following figure shows a top-level block diagram of the SPU.

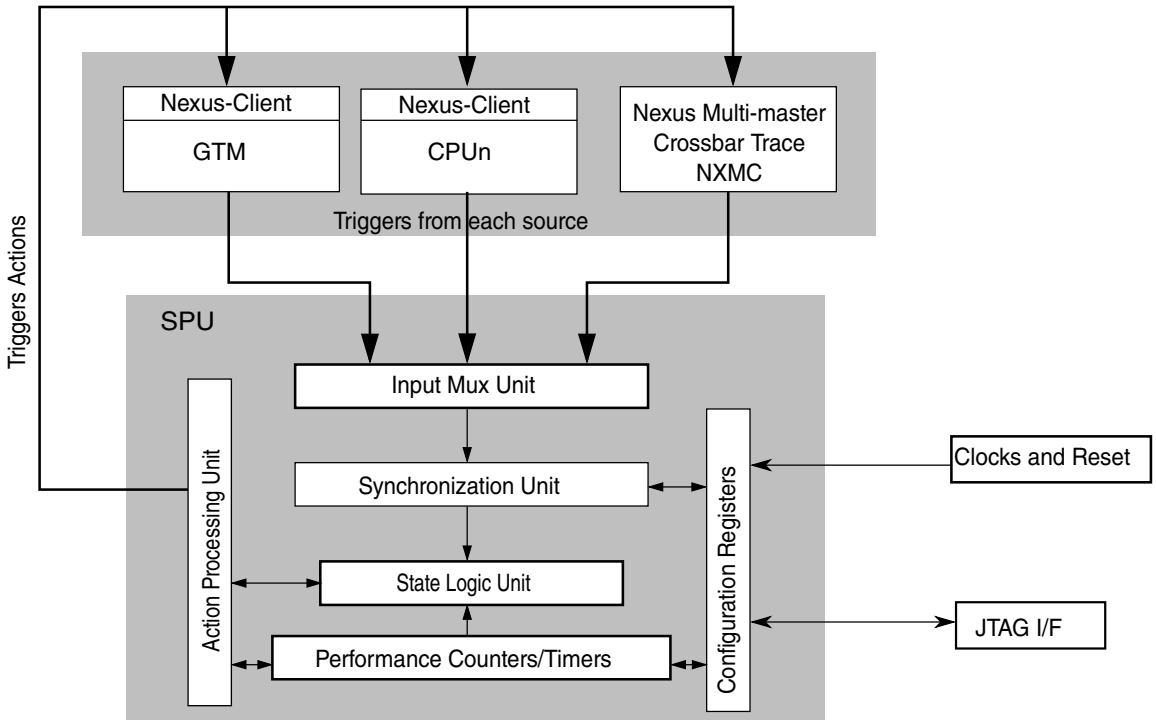

Figure 72-1. SPU block diagram

72.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, GTM, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes but one of the inputs is permanently connected to a high level, so users can only choose 63 of the inputs. Out of these 63 inputs, users can select 16 inputs for each SLU. This is shown in Figure 72-4.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in Figure 72-5. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in Figure 72-6 and Figure 72-7. At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU0 writes to VariableB. If CPU0 writes a value to VariableB which is 0x100, then enable trace for CPU1 and halt CPU0.

The SPU consists of the following sub-blocks:

- Input Mux Unit—receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 × 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in Figure 72-4.
- State Logic Units (SLU)—responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted. These optional inversions coupled with DeMorgan's law allows for generalized signal combinations. This is shown in Figure 72-5.
- Action Processing Unit—takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers—The SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

72.1.3 Features

The features of the SPU are as follows:

- Clients:
  - 3 CPU(s)
  - 1 GTM
  - 2 System Bus clients (NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate.
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers

    - 16 32-bit counters/timers
    - Timer/counter configurability selection via a register
    - Start/increment when used as timer/counter respectively
    - Reset when used as timer/counter respectively
    - Counter value compare match
    - Counter overflow event status
    - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
    - Range support using two counters
    - Use of counter/timer registers to generate counted or timed triggers
    - Use of counter/timer registers to capture system performance statistics
    - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
    - Access to timer/counter values via JTAG
- Prescaler for timer mode only
    - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
    - SPU to/from CPU (fastest clock)
    - SPU to/from NXMC
    - SPU to/from GTM
    - SPU to/from NAR
    - SPU to/from DCI
    - SPU to/from JTAGM
- Interfaces
    - CPU
    - GTM
    - System bus

  - NAR
  - DCI
- Configuration registers—32-bit double word aligned configuration registers (byte, halfword access not supported)
- SPU actions—SPU block triggers various actions based on the derived events, these actions are defined in SPU actions.

72.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Capture counter/timer values[0–15]—place the specified counter/timer value into the trace stream for counters[0–15]
- Halt1—single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2—single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Generate a watchpoint trigger for a respective ID field the NXMC (global timestamp must be enabled from the NAR)
- Capture the global timebase and place it into the trace stream with a watchpoint ID field of respective watchpoints at the NXMC (send TIMESTAMPx where x is related to an watchpoint ID field of NXMC only)
- Single interrupt for INTC to interrupt a CPU—de-assert (cleared) via JTAGM
- Generate a pulse on the EVTO pin—output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source—Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals)—four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note

GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

72.3 SPU enable/disable mode

By default, the SPU is in disabled mode. In this state, all events/inputs are disabled such that no counting or other actions occur. All of the SPU control registers are accessible in this state. All of the configurations must be done before enabling the SPU by programming the SPU Enable/Disable register.

72.4 SPU module interface

The SPU is connected to many clients such as the cores, GTM, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in the following figure.

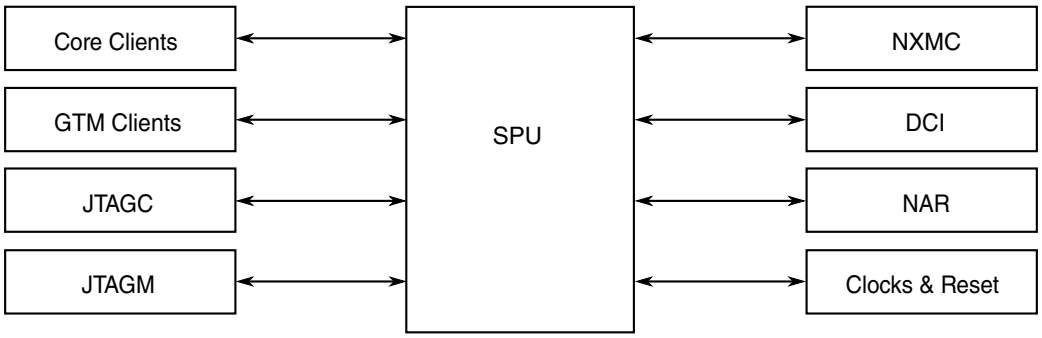

Figure 72-2. SPU module interface

72.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note

The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

The following table lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 0x1–0x49) registers is 4'h3
- Instruction to enable the Counter Control Unit (second set of registers with offsets 0x1–0x48) is 4'h2

Table 72-1. SPU register summary

Offset (hex)	Register	Access	Reset Value

72.5.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 out of 64 inputs for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in Figure 72-4.

Note

Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

72.5.1.1 Level1 Mux Selection 0 (L1SEL0)

The following table shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see the device-specific chapter that describes how the modules are configured.

72.5.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in Level1 input Mux configurations registers) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the following figure for State0. Similar logic is provided for States 1–7.

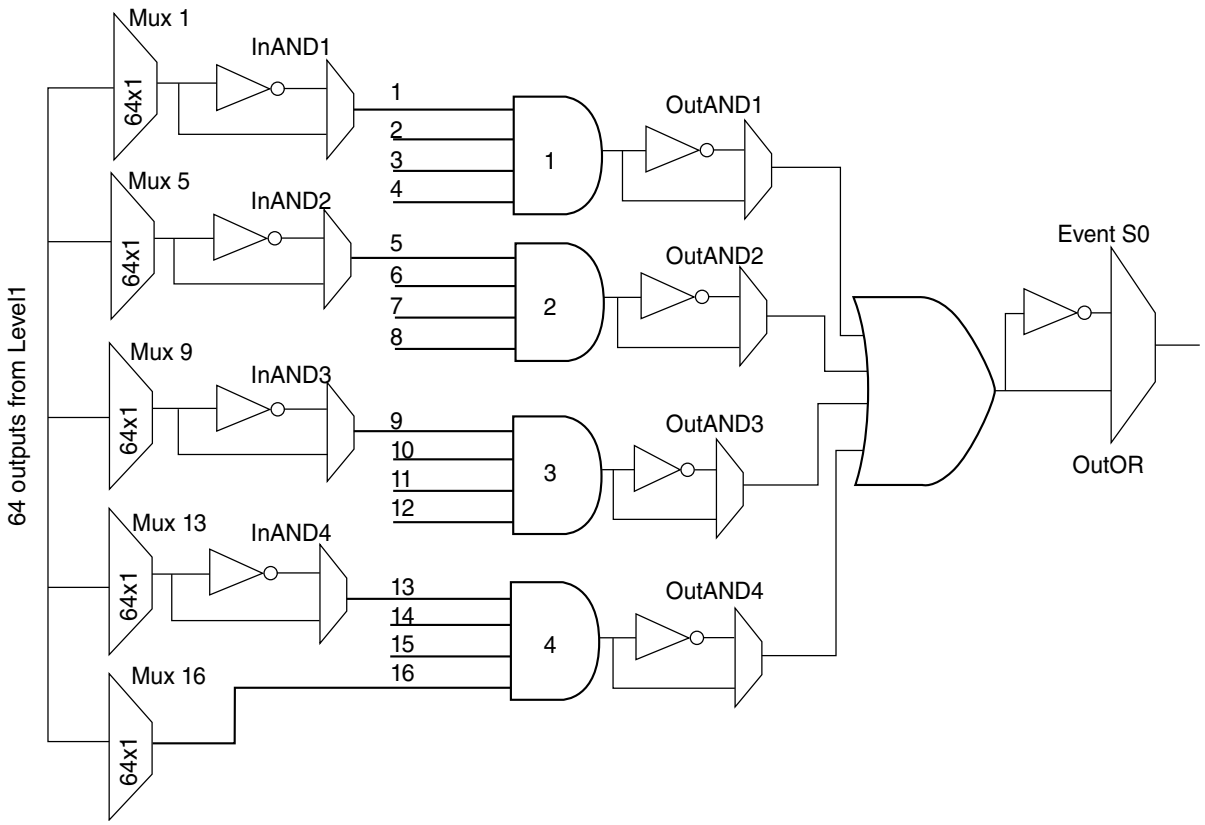

Figure 72-3. Level2 Mux AND gates input pin routing for State0

Note

If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

72.5.2.1 Level2 Mux state n selection 0 (L2nSEL0)

The following table shows the format of the L2nSEL0 register, where n, the state number, is equal to 0–7.

Offset:	0x17 (State0) 0x1B (State1) 0x1F (State2) 0x23 (State3) 0x27 (State4) 0x2B (State5)	Access: User read/write

72.5.3 Sequence unit registers

72.5.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in

the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. The following table shows the format of the IOICn register, where n, the state number, is equal to 0–7.

Offset 0x37 (State0) 0x38 (State1) 0x39 (State2) 0x3A (State3) 0x3B (State4) 0x3C (State5) 0x3D (State6) 0x3E (State7) Access: User read/write

8 OutOR	Output OR GATE Control. 0 Output is used directly (without inversion) for this event 1 Output is inverted for this event
9:31	Reserved. Read returns 0.

72.5.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. The following table shows the format of the SCTRL register.

Offset 0x3F Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	111 State 7 is the Stop state for sequence 4

Table continues on the next page...

Table 72-14. SCTRL register field descriptions (continued)

Field	Description
31	Reserved. Read returns 0.

1. Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.
2. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.

72.5.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

The following table shows the format of the SnGC register, where n, the state number, is equal to 0–7.

Offset: 0x40 (State0), 0x41 (State1), 0x42 (State2), 0x43 (State3), 0x44 (State4), 0x45 (State5), 0x46 (State6), 0x47 (State7) — Access: User read/write

The SnGC register fields are described in the following table.

Table 72-15. SnGC register field descriptions

Field		Description
0		GoTo Control of State Under True Condition. Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition.
TE	0	Disable Goto control
	1	Enable Goto control

Table continues on the next page...

Table 72-15. SnGC register field descriptions (continued)

Field	Description	
3:1	Next State on True Condition. Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state.	
NT	000	Goto State 0
	001	Goto State 1
	010	Goto State 2
	011	Goto State 3
	100	Goto State 4
	101	Goto State 5
	110	Goto State 6
	111	Goto State 7
4	GOTO Control of State Under False Condition. Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5] . If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition.	
FE	0	Disable Goto control
	1	Enable Goto control
7:5	Next State on False Condition. Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state.	
NF	000	Goto State 0
	001	Goto State 1
	010	Goto State 2
	011	Goto State 3
	100	Goto State 4
	101	Goto State 5
	110	Goto State 6
	111	Goto State 7
31:8	Reserved. Read returns 0.	

72.5.4 SLU status (SS) register

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. The following table shows the format of the SS register.

Offset 0x48 Access: User read/write

The SS register fields are described in the following table.

Table 72-16. SS register field descriptions

Field	Description
0 SH0	State Hit 0. This bit is set when State0 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
1 SH1	State Hit 1. This bit is set when State1 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
2 SH2	State Hit 2. This bit is set when State2 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
3 SH3	State Hit 3. This bit is set when State3 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
4 SH4	State Hit 4. This bit is set when State4 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
5 SH5	State Hit 5. This bit is set when State5 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
6 SH6	State Hit 6. This bit is set when State6 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
7 SH7	State Hit 7. This bit is set when State7 is hit/encountered in any of the active sequences 0 State not hit 1 State hit
10 :8 SAS1	Sequence 1 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 1 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state

Table continues on the next page...

Table 72-16. SS register field descriptions (continued)

Field	Description
	110 State6 is the active state
	111 State7 is the active state
13 :11	Sequence 2 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 2 at the clock when these bits are read. The active state might be different in the previous clock and the next clock.
SAS2	000 State0 is the active state
	001 State1 is the active state
	010 State2 is the active state
	011 State3 is the active state
	100 State4 is the active state
	101 State5 is the active state
	110 State6 is the active state
	111 State7 is the active state
16:14	Sequence 3 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 3 at the clock when these bits are read. The active state might be different in the previous clock and the next clock.
SAS3	000 State0 is the active state
	001 State1 is the active state
	010 State2 is the active state
	011 State3 is the active state
	100 State4 is the active state
	101 State5 is the active state
	110 State6 is the active state
	111 State7 is the active state
19 :17	Sequence 4 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 4 at the clock when these bits are read. The active state might be different in the previous clock and the next clock.
SAS4	000 State0 is the active state
	001 State1 is the active state
	010 State2 is the active state
	011 State3 is the active state
	100 State4 is the active state
	101 State5 is the active state
	110 State6 is the active state
	111 State7 is the active state
20	Exception Match 0. This bit indicates the status of the processor exception vector match value of CPU0.
EM0	0 No match
	1 Match occurred
21	Exception Match 1. This bit indicates the status of the processor exception vector match value of CPU1.
EM1	0 No match
	1 Match occured
22	Exception Match 2. This bit indicates the status of the processor exception vector match value of CPU2.

Table continues on the next page...

Table 72-16. SS register field descriptions (continued)

Field	Description
EM2	0 No match 1 Match occurred
23 IM0	Interrupt Match 0. This bit indicates the status of the match value on interrupt priority register of CPU0. 0 No match 1 Match occurred
24 IM1	Interrupt Match 1. This bit indicates the status of the match value on interrupt priority register of CPU1. 0 No match 1 Match occurred
25 IM2	Interrupt Match 2. This bit indicates the status of the match value on interrupt priority register of CPU2. 0 No match 1 Match occurred
31:26	Reserved. Read returns 0

72.5.5 SPU enable (SE) register

The SPU enable/disable register is used to enable and disable the SPU. If disabled, all inputs are masked. The following table shows the format of the SE register.

Offset: 0x49 Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DIV	SED
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SE register fields are described in the following table.

Table 72-17. SE register field descriptions

Field	Description
0 SED	SPU Enable/Disable. This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled
1 DIV	Div Option. Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution. 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required.
31:2	Reserved

NOTE

Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.

72.5.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

72.5.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example: If there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

72.5.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in SPU actions.

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in SPU actions, becomes redundant with Div4 option.

72.5.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions. List of the actions is given in SPU actions. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. The following table shows the bit mapping for all the possible actions. All possible actions are divided in three groups: client based, counter based, system related.

Table 72-18. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]
ID	Name	ID	Name	ID	Name	Comment	
00	Client group	00000	CPU0	0000	No action	—	0=Stop 1=Start

28:31	Reserved

72.5.7.5 Trace group configuration registers (DTMGC, PTMGC, OTMGC and WTMGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace—clients are configured with the DTM trace group configuration (DTMGC) register
- PTM trace—clients are configured with the PTM trace group configuration (PTMGC) register
- OTM trace—clients are configured with the OTM trace group configuration (OTMGC) register
- WTM trace—clients are configured with the WTM trace group configuration (WTMGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

The following table shows the format of the trace group configuration registers.

Offset 0x21 (DTMGC) 0x22 (PTMGC) 0x23 (OTMGC) 0x24 (WTMGC) Access: User read/write

Table 72-26. CCMPn register field descriptions

Field	Description
31:0 COMPARE_VAL	Compare value. This value is compared with the corresponding counter/timer value to generate an event for the SPU.

72.5.10 Status registers

72.5.10.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. The following table shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in Table 72-27. Counter compare values should not be changed dynamically. Thus, these fields should be cleared (by writing 1) only during these conditions:

- Counter is in disabled state (ENABLE bit of CCTRLn set to 0).
- Software reset bit (SW_RESET) is set.

Offset 0x46 Access: User read/write

The CCOMS register fields are described in the following table, where n is the counter number.

Table 72-27. CCOMS register field descriptions

Field	Description
CCn	Counter n Compare. 0 Counter status is not true 1 Counter status is true

72.5.10.2 Counter overflow status (COS)

Whenever a counter overflow occurs, the corresponding counter overflow status register bit is set. The bits in this register can be cleared by writing a 1 to them. The following table shows the format of the COS register. All of the CO fields in the COS register have the same description as shown in Table 72-28.

Offset 0x47 Access: User read/write

Table 72-28. COS register field descriptions

Field	Description
COn	Counter n Overflow. 0 Counter did not overflow 1 Counter overflow occurred

72.5.10.3 Counter capture status (CCAPS)

Whenever a counter value is captured, the corresponding capture status register bit for that counter is set. If the counter capture value causes a FIFO overflow, and thus the captured value is lost, the status bit is not set. The bits in this register can be cleared by writing a 1 to them. The following table shows the format of the CCAPS register.

All of the CC fields in the CCAPS register have the same description as shown in Table 72-29.

Offset 0x48 Access: User read/write

72.6 Functional description

This section discusses the functional description of the SPU.

72.6.1 Input Mux unit

The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in Figure 72-4.

- Level 1 Muxing—At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in Figure 72-4.
- Level 2 Muxing—At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.

  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases

to be achieved without encountering concurrency restrictions. Since there are eight such states, 16 × 8 banks of 64:1 mux are required. The selection mechanism is shown in the following figure.

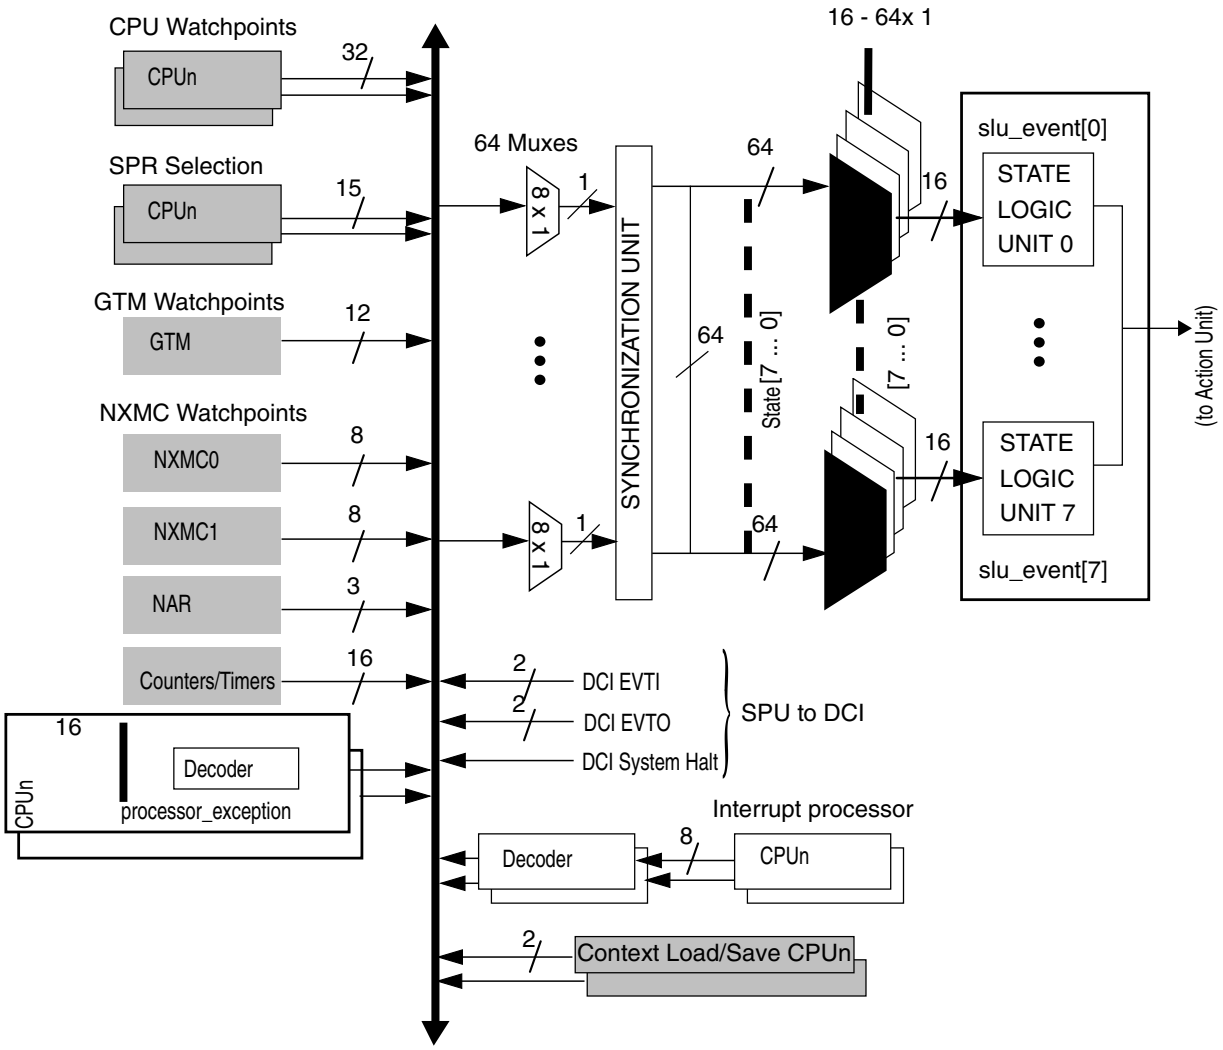

Figure 72-4. Input Mux unit block diagram

72.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input condition as shown in the following table. The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPUn field of the CnPEVP registers as shown in the following table.

Table 72-30. Processor exception processing conditions

CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input—autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input—autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input—vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input—vectored

72.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in the following figure.

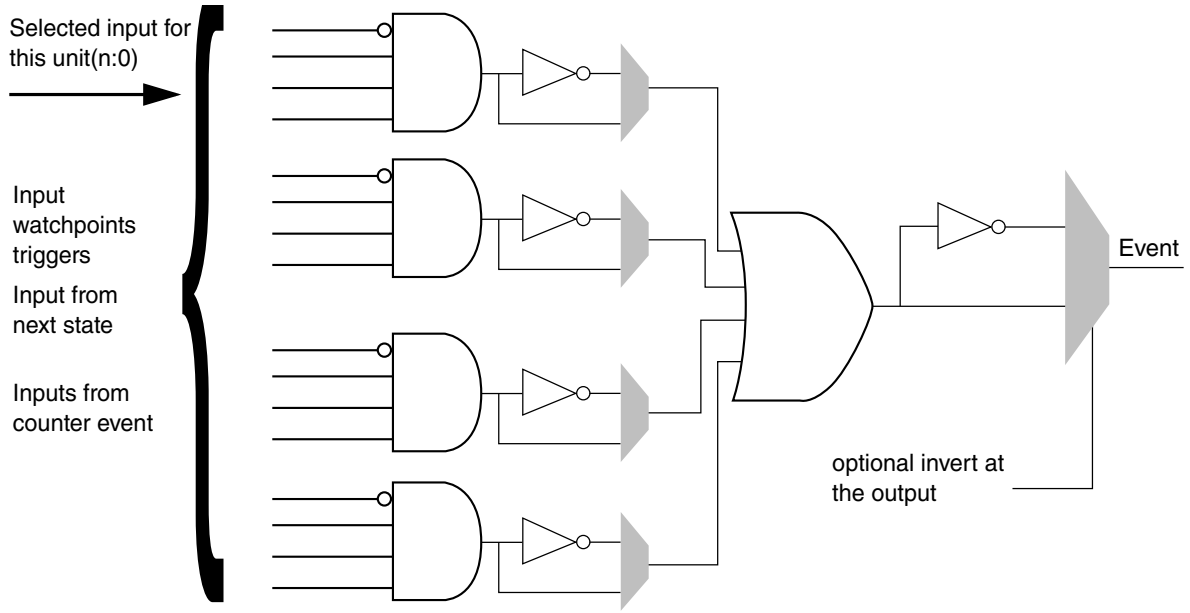

Figure 72-5. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note

With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

72.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn be designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.

For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in the following figure:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic

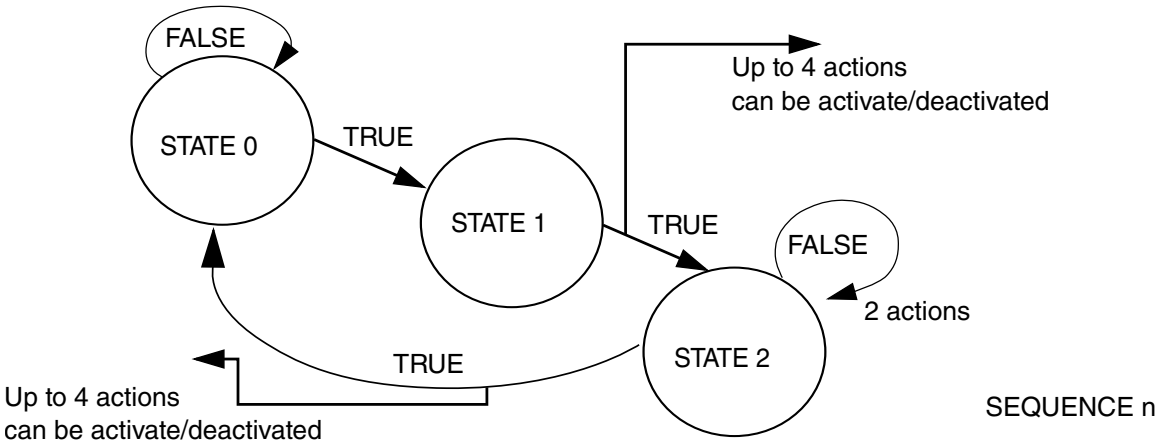

Figure 72-6. Example of a simple configurable if-then-else sequence

72.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in the following figure.

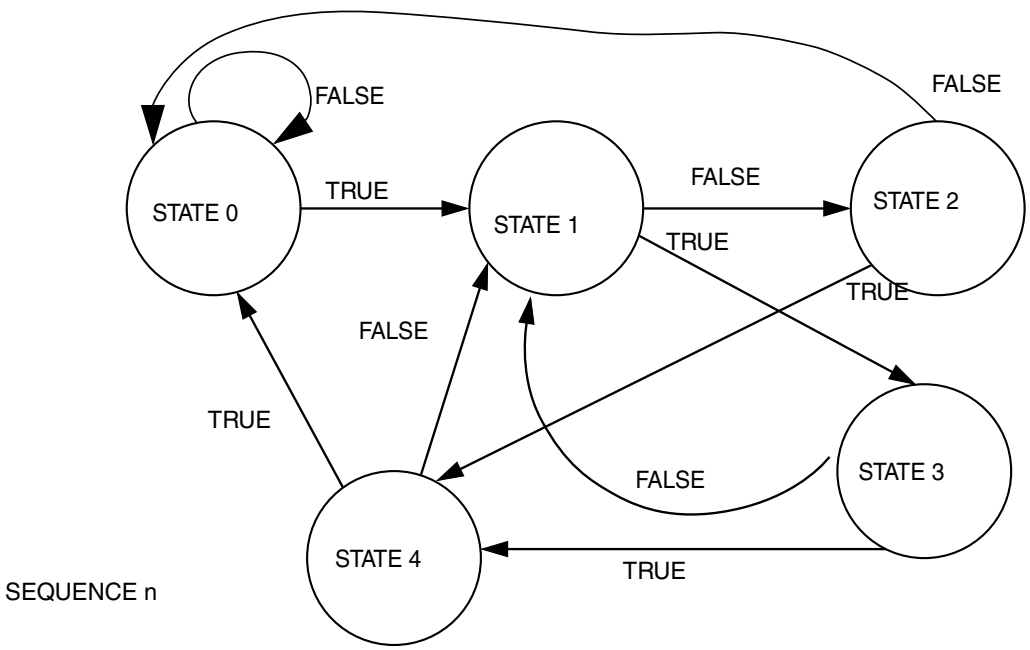

Figure 72-7. Complex sequence example

72.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered, and upon the 12th time of entering the function, stop the trace signal. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

72.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:

- States—each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register.
- Sequence status—each sequence has a field indicating the active state of the state machine. This is a read only field.

72.6.5 Performance counters/timers unit

The SPU counters are 32-bit counters that may be used to delay events, count distances, count latencies or count events as shown in the following figure. Therefore, these counter are used as either counters or timers. The selection between counter or timer for each of the counters is done via configuration register. The basic counting operation is straightforward. Once enabled (default is disabled mode), whenever the selected input is driven to a logic 1, the counter increments using the platform clock.

Each of the counter/timer registers are accessible (via the JTAG interface) for the configuration of timer/counter, the compare registers and global SPU timer/counter status registers. These register are accessible via the JTAG interface even when the SPU is in disabled mode.

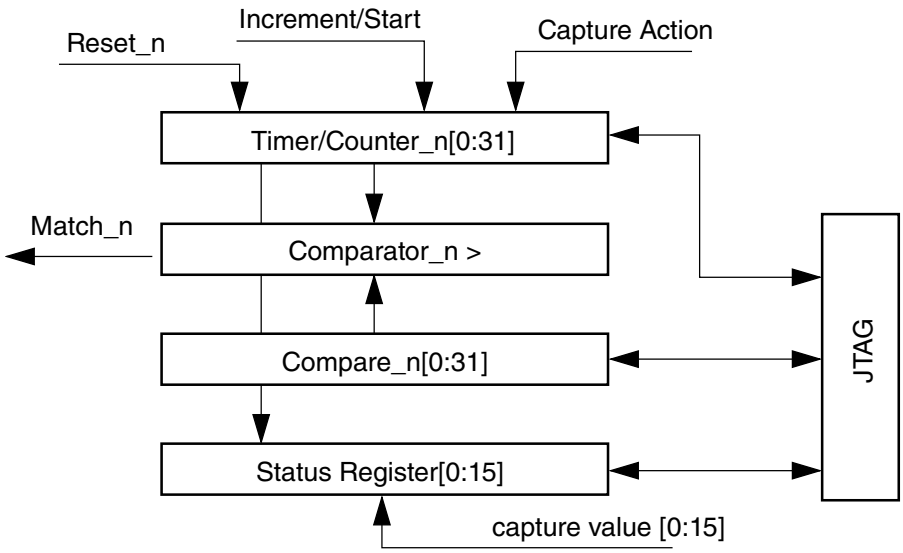

Figure 72-8. Counters/timers overview

72.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register which is accessible to users via JTAG interface. These status registers are if type write 1 to clear (W1C).

There are two classes of signals, actions and events:

- Actions—each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

  On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.

- Events—on a match event, whereby the a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

72.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in the following figure. These inputs include signals from the primary SPU muxes or SPU events of counters.

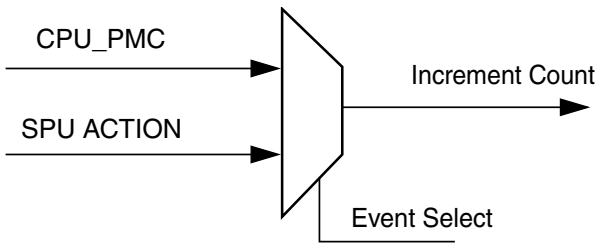

Figure 72-9. Input selection for count increment

72.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in the following figure.

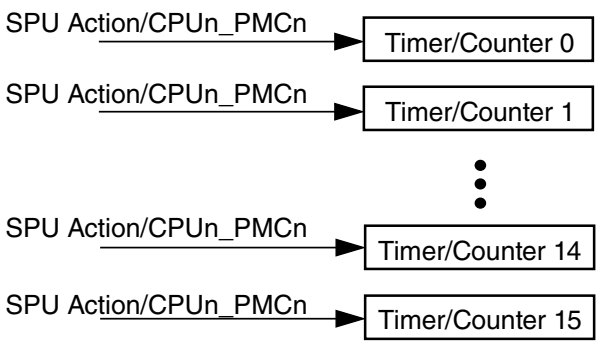

Figure 72-10. SPU counters increment assignment

72.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the following figure.

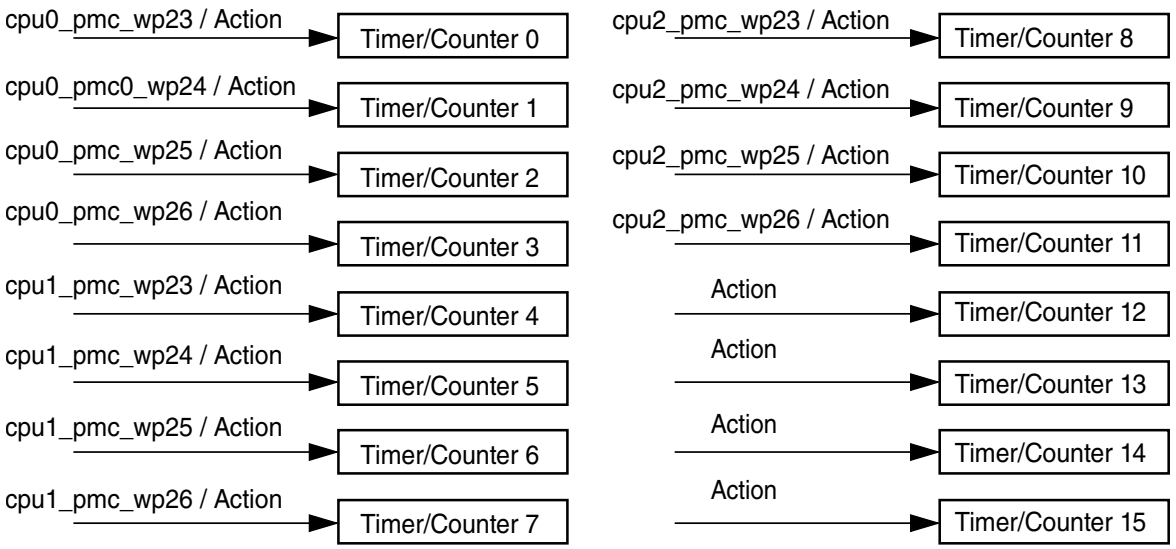

Figure 72-11. CPU PMC mapping inside the SPU unit

72.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the SPU actions. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers. Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

72.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers registers, defined in Table 72-23, are available where the user can group the different traces from same or different clients.

72.6.8 CKSRC and CKDATA format

The format of the CKSRC is defined for the SPU peripheral (as in-circuit trace client) as shown below:

ICT clients	CKSRC value
SPU counter trace client	b00_0000

Table continues on the next page...

ICT clients	CKSRC value
Reserved	b00_0001 — b11_1111

The format for the CKDATA field for the SPU counter trace client is as shown below:

CKDATA	
CKDATA[CTR_index]	CKDATA[CTR_value]
4 bits	32 bits

Chapter 73
JTAG Master (JTAGM)

73.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

73.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:

- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

This figure shows the block diagram of the JTAGM.

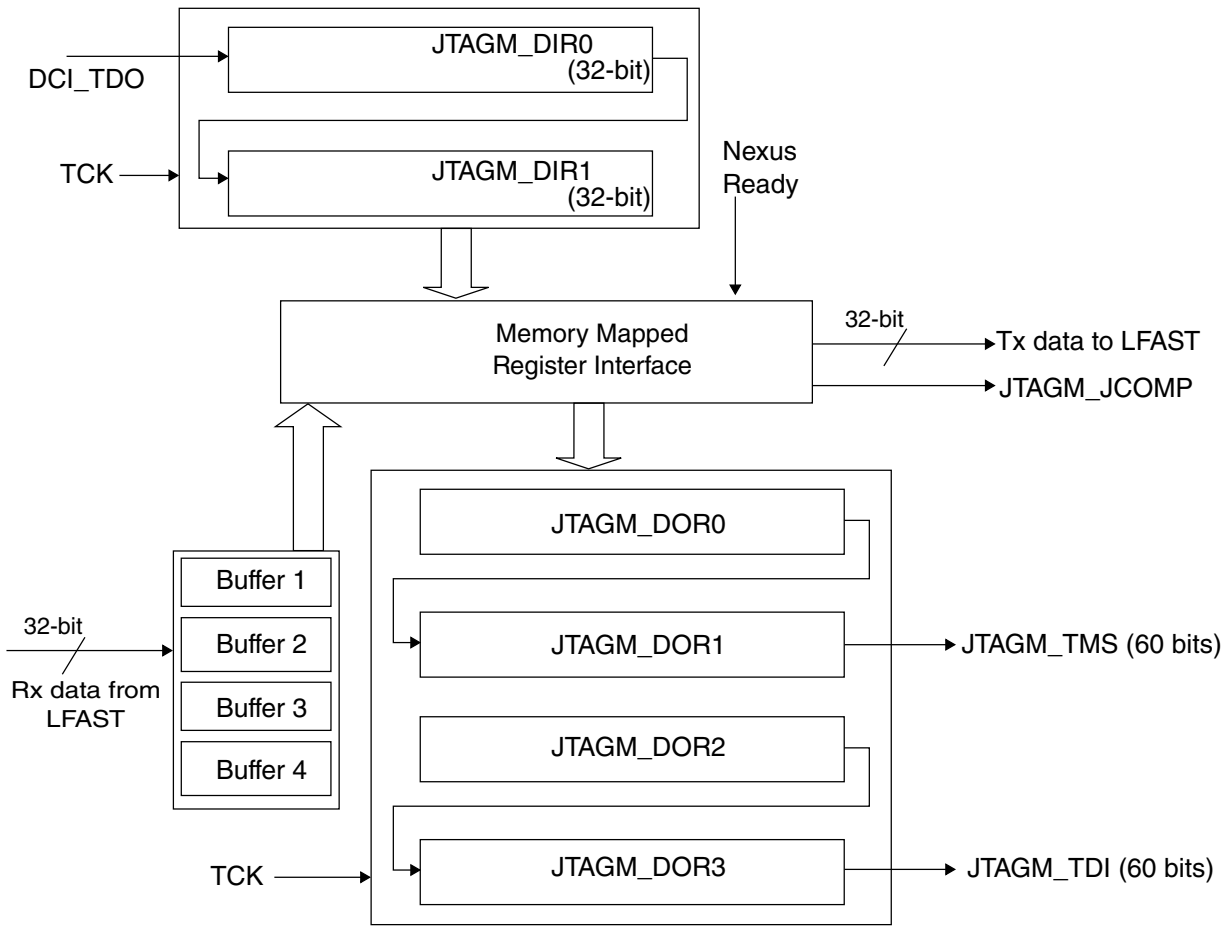

Figure 73-1. JTAGM block diagram

73.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

73.2 Functional description

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

This figure shows the flow diagram of the LFAST to DCI connection.

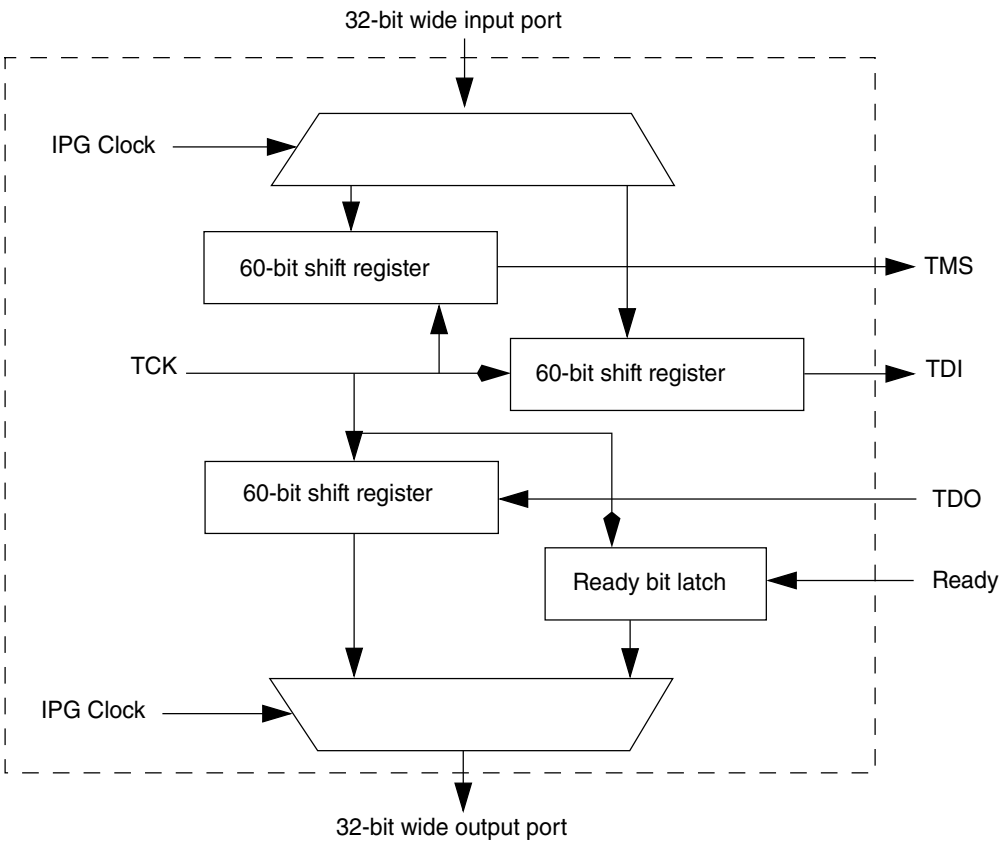

Figure 73-2. LFAST-to-DCI flow diagram

73.2.1 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

NOTE

The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

73.2.2 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the

first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

73.2.3 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

73.2.4 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

73.2.4.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

73.2.4.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

73.2.5 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus $\overline{\text{EVTI}}$ (Event In) and $\overline{\text{EVTO}}$ (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ signals to be embedded into the serial protocol. The $\overline{\text{EVTI}}$0 and $\overline{\text{EVTI}}$1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either $\overline{\text{EVTO}}$0 or $\overline{\text{EVTO}}$1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI.

The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

73.2.6 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in Status register ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).

The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module.

The JTAGM requests data from the LFAST only when at least one internal buffer is free.

73.2.7 JTAGM to DCI serial interface

This figure shows the data transfer timings between JTAGM and DCI.

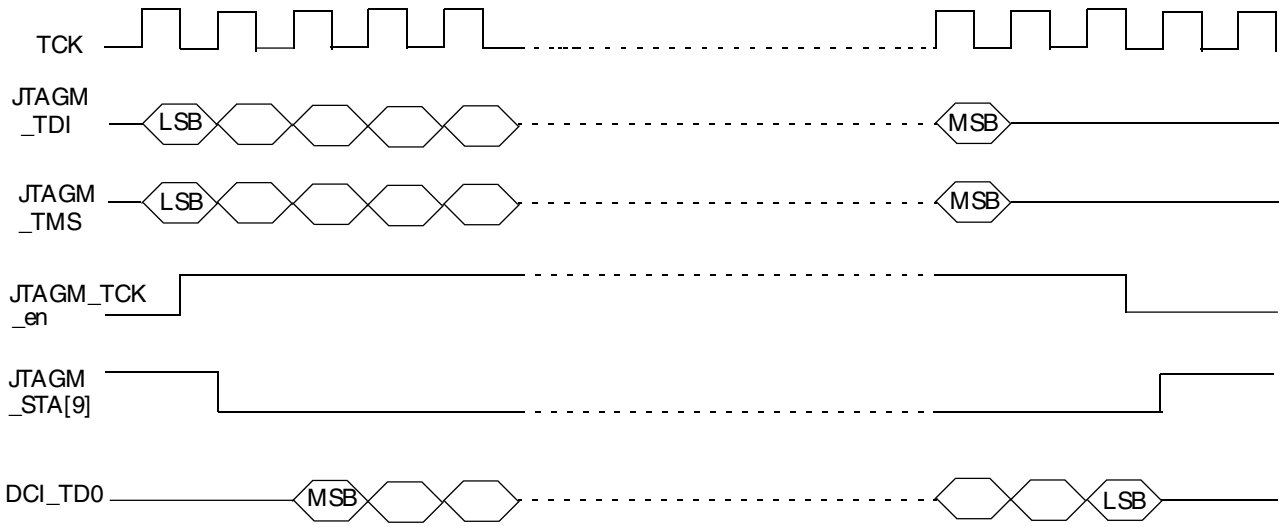

Figure 73-3. JTAGM to DCI serial interface diagram

73.2.8 JTAGM data handling and CRC calculation in LFAST mode

This figure shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

bit 127 to bit 68		bit 67 to bit 8		7	6	5	4	3	2	1	0
TMS (60 bits)		TDI (60 bits)		CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59									
Last TMS bit transmitted by JTAGM	First TMS bit transmitted by JTAGM	Last TDI bit transmitted by JTAGM	First TDI bit transmitted by JTAGM								

Figure 73-4. Bit ordering for LFAST to JTAGM transfer

This figure shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

bit 95 to bit 36		bit 35 to bit 32	bit 31 to bit 8	7	6	5	4	3	2	1	0
TDO (60 bits)		0 pad (4 bits)	JTAGM_SR (24 bits)	CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59	bit 31 to bit 8								
First TDO bit received by JTAGM	Last TDO bit received by JTAGM										

Figure 73-5. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in Figure 73-5).

73.2.9 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

73.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

73.4 Memory mapped registers

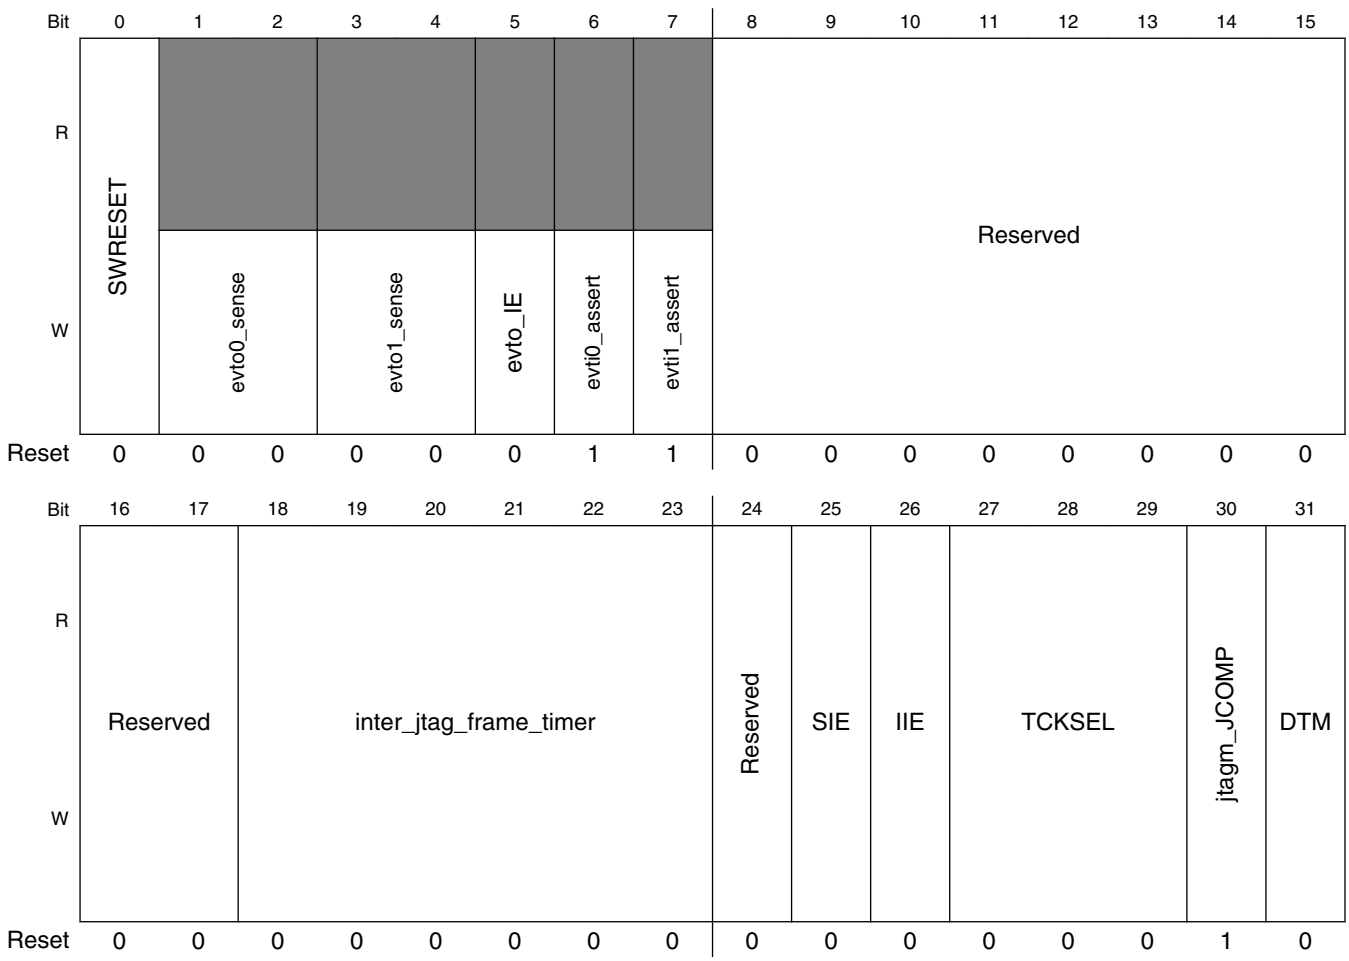
JTAGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JTAGM_MCR)	32	R/W	0300_0002h	73.4.1/3955
4	Status Register (JTAGM_SR)	32	R/W	0020_0200h	73.4.2/3958
8	Data Out Register 0 (JTAGM_DOR0)	32	R/W	0000_0000h	73.4.3/3960
C	Data Out Register 1 (JTAGM_DOR1)	32	R/W	0000_0000h	73.4.4/3960
10	Data Out Register 2 (JTAGM_DOR2)	32	R/W	0000_0000h	73.4.5/3961
14	Data Out Register 3 (JTAGM_DOR3)	32	R/W	0000_0000h	73.4.6/3961
18	Receive CRC Register (JTAGM_RxCRC)	32	R	0000_0000h	73.4.7/3962
1C	Data Input Register 0 (JTAGM_DIR0)	32	R	0000_0000h	73.4.8/3962
20	Data Input Register 1 (JTAGM_DIR1)	32	R	0000_0000h	73.4.9/3962

73.4.1 Module Configuration Register (JTAGM_MCR)

This register contains the status bits for the current transfer.

Address: 0h base + 0h offset = 0h



JTAGM_MCR field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit; after being written with a 1, this bit is auto-cleared within 3 TCK cycles. Writing a 0 has no effect.
1–2 evto0_sense	Determines JTAGM response to activity on $\overline{\text{EVTO0}}$ 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$ 0 edges (default setting) 01 evto0_edge status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$0 10 evto0_edge status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$0 11 evto0_edge status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$0

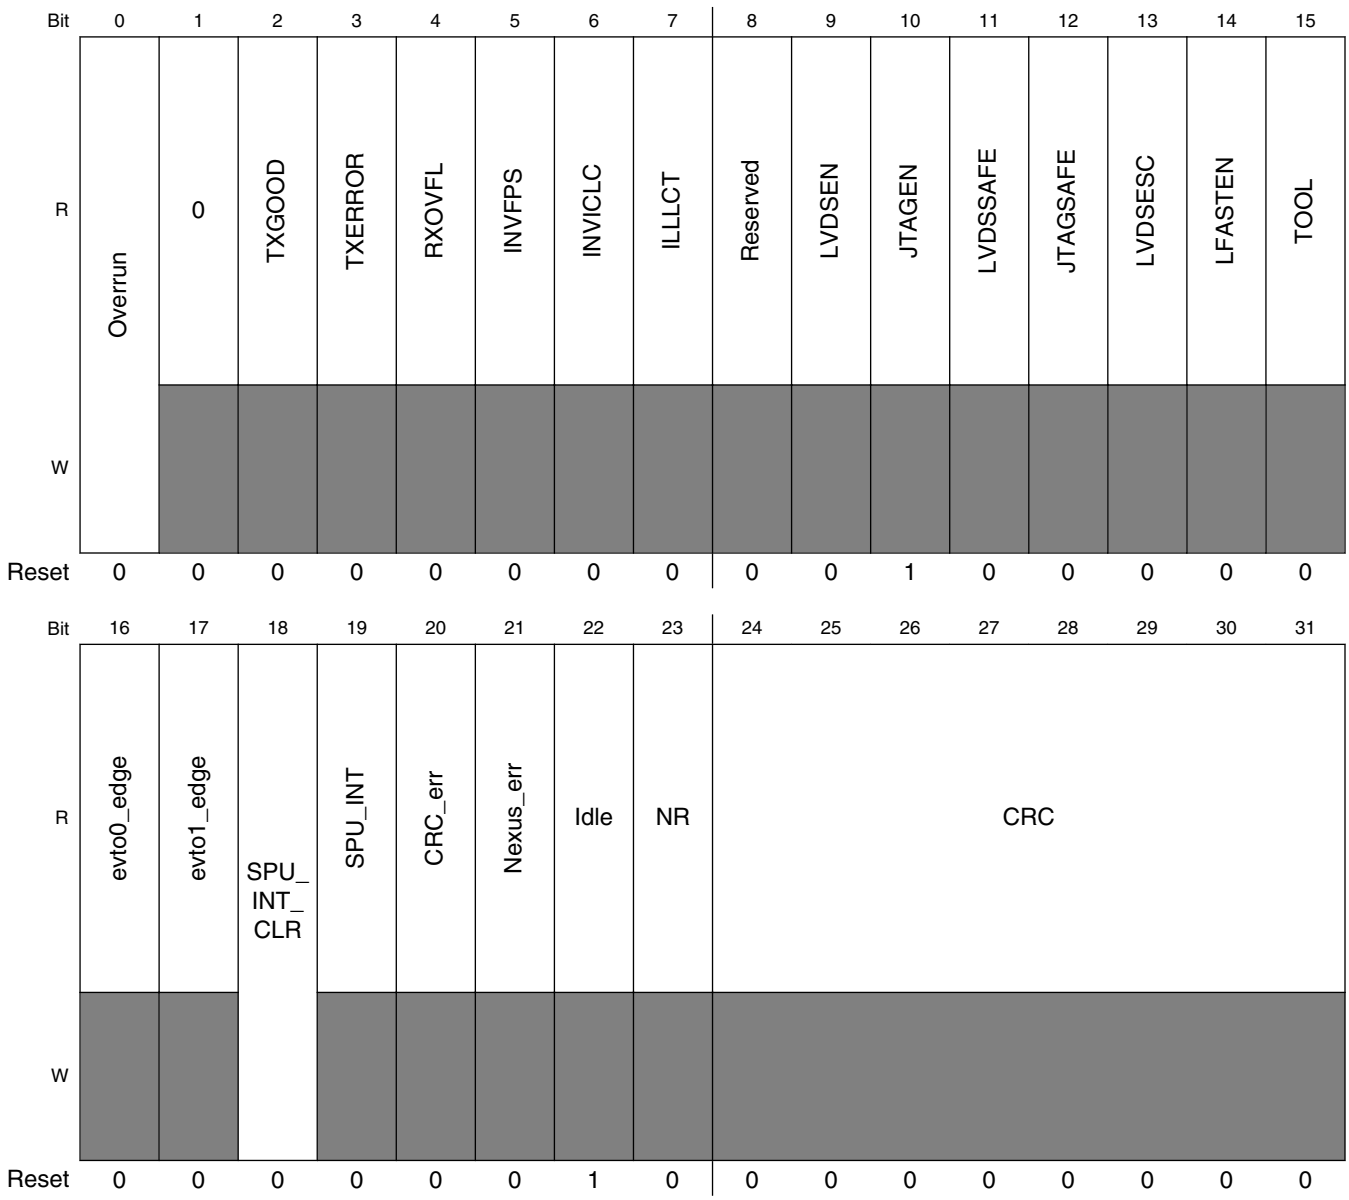
73.4.2 Status Register (JTAGM_SR)

The functionality of some of the SR bits changes depending on the setting of the DTM bit in the MCR. These differences are described in the field descriptions table.

Address: 0h base + 4h offset = 4h



JTAGM_SR field descriptions

Field	Description
0 Overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 TXGOOD	Status information from the LFAST to be used by software: Indicates either data frame or ping frame was transmitted successfully
3 TXERROR	Status information from the LFAST to be used by software: Indicates Tx data Interface not enabled and a frame is ready to be transmitted
4 RXOVFL	Status information from the LFAST to be used by software: Indicates Rx data FIFO overflow
5 INVFPS	Status information from the LFAST to be used by software: Indicates reception of frame with invalid frame payload size
6 INVICLC	Status information from the LFAST to be used by software: Indicates reception of frame with invalid ICLC code
7 ILLLCT	Status information from the LFAST to be used by software: Indicates reception of illegal LCT frame
8 Reserved	This field is reserved. Reserved to 0
9 LVDSEN	DCI status: DCI LVDS port enable
10 JTAGEN	DCI status: DCI JTAG port enable
11 LVDSSAFE	DCI status: DCI LVDS safe mode
12 JTAGSAFE	DCI status: DCI JTAG safe mode
13 LVDSESC	DCI status: DCI LVDS escape mode
14 LFASTEN	DCI status: DCI enable LFAST
15 TOOL	DCI status: DCI tool present, set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit. 0 No activity sensed on $\overline{\text{EVTO}}$ 0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$ 0
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$ 1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$ 1
18 SPU_INT_CLR	Write 1 clears the SPU_INT. This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.

Table continues on the next page...

JTAGM_SR field descriptions (continued)

Field	Description
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. In LFAST mode (DTM = 0), this bit has no effect and should not be used. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24–31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode (DTM = 0): Bit 24:31 contains the CRC. Write has no effect. SW Mode (DTM = 1): • Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. • Writing 1 on bit 24 clears evto0_edge, bit 16 • Writing 1 on bit 25 clears evto1_edge, bit 17

73.4.3 Data Out Register 0 (JTAGM_DOR0)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

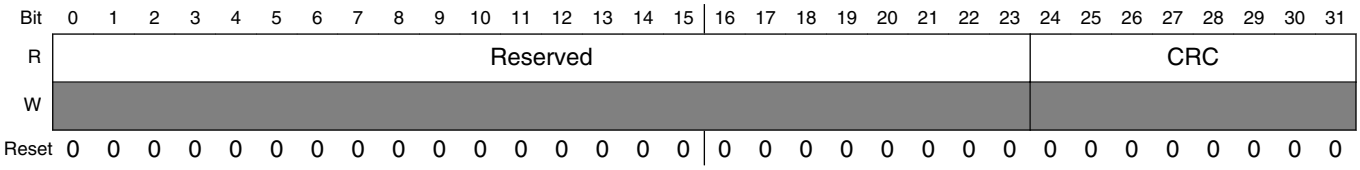
W																Send
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

JTAGM_DOR3 field descriptions

Field	Description
0–27 TDI_LOW	Lower word of data for TDI, bits 27-0. Writable by software only when DTM = 1. TDI_LOW[0] is shifted out first
28–30 Reserved	This field is reserved.
31 Send	Send bit. When this bit is set, data is sent to the DCI. It is a self-clearing bit and is always read as 0. Writable by software only when DTM = 1

73.4.7 Receive CRC Register (JTAGM_RxCRC)

Address: 0h base + 18h offset = 18h

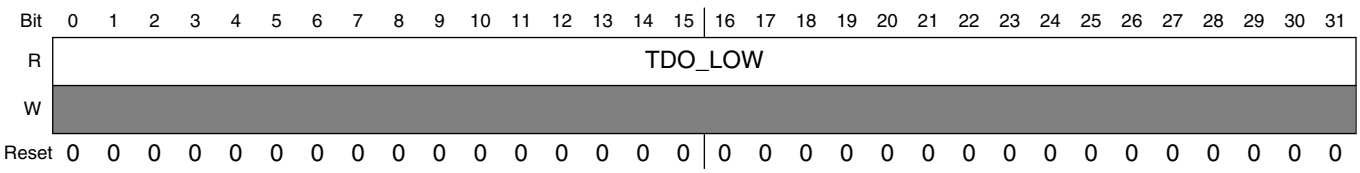


JTAGM_RxCRC field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 CRC	Received CRC. Refers to the CRC of the received LFAST message.

73.4.8 Data Input Register 0 (JTAGM_DIR0)

Address: 0h base + 1Ch offset = 1Ch

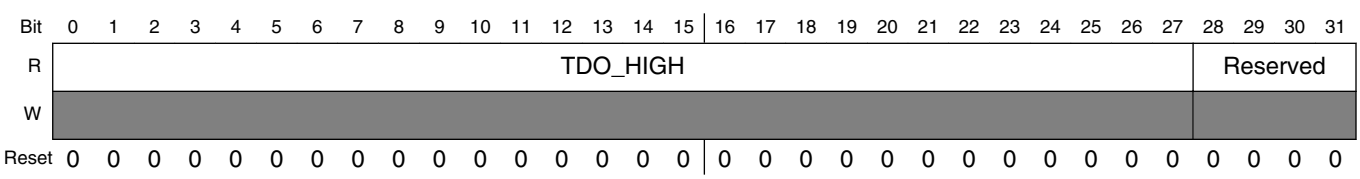


JTAGM_DIR0 field descriptions

Field	Description
0–31 TDO_LOW	Lower word of data received on TDO, bits 0-31

73.4.9 Data Input Register 1 (JTAGM_DIR1)

Address: 0h base + 20h offset = 20h



JTAGM_DIR1 field descriptions

Field	Description
0–27 TDO_HIGH	Higher word of data received on TDO, bits 32-59
28–31 Reserved	This field is reserved.

Chapter 74
Debug Zipwire

74.1 Overview

The Debug SIPI and Debug LFAST modules work together as a single unit called Debug Zipwire. The Debug LFAST portion of the two modules allows for high speed debugging capabilities.

The Debug LFAST operates in slave mode configuration. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

74.2 Debug Zipwire Overview

Dedicated Zipwire functionality is available for debug use allowing support for increased bandwidth read/write operations to the chip memory space performed over the debug interface. This Debug Zipwire function is available on both production and ED devices. The modules used to support Debug Zipwire are the Debug SIPI module, the Debug LFAST module and the LFAST Switch. The Debug Zipwire functionality does not use the LFAST or SIPI modules which support the Zipwire interprocessor bus. The only resource shared between the Debug and interprocessor bus Zipwire interfaces is the use of a single shared LFAST PLL on the Production Device (PD).

The Debug Zipwire interface allows a connected tool to perform 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address in the microcontroller. The Zipwire architecture is fully pipelined and supports multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins. The Debug Zipwire interface does not support streaming mode commands.

For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1 µs.

74.3 Debug Zipwire Block Diagram

Figure 74-1 shows a tool connected to the MCU via five wires. These five pins are shared with the standard JTAG pins, but for simplicity this is not show on the diagram. The MCU Debug Zipwire only supports the Target mode of Zipwire. The Debug SIPI Bus Master Interface is used for all Target Mode transactions. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST Reference clock coming from the MCU clock system.

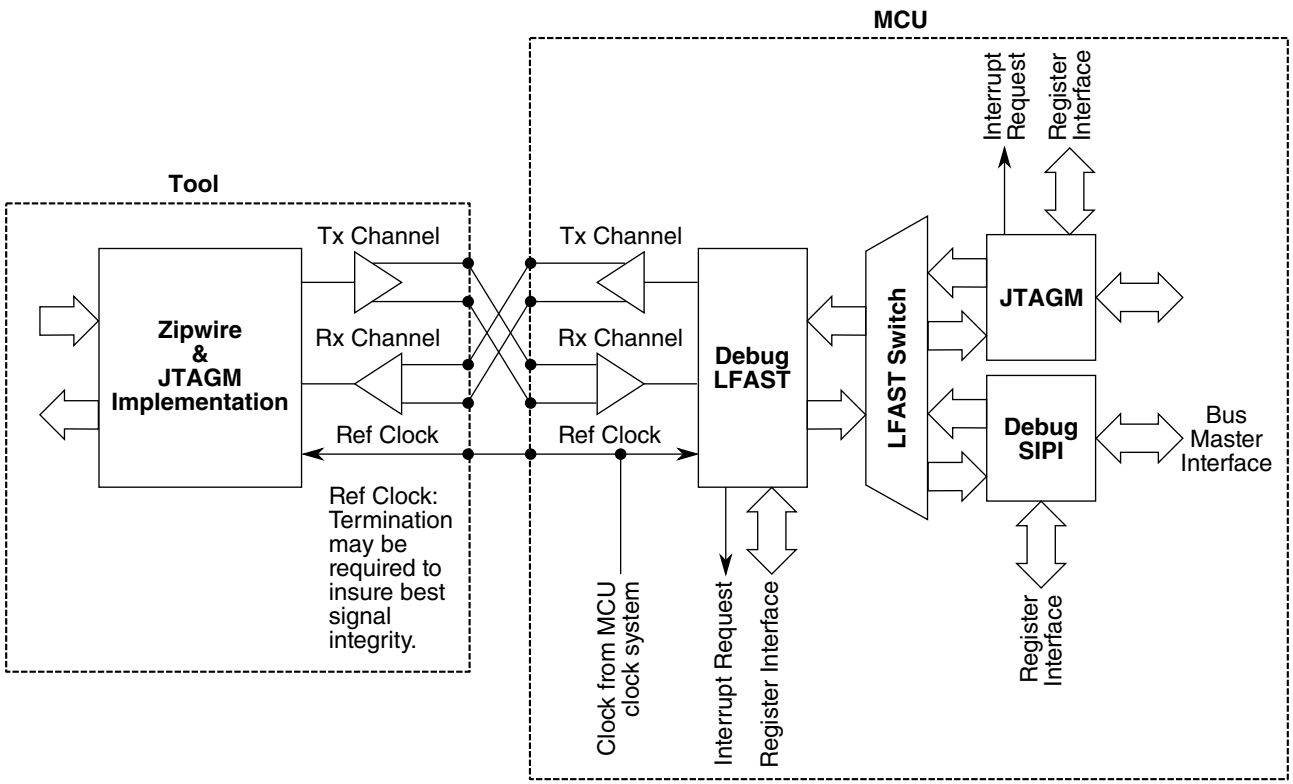


Figure 74-1. Debug Zipwire connection diagram

74.4 Architecture

Debug Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200mV swing. The pads are shared with JTAG signals.

The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). Debug SIPI runs on top of Debug LFAST and is fully encapsulated within the Debug LFAST payload. Debug SIPI uses three fixed sizes of Debug LFAST payload in Debug Zipwire:

- 32-bit
- 64-bit
- 96-bit

The SIPI protocol implements a suite of commands initiated by a tool, for reading and writing any 32-bit address location in a connected MCU. Only the tool can initiate commands. The MCU only responds to commands initiated by the tool and never creates any unsolicited messages.

For Debug Zipwire, a reduced version of the SIPI module called Debug SIPI is used. The Debug SIPI module implements only the recipient part of the SIPI protocol (called Target mode). The Debug SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating tool, Debug SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

74.5 Debug Zipwire implementation

Figure 74-2 shows shows the modules on the production device which support the Debug Zipwire function, along with their interconnections to the debug interface signals.

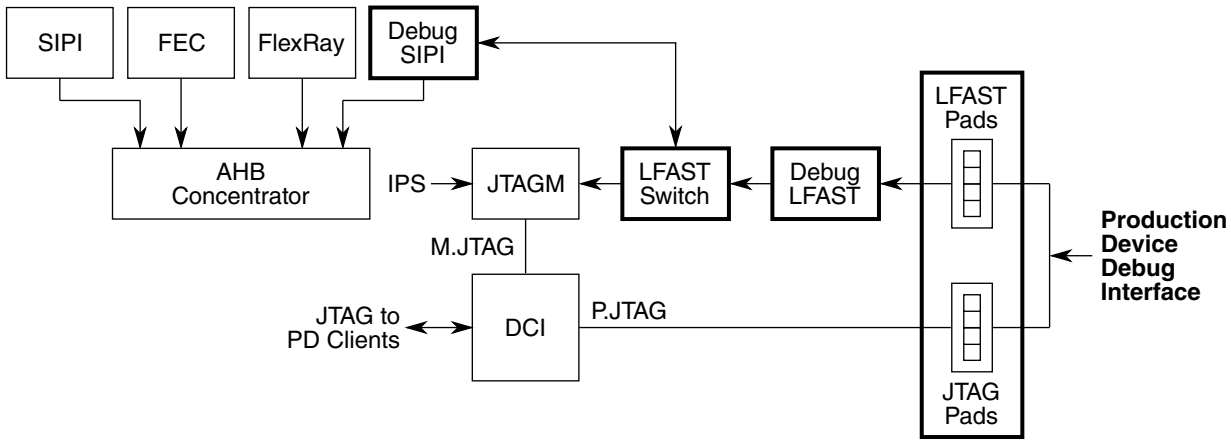

Figure 74-2. Block diagram showing connections for Production Device

Internal connections to other debug modules which are used to support other debug interface protocols such as JTAG and JTAG over LFAST are also shown. The Debug SIPI module is connected to the Debug LFAST module via an LFAST switch module, which controls routing of debug LFAST traffic to either the Debug SIPI or the JTAGM module.

Figure 74-3 shows the equivalent connections for ED devices utilizing the LFAST switch.

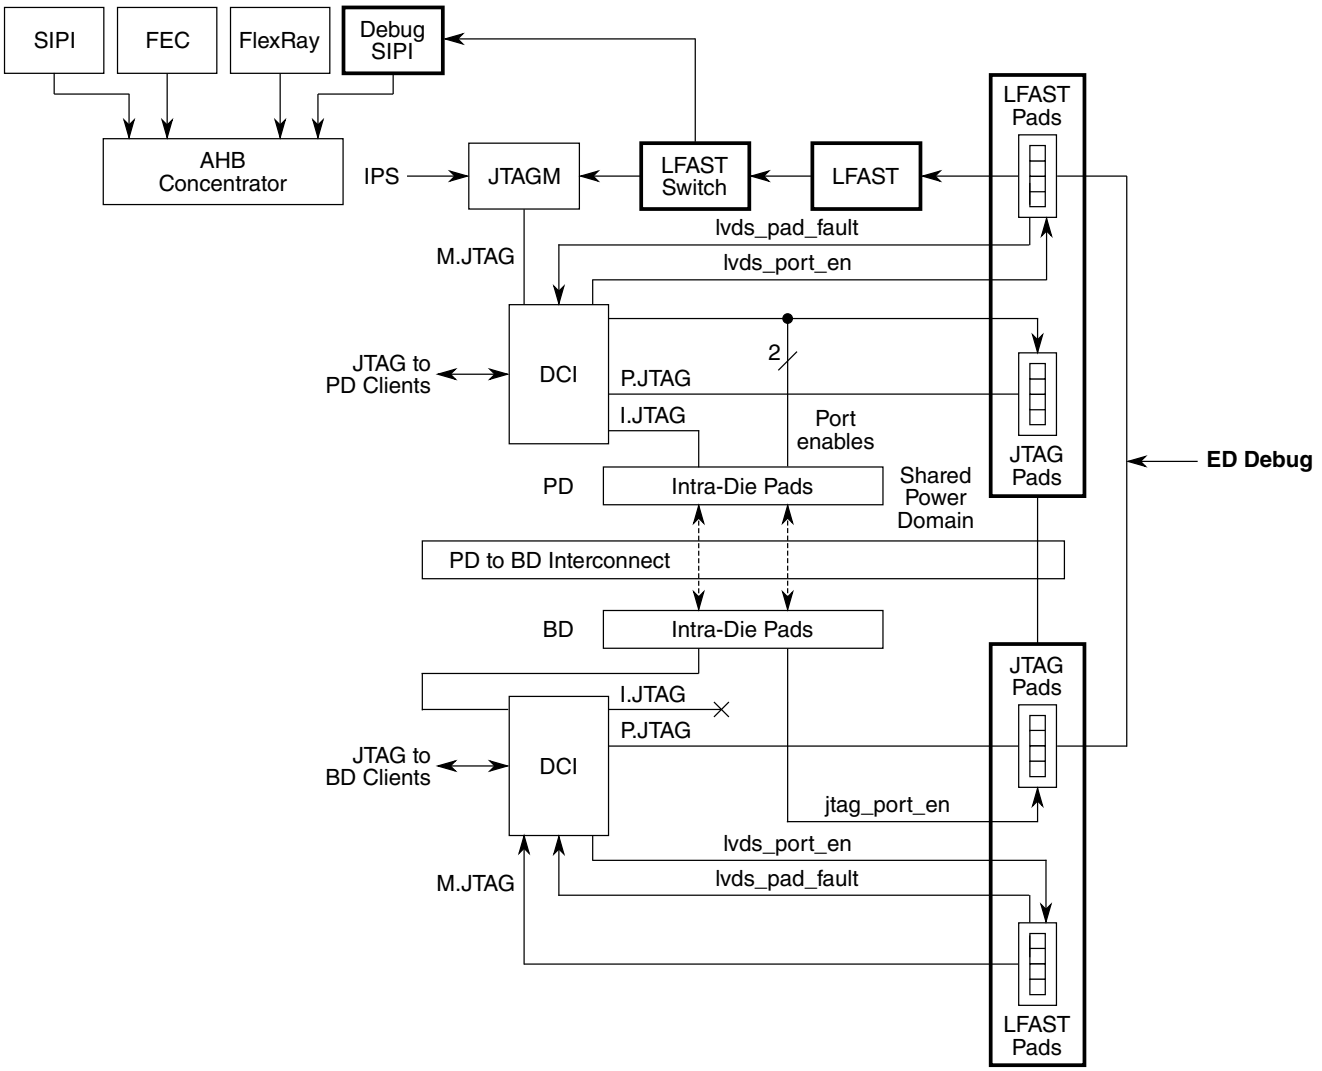

Figure 74-3. Block diagram showing connections for the ED Device

74.6 LFAST clocking

The LFAST implementation includes a dedicated PLL for multiplying a low speed clock source up to 320 MHz for the transmission and reception of data. This PLL is used to support both interprocessor bus Zipwire and Debug Zipwire so care must be taken to ensure that any tool configuration of this resource is compatible with application usage of Interprocessor Bus Zipwire. The high speed asynchronous nature of LFAST, requires that both the local node and remote node, operate from the same, stable, low jitter clock sources. This common low speed clock is referred to a the Reference Clock.

The MCU includes clock multiplexing to allow the source of the LFAST reference clock to come from one of three sources via a programmable clock divider:

- XOSC
- Output of PLL0 (PLL0:PHI)
- External pin

The most expedient source for the reference clock is the 20 MHz crystal oscillator (XOSC) from one MCU. This 20 MHz clock can be used as the LFAST Reference clock for the local LFAST. This same 20 MHz clock must be exported from the local MCU to the remote MCU, to be used as the LFAST reference at the remote MCU.

The 20 MHz clock may be used in the following ways:

- Shared between the MCUs using a dedicated reference clock pin on each MCU
- Divided by 2 and shared as a 10 MHz reference
- Shared as the fundamental clock for the MCU system clock and the LFAST reference clock

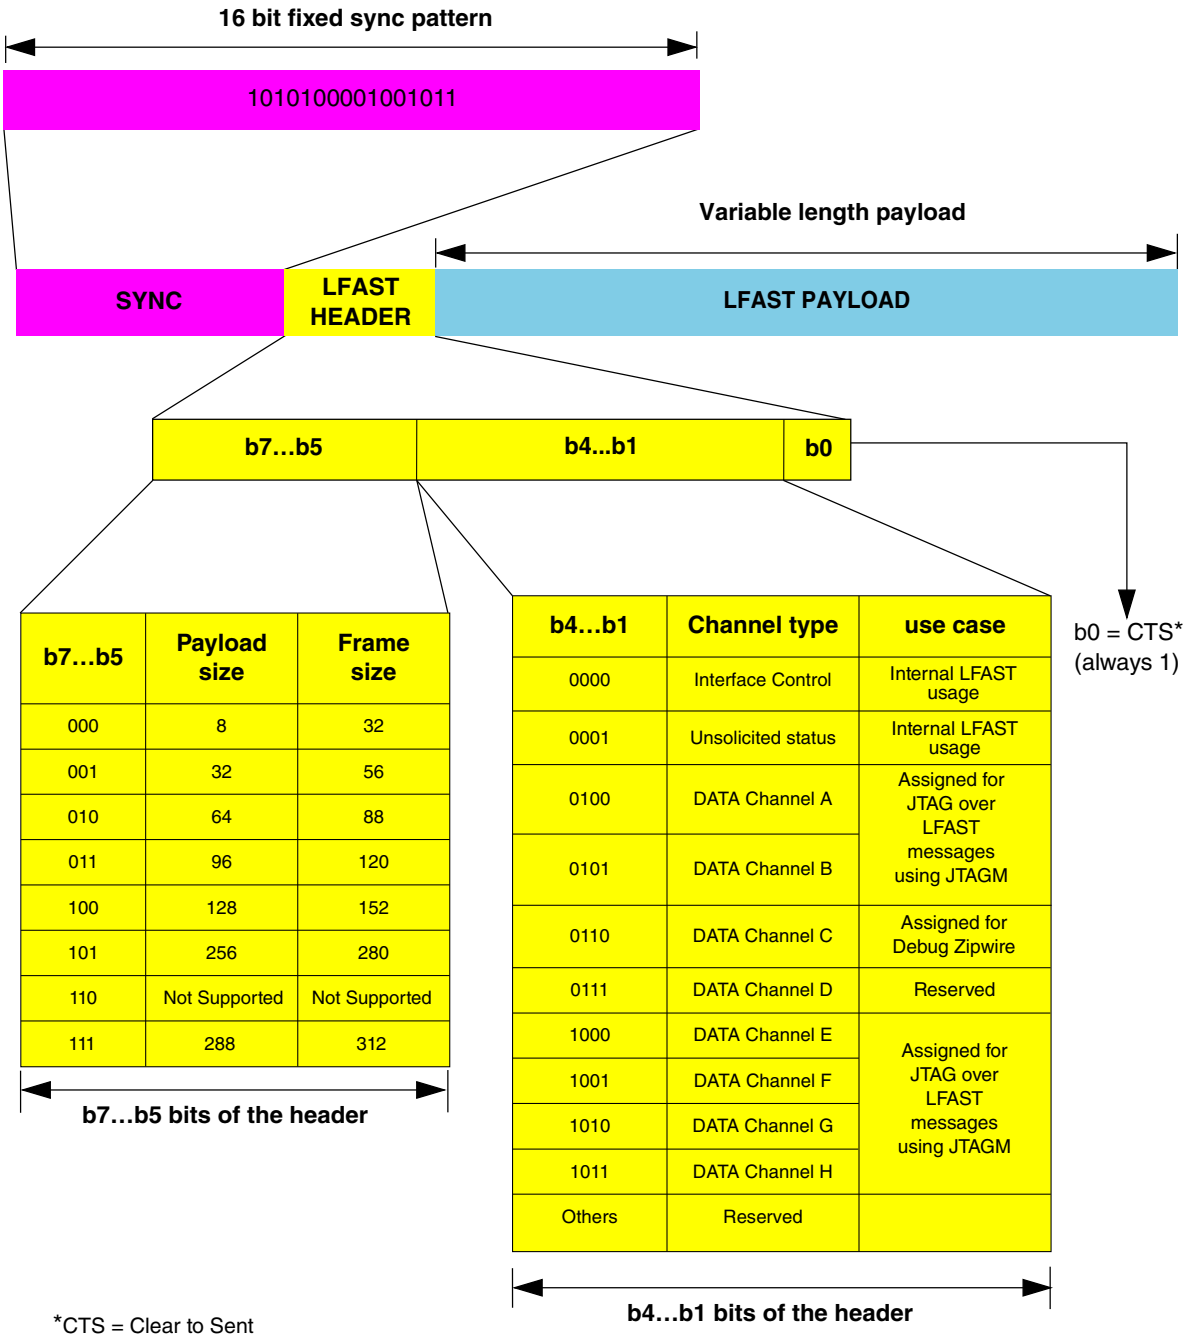
The LFAST PLL for generating the 320 MHz clock, is shared between LFAST for SIPI.

74.7 LFAST switch

Incoming messages on the Debug LFAST interface can be either for JTAG over LFAST use through the JTAGM or debug Zipwire messages. Differentiation of these messages is via use of LFAST channel number. DATA channel C is used to identify high speed Debug SIPI accesses, while JTAG over LFAST messages are supported using LFAST channels A, B, E, F, G, H as shown in Figure 74-4

The LFAST SWITCH module is used to direct LFAST messages based on the above scheme, with JTAG over LFAST messages being routed to the JTAGM IP block and debug Zipwire messages being routed to the Debug SIPI block.

The LFAST switch has no accessible registers and requires no user configuration.



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	Not Supported	Not Supported
111	288	312

b4…b1	Channel type	use case
0000	Interface Control	Internal LFAST usage
0001	Unsolicited status	Internal LFAST usage
0100	DATA Channel A	Assigned for JTAG over LFAST messages using JTAGM
0101	DATA Channel B	
0110	DATA Channel C	Assigned for Debug Zipwire
0111	DATA Channel D	Reserved
1000	DATA Channel E	Assigned for JTAG over LFAST messages using JTAGM
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 74-4. LFAST channel allocation

74.8 Debug SIPI module

The debug SIPI module is used to support high bandwidth read/write accesses over the LFAST debug interface. It is dedicated for debug use and is entirely separate from the SIPI module used to support interprocessor bus zipwire interface.

The debug SIPI characteristics are shown in Table 74-1.

Table 74-1. Debug SIPI feature set

Feature	Debug implementation
Number of channels supported	1
Initiator support	No
Target support	Yes
Block transfer support	No
Chip XBAR connection	M1 on XBAR_1

The debug SIPI module issues read and write accesses via the AHB concentrator connected to physical master port 2 on XBAR_1, which is shared with the ethernet, FlexRay and Zipwire SIPI bus masters.

The debug SIPI memory mapped registers are accessible via PBRIDGE_0 (off platform - slot 10) with base address FFFD_4000h.

The debug SIPI has Logical Bus Master Assignment of 6 for SMPU0 and SMPU1, an NXMC trace source ID (SRC) of 1101b and a trace master ID (MASTER) = 1011b.

The debug SIPI supports only target mode SIPI operations on a single channel with a reduced command set. Commands supported include read (8/16/32 bits) and write (8/16/32 bits) along with the appropriate responses. Other SIPI commands are unimplemented as noted in Table 74-2.

The debug SIPI will be capable of:

- receiving a 64-bit command on LFAST channel C and responding with either a 64-bit response or 32-bit error response on LFAST channel C.
- receiving a 96-bit command on LFAST channel C and responding with either a 32-bit acknowledge or 32-bit error response on LFAST channel C.

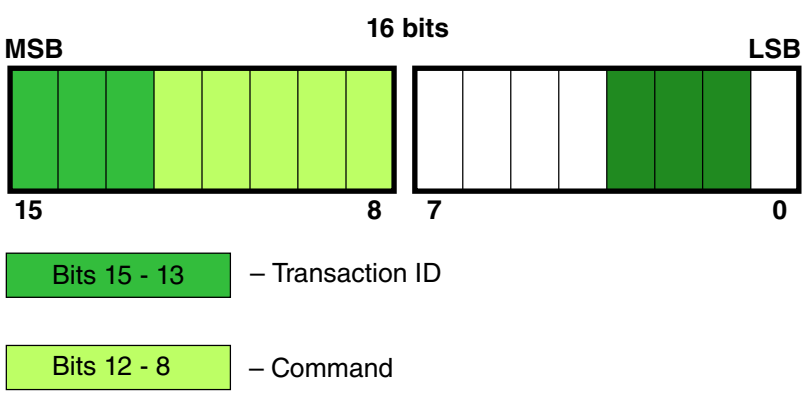


Figure 74-5. Debug SIPI header

NOTE

See Figure 74-4 for description of bits[7:0]

Table 74-2. SIPI header command coding

Bits[12:8] (hex)	Command	Payload Size	Message Direction at chip (SIPI Target)
00	Read 8 bits (Received by SIPI from LFAST)	64	Rx
01	Read 16 bits (Received by SIPI from LFAST)	64	Rx
02	Read 32 Bits (Received by SIPI from LFAST)	64	Rx
03	Reserved	—	—
04	Write 8 bits with ACK (Received by SIPI from LFAST)	96	Rx
05	Write 16 bits with ACK (Received by SIPI from LFAST)	96	Rx
06	Write 32 bits with ACK (Received by SIPI from LFAST)	96	Rx
07	Reserved	—	—
08	ACK – OK (Issued to LFAST from SIPI)	32	Tx
09	ACK – Fault (Issued to LFAST from SIPI)[1]	32	Tx
0A	Read Answer – OK (Issued to LFAST from SIPI)	64	Tx
0B	Reserved	—	—
0C	Unimplemented – Trigger comm and with ACK	32	—
0D	Reserved	—	—
…	…	…	…
11	Reserved	—	—
12	ID Register Read Request	32	Rx
13	Reserved	—	—
…	…	…	…
16	Reserved	—	—
17	Unimplemented – Stream Data with ACK (32 bytes)	288	—
18	Reserved	—	—
…	…	…	…
1F	Reserved	—	—

1. ACK – Fault is also referred to as “NACK” and “ACK Error” in the HSSL/SIPI Interprocessor Bus Protocol Specification.

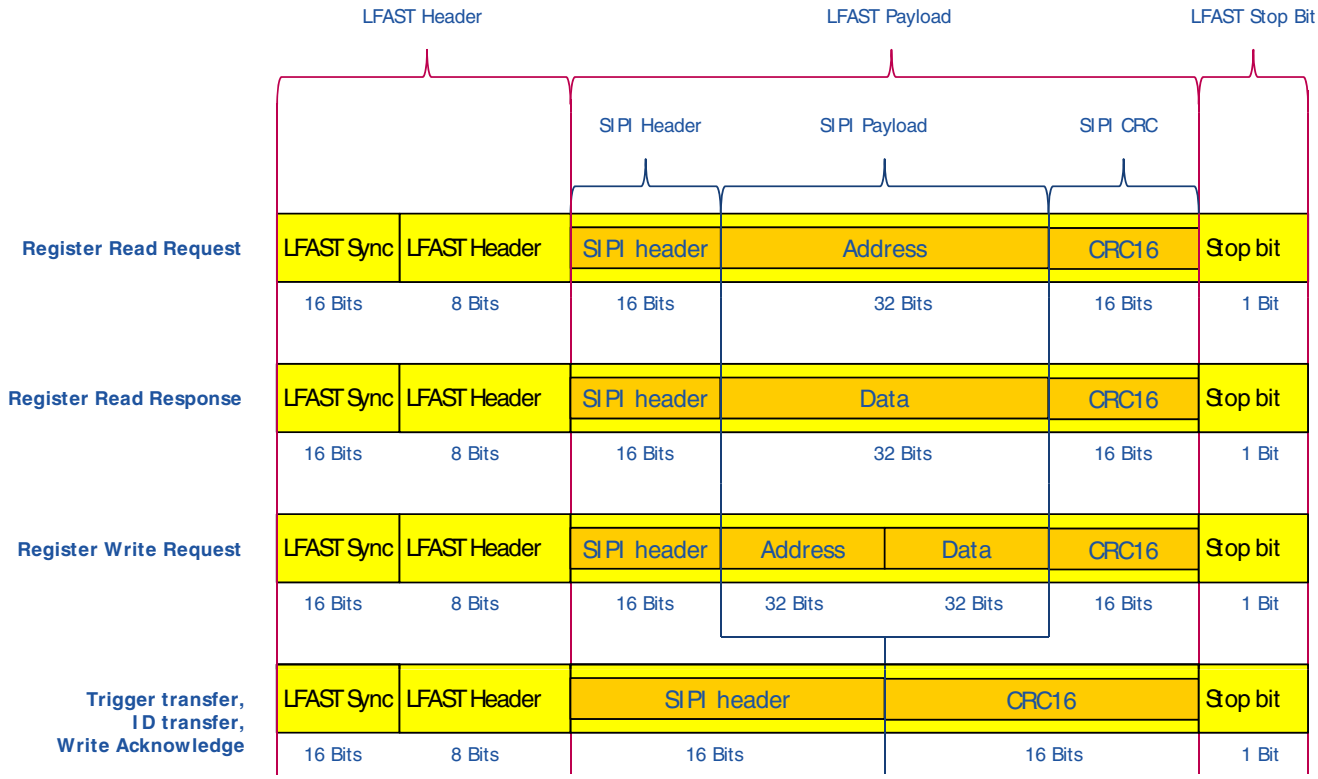

Figure 74-6. Zipwire message format

NOTE

Identification Register Read is the same as the Register Read response format.

74.8.1 ED power supply constraints

For ED devices the following power domain user constraints must be observed:

- The Vdd_hv_jtag_osc and Vdd_hv_io_bd supplies need to be connected on the application PCB.
- For cold start operation where a tool must be able to communicate via JTAG and read/write ED RAM contents, Vdd_lv_stby, Vdd_hv_jtag_osc and Vdd_hv_io_bd must remain powered.
- For cold start operation where only ED RAM contents have to be maintained, only Vdd_lv_stby must remain powered.

74.9 Debug Zipwire interconnections

Debug LFAST has the following connections:

- Tx and Rx connections to the pads via the SIUL and the MSCR registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Connected to the LFAST Switch. This allows LFAST data to be dynamically routed to/from either Debug SIPI for Debug Zipwire operation or JTAGM for JTAG over LFAST operation.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

LFAST Switch has the following connections:

- Tx Data Port/Rx Data port directly connected to Debug SIPI.
- Tx Data Port/Rx Data port directly connected to JTAGM.
- Tx Data Port/Rx Data port directly connected to Debug LFAST.
- LFAST switch has no IPS interface; no registers; no interrupts.

Debug SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers. For the Debug SIPI, a restricted set of registers is implemented. In use, no configuration of these registers is needed from either s/w or a connected tool, as the default settings should be usable for typical operation.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.

74.10 Debug Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Inititator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

Bandwidth is the rate at which data can be read or written between the tool and the MCU. It assumes that read or write commands from the Inititator node (the Tool), can be sent continuously at the highest speed the Target node can consume those commands.

Latency is the time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

74.10.1 Read performance

A Zipwire read operation consists of three stages:

- Inititator sends SIPI Read command to Target.
- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data

- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in a LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 278 ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of 6 × slow XBAR cycles to read different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, time for SIPI to read an address location is:

- (13 × 50 MHz clocks) + (6 × 100 MHz clocks) = 320 nS

74.10.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

Read Bandwidth = 4 bytes in 320 ns = 12.5 MB/second

74.10.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

Read Latency = 278 ns + 320 ns + 278 ns = 876 ns

74.10.2 Write performance

A Zipwire write operation consists of three stages:

- Inititator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address
- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header
- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 378 ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 178 ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of 5 × slow XBAR cycles to write different memories.
- Slow XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, the time for SIPI to write an address location is:

- (13 × 50 MHz clocks) + (5 × 100 MHz clocks) = 320 ns

74.10.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = 4 bytes in 378 ns = 10.6 MB/second

74.10.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = 378 ns + 310 ns + 178 ns = 866 ns

Chapter 75
Debug Serial Interprocessor Interface (SIPI)

75.1 Introduction

The Debug Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the Debug LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. Debug SIPI defines point-to-point full duplex communication between two nodes, where LFAST works as a physical medium of communication between both the devices.

Debug SIPI implements the Target mode of a communication protocol in hardware. Debug SIPI can interpret 'read' and 'write' commands received from an LFAST module and convert them into bus accesses to local memory; then send back to the LFAST module either read data or a write acknowledge response. This provides a mechanism for an external device, such as an external tool, to read and write the address map of the local MCU. The bandwidth of these read/write commands is approximately 10 MBytes/second when accessing random addresses using 32-bit transfers.

75.2 Overview

Debug SIPI can access memory mapped resources directly through its AHB master interface. SIPI have four channels, 0, 1, 2, 3. Payload width for all channels is 32 bits.

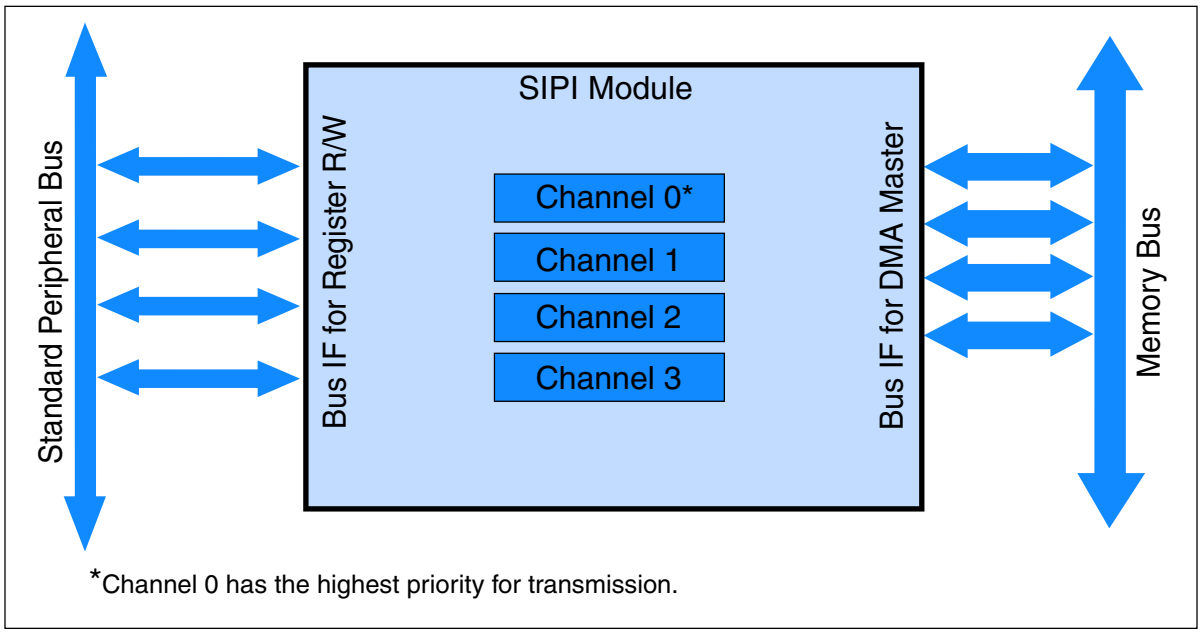

Figure 75-1. SIPI module

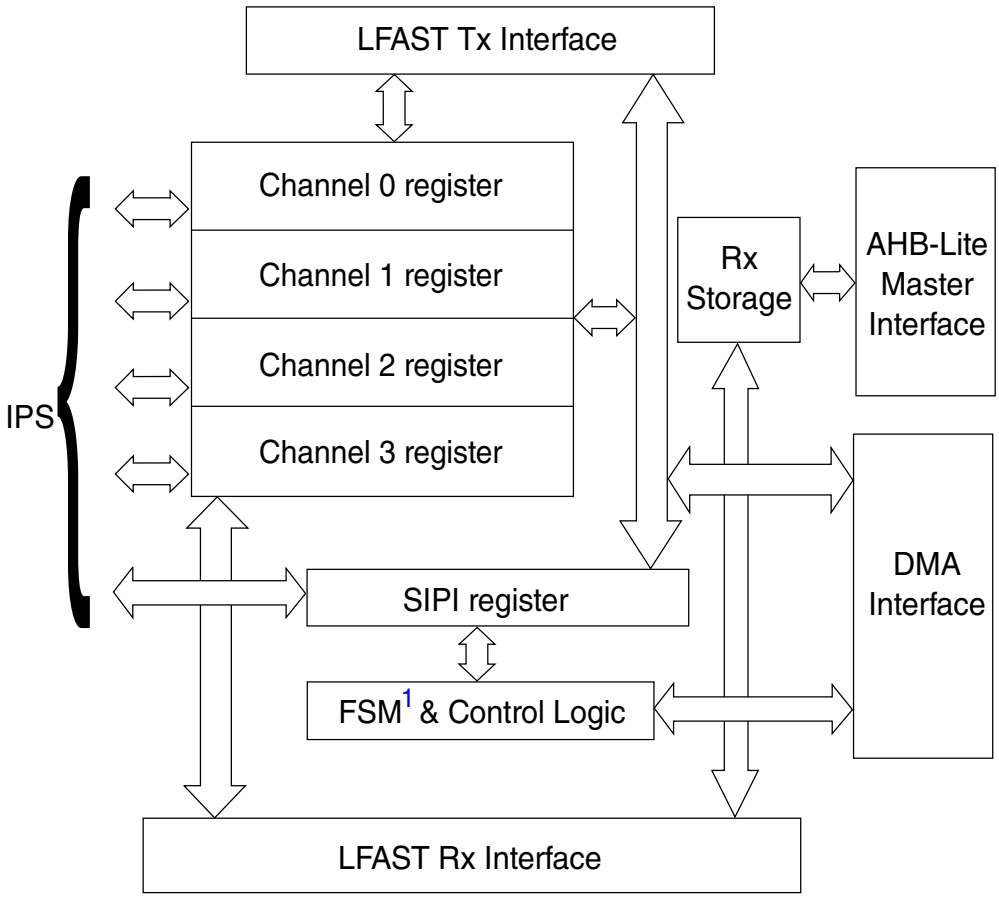
75.3 Debug SIPI block diagram



[1] Finite State Machine

Figure 75-2. SIPI block diagram

75.4 Feature description

This section describes the features of the Debug SIPI module.

75.4.1 Main features

- Supports 8, 16 and 32-bit read and write commands.
- Command/response includes a 16-bit CRC to ensure data integrity.
- Command/response includes a 2-bit tag to allow tracking of data to commands in a pipelined system.

- Command/response includes a 3-bit channel identifier to allow multiple Initiators to send commands to a single target node.
- Command/response includes a 16-bit header that defines, the function, channel and tag.
- Every command generates a response to allow a 'sliding window' flow control protocol to be implemented.
- AHB master interface that is used by target node to access memory mapped resources.

75.4.2 Standard features

- IPS bus interface (PBRIDGE)
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

75.5 Debug SIPI operation from reset

When the Debug SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

75.6 Functional description

75.6.1 External signals

The Debug SIPI has no chip external signals.

75.6.2 Frame format

All frames have the same general format:

- 16 bit header

- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

75.6.2.1 Register read request

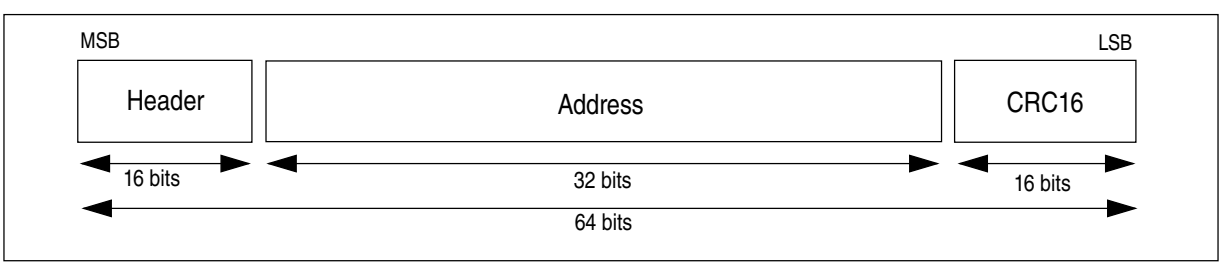


Figure 75-3. SIPI register read request

75.6.2.2 Register read response, ID request response

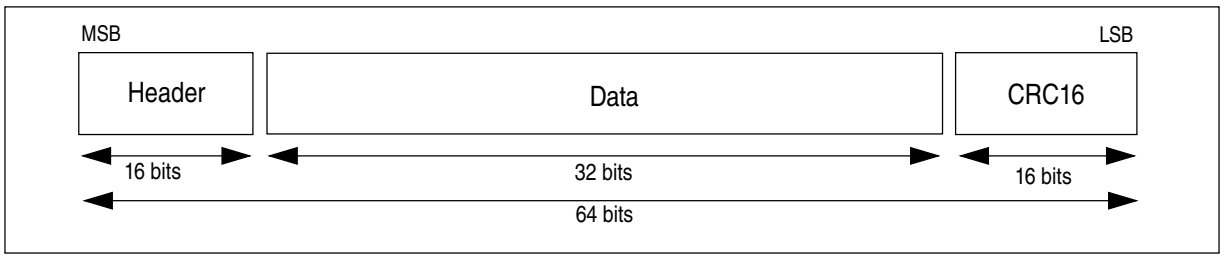

Figure 75-4. SIPI read response

75.6.2.3 Register write request

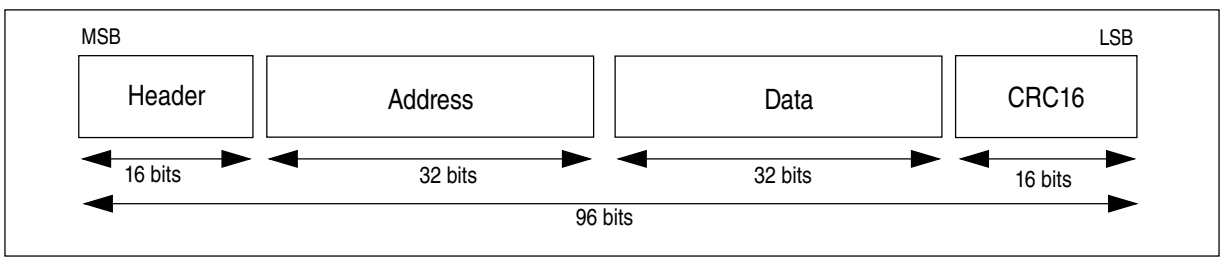

Figure 75-5. SIPI register write request

75.6.2.4 ID transfer, write acknowledge

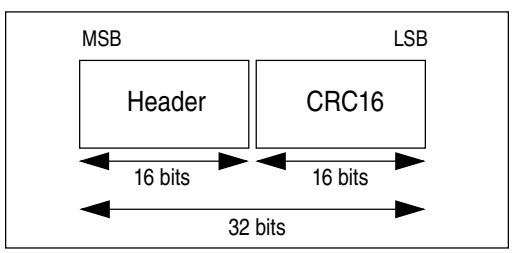

Figure 75-6. SIPI write acknowledge

75.6.2.5 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

75.6.2.5.1 Debug SIPI header coding

Figure 75-7, Table 75-1, and Figure 75-8 show how the Debug SIPI header bits are coded.

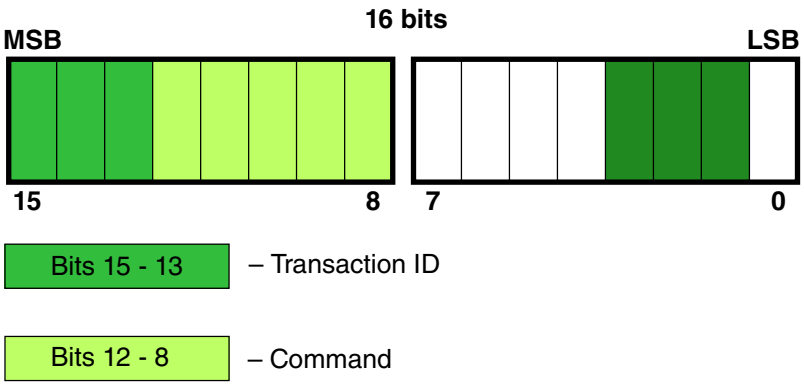

Figure 75-7. Debug SIPI header coding

Table 75-1 shows the command coding for the bits[12:8] of the header.

Table 75-1. Debug SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—
04	Write 8 bits with ACK	96
05	Write 16 bits with ACK	96
06	Write 32 bits with ACK	96
07	Reserved	—
08	ACK – OK	32
09	ACK – Fault	32
0A	Read Answer – OK	64
0B	Reserved	—
0C	Reserved	—
0D	Reserved	—
…	…	…
11	Reserved	—
12	ID Register Read Request	32
13	Reserved	—
…	…	…
16	Reserved	—
17	Reserved	—
18	Reserved	—
…	…	…
1F	Reserved	—

Figure 75-8 shows the channel number field in the header.

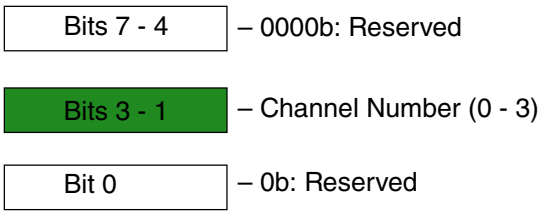

Figure 75-8. Debug SIPI header channel field

75.6.2.6 Address field

The address field is 32 bits wide with the MSB transmitted first.

75.6.2.7 Payload field

Table 75-2 shows the payload sizes of LFAST frames.

Table 75-2. Payload size of LFAST channel frame

LFAST Code	Debug SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16
101b	101b	256	32
110b	110b	512	64
111b	111b	288	36

Table 75-3 shows the converted coding of LFAST for a given Debug SIPI code.

Table 75-3. Converted coding of LFAST channel code for Debug SIPI headers

LFAST Code	Debug SIPI Code	Channel (hex)[1]
0100b	100b	A
0101b	101b	B
0110b	110b	C
0111b	111b	D
1000b	000b	E (not used by Debug SIPI)
1001b	001b	F (not used by Debug SIPI)
1010b	010b	G (not used by Debug SIPI)
1011b	011b	H (not used by Debug SIPI)

1. Debug SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
   Debug SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
   Debug SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
   Debug SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

75.6.2.8 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). MSB is sent first in the data stream.

75.6.2.8.1 CRC field examples

75.6.2.8.1.1 Example 1 – 32 bit write

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

75.6.2.8.1.2 Example 2 – 32 bit read

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

75.6.2.8.1.3 Example 3 – Event command

- Header = 6C0Eh
- CRC = B286h

75.7 Transfer types

This section describes the available transfer types of the Debug SIPI module. The Debug SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

75.7.1 Read transfer

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

75.7.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in Figure 75-9.

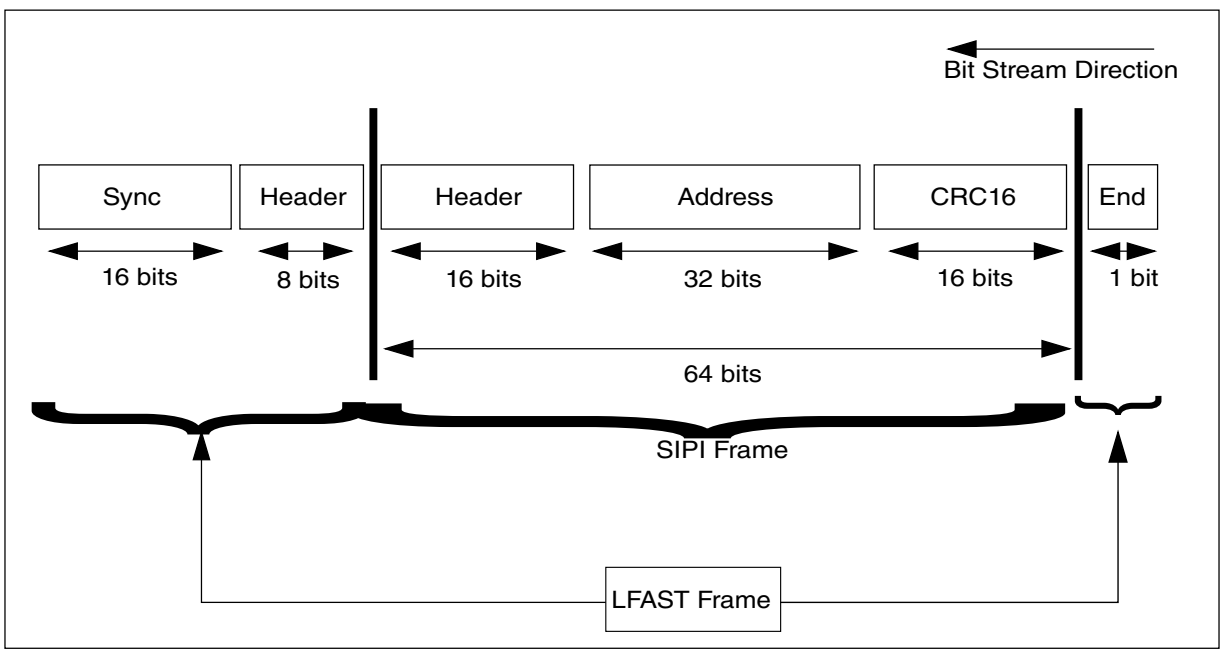

Figure 75-9. Read request transfer

75.7.2 Register read answer transfer

In response to a read request, Debug SIPI sends header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see Figure 75-10). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see Figure 75-11).

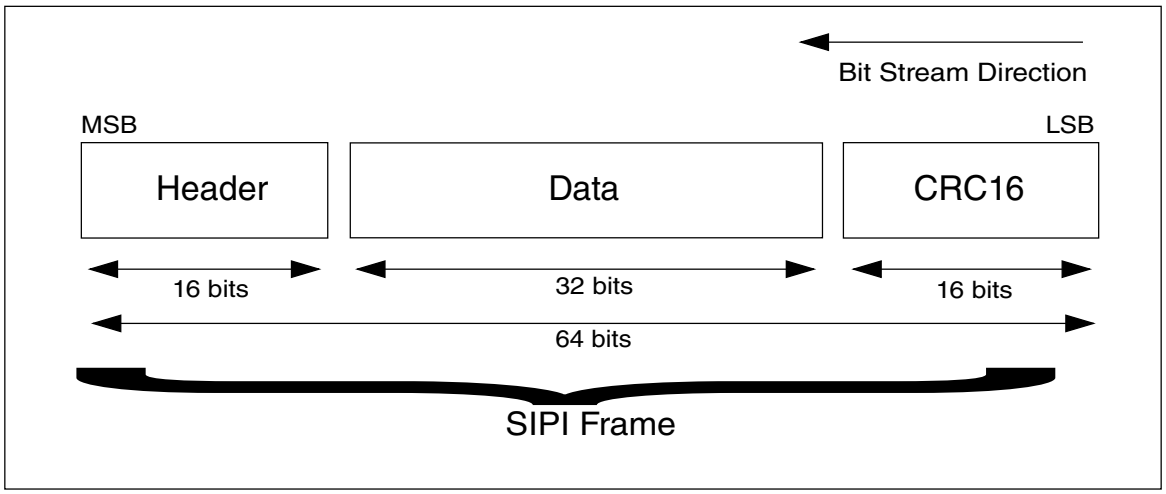

Figure 75-10. Read answer transfer

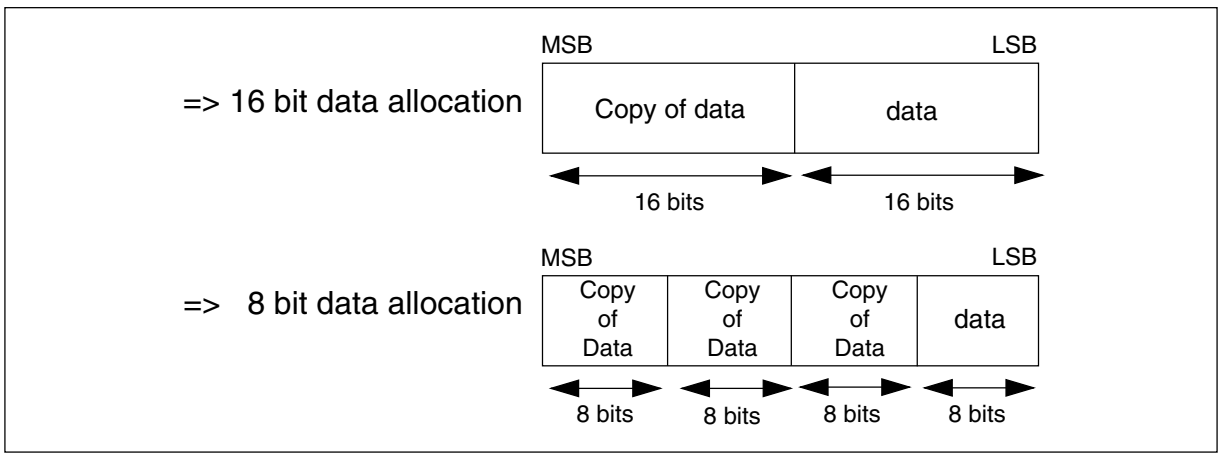

Figure 75-11. Data allocation

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)

- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
  - Bit[0]:
    - 0 - halfword 1 enabled (MSB)
    - 1 - halfword 0 enabled (LSB)

75.7.3 Register Write transfer

Register Write transfer can be of type:

- Normal write transfer - channels 0, 1, 2 and 3

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see Normal write transfer) as shown in Figure 75-12.

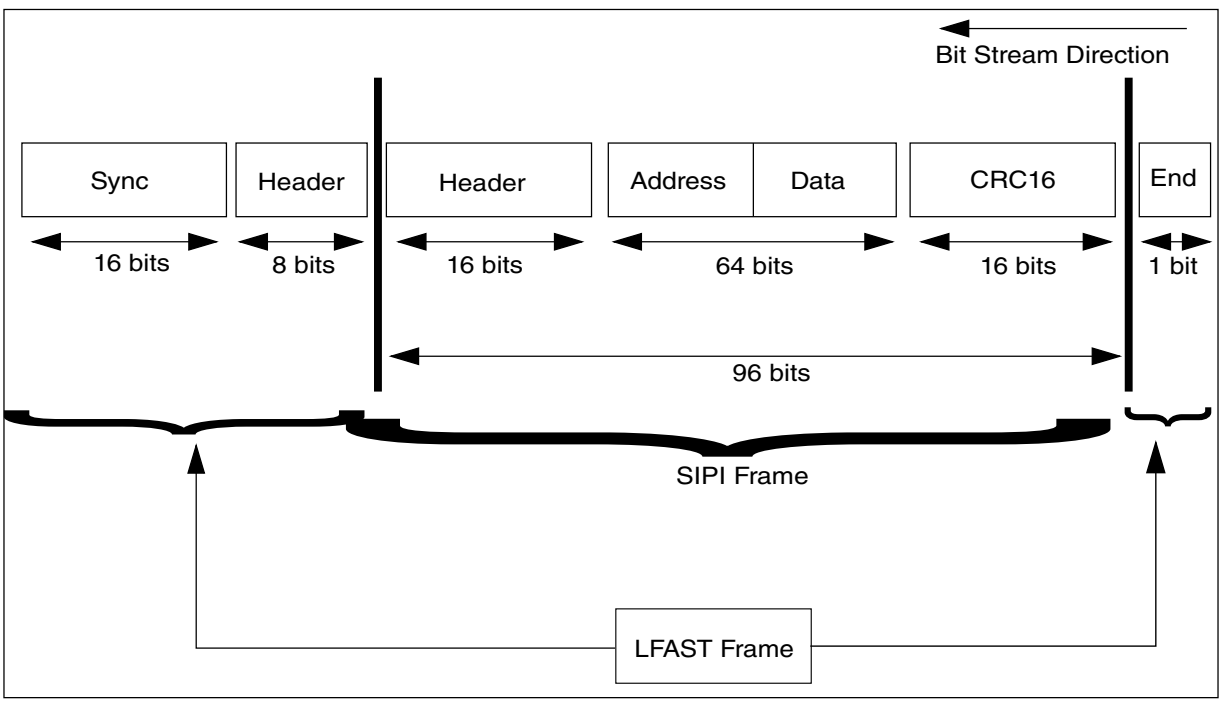

Figure 75-12. Register write transfer (showing LFAST frame encapsulation)

75.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in Figure 75-13.

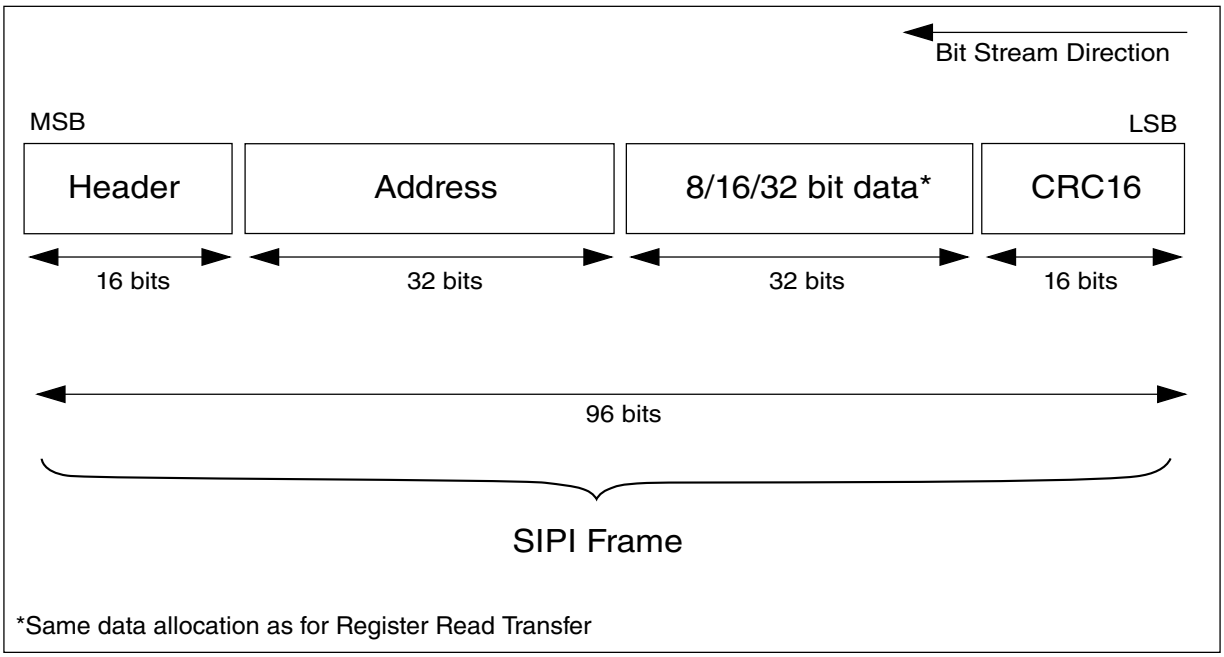

Figure 75-13. Write transfer (LFAST frame encapsulation is not shown)

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
  - Bit[0]:
    - 0 - half-word 1 enabled (MSB)
    - 1 - half-word 0 enabled (LSB)

75.7.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see Write Aknowledge transfer. The CRC bits are calculated on the header field.

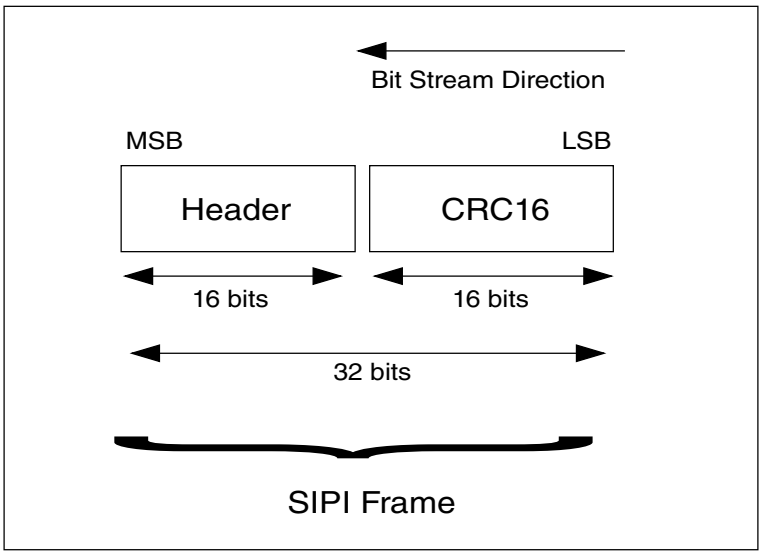

Figure 75-14. Write Aknowledge transfer (LFAST encapsulation is not shown)

75.7.5 ID request response

75.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in Figure 75-15.

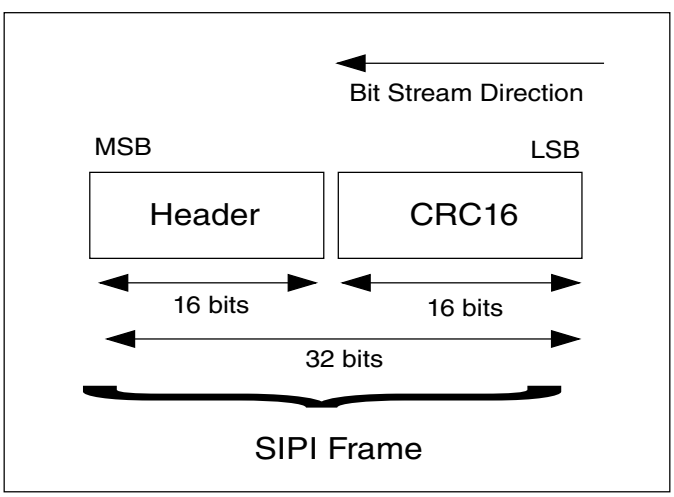

Figure 75-15. ID request transfer (LFAST encapsulation is not shown)

75.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in Figure 75-16.

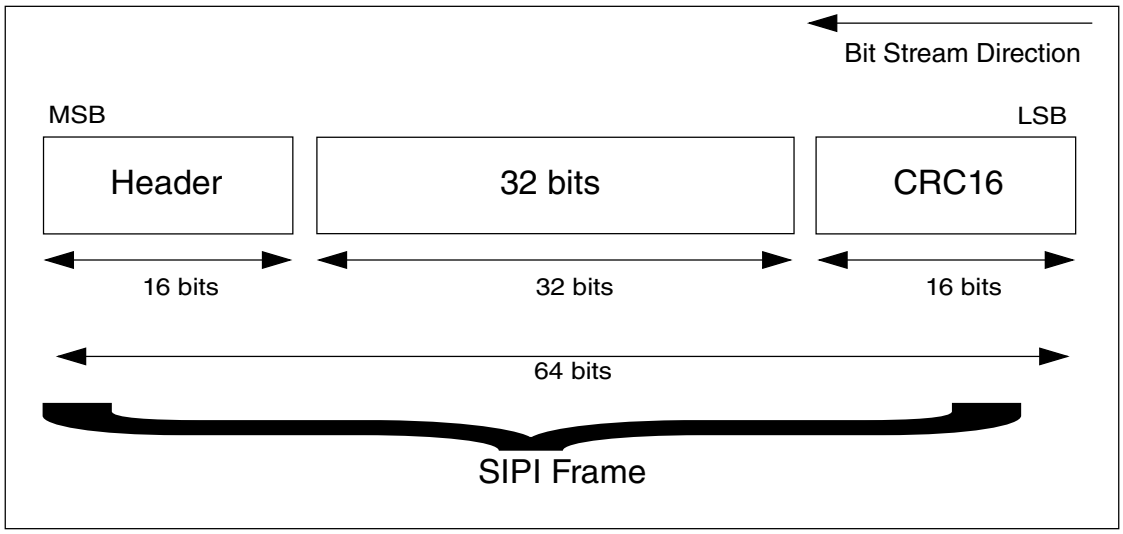

Figure 75-16. ID request response transfer

Note

The ID request response contains the value of the CHIP ID in place of data.

75.8 Transfer API and flow charts

On a single Write transfer request reception (Figure 75-17):

1. Debug SIPI will place the address, data and control information on its AHB master interface.
2. When the process completes, the Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

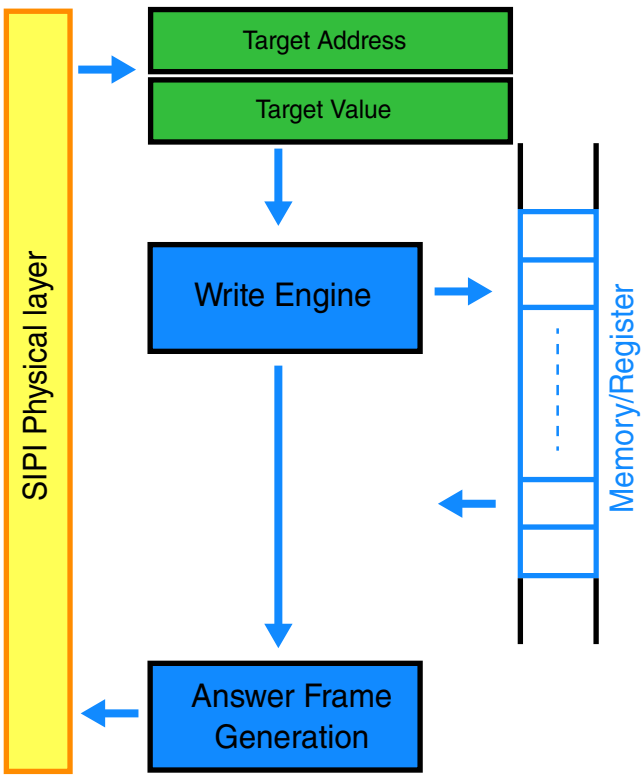

Figure 75-17. SIPI single register write API – Flow Chart

On Multiple Write transfer request reception:

1. Debug SIPI will place the address, data and control information on its AHB Master Interface.
2. When the process completes, Debug SIPI will generate an acknowledge frame and send it back to the LFAST.

On Single Read transfer request reception:

1. Debug SIPI will place the address and control information on its AHB Master Interface.
2. When the process completes, Debug SIPI will send read response back to LFAST.

On Multiple Read transfer request reception:

1. Debug SIPI then will start reading data through its AHB interface.
2. When the transfer is completed and all data registers are full, it will calculate CRC and send the response frame back to LFAST.

75.9 CRC calculation

Example: If header is AABBh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

1) The CRC seed is initialized by FFFF_FFFFh.

2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).

3) So the header will be sent as DD55_0000h.

4) Address will be sent as 22CC_4488h.

5) Data will be sent as FF77_BB33h.

75.10 Memory map and register definition

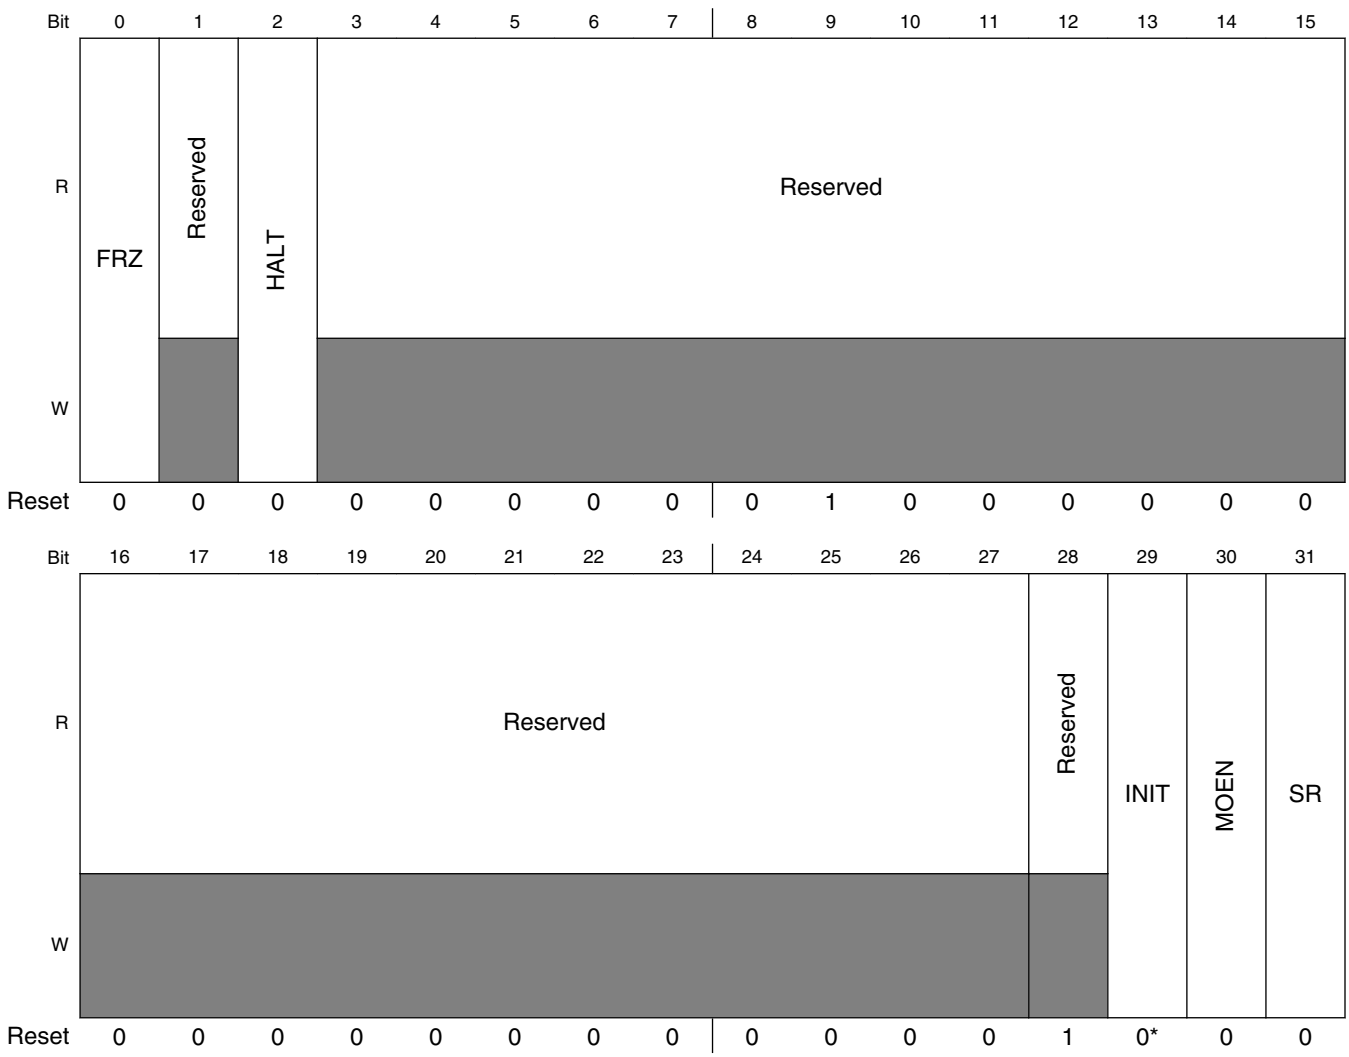
SIPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
9C	SIPI Module Configuration Register (SIPI_MCR)	32	R/W	See section	75.10.1/ 3998
A0	SIPI Status Register (SIPI_SR)	32	R	0000_0000h	75.10.2/ 4000

75.10.1 SIPI Module Configuration Register (SIPI_MCR)

The SIPI_MCR is a global 32-bit configuration register.

Address: 0h base + 9Ch offset = 9Ch



* Notes:
- INIT field: Can only be written when SIPI_MCR[MOEN] = 1.

SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode.

Table continues on the next page...

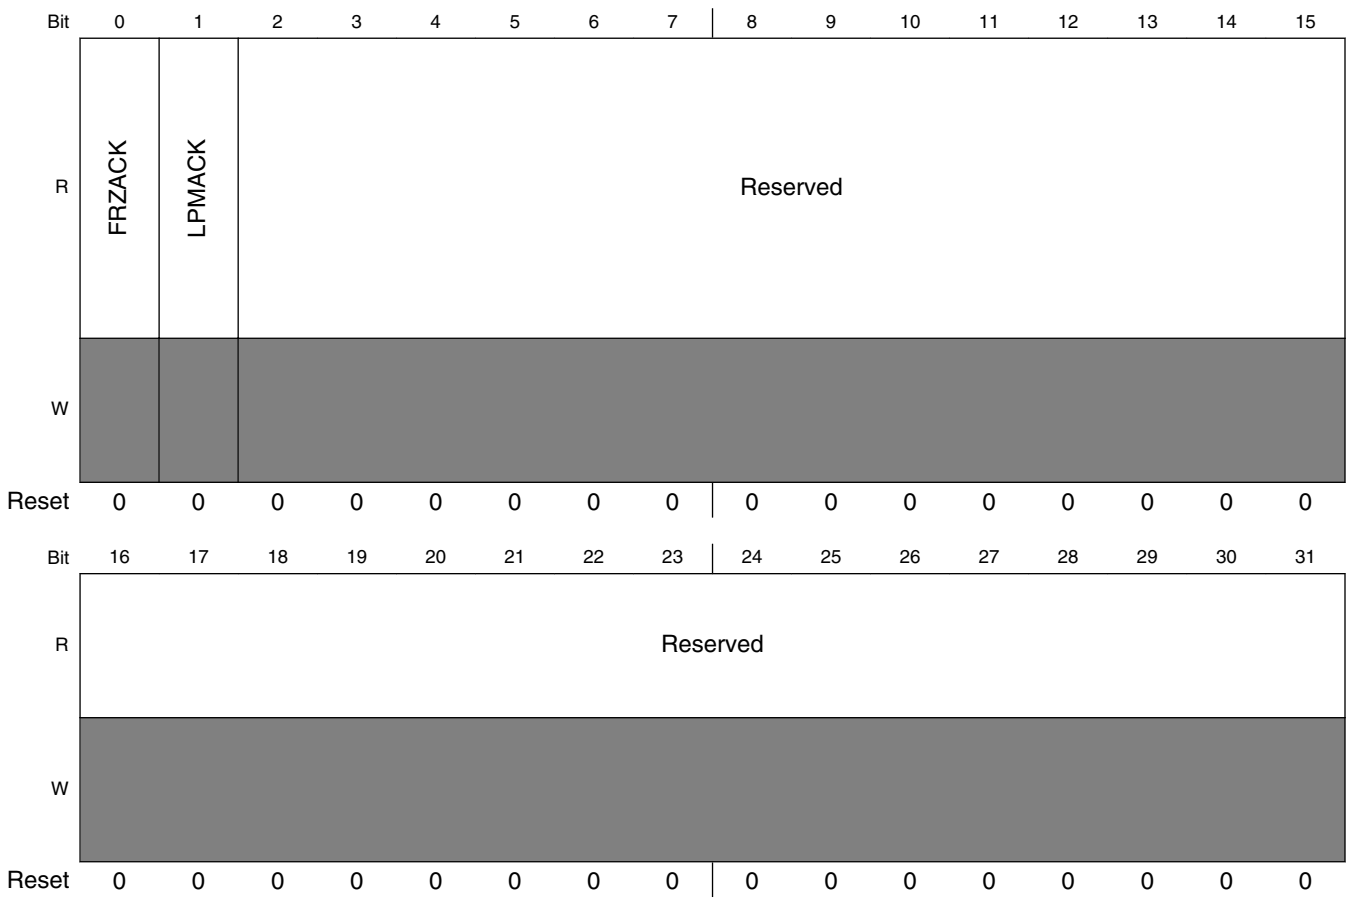
SIPI_MCR field descriptions (continued)

Field	Description
	NOTE: Can only be written when SIPI_MCR[MOEN] = 1. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1 Reserved	This field is reserved.
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–27 Reserved	This field is reserved.
28 Reserved	Target Enable This field is reserved.
29 INIT	Initialization Mode Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, all SIPI operations are immediately stopped.
31 SR	Soft Reset Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

75.10.2 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h



SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge.

Table continues on the next page...

SIPI_SR field descriptions (continued)

Field	Description
	This read-only bit indicates that SIPI is in Disable Mode. Either of these low power modes can not be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI is not in low power mode 1 SIPI is either in Disable Mode
2–31 Reserved	This field is reserved.

Chapter 76
LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed debug

76.1 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

76.2 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

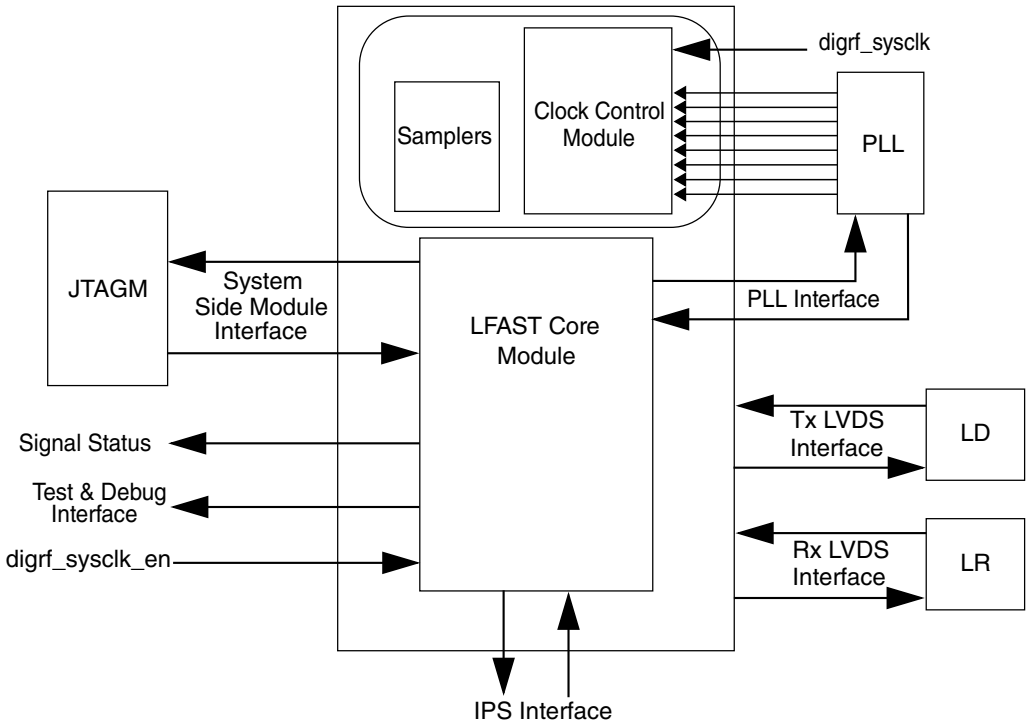


Figure 76-1. LFAST block diagram

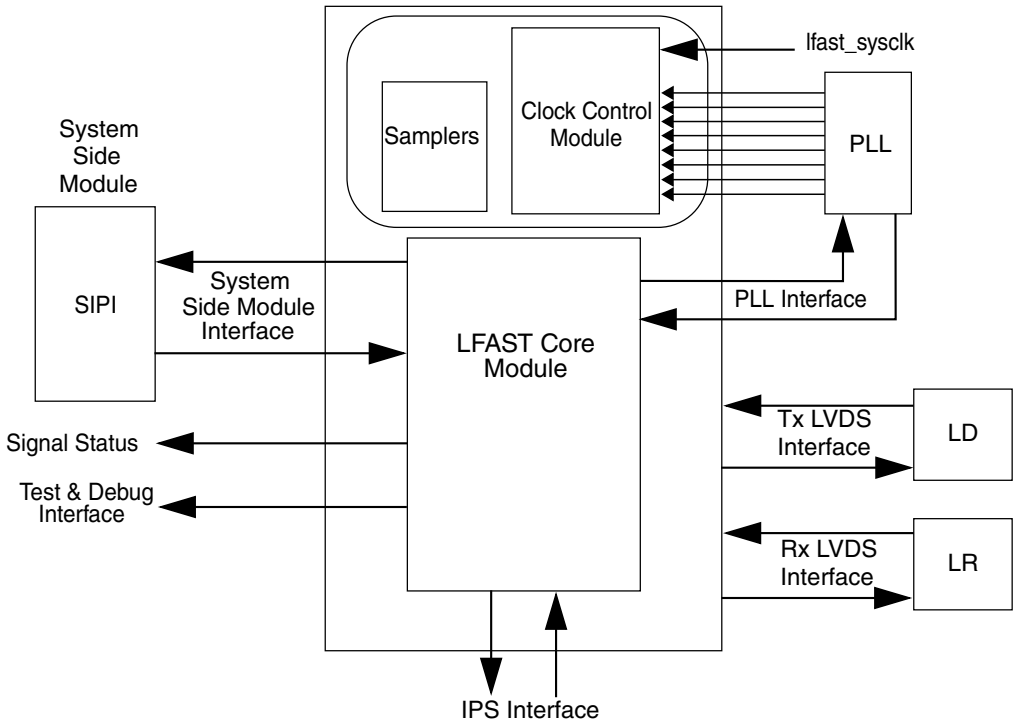

Figure 76-2. LFAST block diagram

76.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
  - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface with maximum data rate of 320 Mbps.

76.3.1 LFAST operating data rates

Table 76-1. Operating modes for LFAST interface

Interface	Tx/Rx Data Rate
LFAST Transmit	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps
LFAST Receive	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low and data rates 312 Mbps and 320 Mbps is referred to as high data rates.

76.4 LFAST frame structure

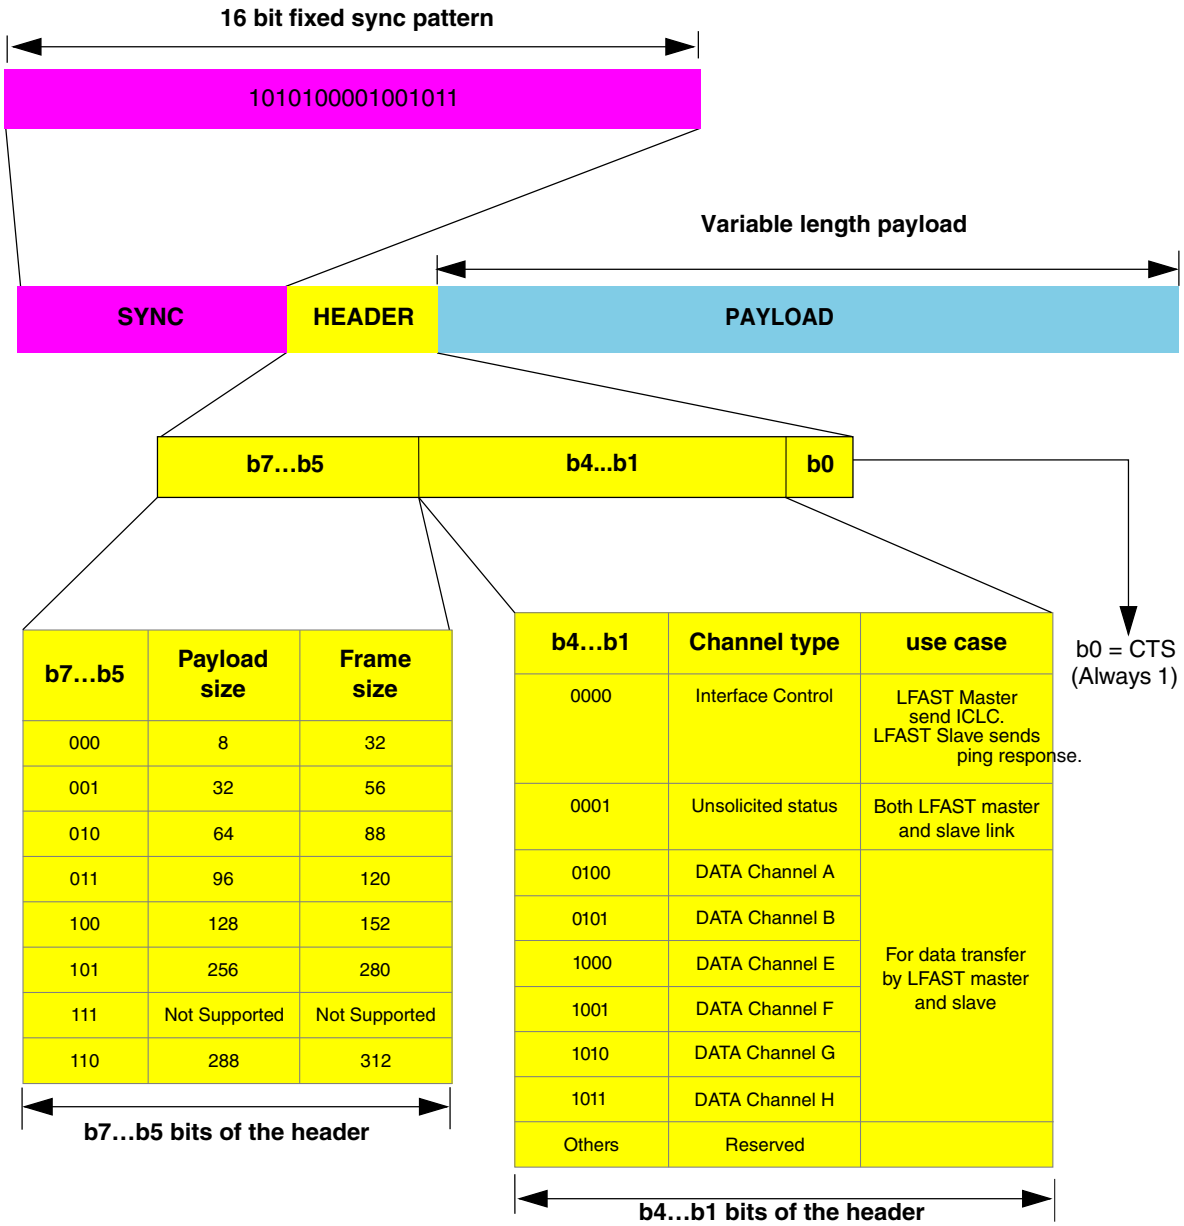
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See Figure 76-3 for details of the LFAST frame.



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported
110	288	312

b4…b1	Channel type	use case
0000	Interface Control	LFAST Master send ICLC. LFAST Slave sends ping response.
0001	Unsolicited status	Both LFAST master and slave link
0100	DATA Channel A	For data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 76-3. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

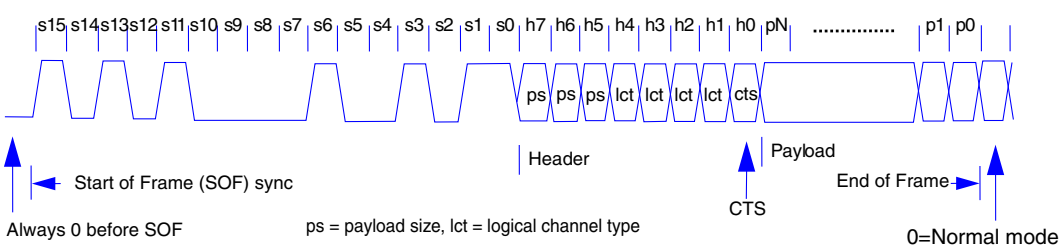


Figure 76-4. Serial frame structure

The frame structure is shown in Figure 76-4 and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in Table 76-2 :

Table 76-2. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

76.5 Features

- Supports slave only mode.
- Supports asynchronous data transfer at data rates up to a maximum of 320 Mbps.

- Transmits and receives data, ICLC and unsolicited frames.
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation .
- Supports for detection of unsupported channel number and unsupported payload size.

76.6 Memory map and register definition

All registers are 32 bits wide.

LFAST memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	LFAST Mode Configuration Register (LFAST_MCR)	32	R/W	See section	76.6.1/4011
4	LFAST Speed Control Register (LFAST_SCR)	32	R/W	0001_0000h	76.6.2/4013
8	LFAST Correlator Control Register (LFAST_COCR)	32	R/W	0000_000Eh	76.6.3/4014
C	LFAST Test Mode Control Register (LFAST_TMCR)	32	R/W	0000_0000h	76.6.4/4016
10	LFAST Auto Loopback Control Register (LFAST_ALCR)	32	R/W	0000_0000h	76.6.5/4017

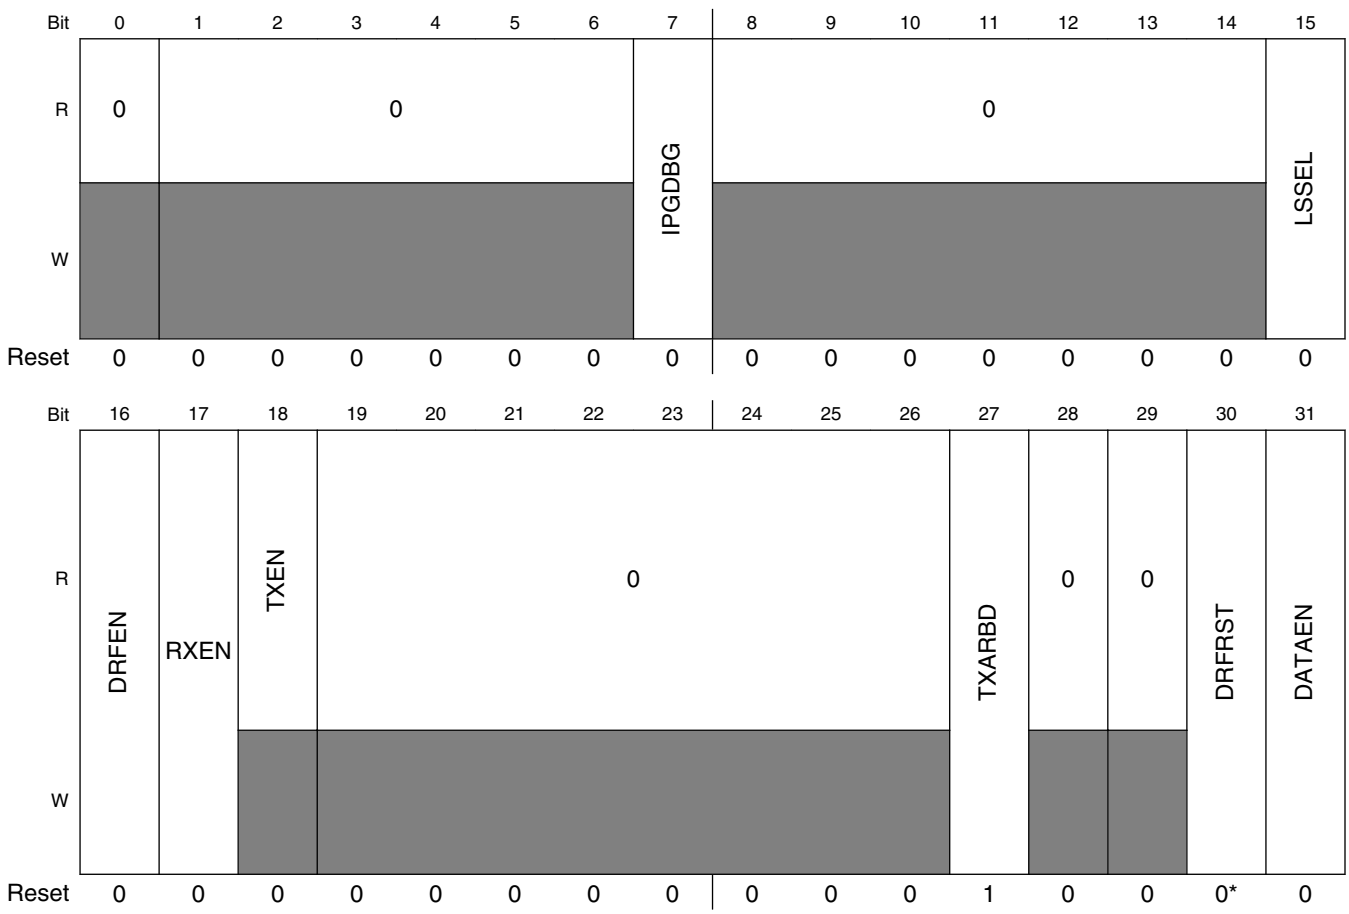
76.6.1 LFAST Mode Configuration Register (LFAST_MCR)

Address: 1h base + 0h offset = 1h



* Notes:

- DRFRST field: Set by user software and then cleared by system hardware.

LFAST_MCR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit shows the whether the transmitter is enabled or disabled. This field is read only in slave only mode (LFAST_GSR[DUALMD] = 0) and must not be written. 0 LFAST transmitter Interface is disabled. 1 LFAST transmitter Interface is enabled.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset..

Table continues on the next page...

LFAST_MCR field descriptions (continued)

Field	Description
	0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

76.6.2 LFAST Speed Control Register (LFAST_SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 1h base + 4h offset = 5h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															DRMD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0							RDR	0							TDR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

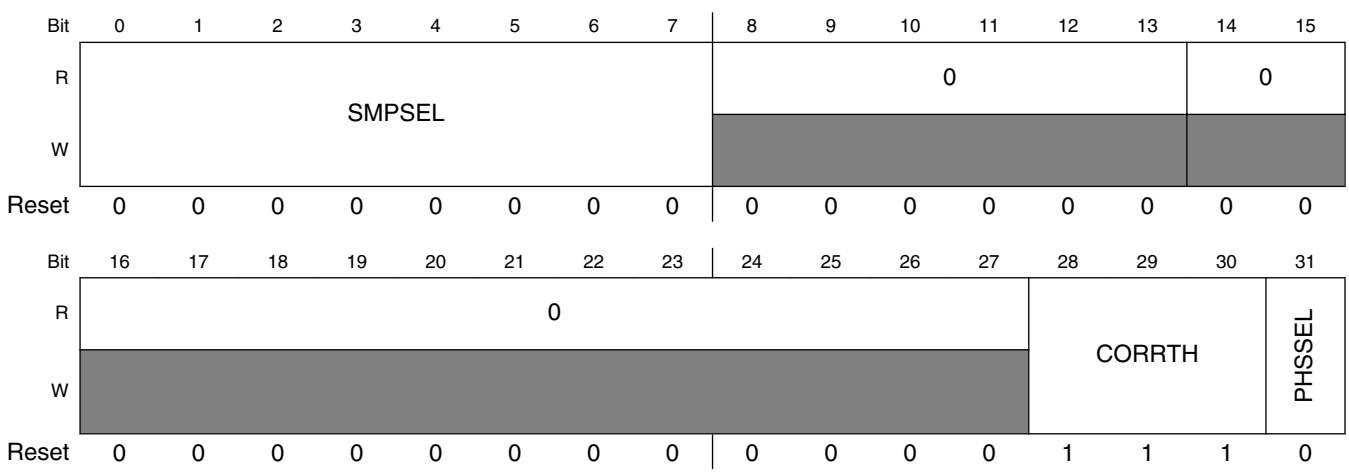
LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. This bit shouldn't be modified by S/W and left as SCR[DRMD] =1.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit shows the data rate of the receiver. This bit should not be modified by S/W in slave only mode (LFAST_GSR[DUALMD] = 0). 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is 312/320 Mbps.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit shows the data rate of the transmitter. This bit should not be modified by S/W in slave only mode (LFAST_GSR[DUALMD] = 0). 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is 312 /320 Mbps.

76.6.3 LFAST Correlator Control Register (LFAST_COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 1h base + 8h offset = 9h



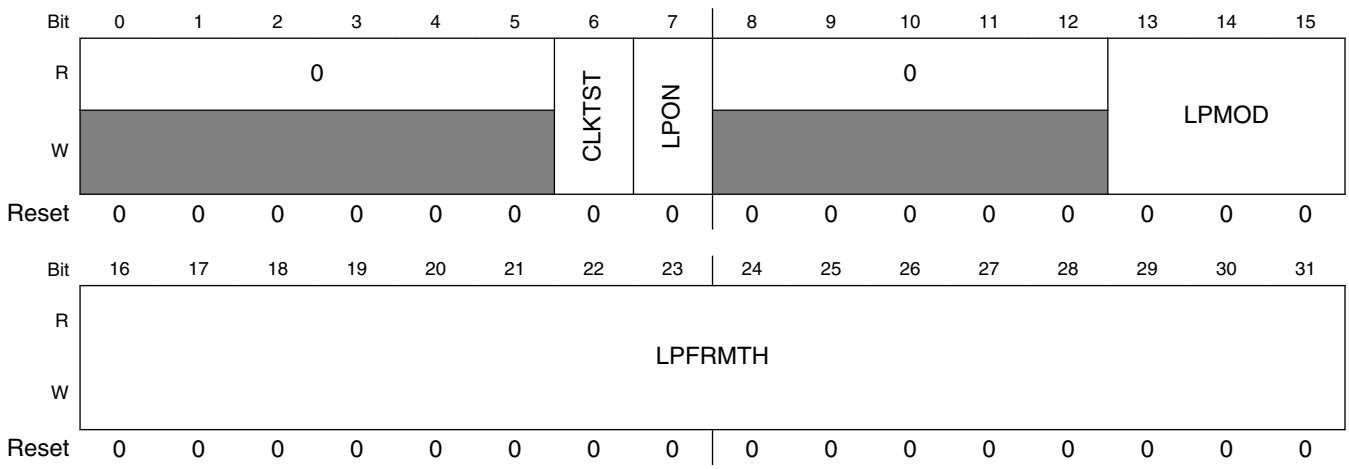
LFAST_COCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0. 00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

76.6.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 1h base + Ch offset = Dh



LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by H/W on reception of an ICLC command. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved

Table continues on the next page...

LFAST_TMCR field descriptions (continued)

Field	Description
	110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

76.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 1h base + 10h offset = 11h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															LPCNTEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_ALCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LPCNTEN	Auto Loopback Frame Transmission Count Enable. Enables fixed number of auto pre-defined loopback frame transmission. This field can only be written when TMCR[LPON] = 0. 0 Infinite pre-defined loopback frame transmission enabled 1 Fixed count of pre-defined loopback frame transmission enabled
16–31 LPFMCNT	Auto Loopback Frame Transmission Count. Defines the number of pre-defined auto loopback frames to be sent. The pre-defined loopback frame has payload CBh, header 13h and valid sync. This mode is valid if TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Send 1 frame with correct sync, header and payload

Table continues on the next page...

LFAST_ALCR field descriptions (continued)

Field	Description
	... FFFEh Send 65534 frames with correct sync, header and payload FFFFh Send 65535 frames with correct sync, header and payload

76.6.6 LFAST Rate Change Delay Control Register (LFAST_RCDCR)

Address: 1h base + 14h offset = 15h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_RCDCR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 DRCNT	Data Rate Controller Counter Value. Defines the number of cycles of Phase 0 clock needed by the Tx interface Data rate change controller to switch from one speed mode to another. The arbitrator ignores all requests during this period. This field can only be written when MCR[DRFEN] = 1. Number of cycles = DRCNT value.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

76.6.7 LFAST Wakeup Delay Control Register (LFAST_SLCR)

Address: 1h base + 18h offset = 19h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ...

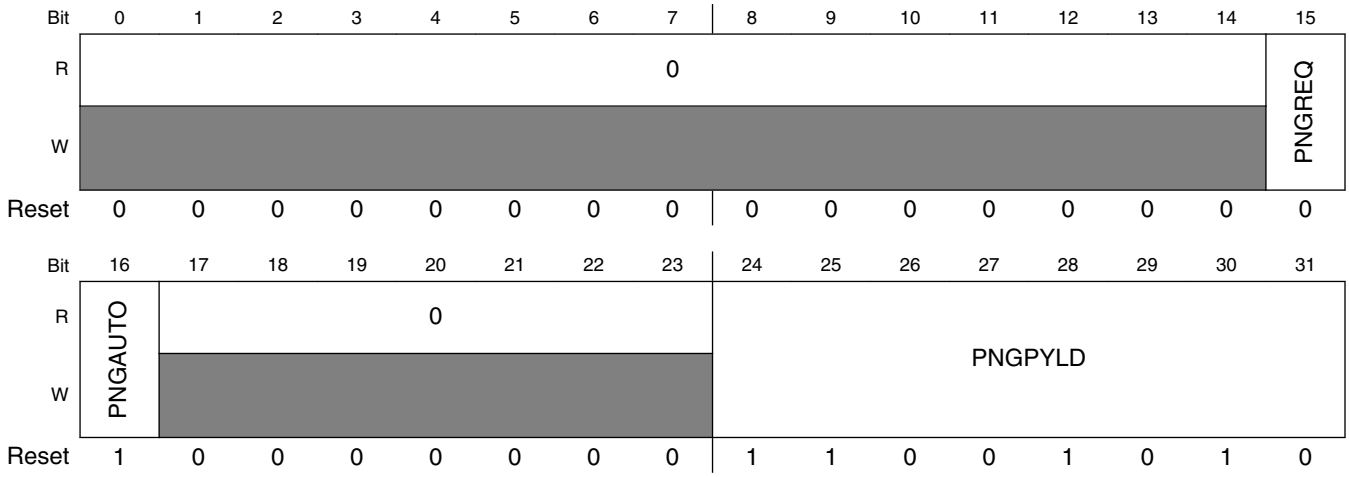
Table continues on the next page...

LFAST_SLCR field descriptions (continued)

Field	Description
	12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 µs) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 µs) ... Eh 14 cycles Fh 15 cycles

76.6.8 LFAST Ping Control Register (LFAST_PICR)

Address: 1h base + 20h offset = 21h

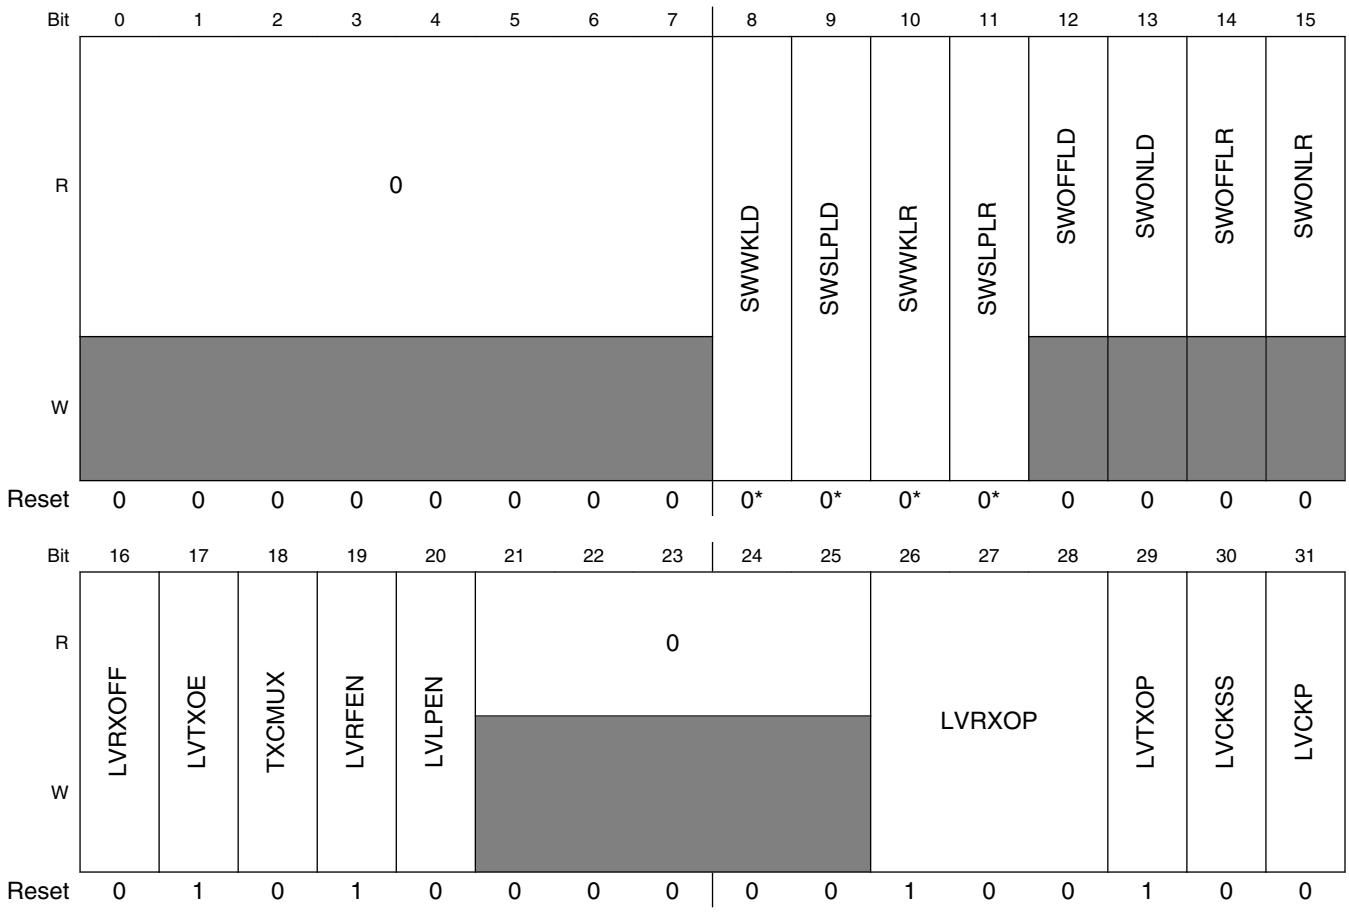


LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. This bit should not be modified by S/W.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0.

76.6.9 LFAST LVDS Control Register (LFAST_LCR)

Address: 1h base + 40h offset = 41h



* Notes:
- SWSLPLR field: Set by user software and cleared by system hardware.
- SWWKLR field: Set by user software and cleared by system hardware.
- SWSLPLD field: Set by user software and cleared by system hardware.
- SWWKLD field: Set by user software and cleared by system hardware.

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field.

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
	0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
13 SWONLD	SW signal to turn ON the LVDS LD. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
15 SWONLR	SW signal to turn ON the LVDS LR. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled

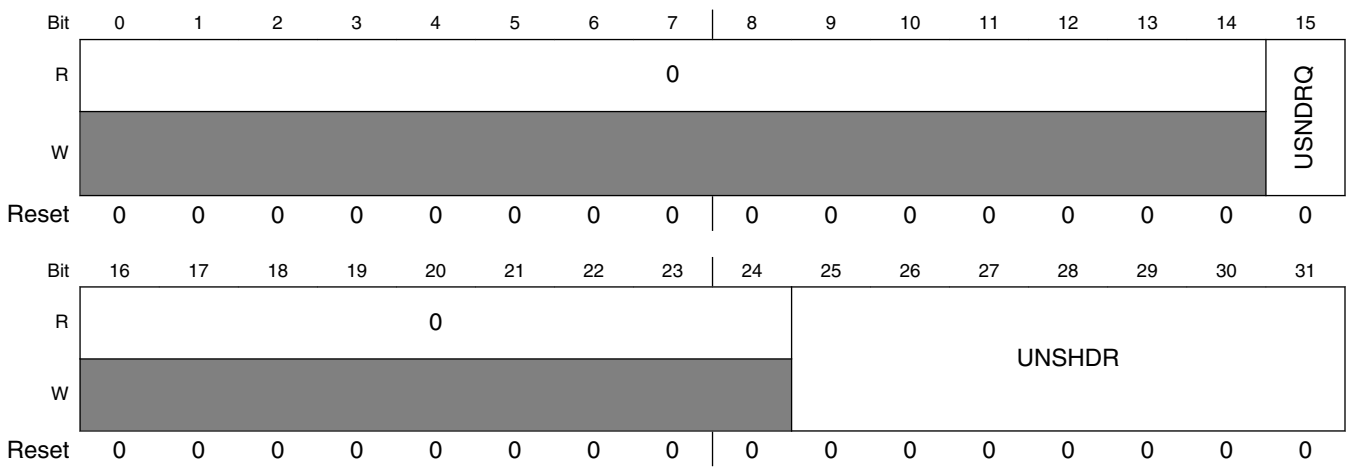
Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–28 LVRXOP	LVRXOP[2] disables termination resistance: 0 Disable termination 1 Enable termination LVRXOP[1] Not used LVRXOP[0] Defines the LVDS LR Bias current reference
29 LVTXOP	Control signal for LFASTand Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Data select. This bit is used for selecting use of clock sampled data or normal data in LVDS. 0 normal data to be used inside the LVDS 1 synchronized data to be used inside the LVDS
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

76.6.10 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 1h base + 44h offset = 45h



LFAST_UNSTCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_UNSTCR field descriptions (continued)

Field	Description
15 USNDRQ	Tx Unsolicited send request. Set by user software and cleared by system hardware. 0 No valid Unsolicited frame exists 1 Valid Unsolicited frame exists for transmission
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 UNSHDR	Tx Unsolicited message header. This field can only be written when LFAST_UNSTCR[USNDRQ] = 0

76.6.11 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)

Address: 1h base + 48h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

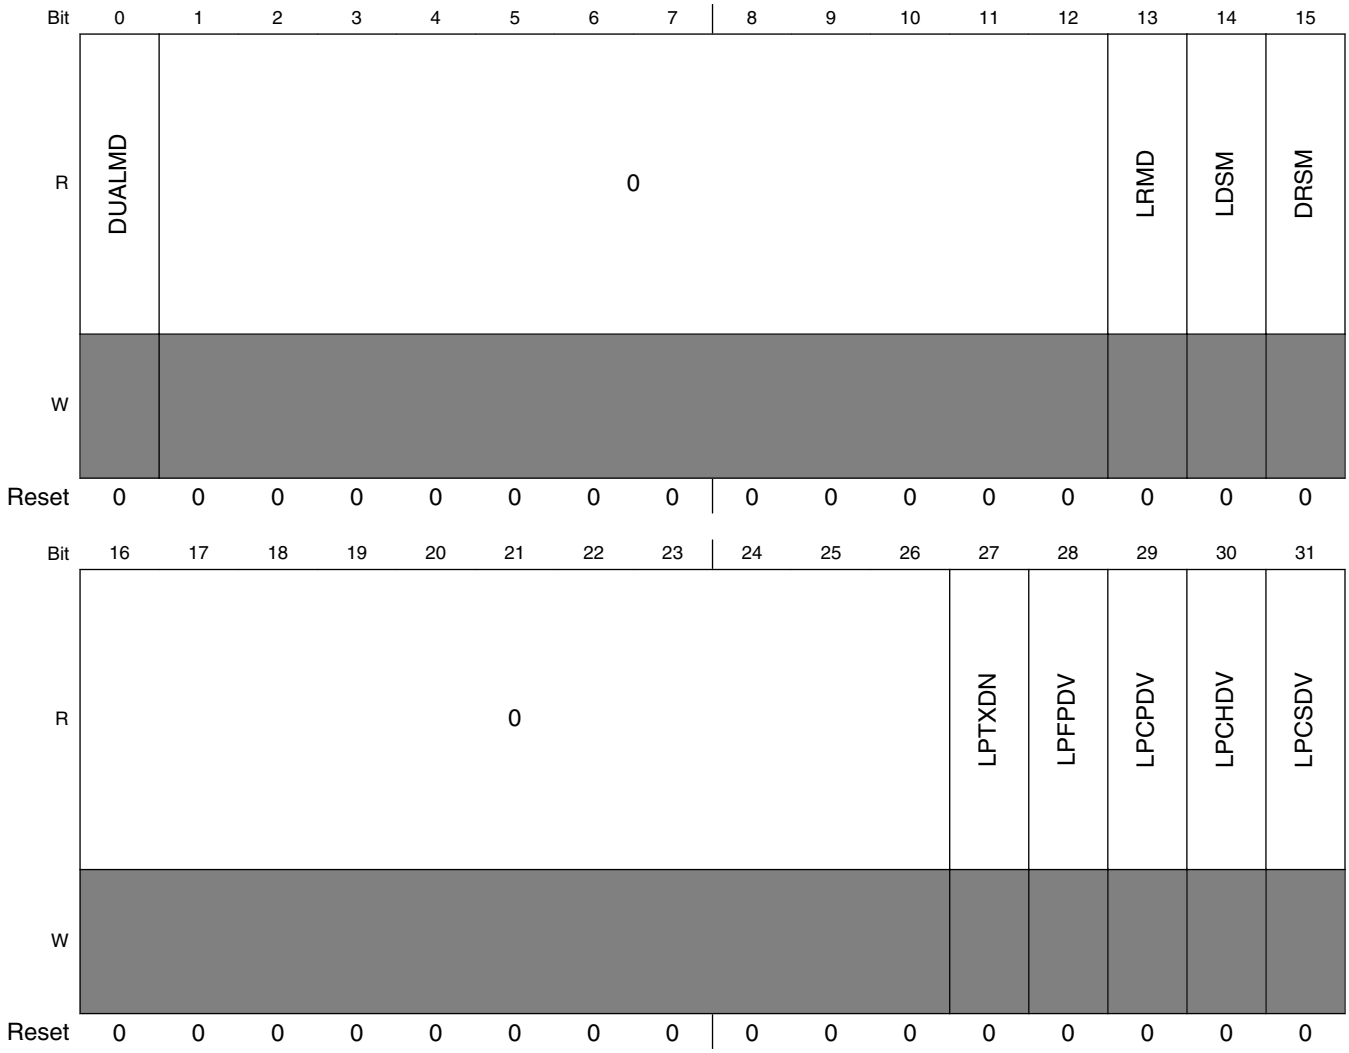
LFAST_UNSTDR*n* field descriptions

Field	Description
0–31 UNTXD	Unsolicited Transmit Data 8-0. This represents 9 registers for Unsolicited transmit data. The first bit to transmitted as part of the payload will be from UNTXD8[31], second bit from UNTXD8[30], and so on. So the last bit transmitted will be from UNTXD0[0] in case of 288 bit payload.

76.6.12 LFAST Global Status Register (LFAST_GSR)

Address: 1h base + 80h offset = 81h



LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode 0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active.

Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

76.6.13 LFAST Data Frame Status Register (LFAST_DFSR)

Address: 1h base + 94h offset = 95h

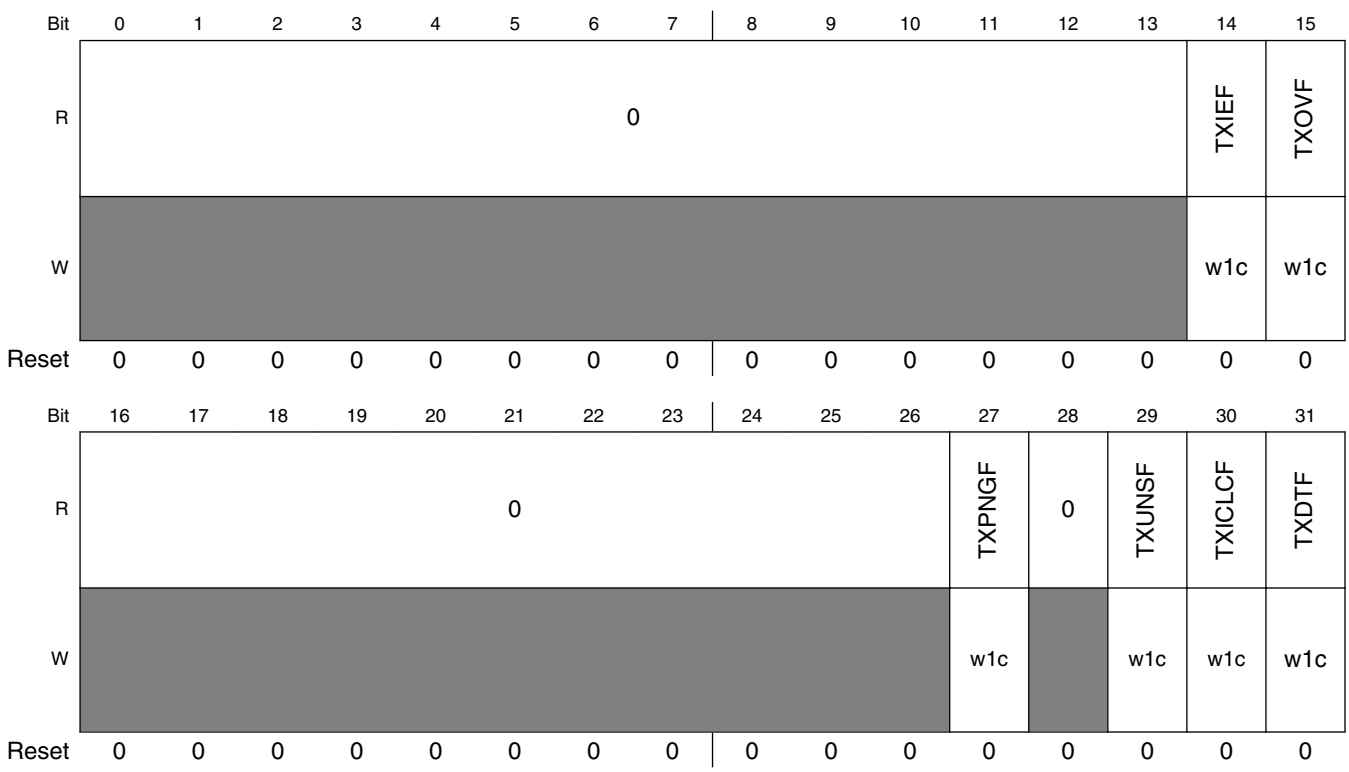
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0		RXDCNT						0					RXFCNT			0		TXDCNT							0					TXFCNT		
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_DFSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 RXDCNT	Unread Rx Frame Data Count. Indicates the number of unread data stored in the Rx Data FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 RXFCNT	Unread Rx Frame Count. Indicates the number of unread data frames stored in the Rx Data FIFO.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TXDCNT	Unread Tx Frame Data Count. Indicates the number of unread data stored in the Tx Data FIFO.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TXFCNT	Unread Tx Frame Count.Count of pending Data Frames programed by System Side Module.

76.6.14 LFAST Tx Interrupt Status Register (LFAST_TISR)

Address: 1h base + 98h offset = 99h



LFAST_TISR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIEF	TxData Interface not enabled. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 TXOVF	Transmit Data FIFO Overflow Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGF	Ping response frame transmitted interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TXUNSF	Unsolicited Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 TXICLCF	ICLC Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 TXDTF	Data Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred

76.6.15 LFAST Rx Interrupt Status Register (LFAST_RISR)

Address: 1h base + 9Ch offset = 9Dh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_RISR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RXUOF	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt event has not occurred 1 Interrupt event has occurred
9–10 Reserved	Reserved. The User should ignore the bit in this mode. This field is reserved.
11 RXUFF	Rx Data FIFO Underflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
12 RXOFF	Rx Data FIFO Overflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
13 RXSZF	Frame with unsupported frame size received. See "Frames Supported by LFAST interfaces" table for details. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame with payload size for a frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
14 RXICF	Invalid ICLC code Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 RXLCEF	Invalid Logical Channel Type. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSF	Frame with CTS bit Low Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 RXDF	Data frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 RXUNSF	Unsolicited Frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

76.6.16 LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)

Address: 1h base + A0h offset = A1h

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_UNSRDR*n* field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

76.7 Functional description

76.7.1 LFAST Interface enable signal (lfast_sysclk_en)

The LFAST interface enable signal (lfast_sysclk_en) signal is present only in the case LFAST Slave . It also functions as the LFAST Interface control Signal. The interface control functions are:

LFAST interface enable (lfast_sysclk_en) negation:

1. If LCR[SWONLD] = 0, the LD LVDS pad is shut down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is shut down.

3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then S/W writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

1. The LD LVDS pad is power up, if all conditions are met:
   - LCR[SWOFFLD] = 0.
   - LCR[SWONLD] = 1.
   - MCR[TXEN] = 1.
   - When frame ICR[ICLCPLD] = 31h is received.
2. LR LVDS pad is powered up if all conditions are met:
   - LCR[SWOFFLR] = 0.
   - LCR[SWONLR] = 1.
   - MCR[RXEN] = 1.

76.7.2 Line Receiver

This section describes the Line Receiver.

76.7.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 76-5 shows the block diagram of Uplink Controller.

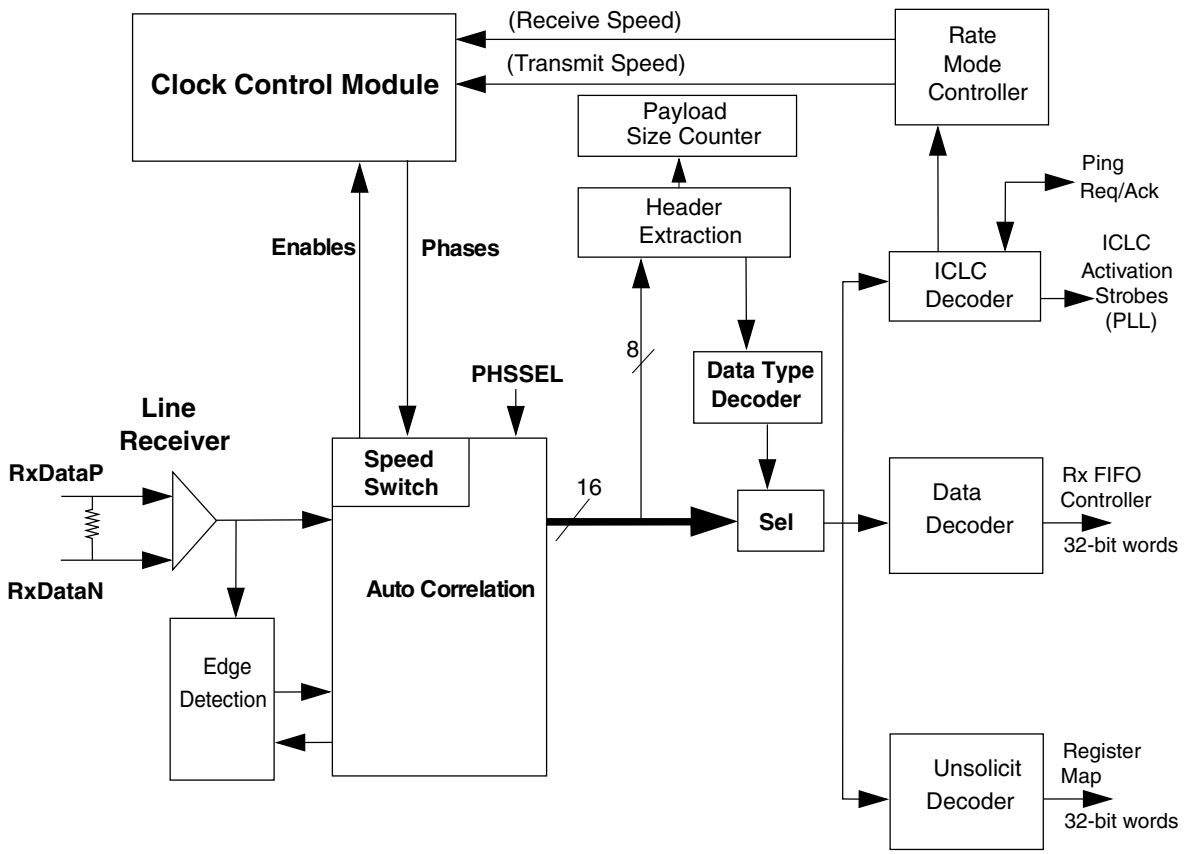

Figure 76-5. Top Level Receive Controller

76.7.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

76.7.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

76.7.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 76-6 shows the block diagram of Hunt Correlation mode.

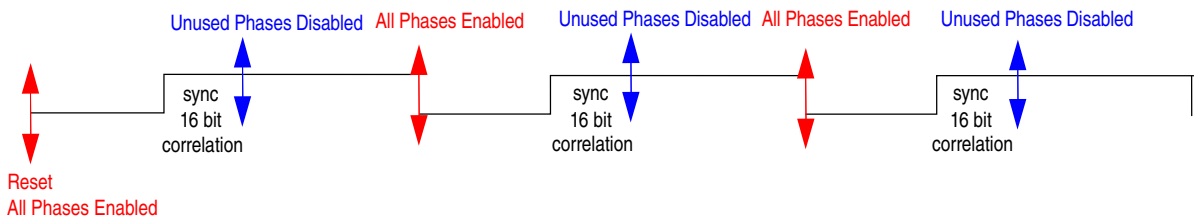

Figure 76-6. Hunt Correlation mode

76.7.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

76.7.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

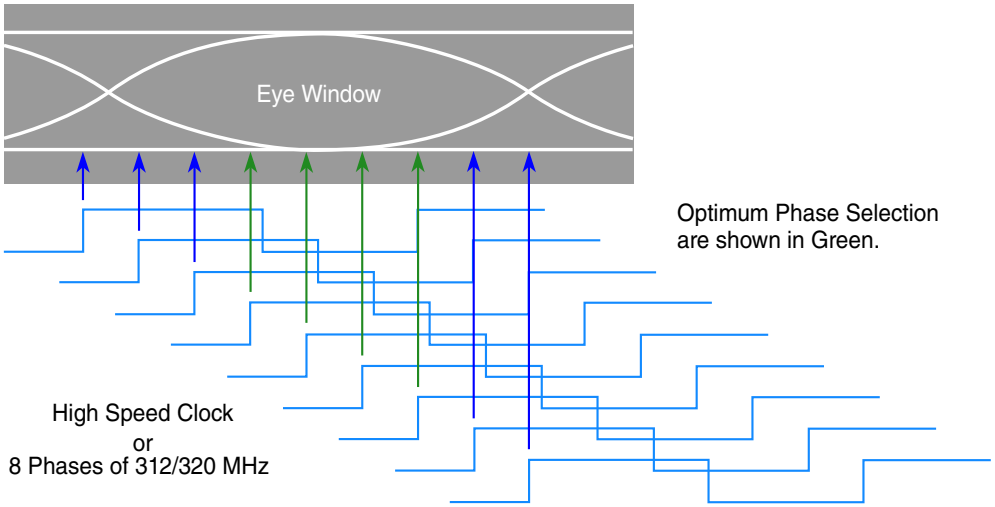

Figure 76-7. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

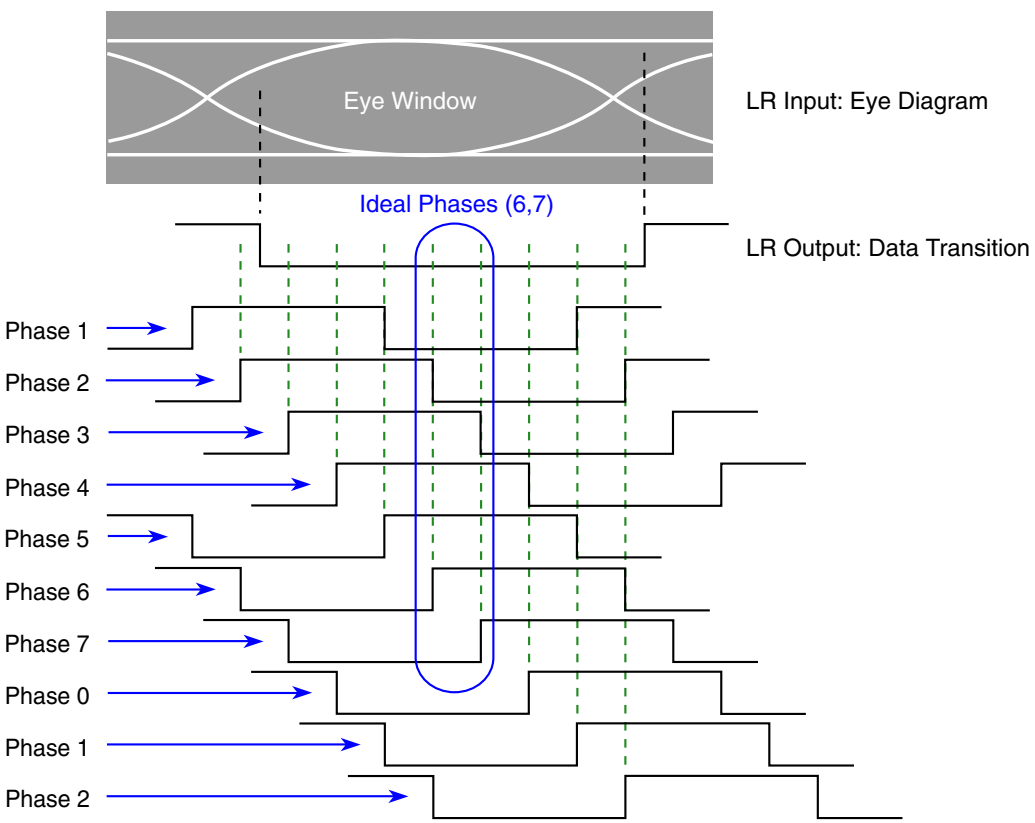

Figure 76-8. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in Figure 76-9 and Figure 76-10.

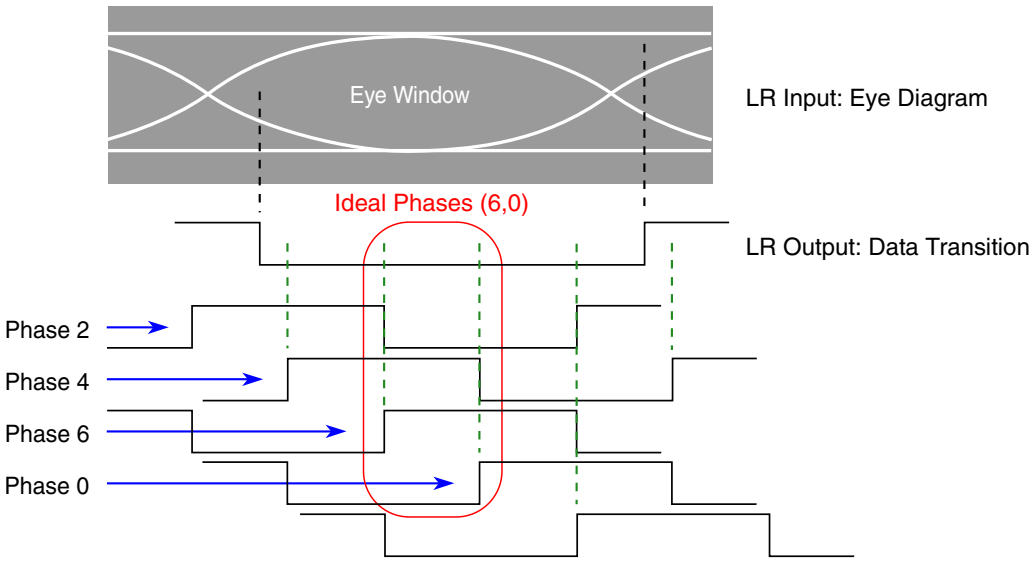

Figure 76-9. High Speed 4 Phase Clock Alignment Example

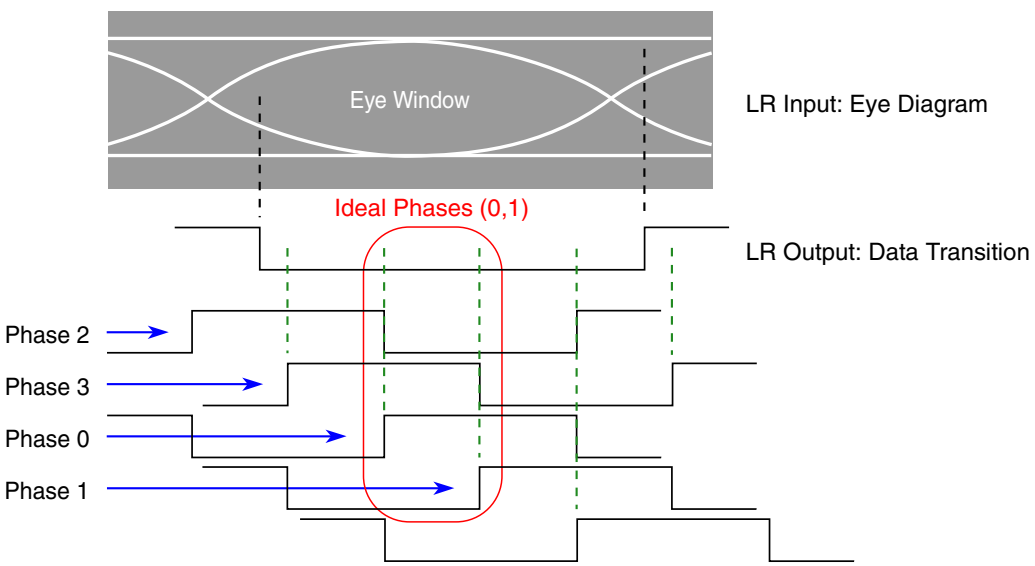

Figure 76-10. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed (312/320 MHz) 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in Table 76-3, Table 76-4, and Table 76-5 before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 76-3. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 76-4. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See Table 76-4, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 76-5. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 76-5. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See Table 76-5, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

76.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

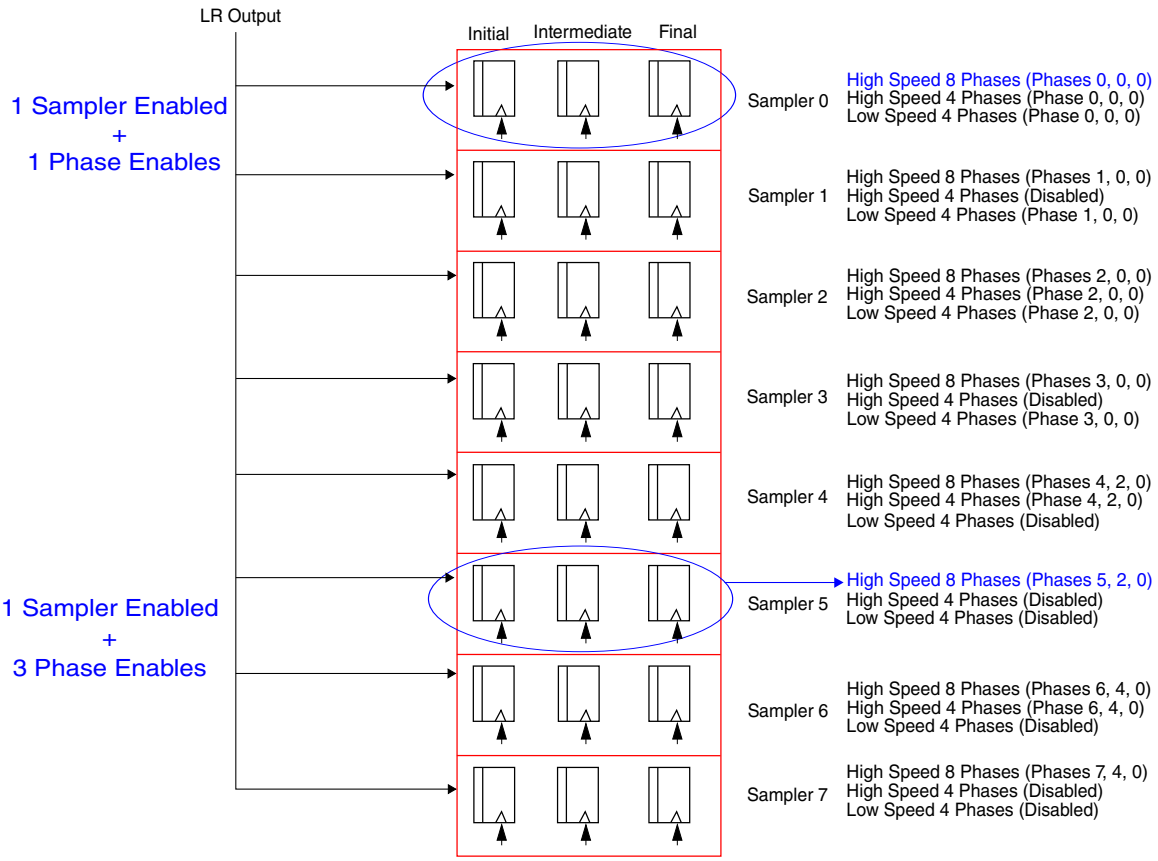

Figure 76-11. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

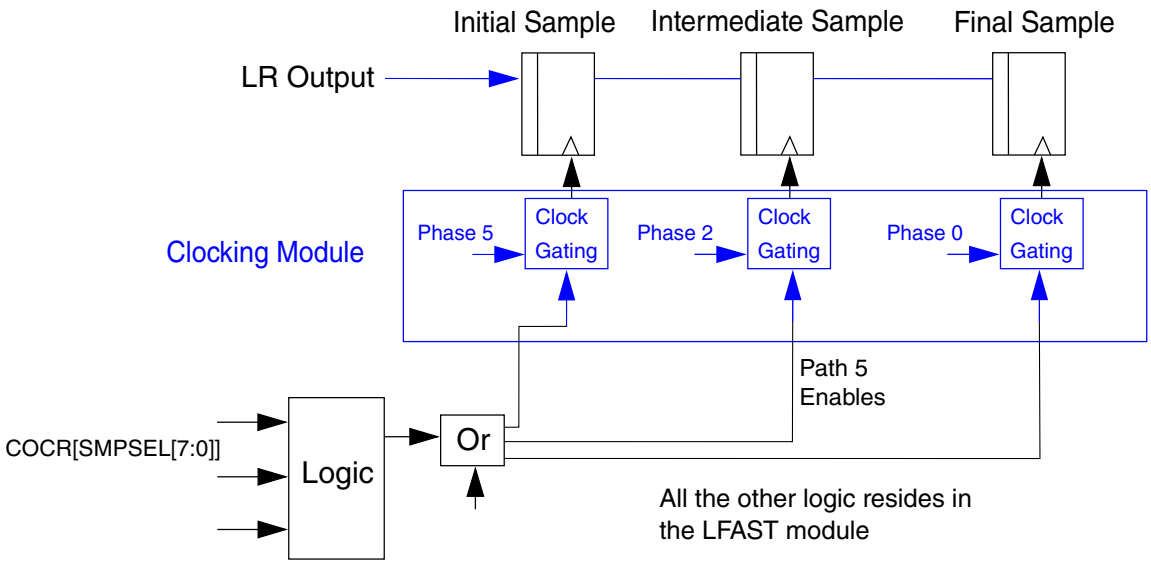

Figure 76-12. Sampler 5 Logic

76.7.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the Figure 76-13.

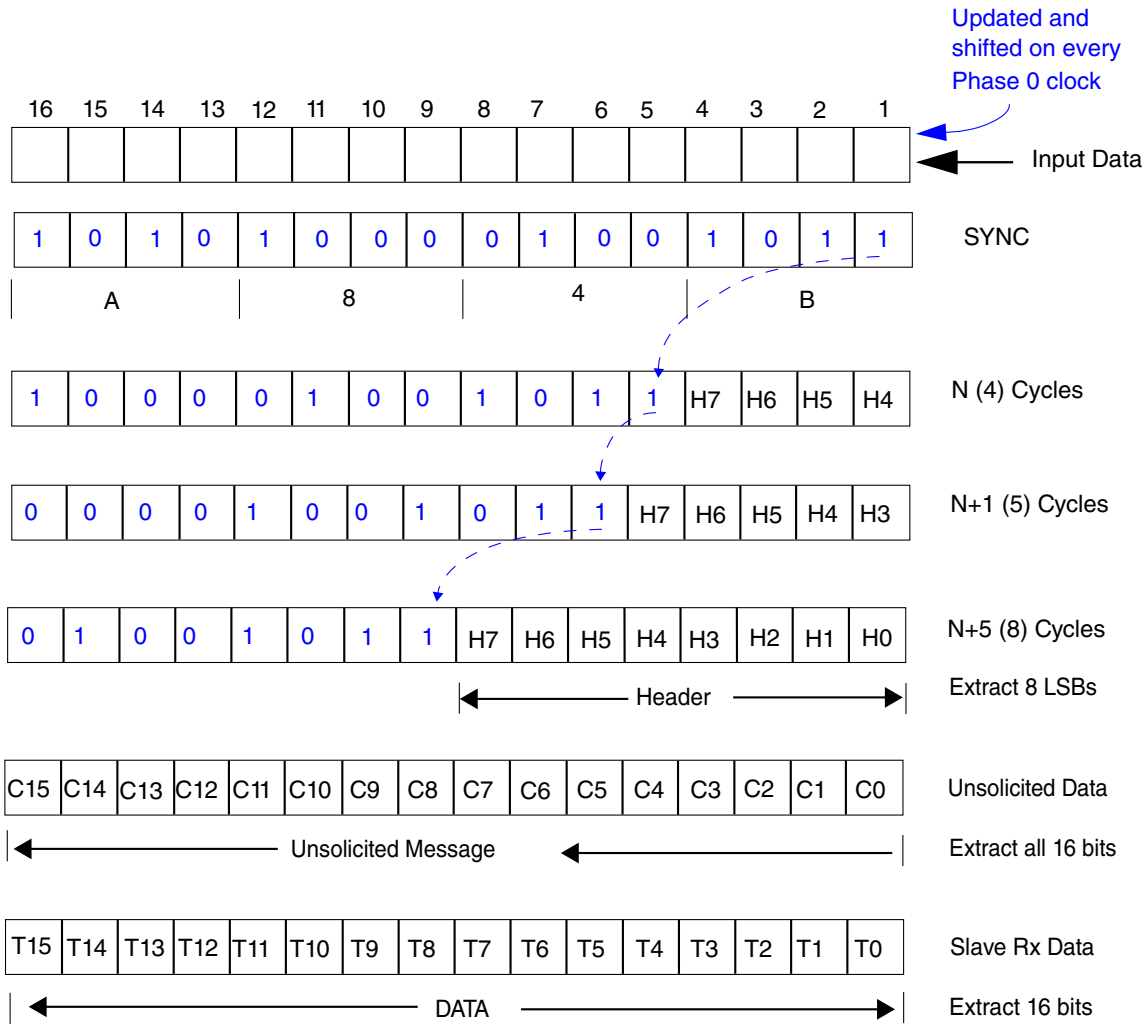

Figure 76-13. Extracting Header and Payload from the 16-bit output from Auto correlation.

76.7.3 Transmit Controller

This section describes the Transmit Controller.

76.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

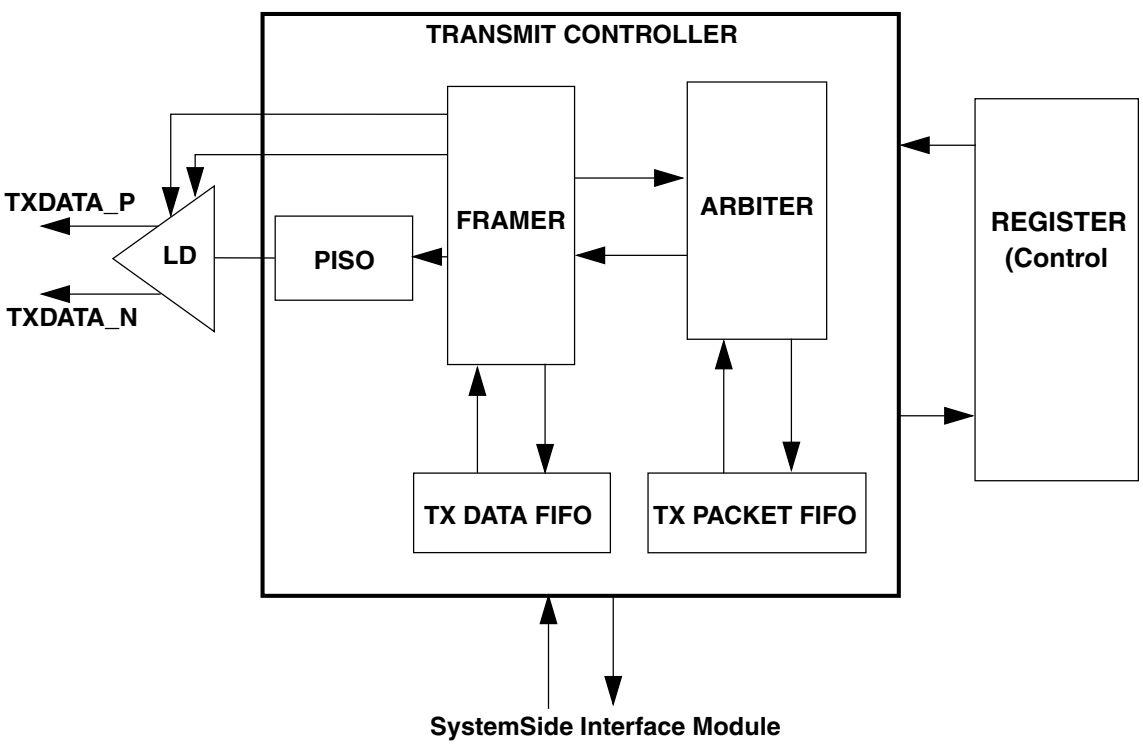

Figure 76-14. Transmit Controller Connections

76.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in Table 76-6

Table 76-6. Priority Levels for the Tranmsit Controller

Request	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
LFAST interface enable (lfast_sysclk_en)	1	• LFAST interface enable (lfast_sysclk_en) is asserted • LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	• TMCR[LPON] = 1 • LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	• Valid only if Last Frame with header b0 = 1 received from the peer LFAST • UNSTCR[USNDRQ] = 1

Table continues on the next page...

Table 76-6. Priority Levels for the Tranmsit Controller (continued)

Request	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
Data frame from Tx FIFO	7	• Tx FIFO contains one or more frames • Last Frame with header b0 = 1 received from the peer LFAST device • MCR[DATAEN] = 1
Clock mode test	8	• TMCR[CLKTST] = 0 • LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

76.7.3.3 Line Driver digital connections

76.7.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

  The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down

completely. In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

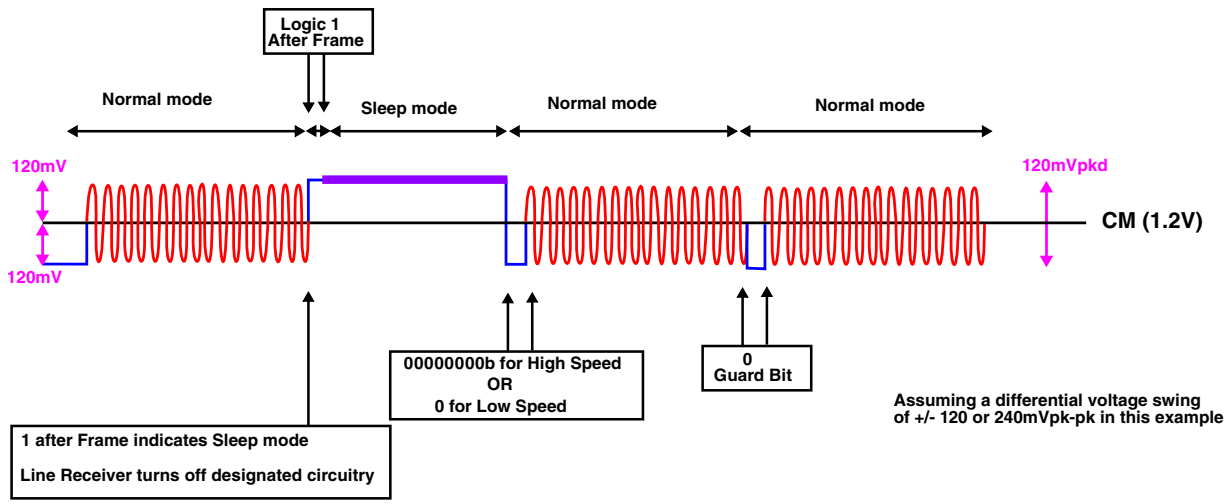

Figure 76-15. Example of Sleep mode

As shown in Figure 76-15 before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 76-7. Line Driver States

LD State	LFAST Slave Triggers
Shutdown	• LFAST interface enable (lfast_sysclk_en) negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

76.7.4 Frames supported

Table 76-8 provides the frames supported and their permissible payload sizes

Table 76-8. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO[1]	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

76.7.5 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

76.7.5.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

76.7.5.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

76.7.5.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer

76.7.5.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

76.7.5.2 Unsolicited flow

76.7.5.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

76.7.5.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

76.7.5.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

76.7.5.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

76.7.5.3.1 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

76.7.5.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

76.7.5.3.1.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

76.7.5.3.1.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

76.7.5.3.1.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

76.7.5.3.1.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

76.7.5.3.1.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

76.7.5.3.1.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

76.7.6 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

76.7.6.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 76-9. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

76.7.6.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

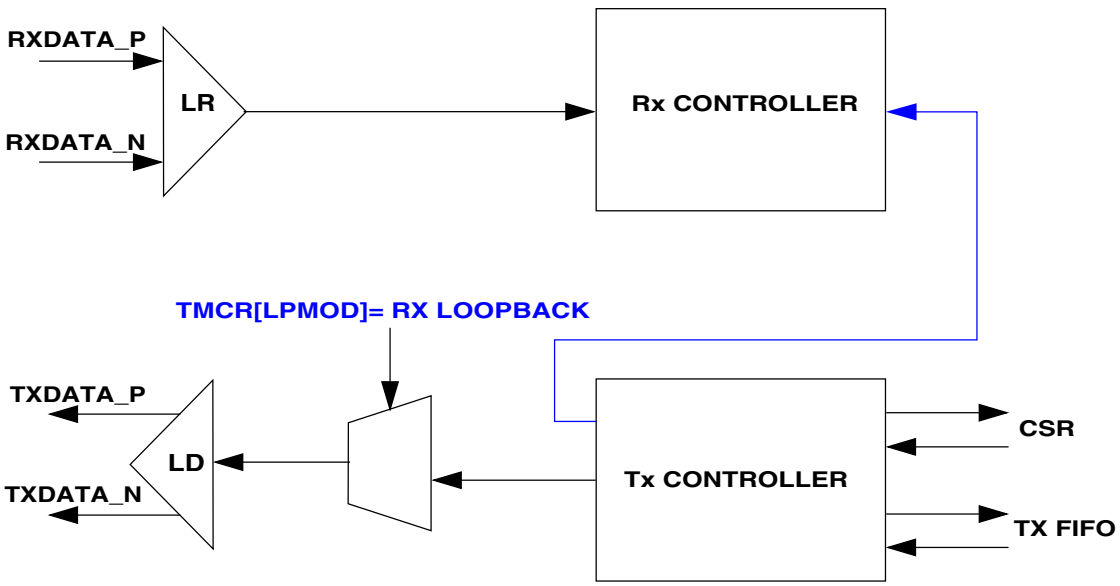

Figure 76-16. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

76.7.6.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

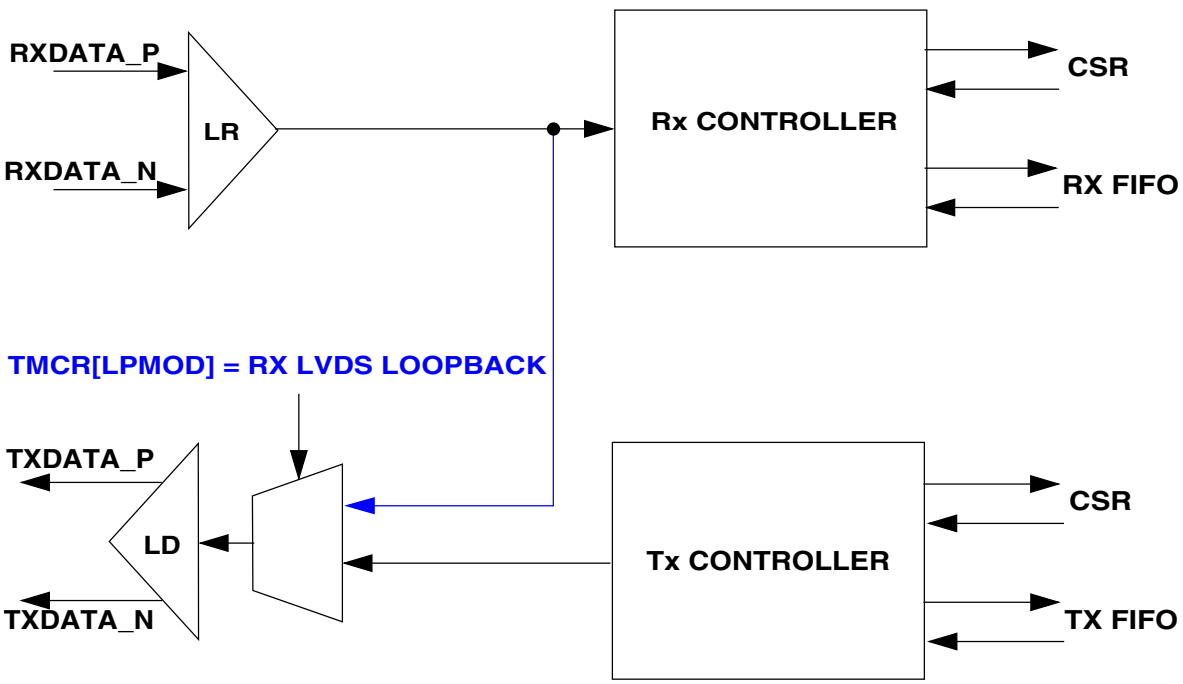

Figure 76-17. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   - S/W writes TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.
  - Deassertion of the LFAST interface enable (lfast_sysclk_en).

76.7.6.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

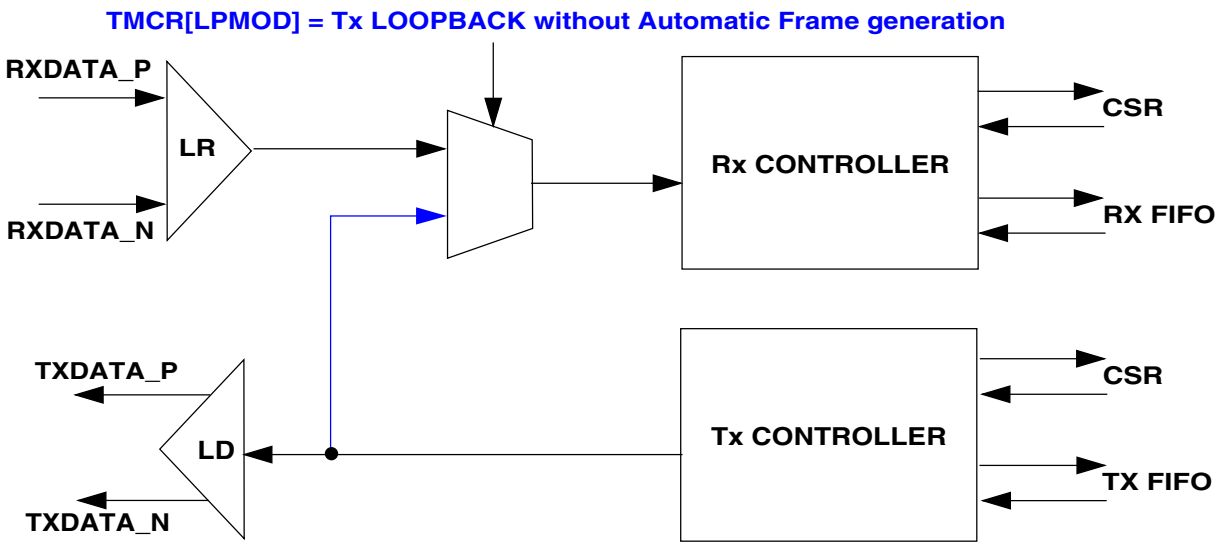

Figure 76-18. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

76.7.6.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

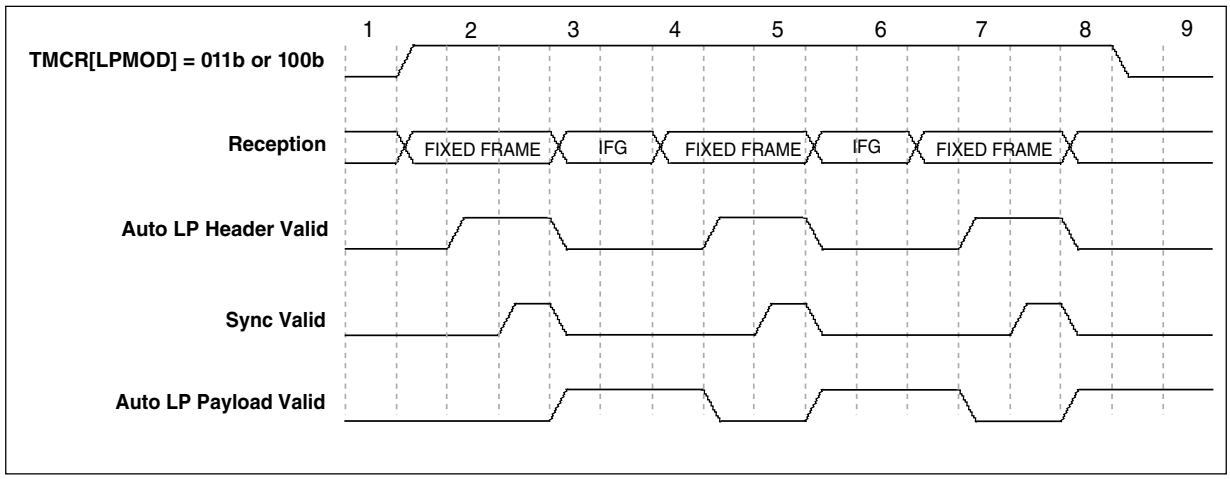

Figure 76-19. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

76.7.6.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

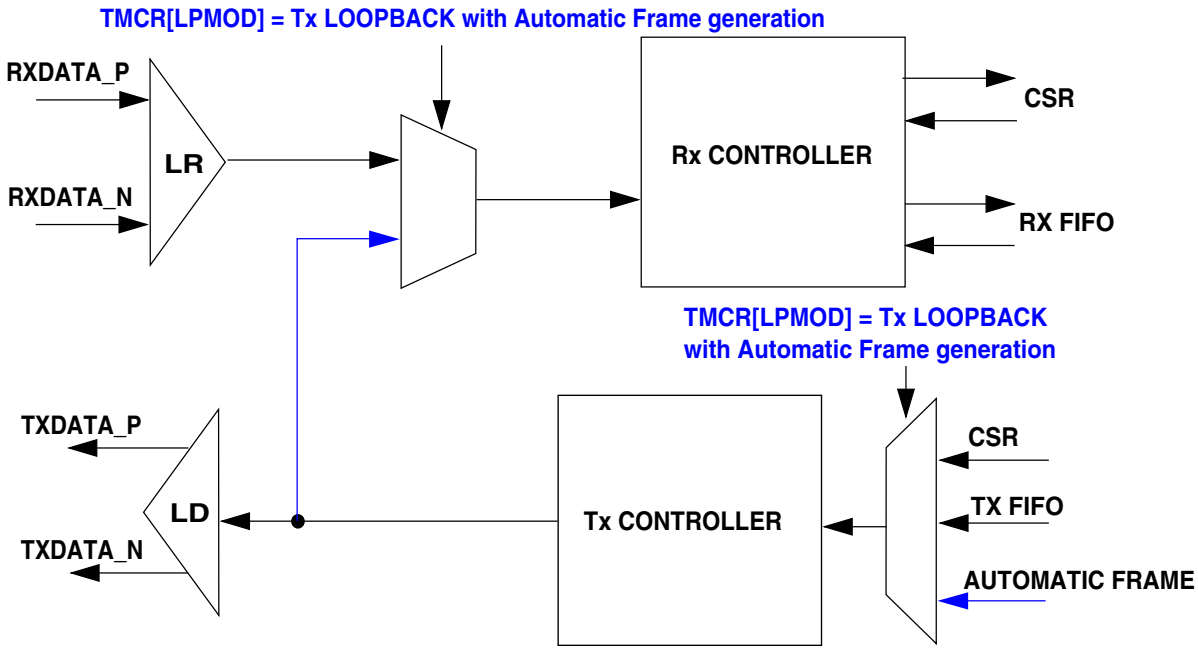

Figure 76-20. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

76.7.6.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

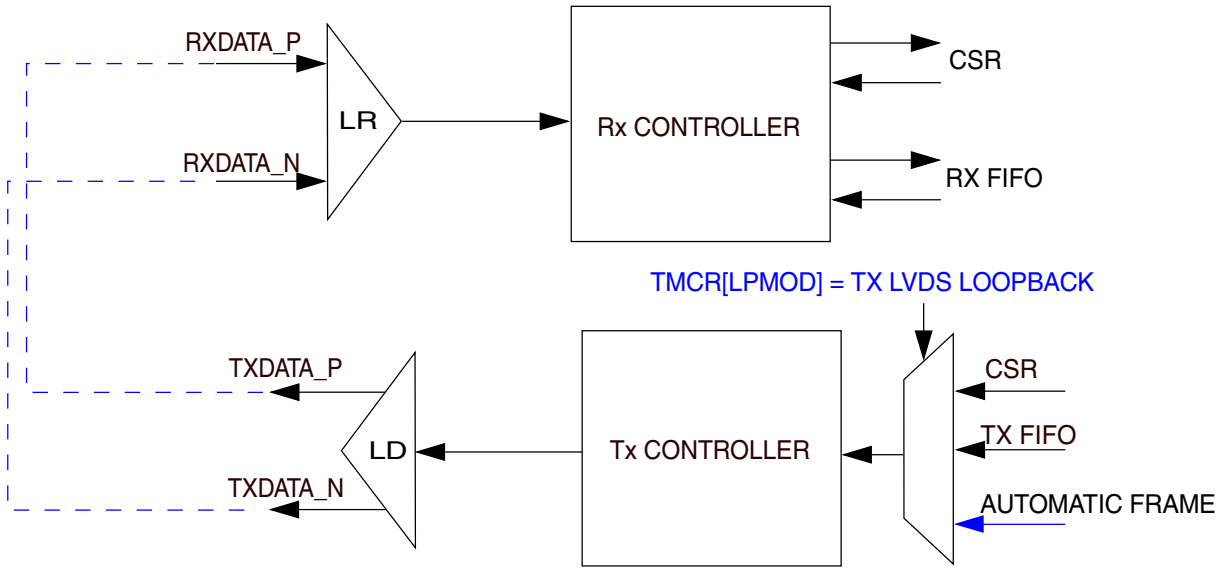

Figure 76-21. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

76.7.6.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

76.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 76-10. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet[3]	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

3. Ping response packet

76.9 Resets

The various blocks in LFAST are reset as described in the table below.

Table 76-11. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reseted while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON]

Table continues on the next page...

Table 76-11. Recommended receive exception handling mechanism (continued)

Reset	Blocks Reset
	• ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ] These bits doesn't remain reseted while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only • TISR, • RISR, • RIISR, • GSR[LPTXDN] and GSR[LPFPDV] • These bits doesn't remain reseted while the LFAST interface enable (lfast_sysclk_en) is High.

76.10 Clocks

The LFAST mainly works on two clocks:

- System Bus Clock used to program the registers.
- System Side Module clock, which is synchronous to the System Bus clock.

76.10.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

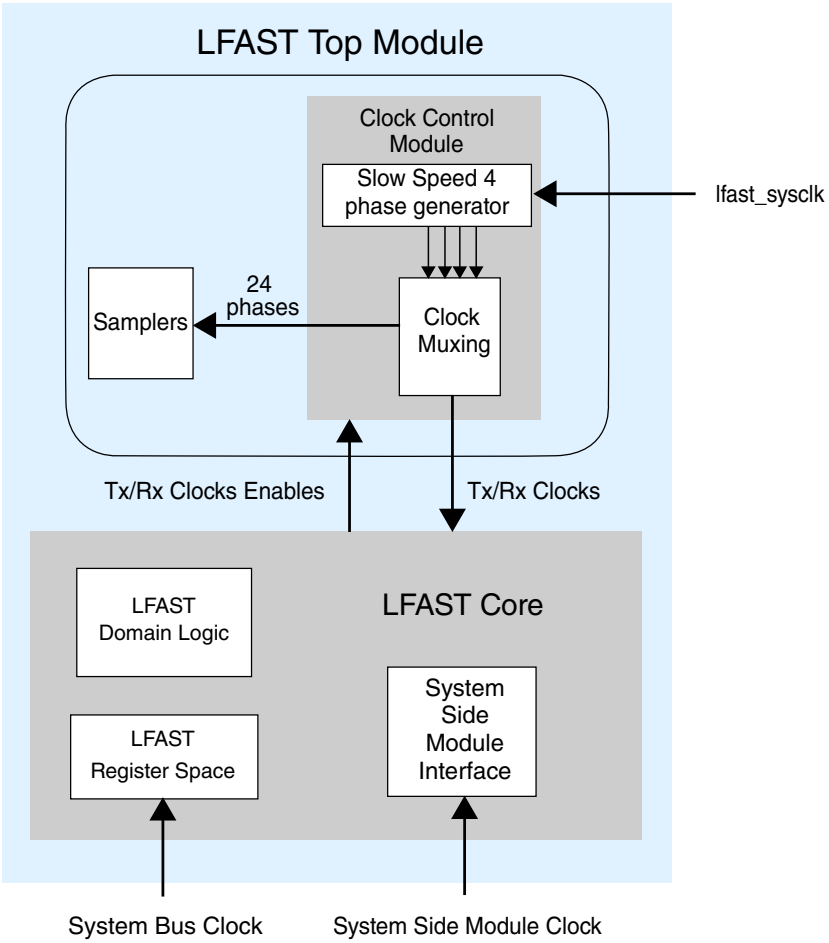

Figure 76-22. LFAST module clock domains

76.10.2 Slow speed clock

76.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in Figure 76-23, Figure 76-24 and Figure 76-25.

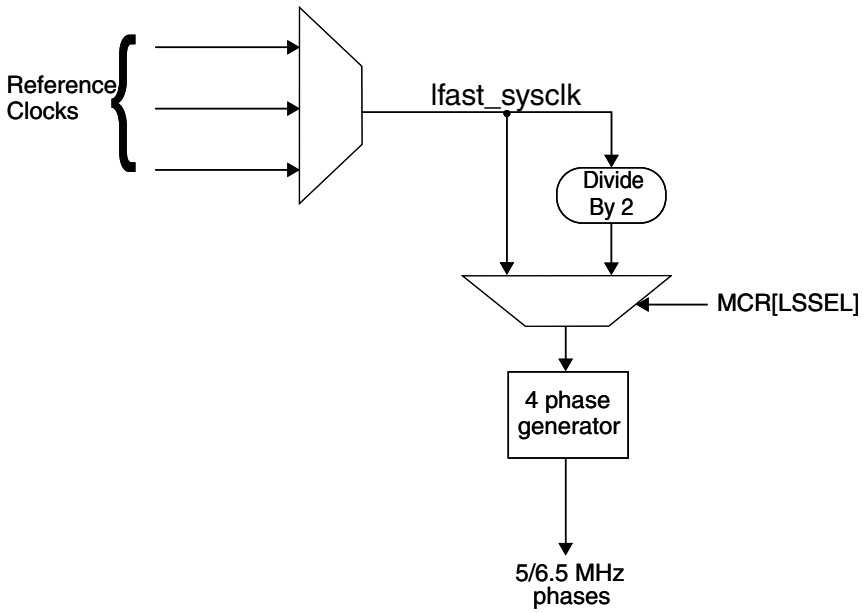

Figure 76-23. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in Figure 76-23.

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 76-24 (selected clock path shown in green).

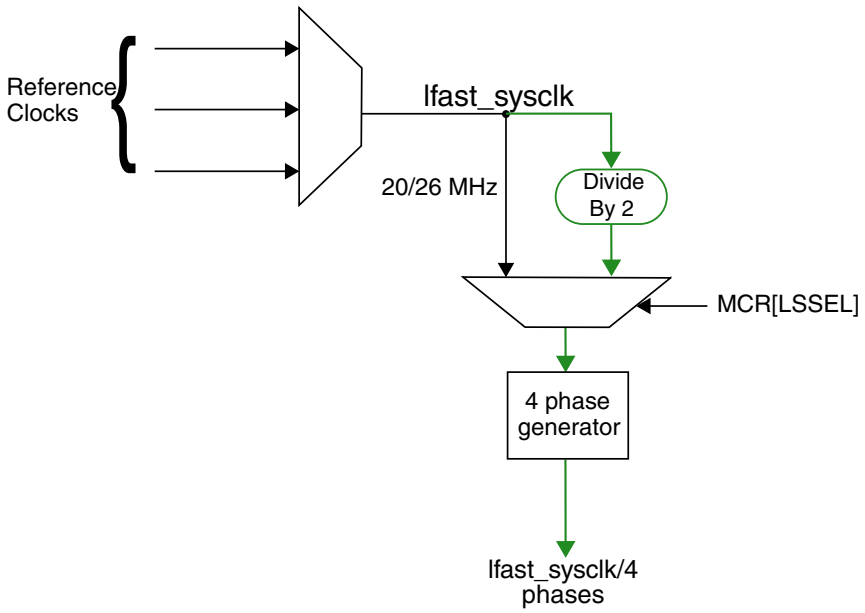

Figure 76-24. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 76-25 (selected clock path selected shown in magenta).

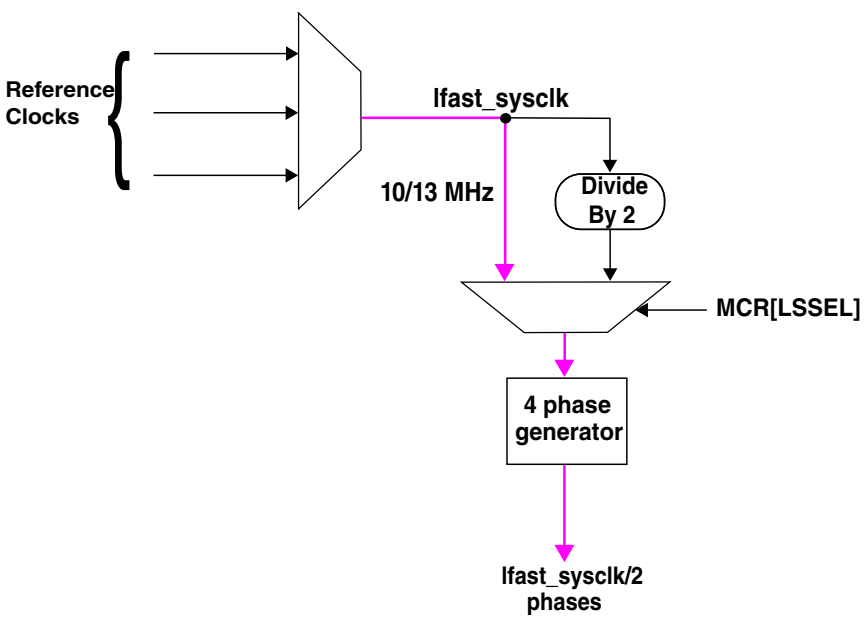

Figure 76-25. External clock muxing of lfast_sysclk of 10 MHz

76.10.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using lfast_sysclk.

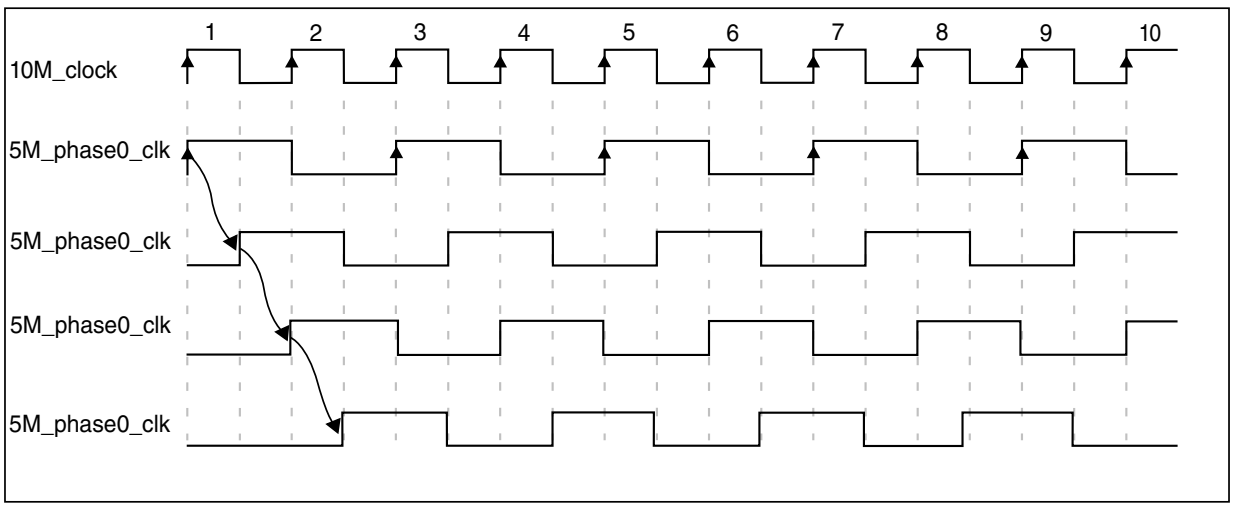

Figure 76-26. Slow speed 4 phases generation

76.10.3 Rx Controller Clocks

76.10.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

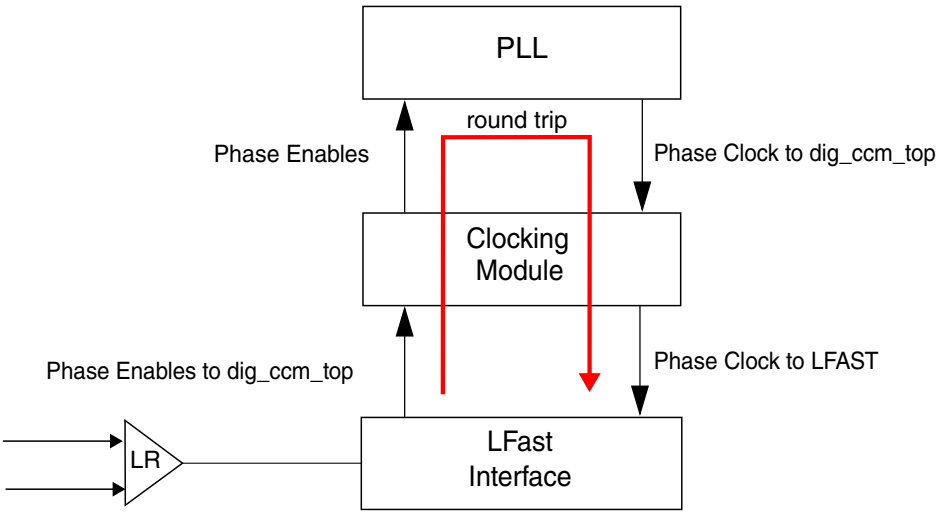

Figure 76-27. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

76.10.5 Clock module requirements for low speed phases

76.10.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 76-12. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

76.10.6 Tx Controller Clocks

76.10.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 76-13. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

76.10.6.2 Transmit Clock Muxing

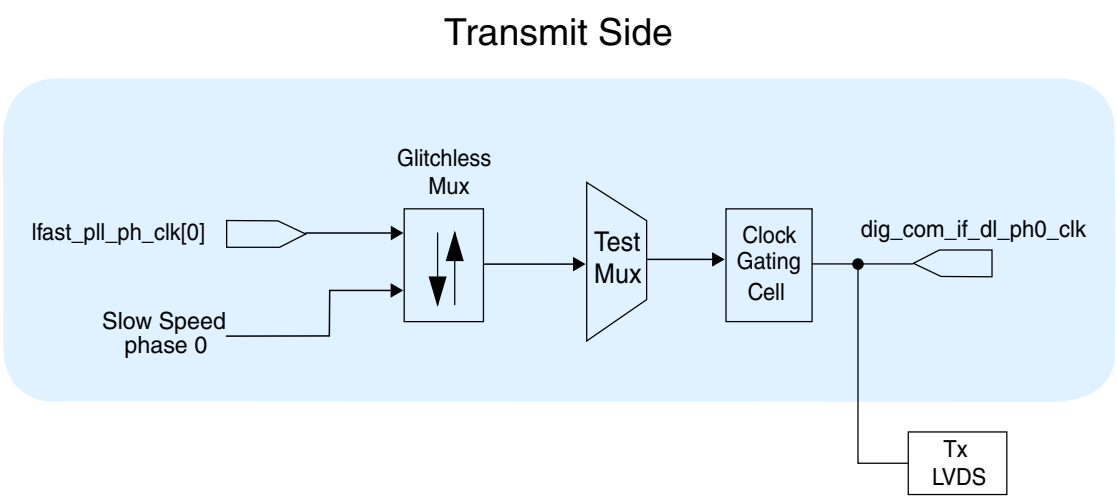

Figure 76-28. Transmit Clocks Muxing

76.10.6.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

Chapter 77
Development Trigger Semaphore (DTS)

77.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus Auxiliary port.

77.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTO). The registers are as follows:

- DTS_SEMAPHORE register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.

- DTS_SEMAPHORE_B register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access or debug Zipwire.
- DTS_STARTUP register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in the following figure.

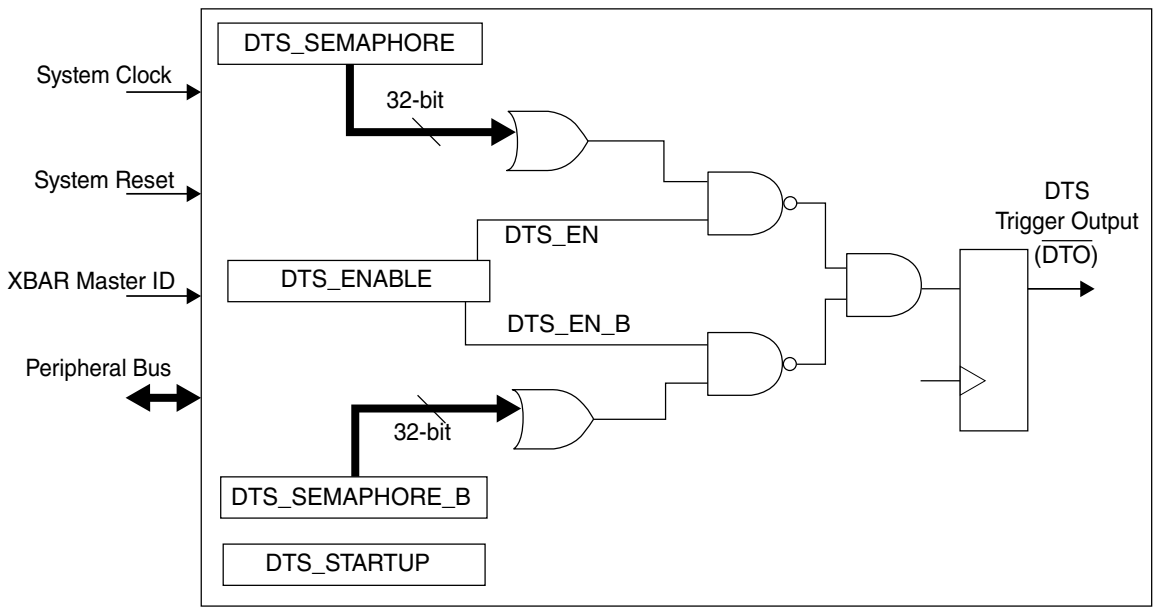

Figure 77-1. DTS block diagram

The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Debug and Calibration Interface (DCI). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note

When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1 or DTS_ENABLE[DTS_EN_B] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and

EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

The following figure shows an example of the chain of events that begins with setting of a bit in the DTS_SEMPAHORE register and the clearing of the register caused by a Nexus read.

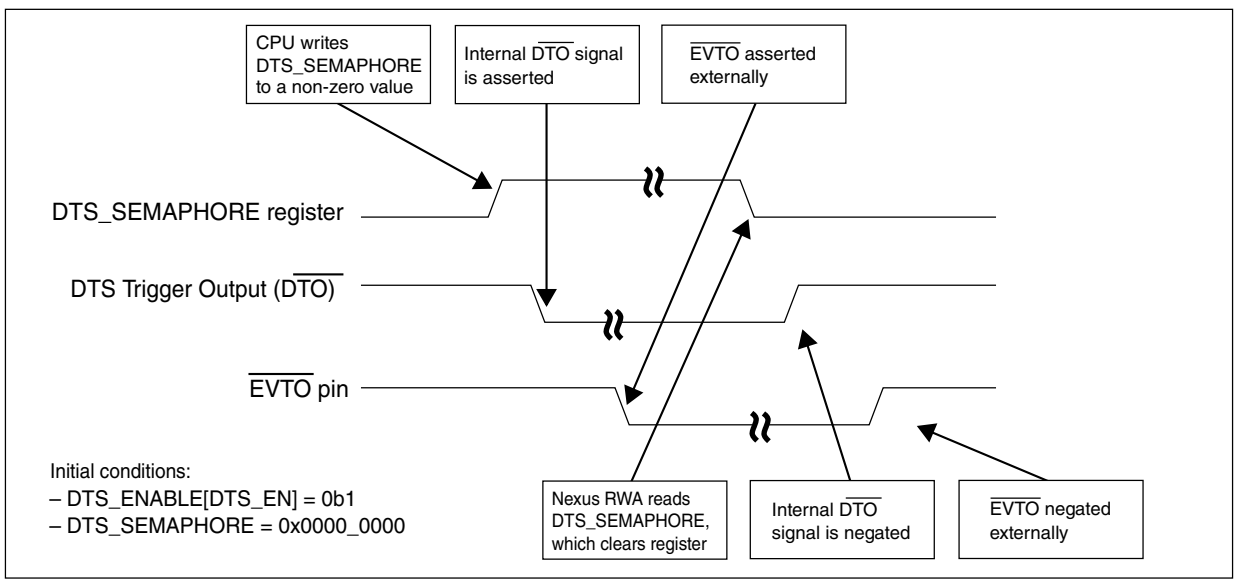

Figure 77-2. DTO event sequence example

77.3 DTS device connections

The following figure shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

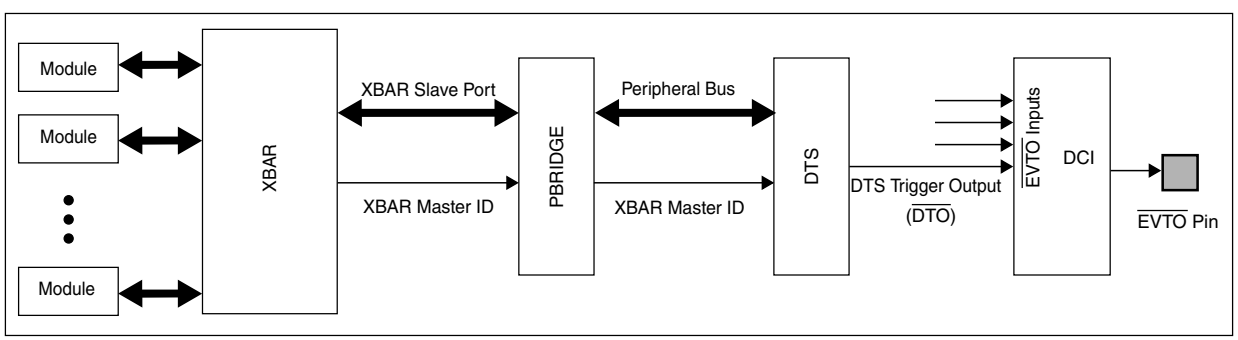

Figure 77-3. DTS device connections

The registers have limited access as described in DTS register access. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool or debug Zipwire can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access or debug Zipwire.

Note

Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

77.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in the following table. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 77-1. DTS register access effects

Register	32-bit read				32-bit write			
	RWA[1] or debug Zipwire	Core	eDMA	Other crossbar masters	RWA [1] or debug Zipwire	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear[2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear[2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore registers by Nexus Read/Write Access module or debug Zipwire is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note

The XBAR Master ID should not be confused with the Master Port number of the XBAR. See the Crossbar Switch (XBAR) chapter for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core or debug Zipwire. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

77.4 Memory mapped registers

Only certain types of accesses are allowed to the DTS registers. See the description for each register to determine the accesses that are allowed.

DTS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Output Enable Register (DTS_ENABLE)	32	R/W	0000_0000h	77.4.1/4077
4	Startup Register (DTS_STARTUP)	32	R/W	0000_0000h	77.4.2/4078
8	Semaphore Register (DTS_SEMAPHORE)	32	R/W	FFFF_FFFFh	77.4.3/4079
C	Semaphore Extension (DTS_SEMAPHORE_B)	32	R/W	FFFF_FFFFh	77.4.4/4080

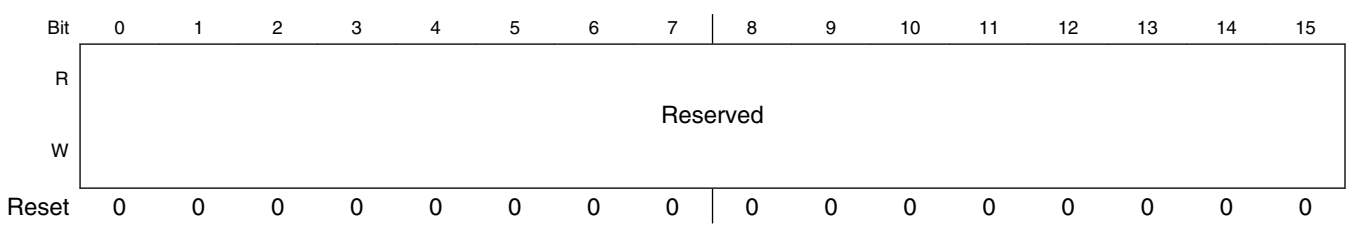
77.4.1 Output Enable Register (DTS_ENABLE)

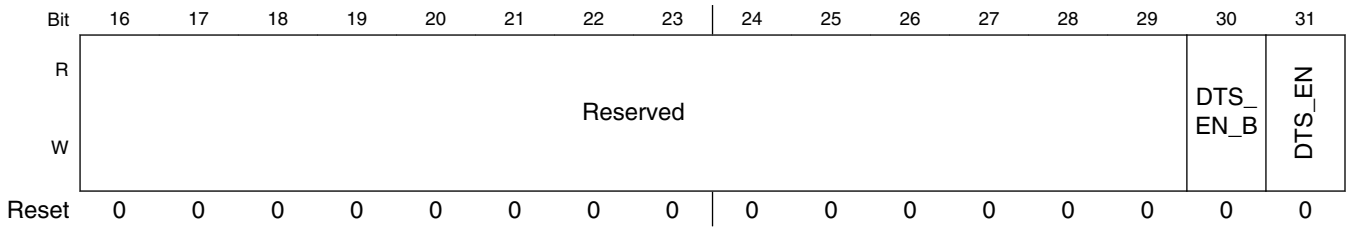
The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA) or debug Zipwire.

NOTE

Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Address: 0h base + 0h offset = 0h





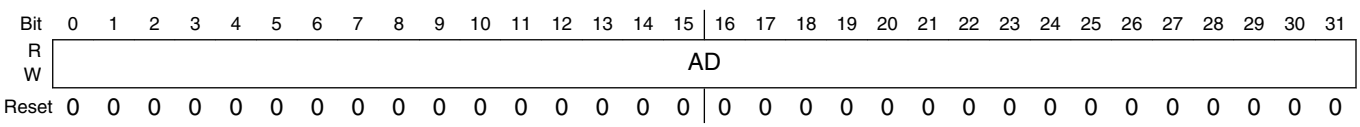
DTS_ENABLE field descriptions

Field	Description
0–29 Reserved	This field is reserved.
30 DTS_EN_B	DTS Enable B. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
31 DTS_EN	DTS Enable. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

77.4.2 Startup Register (DTS_STARTUP)

The DTS_STARTUP register is used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA) or debug Zipwire.

Address: 0h base + 4h offset = 4h



DTS_STARTUP field descriptions

Field	Description
0–31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application

DTS_STARTUP field descriptions (continued)

Field	Description
	software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access or debug Zipwire to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

77.4.3 Semaphore Register (DTS_SEMAPHORE)

The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DTS_SEMAPHORE field descriptions

Field	Description
0–31 ST	Semaphore Trigger. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

77.4.4 Semaphore Extension (DTS_SEMAPHORE_B)

The DTS_SEMAPHORE_B register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + Ch offset = Ch

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

DTS_SEMAPHORE_B field descriptions

Field	Description
0–31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA or debug Zipwire. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

77.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note

It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

The following table shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

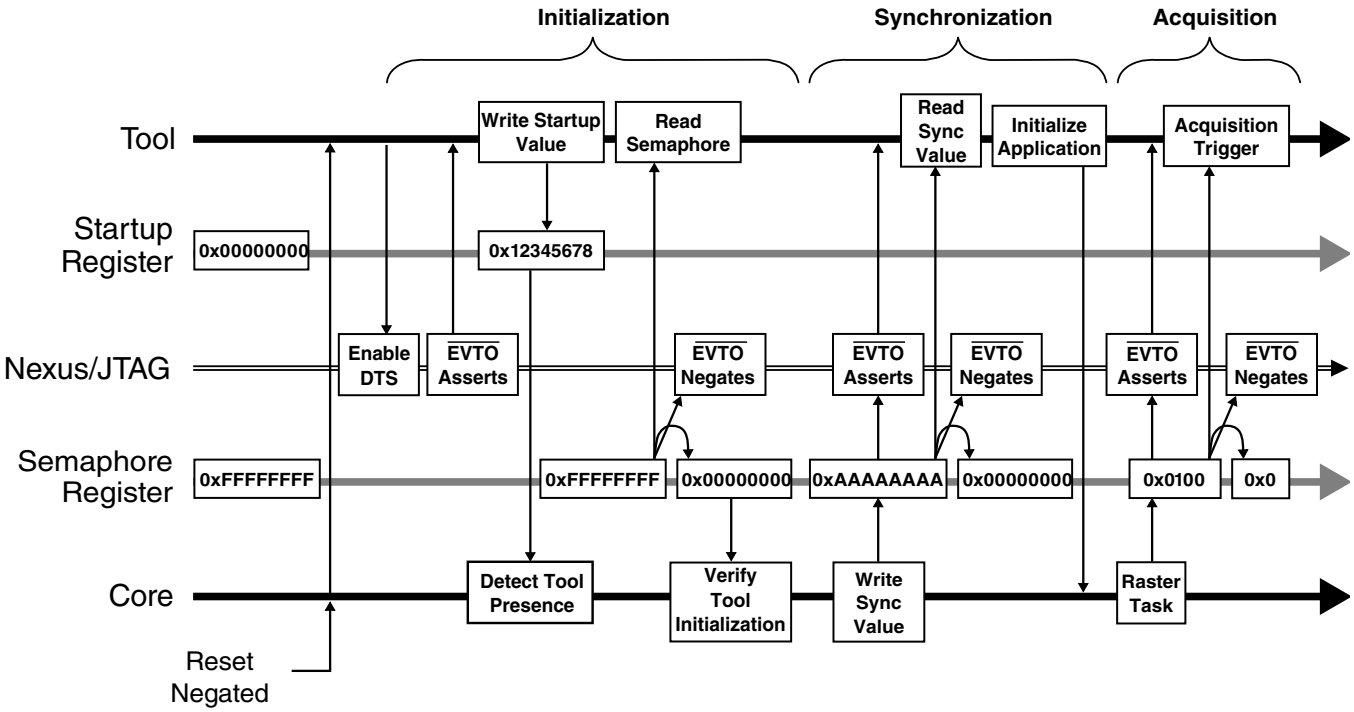

Figure 77-4. DTS startup sequence example

Chapter 78
Nexus Aurora Router (NAR)

78.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in the following figure. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

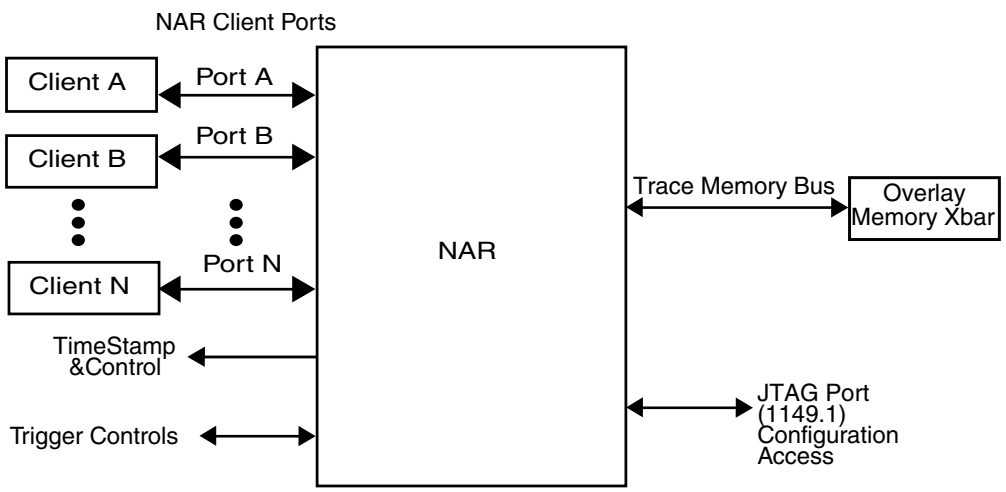

Figure 78-1. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

78.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (IEEE 1149.1) port.

78.3 Features

The NAR supports the following features:

- Connects 7 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility

- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domians.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

78.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (IEEE 1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 78-1. NAR registers

Register name	Read/Write	JTAG index (NAR relative)
NAR_CR—NAR Control Register	R/W	0
NAR_ST—NAR Status Register	R	1
NAR_SFR—Source Filter Register	R/W	2
NAR_TFR—Type Filter Register	R/W	3
NAR_TBALO—Trace memory port base address, low	R/W	4
NAR_TBAHI—Trace memory port base address, high	R/W	5
NAR_TCR—Trace Memory bus control register	R/W	6

Table continues on the next page...

Table 78-1. NAR registers (continued)

Register name	Read/Write	JTAG index (NAR relative)
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)
NAR_CSSR–Client Suppress Status Register	R	B
NAR_CDR—Client Disable Register	R/W	C
NAR_AHFPAR—Trace memory fill level and partition configuration	R/W	E

78.4.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following table shows the format of the NAR_CR.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NCD	TEN	TRS	TSG		SED	SRD	TBW	AQP		0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 78-2. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See Disabled for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages

Table continues on the next page...

Table 78-2. NAR_CR field descriptions (continued)

Field	Description
	1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). **Note:** Some clients may only support timestamps on every message. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 Reserved 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9	Reserved and must be written with 0s.
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 Aurora out is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved

Table continues on the next page...

Table 78-2. NAR_CR field descriptions (continued)

Field	Description
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2	Reserved and must be written with 0.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

78.4.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following table shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 78-3. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode

Table continues on the next page...

Table 78-3. NAR_ST field descriptions (continued)

Field	Description
	001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See Table 78-17 for coding
23–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)

78.4.3 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results.

78.4.3.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	FE2	SF2				0	0	0	FE3	SF3				0	ACC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 78-4. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field.
17–15	Reserved

Table continues on the next page...

Table 78-4. NAR_SFR field descriptions (continued)

Field	Description
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

78.4.3.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TFI	FE0	TF0						0	FE1	TF1					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

5–0 SF3	Type Filter 3. The message TCODE is compared with this field.

78.4.4 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

78.4.4.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following tables show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 78-6. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 78-7. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

78.4.4.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following table shows the format of the NAR_TCR.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BTM	BTS		BTH		0	0	0	TBW	MXFR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MXFR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 78-8. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
23 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

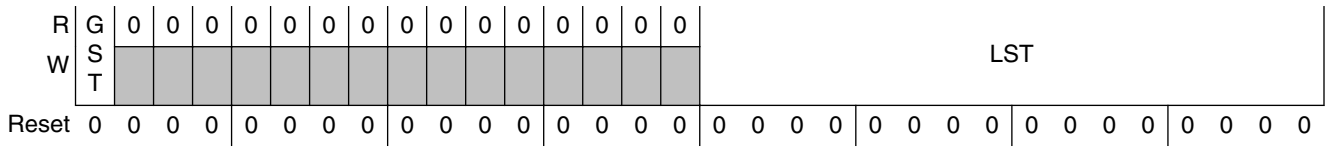
78.4.5 Suppress mode triggers registers (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in Suppress mode. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following table, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7-A

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...



The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 78-9. NAR_STCR field descriptions

Field	Description	
31 GST	Global Suppress Trigger. 0 The associated trigger cannot cause NAR to enter global suppress mode 1 The associated trigger is enabled for global suppress mode	
29–16	Reserved	
15–0 LST	Local Suppress Trigger.	
	0000000000000000	The associated trigger is disabled for local suppress mode for all clients
	xxxxxxxxxxxxxxx1	Trigger is enabled for Client 1 local suppress

	x1xxxxxxxxxxxxxx	Trigger is enabled for Client 15 local suppress
	1xxxxxxxxxxxxxxx	Trigger is enabled for Client 16 local suppress
	All other options	Reserved

78.4.6 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger

causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following table, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

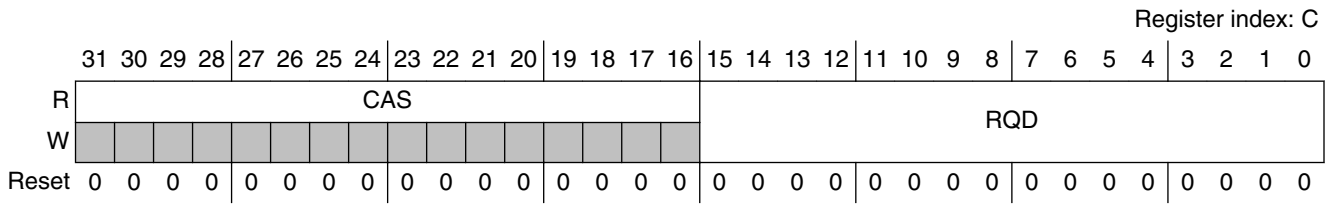
78.4.7 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following table, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.



The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 78-11. NAR_CDR field descriptions

Field	Description	
31–16	Client Activity Status.	
CAS	xxxxxxxxxxxxxxx1	Client 1 is active with new data
	xxxxxxxxxxxxxx1x	Client 2 is active with new data
	xxxxxxxxxxxxx1xx	Client 3 is active with new data
	xxxxxxxxxxxx1xxx	Client 4 is active with new data
	xxxxxxxxxxx1xxxx	Client 5 is active with new data
	xxxxxxxxxx1xxxxx	Client 6 is active with new data
	xxxxxxxxx1xxxxxx	Client 7 is active with new data

78.4.8 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following table shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0			0		

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	AHB0 1kEN	0	0	0	0	0	0	AHB_01K_Marker			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_AHFPAR is described in the following table.

Table 78-12. NAR_AHFPAR field description

FIELD	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** memory ranges from 1K to 15K

78.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

78.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/ filtering when two output ports are enabled, enabling timestamp and so on.

4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note

The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see Suppress mode. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

78.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in the following table.

Table 78-13. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

78.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

78.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

78.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

78.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

78.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in the following table on the incoming messages before transmitting to one of the output ports.

Table 78-14. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

78.5.3 Data reception and arbitration

The NAR supports 7 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn × 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

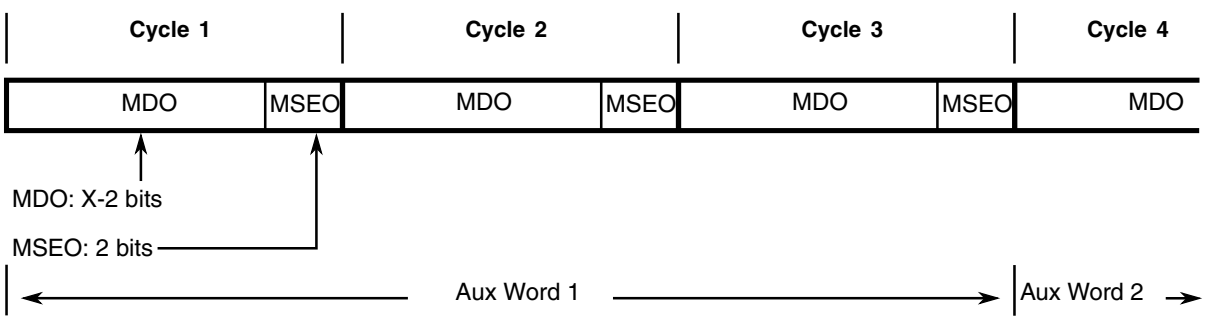

Figure 78-2. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give

preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

78.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

78.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

78.5.6 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

78.5.6.1 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

78.5.7 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)

- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 × 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

78.5.8 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the circumstances shown in Table 78-18.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 78-15. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value

Table continues on the next page...

Table 78-15. NAR message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message[1]	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC [2]	NAR source ID
	4	4	fixed	ETYPE	See Table 78-16
	12	12	fixed	ECODE	See Table 78-17
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message[3]	6	6	fixed	TCODE	TCODE value = 15
	6	6	fixed	SRC [2]	NAR source ID
	6	6	fixed	WPHIT	See Table 78-18
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2012 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2012 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

78.5.8.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in the following table.

Table 78-16. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 78-17.
0011 (h'3)	Trace memory bus port read/ write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.[2]
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 78-17	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 78-17), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1101 (h'D)	Receive Queue Overrun	Minor	Drop message	If a client sends a data word that the NPC cannot accept (due to a full receive queue), the new data word will be dropped2.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

2. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in the following table.

Table 78-17. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.

Table continues on the next page...

Table 78-17. Configuration error codes (continued)

ECODE	ETYPE	Description	NAR action	Comment
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

78.5.8.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 78-18. Watchpoint hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

78.5.9 Timestamp function

The NAR and its clients may transmit timestamps to allow precise ordering of events. Synchronous or asynchronous clients use the NAR timer value broadcasted over a bus to ensure that all timestamps are in sync as shown in the following figure. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

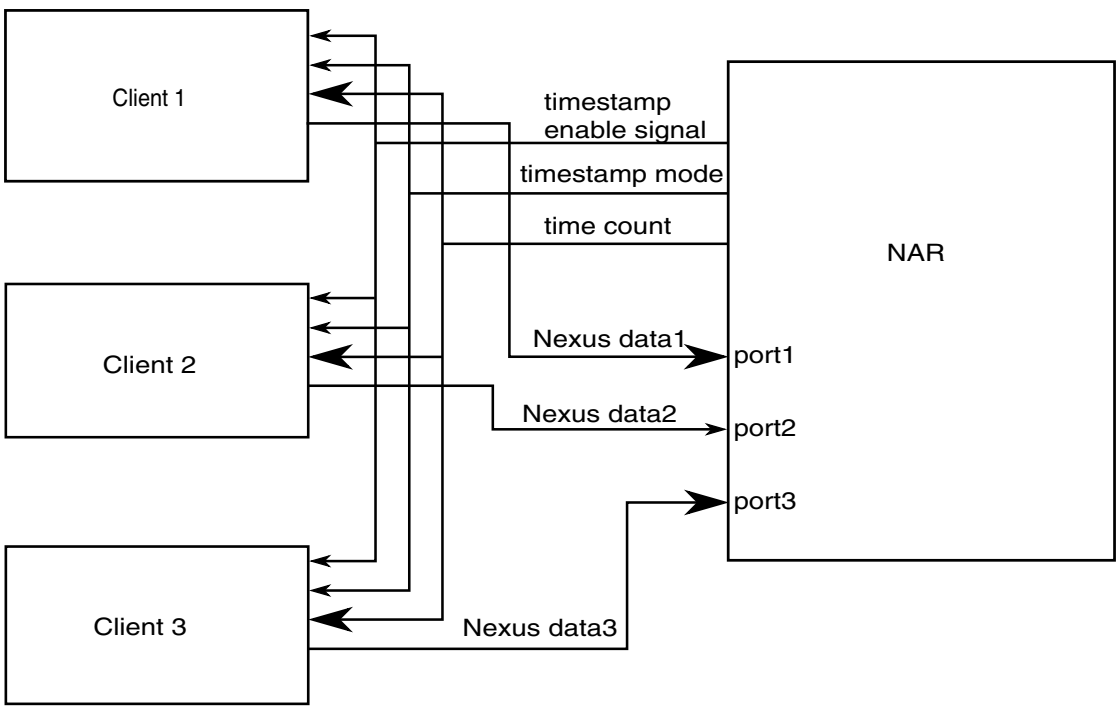

Figure 78-3. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The timestamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode, and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

78.5.10 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:

- AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
- Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)

- Thus, the total block size is (0xC0 × 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

78.5.11 Configuration/debug interface JTAG

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in Table 78-19. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

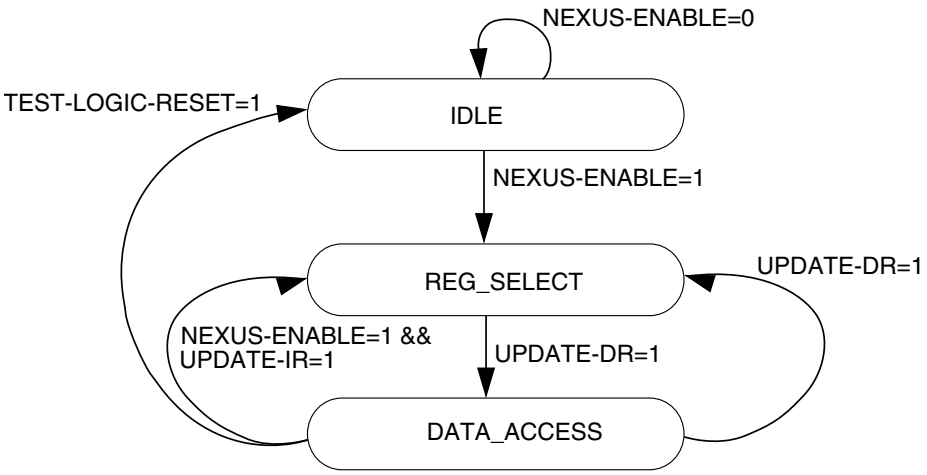

Figure 78-4. Nexus controller state machine

Table 78-19. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

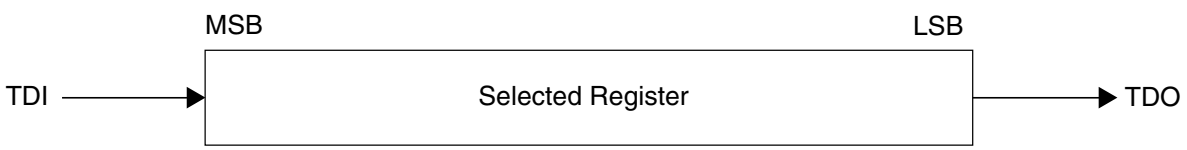

Figure 78-5. Shifting data into register

78.5.11.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

78.5.11.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 78-4, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 78-20. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

78.5.11.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in Table 78-1.

Table 78-21. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 78-22. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

78.5.12 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface

- Early Write (for higher BW in special module)
- 32-bit address bus width
- 64-bit data bus width
- Transfer Types
- IDLE, NONSEQ, SEQ
- Single Transfers
- Burst Transfers
- Configurable support for INCR
- Configurable support for INCR4, INCR8, INCR16, WRAP4
- Response Type
- OKAY, ERROR
- Transfer Size
- Byte, Half Word, Word, Double-Word
- Protection Control
- Cacheable/ Non Cacheable Access Control
- User/Privilege Access

- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

78.5.12.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

78.5.12.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

78.5.12.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

78.5.13 Legacy client interface controller

This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in Figure 78-6.

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of paramaterizeable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

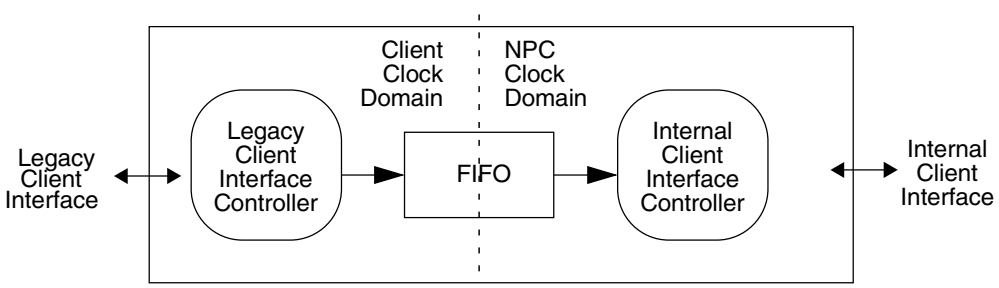

Figure 78-6. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how may spaces are freed in receive queue.

78.6 Application information

The base application for the NAR is collecting and collating Nexus trace data.

Example flow of NAR configuration for different cases.

Configuration with Two output port enabled

1. For Two port enabled one port must be Message Select (MSP) and other Alternate (ALT); Trace Memory and Aurora ports with multiple clients

   Selection of MSP port depends on user choice. One option could be based on the requirement of Filtering. If Messages from some known sources with some specific type (if any) is required to be sent to a particular port then select user can select that port as MSP. All other messages will go to the Alternate port. The filter can be used as inverted manner where unmatched messages will go to MSP. (Please see section "Output arbitration" for details)
   - Configure the Source Filter register (NAR_SFR), To enable proper filtering of messages based on Message source going to MSP or ALT port
     - Example: for DWPU connected in Nexus out port set the source ID of the core and NXMC in any two source filter type and enable it
   - Configure the Type Filter register (NAR_TFR), To enable proper filtering of messages based on Message Type going to MSP or ALT port
     - Example: for DWPU connected in Nexus out port set the Type of messages in any two Type filter type and enable it
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)
   - Configure NPC suppress trigger registers NAR_STCR[x] (x=0-3) (suppress the clients for which data is not to be forwarded at output) (Difference between suppressing and disabling is that suppressing can be done dynamically during NAR operation but disabling can't be done this way which may leads to system hang)
   - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
   - Configure the NAR control register for other controls and Enable NAR
     - Set the MSP as Nexus Out and ALT as Trace memory
     - Set AQP for partitioning the Main Queue for ALT and MSP ports

- Set time stamp controls
- Enable NAR to start operation
- Configuration for Single Output port with single partition in NAR central Message Queue

2. Only Trace Memory port is enabled with multiple client
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)
   - Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
   - Configure the NAR control register for other controls and Enable NAR
     - Set the Trace Memory port as ALT port (Alternate port is only the main port in single out port application)
     - Set AQP for disabling partitioning
     - Set time stamp controls
     - Set watch point controls
     - Enable NAR to start operation

Chapter 79
Nexus Module

79.1 Introduction

The e200z425Bn3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

79.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

79.1.2 Terms and Definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 79-1. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

79.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations

(not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

79.1.4 Functional Block Diagram

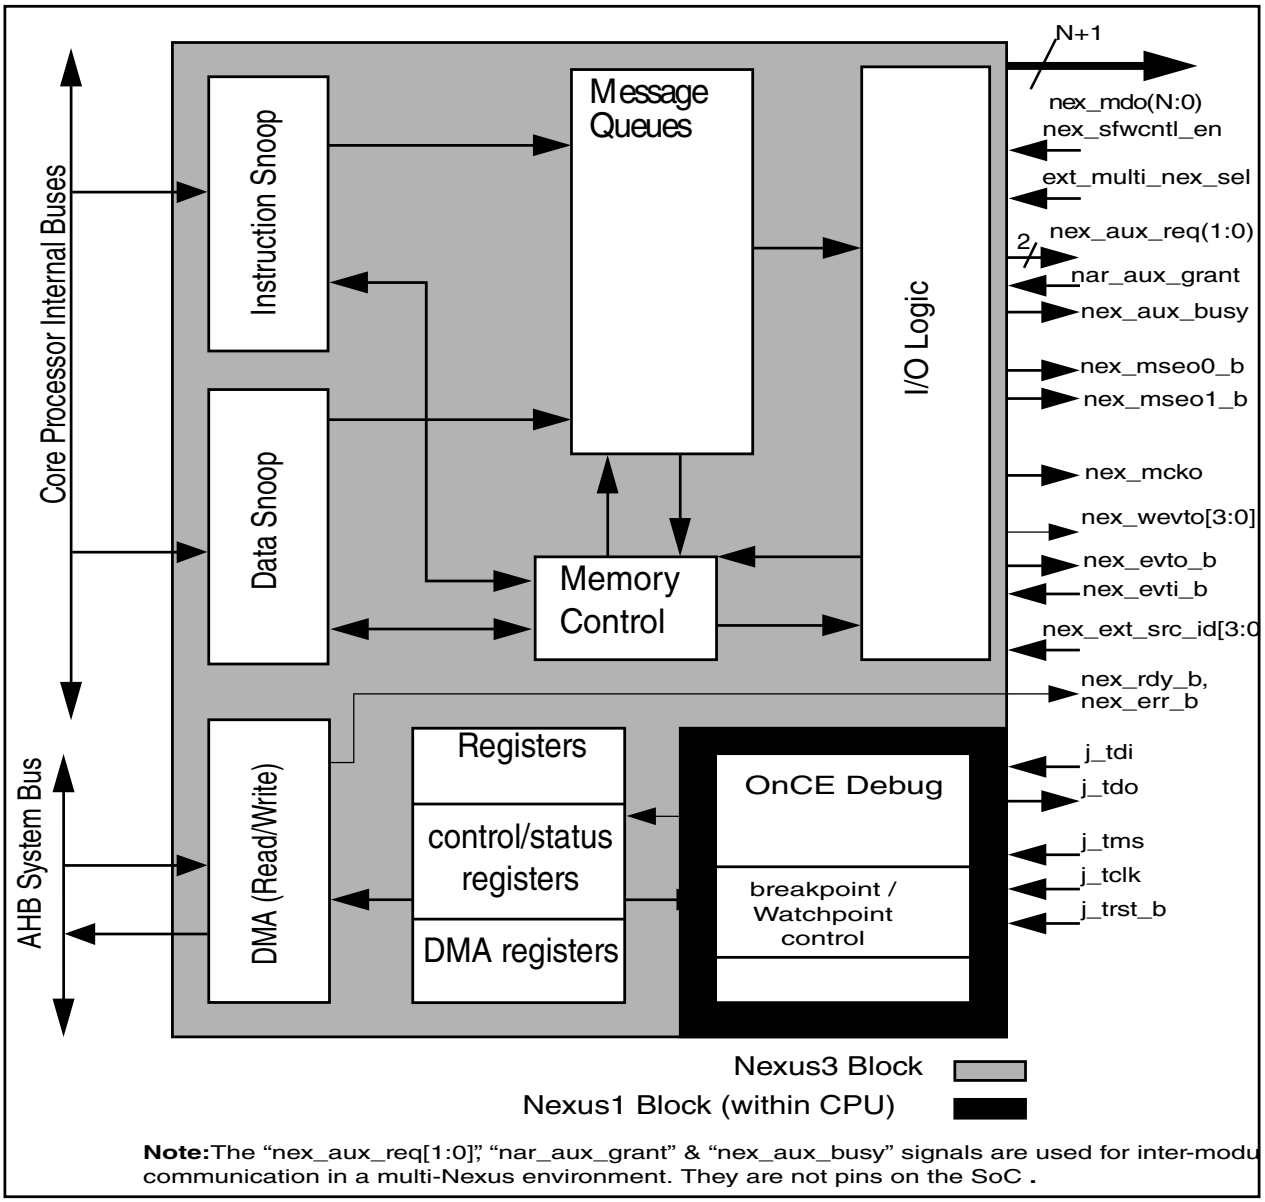

Figure 79-1. Nexus 3 functional block diagram

79.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

79.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

79.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001 2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 79-2.

Table 79-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 79-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 79-7)

Table continues on the next page...

Table 79-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 79-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace -	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier

Table continues on the next page...

Table 79-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Read Message w/ Sync	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 79-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 79-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Branch Trace Messaging types)
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 79-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)

Table continues on the next page...

Table 79-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 79-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 79-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 79-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 79-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost

Table continues on the next page...

Table 79-4. Error Type (ETYPE) Encoding (TCODE = 8) (continued)

Error Type	Description
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 79-5 shows the encodings used for resource codes for certain messages.

Table 79-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 79-6 shows the event code encodings used for certain messages.

Table 79-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 79-7 shows the data trace size encodings used for certain messages.

Table 79-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)

Table continues on the next page...

Table 79-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

79.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 79-8. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)	0x1	R	0x02	-	
Port Configuration Register (PCR)[3]	PCR_INDEX[2]	R/W	-	-

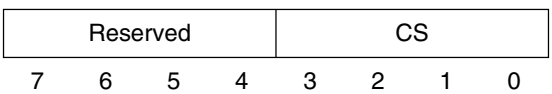
1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

79.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.



Nexus Reg# - 0x1; Read-only; Reset - 0x0

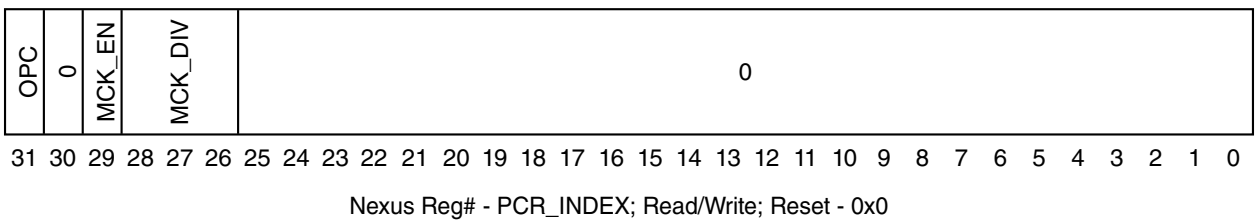
Figure 79-2. Client Select Control (CSC) register

Table 79-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

79.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.



Nexus Reg# - PCR_INDEX; Read/Write; Reset - 0x0

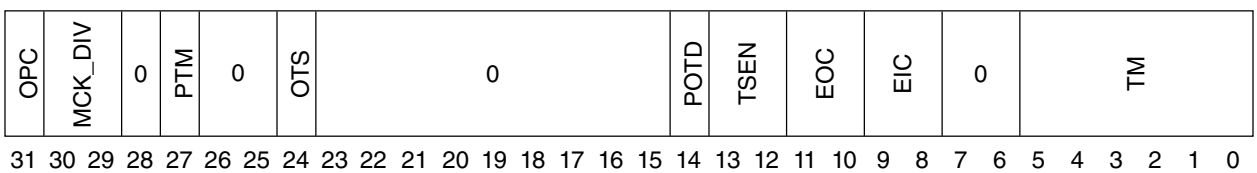
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

79.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 79-4 and its fields are described in Table 79-11.



Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.
1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.

Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

79.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z425Bn3) Core Debug Support chapter.

Development Control Register 2 is shown in Figure 79-5 and its fields are described in Table 79-12.

Figure 79-5. Development Control Register 2

1. EOC bits in DC1 must be programmed to trigger $\overline{\text{EVTO}}$ on Watchpoint occurrence for EWC bits to have any effect.

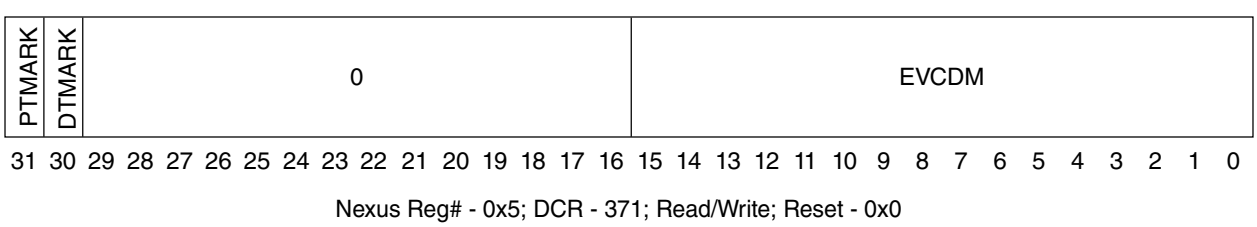
79.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in Figure 79-7 and its fields are described in Table 79-14.



Nexus Reg# - 0x5; DCR - 371; Read/Write; Reset - 0x0

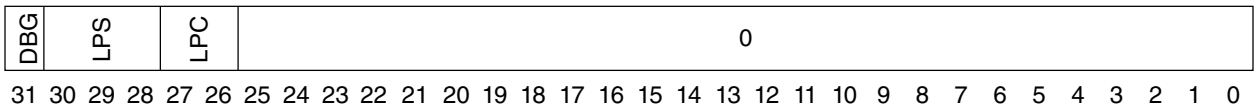
1. Refer to Table 5 for implemented EVCODEs.
1. Refer to Table 5 for implemented EVCODEs.

79.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.



Nexus Reg# - 0x4; DCR - 409; Read-only; Reset - 0x0

25:0	—	Reserved for future functionality (read as 0)

79.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that

direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z425Bn3) Core Debug Support chapter.

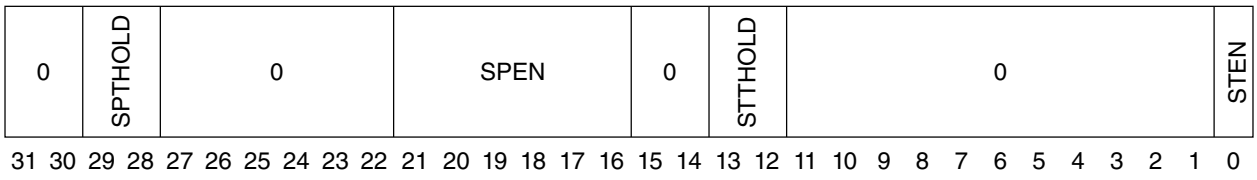
79.4.9 Nexus Overrun Control Register (OVCR)

The Nexus Overrun Control register controls Nexus behavior as the internal message queues fill up. Response options include suppressing selected message types, or stalling processor instruction execution.



Nexus Reg# - 0x32; DCR - 410; Read/Write; Reset - 0x0

Figure 79-15. Nexus Overrun Control Register

Bits	Name	Description
31:30	—	Reserved, should be cleared
29:28	SPTHOLD	Suppression Threshold 00 - Suppression threshold is when message queues are 1/4 full 01 - Suppression threshold is when message queues are 1/2 full 10 - Suppression threshold is when message queues are 3/4 full 11 - Reserved
27:22	—	Reserved, should be cleared
21:16	SPEN	Suppression Enable 000000 - Suppression is disabled xxxxx1 - Ownership Trace message suppression is enabled xxxx1x - Data Trace message suppression is enabled xxx1xx - Program Trace message suppression is enabled xx1xxx - Watchpoint Trace message suppression is enabled x1xxxx - Reserved 1xxxxx - Data Acquisition message suppression is enabled

0	STEN	Stall Enable 0 - Stalling is disabled 1 - Stalling is enabled

Figure 79-16. Nexus Overrun Control Register Fields

79.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0
31 30	29 28	27 26	25 24	23 22 21 20 19 18 17 16	15	14	13	12	11 10 9 8	7	6	5	4	3	2 1 0

Figure 79-25. Data Trace End Address 4 (DTEA4) register

Table 79-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 79-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

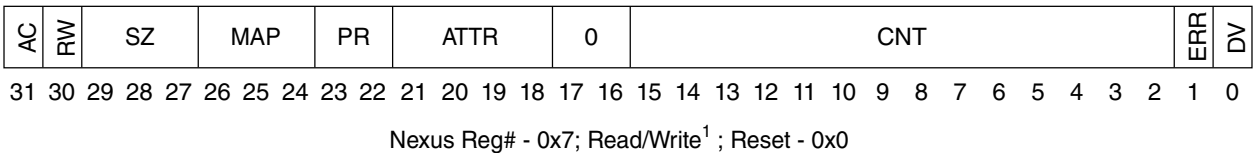
Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

79.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 79-25.



Nexus Reg# - 0x7; Read/Write[1] ; Reset - 0x0

Figure 79-26. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 79-24. RWCS field description

Bits	Name	Description

Table 79-24. RWCS field description (continued)

Bits	Name	Description
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR	Read/Write Access Error (see Table 79-25)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 79-25)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 79-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

79.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

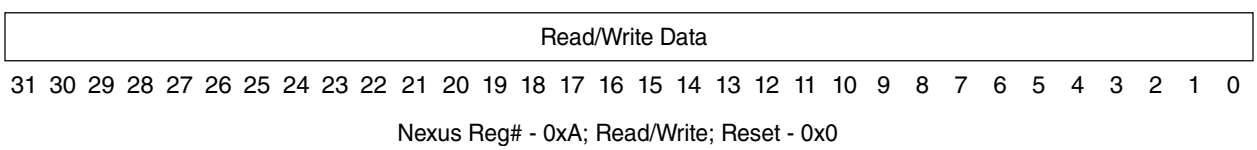

Figure 79-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 79-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 79-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 79-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 79-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	-	-	-	AHB[7:0]

Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

79.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# - 0x9; Read/Write; Reset - 0x0

Figure 79-28. Read/Write Access Address (RWA) register

79.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 79-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 79-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

(7bits)	(1 bit)
Nexus Register Index	R/W

RESET Value: 0x0

Nexus Register Index	Selected from values in Table 79-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

79.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 79-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

79.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

79.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

79.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

79.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

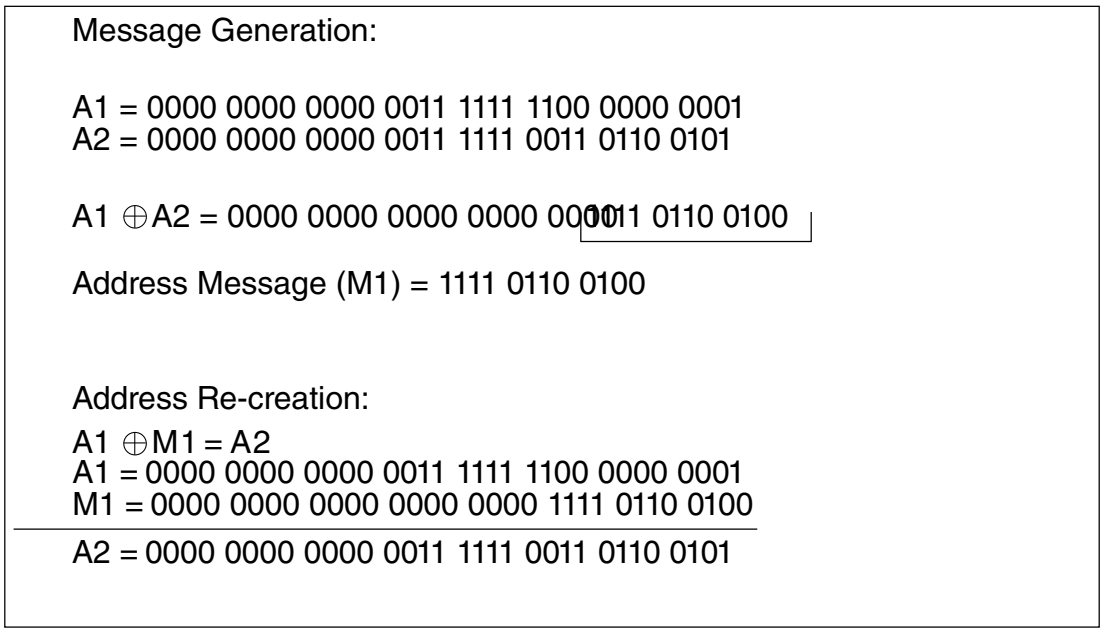

Figure 79-29. Relative address generation and recreation

79.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

79.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

79.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

79.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

79.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

79.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 79-28 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 79-28.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 79-28. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message

Table continues on the next page...

Table 79-28. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

79.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

79.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

79.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

79.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

79.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

79.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

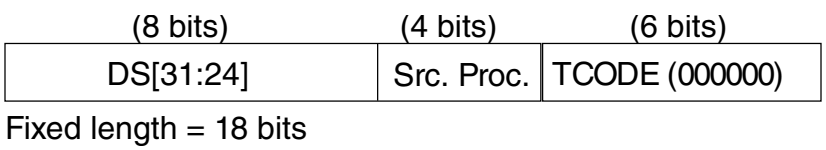

Figure 79-30. Debug Status message format

79.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 79-3 and Table 79-4):

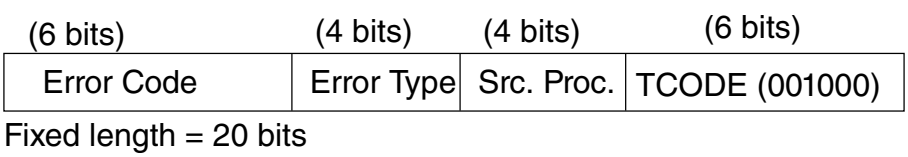

Figure 79-31. Error message format

79.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

79.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

79.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z425Bn3) processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

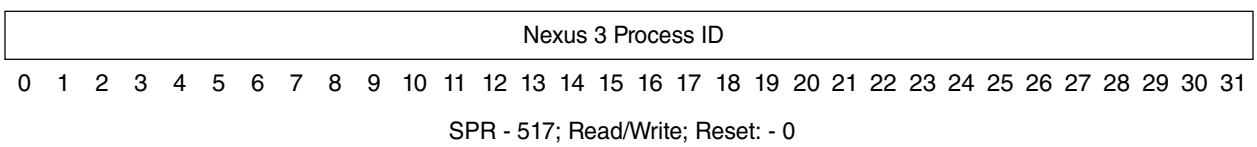

Figure 79-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for

PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.

- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

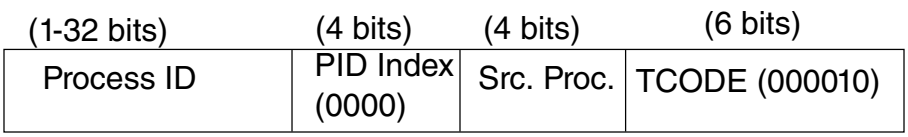

Figure 79-33. Ownership Trace Message format

79.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z425Bn3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z425Bn3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

79.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

79.12.1.1 Indirect Branch Message instructions

Table 79-29 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 79-29. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

79.12.1.2 Direct Branch Message Instructions

Table 79-30 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 79-30. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

79.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

79.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

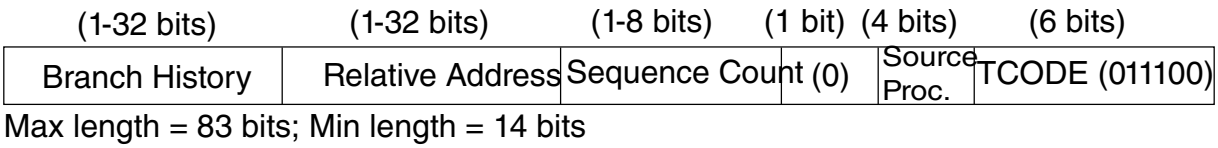
Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

79.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

79.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

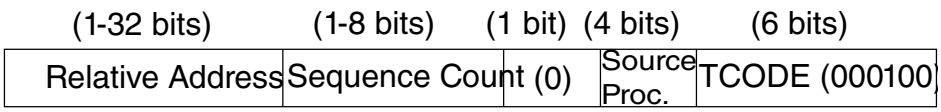


Max length = 83 bits; Min length = 14 bits

Figure 79-34. Indirect branch message (history) format

79.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:



Max length = 51 bits; Min length = 13 bits

Figure 79-35. Indirect branch message format

79.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

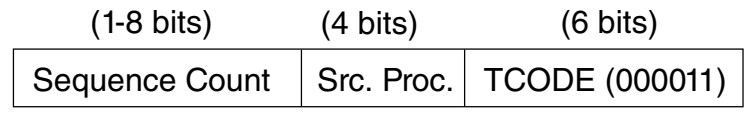


Figure 79-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

79.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

79.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

79.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 79-31. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

79.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

79.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

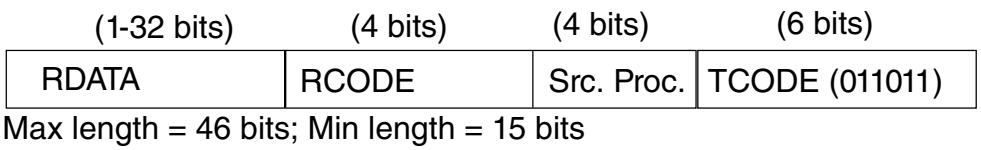

Figure 79-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 79-32. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

79.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 79-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

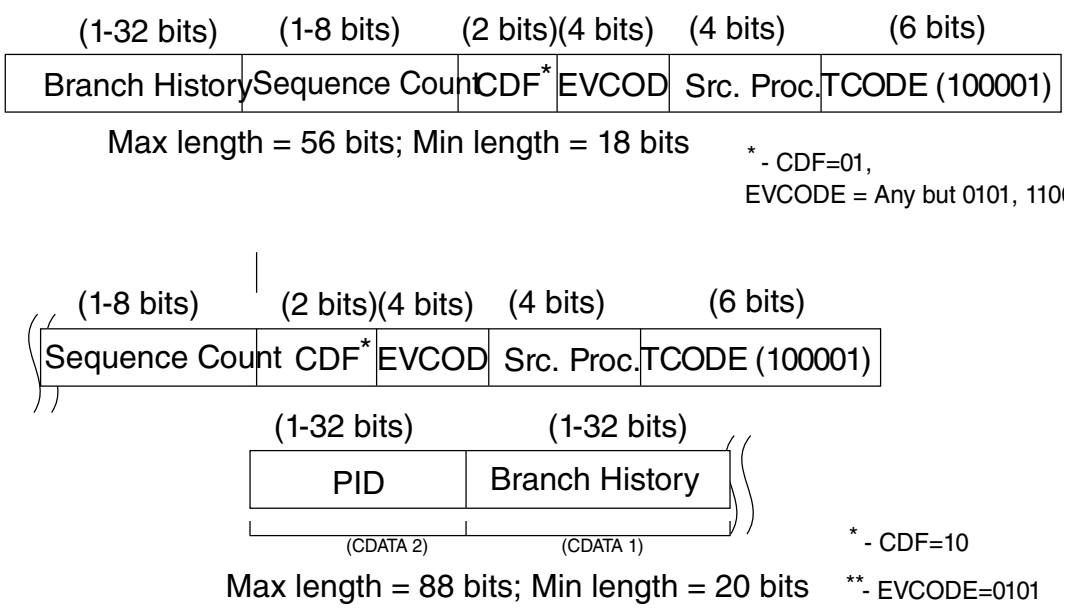

Figure 79-38. Program Correlation message formats

If timestamping is enalbed, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

79.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

79.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

79.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 79-33):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.

- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in Table 79-33.

Table 79-33. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

79.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 79-33):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

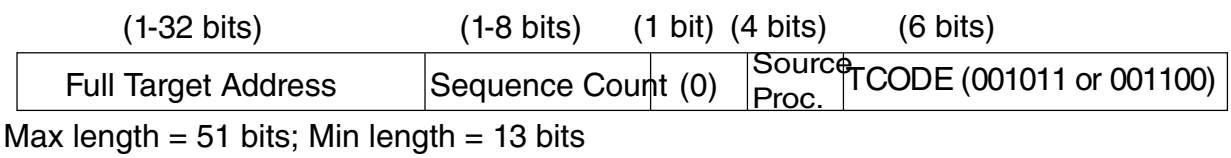

Figure 79-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

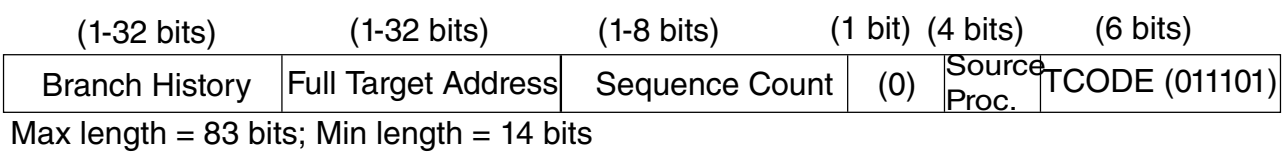

Figure 79-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 79-34.

Table 79-34. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

79.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

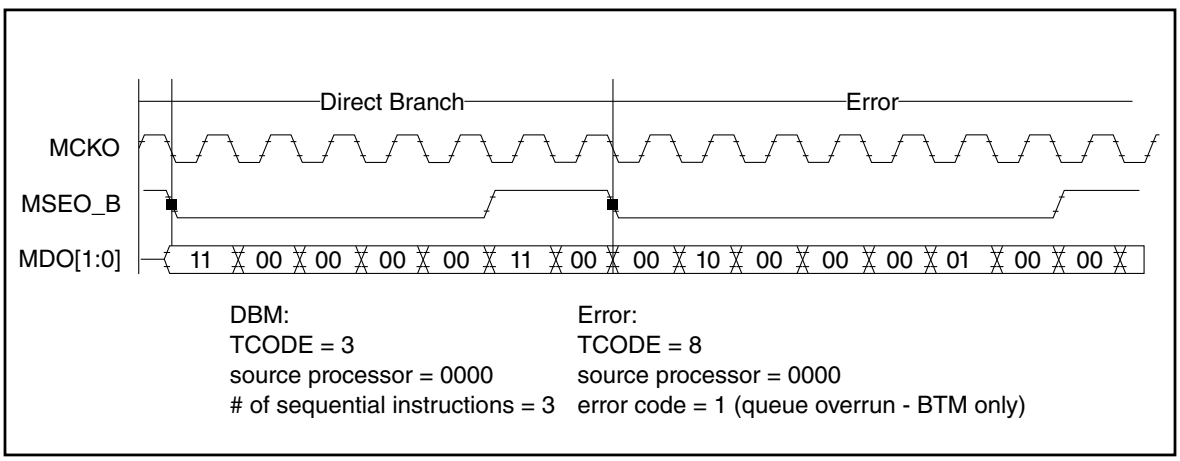

Figure 79-43. Program Trace - Direct Branch (traditional) & Error messages

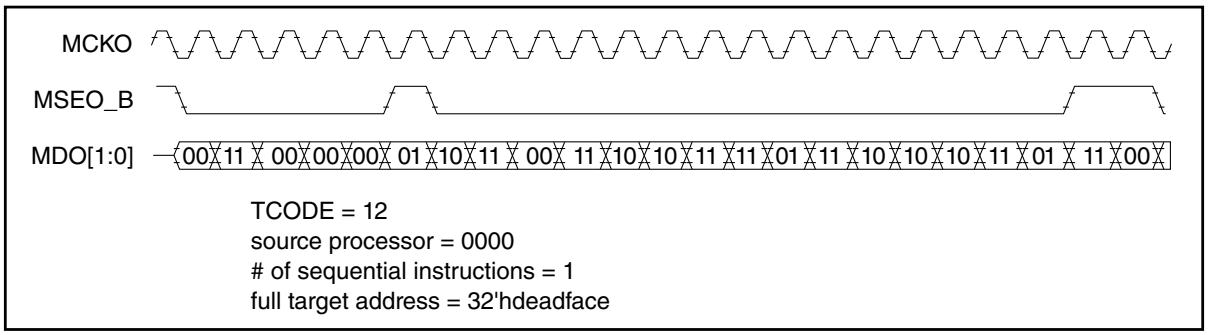

Figure 79-44. Program Trace - Indirect Branch w/ Sync. message

79.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

79.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z425Bn3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

79.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

79.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 79-45. Data Write message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

79.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 79-46. Data Read fessage format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Note

* Core (e200z425Bn3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** =

0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z425Bn3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

79.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 79-35):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

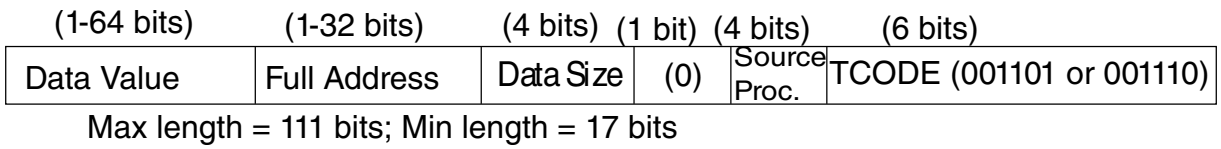

Figure 79-47. Data Write/Read with Sync. message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in Table 79-35.

Table 79-35. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

79.13.3 DTM Operation

79.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

79.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

79.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

79.13.3.4 Bus Cycle special cases

Table 79-36. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)

Table continues on the next page...

Table 79-36. Bus Cycle Special Cases (continued)

Special Case	Action
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z425Bn3) Core Debug Support chapter.)

Note

A store to the store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

79.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

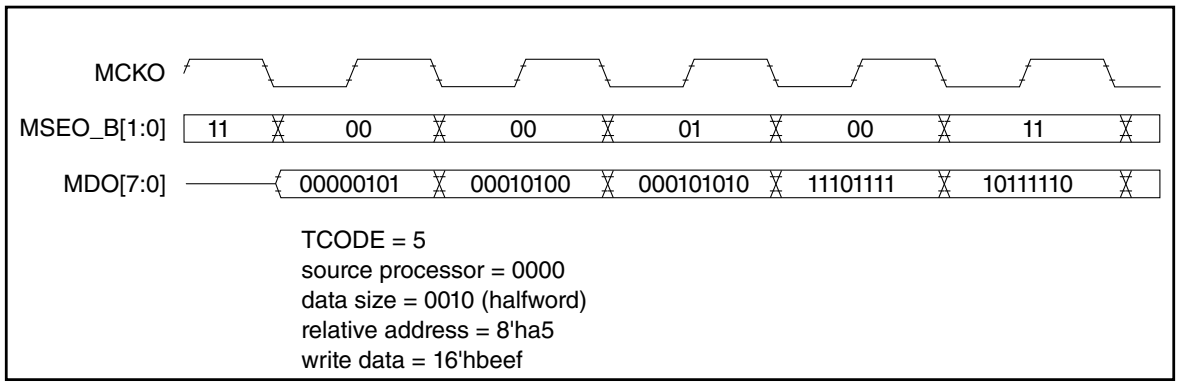

Figure 79-48. Data Trace - Data Write Message

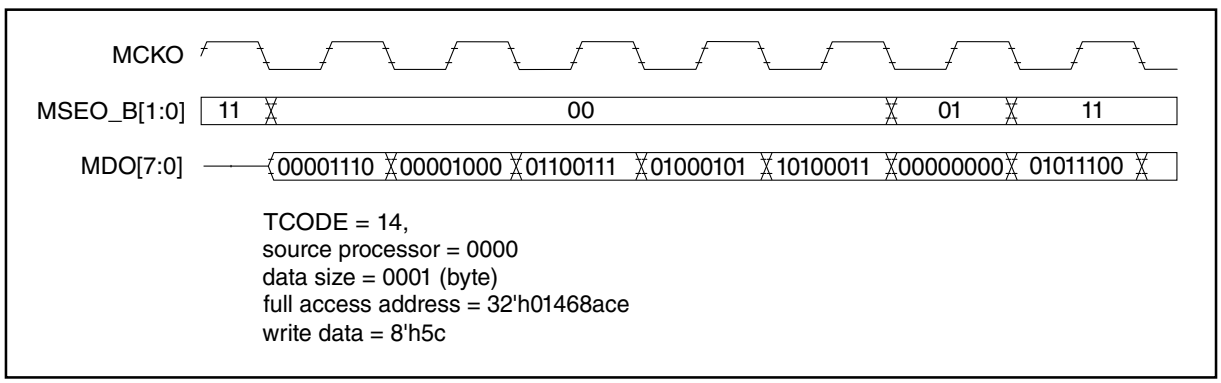

Figure 79-49. Data Trace — Data Read w/ Sync message

79.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

79.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

79.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

79.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z425Bn3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

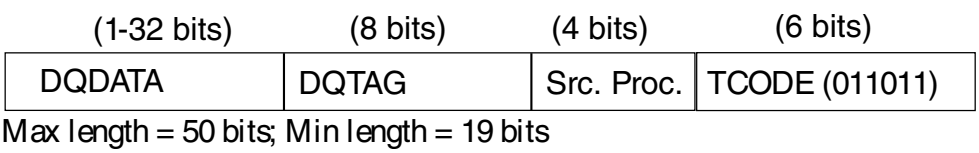

Figure 79-50. Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

79.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z425Bn3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 79-39 for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

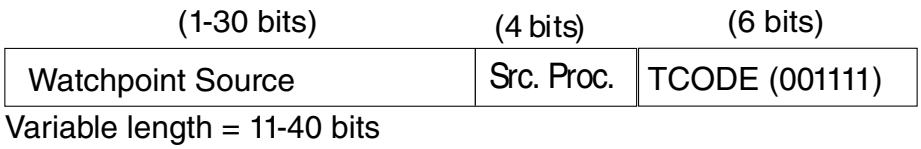

Figure 79-51. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 79-37. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
000000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX - Watchpoint #3 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXX1XXXX - Watchpoint #4 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXX1XXXXX - Watchpoint #5 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXX1XXXXXX - Watchpoint #6 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXX1XXXXXXX - Watchpoint #7 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXX1XXXXXXXX - Watchpoint #8 enabled for WTM	
XXXXXXXXXXXXXXXXXXXX1XXXXXXXXX - Watchpoint #9 enabled for WTM	
XXXXXXXXXXXXXXXXXXX1XXXXXXXXXX - Watchpoint #10 enabled for WTM	
XXXXXXXXXXXXXXXXXX1XXXXXXXXXXX - Watchpoint #11 enabled for WTM	
XXXXXXXXXXXXXXXXX1XXXXXXXXXXXX - Watchpoint #12 enabled for WTM	
XXXXXXXXXXXXXXXX1XXXXXXXXXXXXX - Watchpoint #13 enabled for WTM	

Table 79-37. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
XXXXXXXXXXXXXXX1XXXXXXXXXXXXXXX	Watchpoint #14 enabled for WTM
XXXXXXXXXXXXXX1XXXXXXXXXXXXXXXX	Watchpoint #15 enabled for WTM
XXXXXXXXXXXXX1XXXXXXXXXXXXXXXXX	Watchpoint #16 enabled for WTM
XXXXXXXXXXXX1XXXXXXXXXXXXXXXXXX	Watchpoint #17 enabled for WTM
XXXXXXXXXXX1XXXXXXXXXXXXXXXXXXX	Watchpoint #18 enabled for WTM
XXXXXXXXXX1XXXXXXXXXXXXXXXXXXXX	Watchpoint #19 enabled for WTM
XXXXXXXXX1XXXXXXXXXXXXXXXXXXXXX	Watchpoint #20 enabled for WTM
XXXXXXXX1XXXXXXXXXXXXXXXXXXXXXX	Watchpoint #21 enabled for WTM
XXXXXXX1XXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #22 enabled for WTM
XXXXXX1XXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #23 enabled for WTM
XXXXX1XXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #24 enabled for WTM
XXXX1XXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #25 enabled for WTM
XXX1XXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #26 enabled for WTM
XX1XXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #27 enabled for WTM
X1XXXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #28 enabled for WTM
1XXXXXXXXXXXXXXXXXXXXXXXXXXXXXX	Watchpoint #29 enabled for WTM

79.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

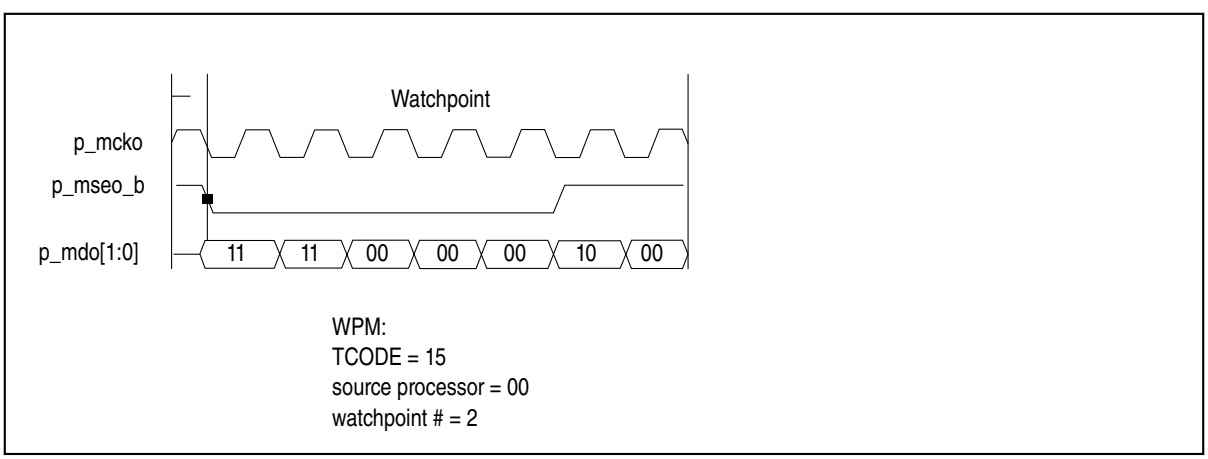

Figure 79-52. Watchpoint Message & Watchpoint Error message

79.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

79.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:

- Access Control (AC) → 1b'1 (to indicate start access)
- Map Select (MAP) → 3b'000 (primary memory map)
- Access Priority (PR) → 2b'11 (highest priority)
- Read/Write (RW) → 1b'1 (write access)
- Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data (RWD) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 79-39 for details) and clears the ERR bit in the RWCS register. Otherwise, if the access completes with an error, the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once the DV bit has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start**, and **nex_rdy_b** pins, as well as the AC, DV, and ERR bits within the RWCS, provide Read/Write Access status to the external development tool.

79.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block then arbitrates for the AHB system bus and transfers the first data value from the RWD register to the memory-mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output is asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA register is incremented to the next word size (specified in the SZ field) the number from the CNT field is decremented. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS register. Otherwise, the ERR bit is set and the DV bit is cleared to indicate an error has occurred, , the block transfer is aborted, and the AC bit in the RWCS register is cleared. Clearing the DV bit indicates that the device is ready for the next access in the block transfer, or that an error has occurred.
3. If the AC bit has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS register are not changed when executing a block write access. The original values can be read by the external development tool at any time.

79.16.3 Single read access

1. Initialize the Read/Write Access Address (RWA)register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)

- Access Priority (PR) → 2b'11 (highest priority)
- Read/Write (RW) → 1b'0 (read access)
- Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

An Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 79-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred. The **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit is cleared in either case.
4. The data can then be read from the Read/Write Access Data register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start**and **nex_rdy_b** pins as well as the AC, DV, and ERR bits within the RWCS register provide Read/Write Access status to the external development tool.

79.16.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the

RWCS register and asserts the **nex_rdy_b** pin (see Table 79-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS register, and asserts the **nex_rdy_b** pin (see Table 79-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the RWD register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

79.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

79.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

79.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
    a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
    b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

79.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

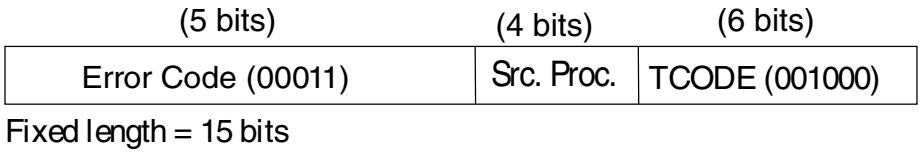

Figure 79-53. Error message format1

79.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

79.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_evto_b** pin, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 79-39. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z425Bn3) Core Debug Support chapter.

Table 79-38. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 79-39.

Table 79-39. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.
nex_ahb_start	O	AHB Start (**nex_ahb_start**) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one **nex_clk** clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, **nex_ahb_start** remains de-asserted.
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted.
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 79-40. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 79-42.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

79.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 79-41. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 79-41. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 79-54 illustrates the state diagram for single pin MSEO transfers.

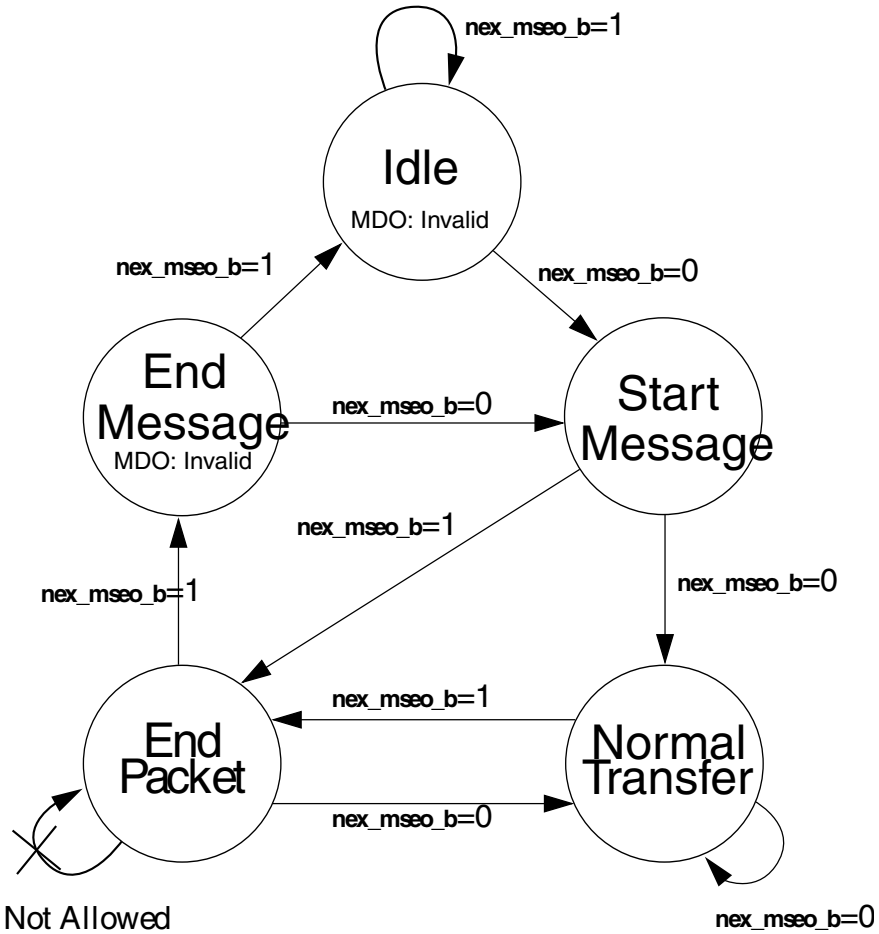

Figure 79-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 79-55 illustrates the state diagram for dual pin MSEO transfers.

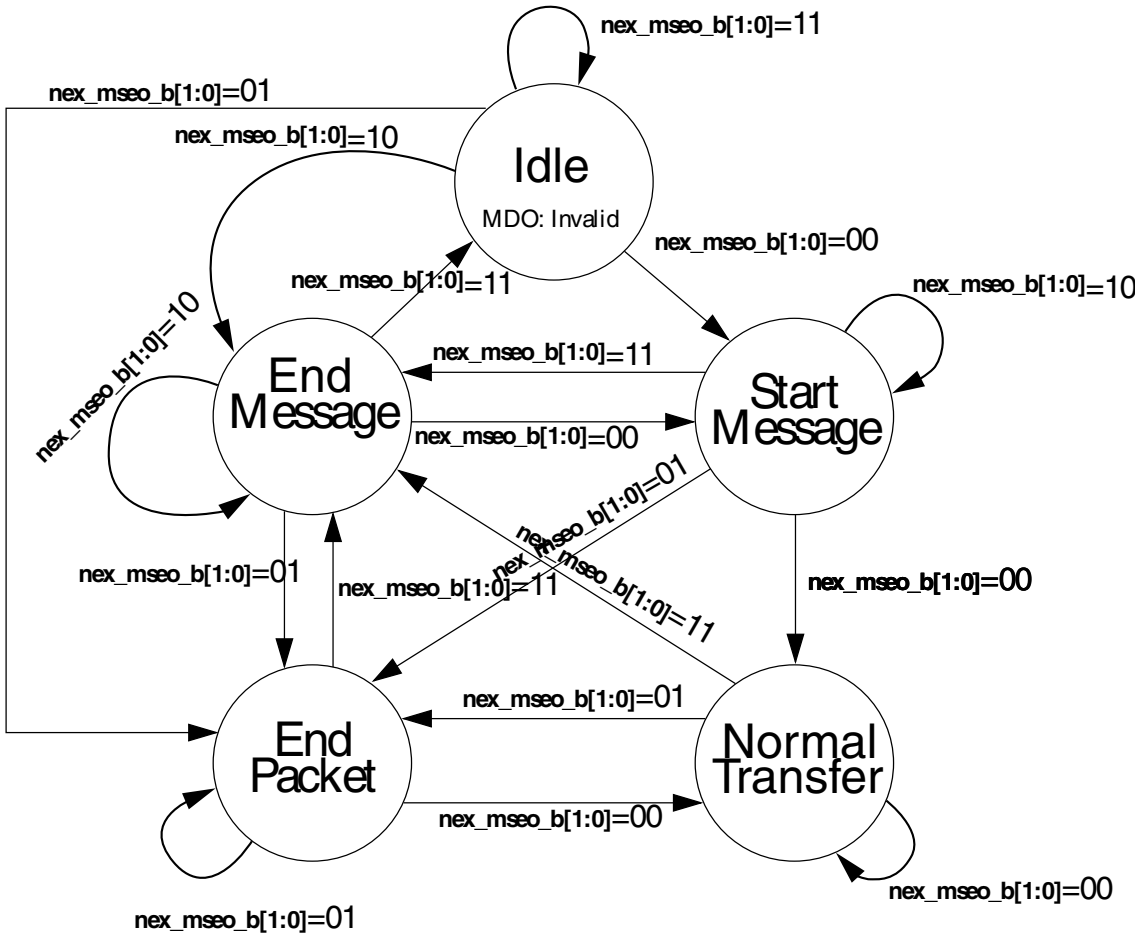

Figure 79-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

79.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

79.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 79-42 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 79-42. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

79.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 79-43 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 79-44 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 79-43. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 79-44. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 79-44. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
						P					
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 79-45 and Table 79-46 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 79-45. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 79-46. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)

3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

79.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

79.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

79.22.1 JTAG sequence for accessing internal Nexus registers

Table 79-49. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

79.22.2 JTAG sequence for read access of memory-mapped resources

Table 79-50. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

79.22.3 JTAG sequence for write access of memory-mapped resources

Table 79-51. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** pin
8	—	If CNT > 0, go back to Step #5

Chapter 80
Nexus Module

80.1 Introduction

The e200z710n3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

80.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

80.1.2 Terms and definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 80-1. Terms and definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

80.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
    - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
    - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
    - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
    - One (1) Read/Write Error pin (**nex_err_b**) pin
    - One (1) Watchpoint Event output pin (**evto_b**)
    - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
    - One (1) Event In pin (**nex_evti_b**)
    - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)
- Indicates to the FCCU whether it becomes active during functional mode.

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

80.1.4 Functional block diagram

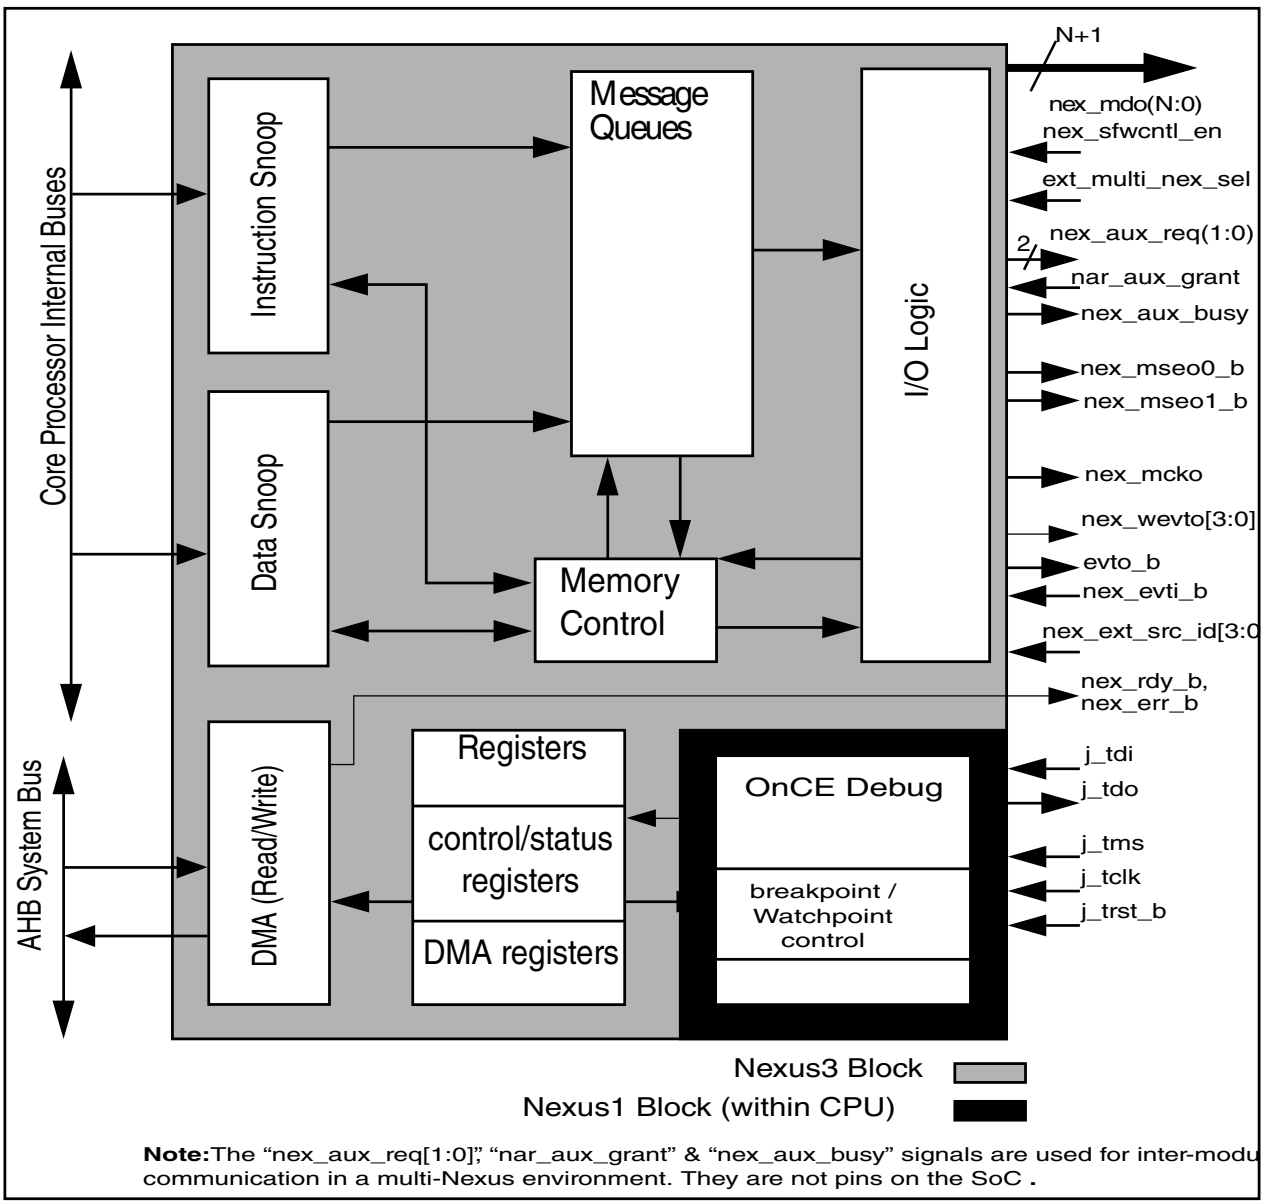

Figure 80-1. Nexus 3 functional block diagram

80.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

80.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

80.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 80-2.

Table 80-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 80-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table continues on the next page...

Table 80-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 80-7)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)

Table continues on the next page...

Table 80-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 80-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 80-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 80-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions

Table continues on the next page...

Table 80-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description

	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 80-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 80-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 80-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 80-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 80-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 80-5 shows the encodings used for resource codes for certain messages.

Table 80-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 80-6 shows the event code encodings used for certain messages.

Table 80-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace

Table continues on the next page...

Table 80-6. Event Code (EVCODE) Encoding (TCODE = 33) (continued)

Event Code	Description
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 80-7 shows the data trace size encodings used for certain messages.

Table 80-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

80.4 Nexus 3 Programmer's model

This section describes the Nexus 3 programmer's model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 80-8. Nexus 3 register map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2]	0x1	R	0x02	-

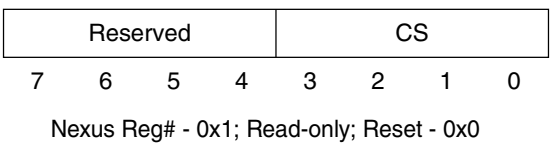
1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.

3. The "PCR_INDEX" is a parameter determined by the SoC.

80.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.



Nexus Reg# - 0x1; Read-only; Reset - 0x0

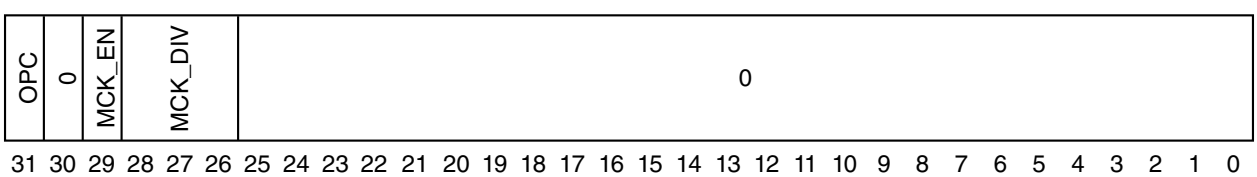
Figure 80-2. Client Select Control (CSC) register

Table 80-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

80.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.



Nexus Reg# - PCR_INDEX; Read/Write; Reset - 0x0

Figure 80-3. Port Configuration Register

Table 80-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality

Table continues on the next page...

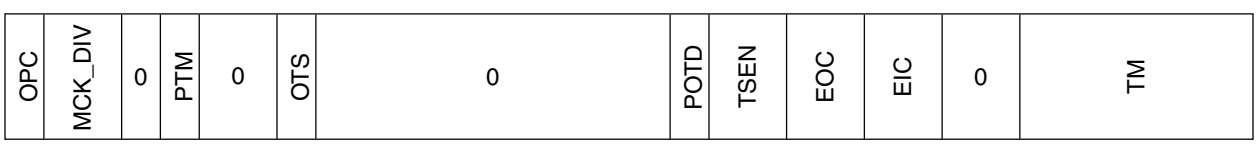
Bit	Name	Description
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

80.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 80-4 and its fields are described in Table 80-11.



Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering. Refer to External Hardware Trigger Controls for more information on external hardware triggering.

Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering. Refer to External Hardware Trigger Controls for more information on external hardware triggering.

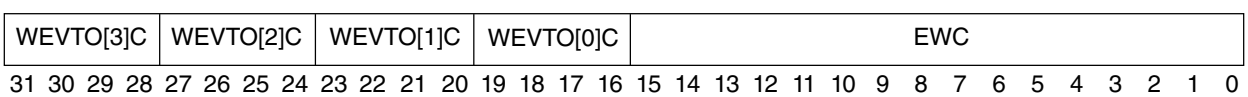
Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

80.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z710n3) Core Debug Support chapter.

Development Control Register 2 is shown in Figure 80-5 and its fields are described in Table 80-12.



Nexus Reg# - 0x3; DCR - 369; Read/Write; Reset - 0x0

1. EOC bits in DC1 must be programmed to trigger $\overline{\text{EVTO}}$ on Watchpoint occurrence for EWC bits to have any effect.

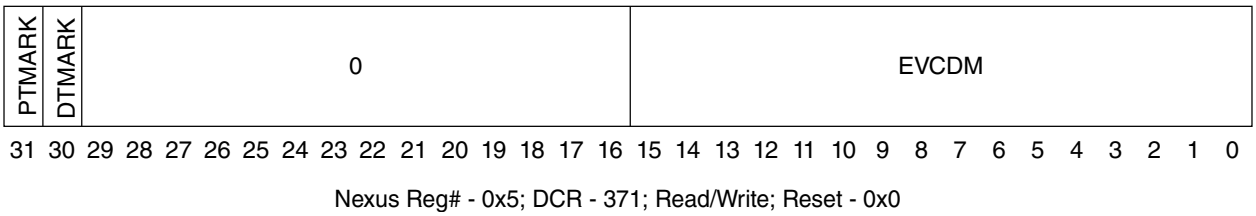
80.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in Figure 80-7 and its fields are described in Table 80-14.



Nexus Reg# - 0x5; DCR - 371; Read/Write; Reset - 0x0

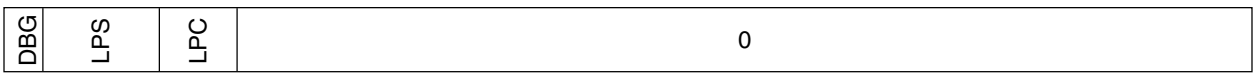
80.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.



31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

80.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data

Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z710n3) Core Debug Support chapter.

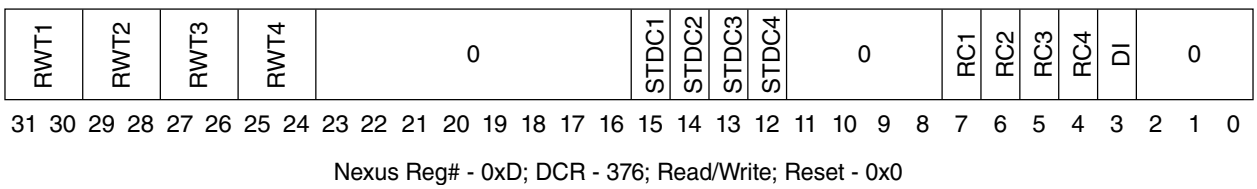
Figure 80-16. Nexus Overrun Control Register Fields

80.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.



Nexus Reg# - 0xD; DCR - 376; Read/Write; Reset - 0x0

Figure 80-17. Data Trace Control Register

Table 80-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

80.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 80-25.

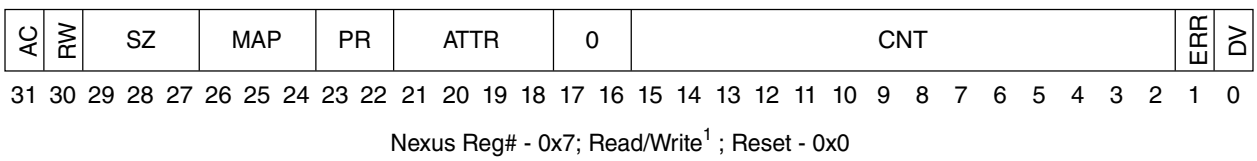

Figure 80-26. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 80-24. RWCS field description

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access
RWCS[30]	RW	Read/Write Select 0 Read access 1 Write access
RWCS[29:27]	SZ	Word Size 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 64-bit (doubleword, requires two passes through RWD) 100 - 111 Reserved (default to word)
RWCS[26:24]	MAP	MAP Select 000 Primary memory map 001-111 Reserved
RWCS[23:22]	PR[1]	Read/Write Access Priority

Table continues on the next page...

Table 80-24. RWCS field description (continued)

Bits	Name	Description
		00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority
RWCS[21:18]	ATTR	Access Attributes 0xxx Reserved 1xxx Reserved x0xx **p_d_hprot[4]** driven to 0 for accesses x1xx **p_d_hprot[4]** driven to 1 for accesses xx0x **p_d_hprot[3]** driven to 0 for accesses xx1x **p_d_hprot[3]** driven to 1 for accesses xxx0 **p_d_hprot[2]** driven to 0 for accesses xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	RES - Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR[2]	Read/Write Access Error (see Table 80-25)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 80-25)

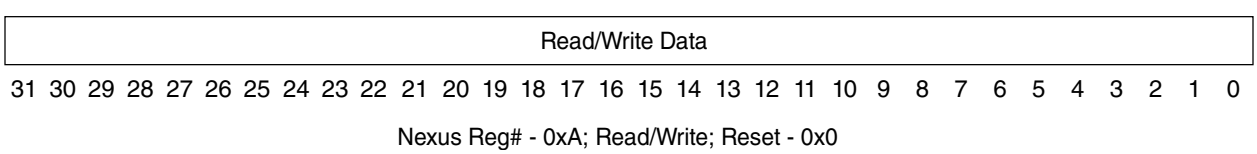
1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 80-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

80.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.



Nexus Reg# - 0xA; Read/Write; Reset - 0x0

Figure 80-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 80-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 80-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 80-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 80-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	-	-	-	AHB[7:0]
Byte @001	0 0 1	-	-	-	AHB[15:8]
Byte @010	0 1 0	-	-	-	AHB[23:16]
Byte @011	0 1 1	-	-	-	AHB[31:24]
Byte @100	1 0 0	-	-	-	AHB[39:32]
Byte @101	1 0 1	-	-	-	AHB[47:40]
Byte @110	1 1 0	-	-	-	AHB[55:48]
Byte @111	1 1 1	-	-	-	AHB[63:56]
Half @000	0 0 0	-	-	AHB[15:8]	AHB[7:0]
Half @010	0 1 0	-	-	AHB[31:24]	AHB[23:16]
Half @100	1 0 0	-	-	AHB[47:40]	AHB[39:32]
Half @110	1 1 0	-	-	AHB[63:56]	AHB[55:48]
Word @000	0 0 0	AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

80.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

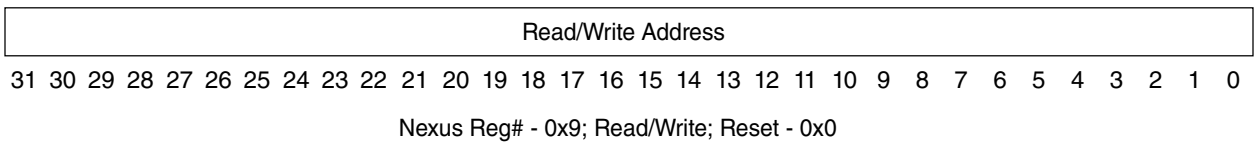


Figure 80-28. Read/Write Access Address (RWA) register

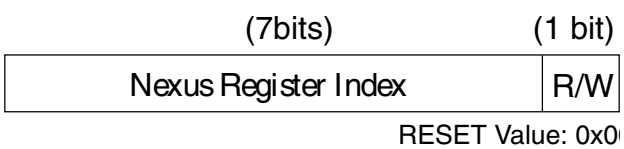
80.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 80-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 80-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:



Nexus Register Index	Selected from values in Table 80-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
    a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
    b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

80.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 80-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

80.7 Nexus message fields

Nexus messages are composed of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

80.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

80.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

80.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

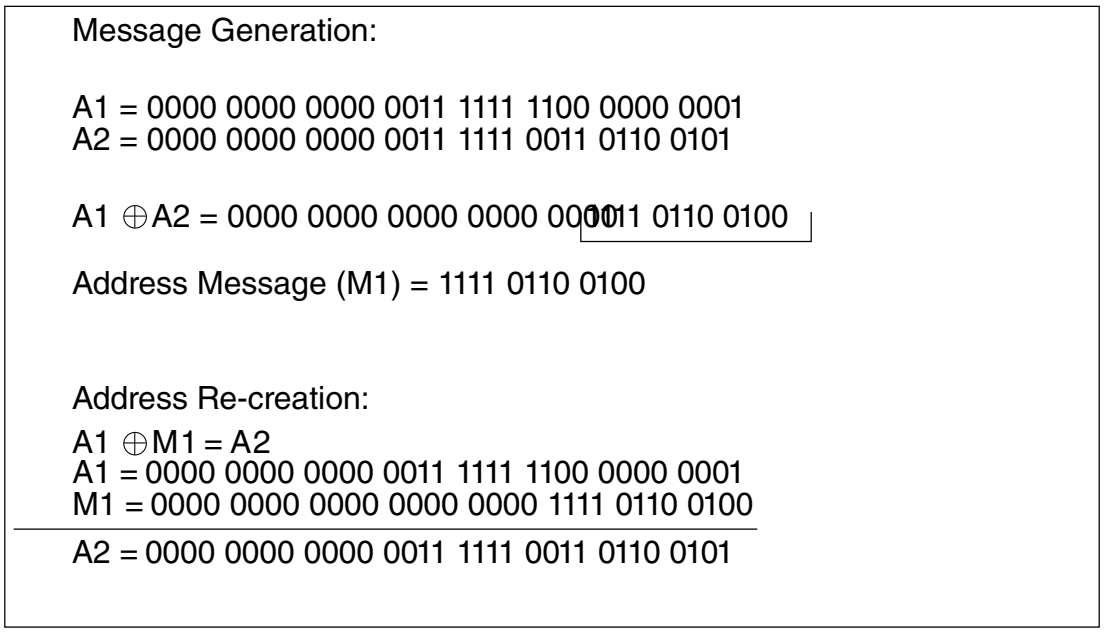


Figure 80-29. Relative address generation and recreation

80.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

80.7.5 Timestamp field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the nex_tsen input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of nex_tsmode[0:1] and the timestamp value is based on the nex_timebase[0:29] inputs. These signals are first synchronized to the nex_clk clock domain, and for nex_timebase[0:29], a gray-code to binary value

conversion is performed. The timestamp value is applied to messages as they exit the message queues. Leading zeros in the timestamp value are removed. shows the nex_tsmode[0:1] encodings used for the timestamp mode.

Table 80-28. nex_tsmode[0:1] timestamp mode encoding

nex_tsmode[0:1]	Timestamp Mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

80.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

80.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

80.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

80.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

80.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 80-29 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 80-29.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 80-29. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

80.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

80.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

80.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

80.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

80.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

80.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

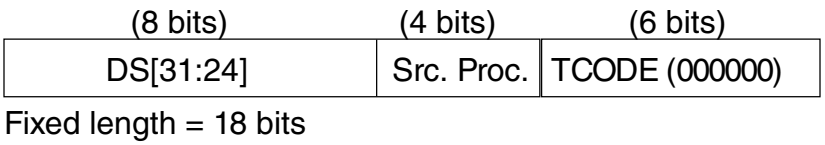

Figure 80-30. Debug Status message format

80.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 80-3 and Table 80-4):

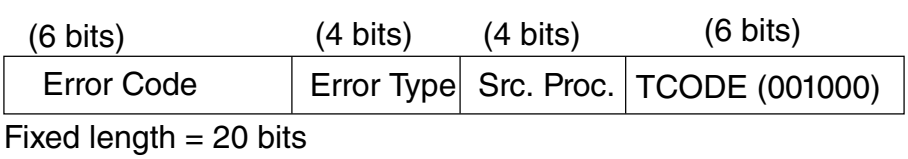

Figure 80-31. Error message format

80.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

80.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

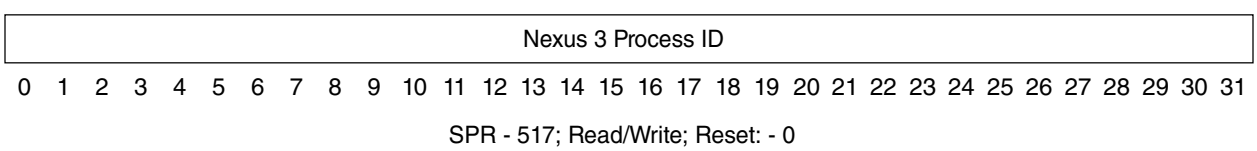
80.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z710n3) processors contain a *Power ISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.



SPR - 517; Read/Write; Reset: - 0

Figure 80-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 80-33. Ownership Trace Message format

80.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z710n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for

Core (e200z710n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

80.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

80.12.1.1 Indirect Branch Message instructions

Table 80-30 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 80-30. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

80.12.1.2 Direct Branch Message Instructions

Table 80-31 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 80-31. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

80.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

80.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

80.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

80.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

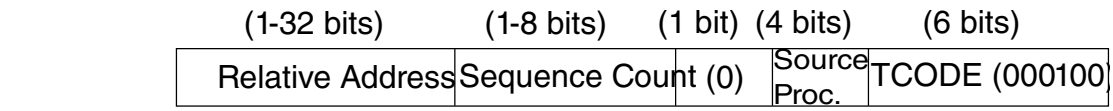
(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

Figure 80-34. Indirect branch message (history) format

80.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

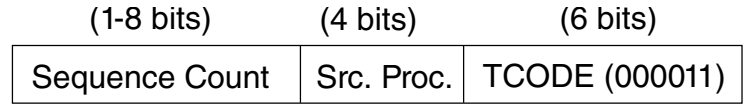


Max length = 51 bits; Min length = 13 bits

Figure 80-35. Indirect branch message format

80.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:



Max length = 18 bits; Min length = 11bits

Figure 80-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

80.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

80.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

80.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 80-32. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

80.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

80.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

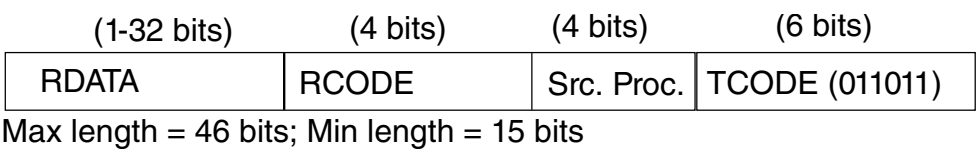


Figure 80-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 80-33. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

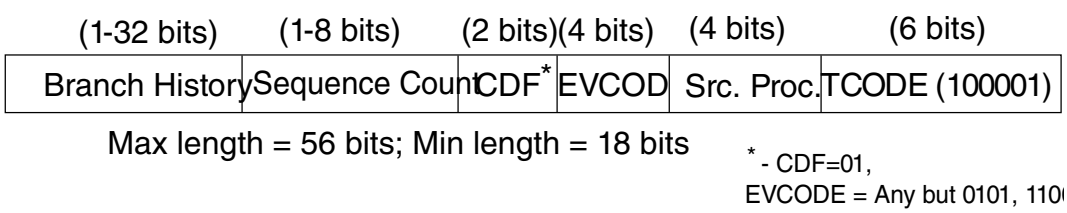
80.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 80-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:



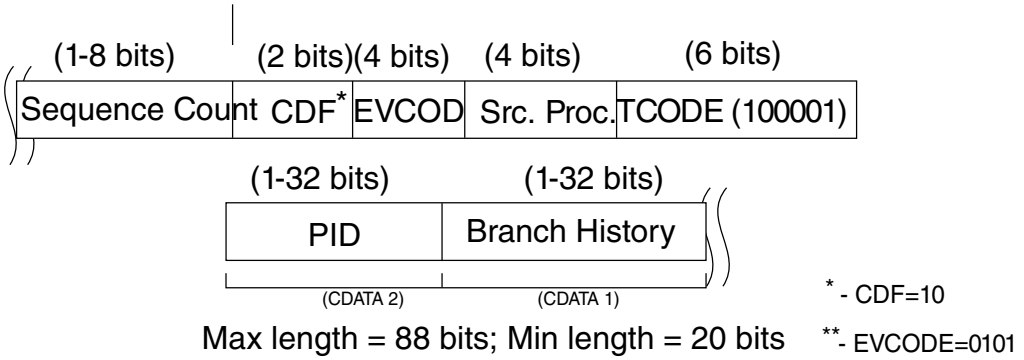


Figure 80-38. Program Correlation message formats

80.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

80.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

80.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 80-34):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in Table 80-34.

Table 80-34. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.

Table continues on the next page...

Table 80-34. Program Trace exception summary (continued)

Exception Condition	Exception Handling
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

80.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 80-34):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

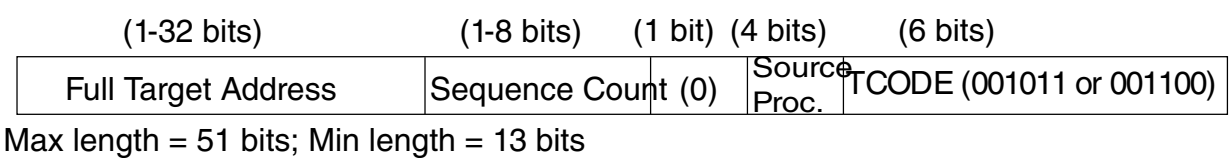

Figure 80-39. Direct/Indirect Branch with Sync message format

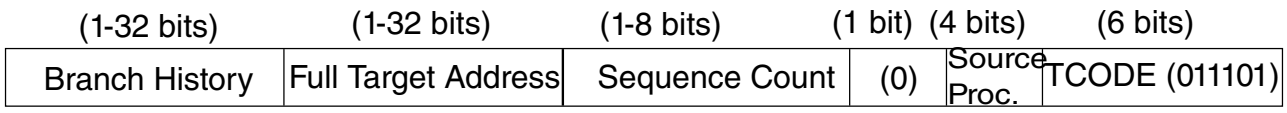
The format for Program Trace Indirect Branch History with Sync. messages is as follows:



Max length = 83 bits; Min length = 14 bits

Figure 80-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 80-35.

Table 80-35. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

80.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

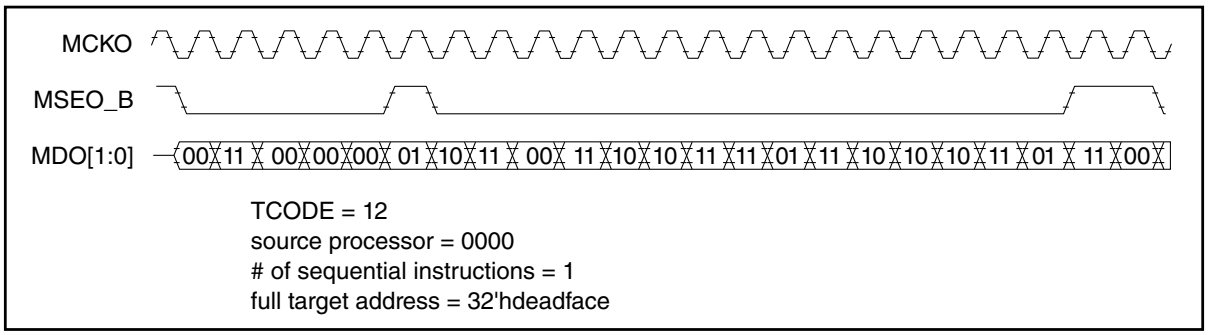

Figure 80-44. Program Trace - Indirect Branch w/ Sync. message

80.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

80.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z710n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of the following ways:

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

80.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

80.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 80-45. Data Write message format

80.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 80-46. Data Read fessage format

Note

* Core (e200z710n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z710n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

80.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 80-36):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

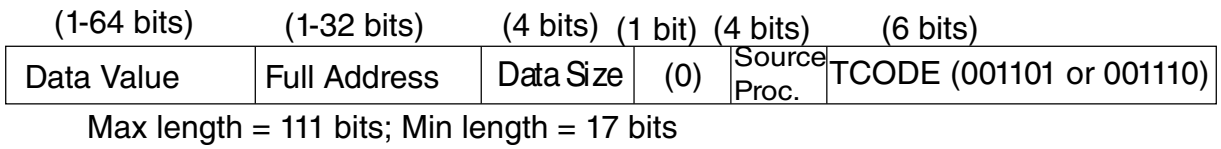

Figure 80-47. Data Write/Read with Sync. message format

Exception conditions that result in Data Trace Synchronization are summarized in Table 80-36.

Table 80-36. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

80.13.3 DTM Operation

80.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

80.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

80.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

80.13.3.4 Bus Cycle special cases

Table 80-37. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$), [1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the

doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z710n3) Core Debug Support chapter.)

Note

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

80.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

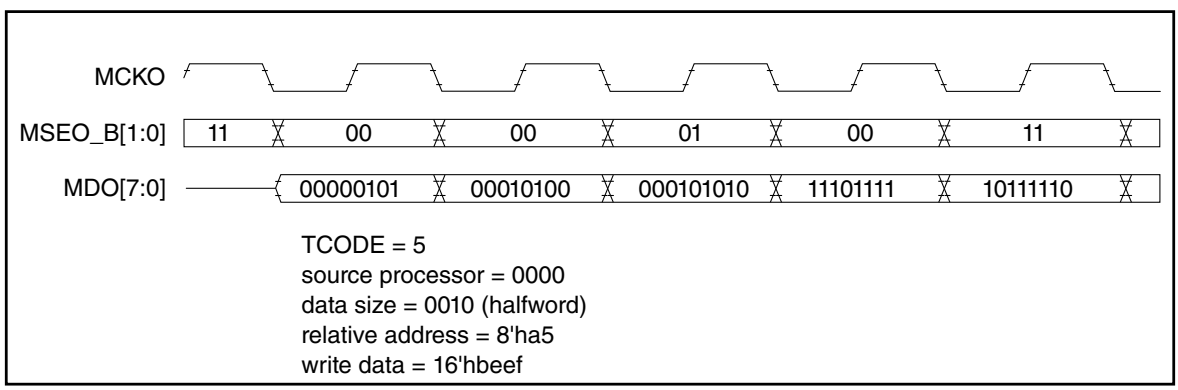

Figure 80-48. Data Trace - Data Write Message

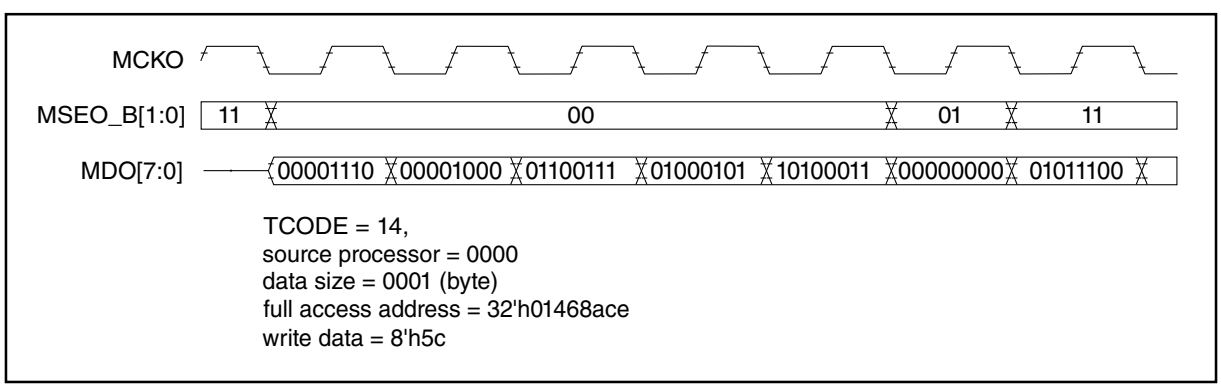

Figure 80-49. Data Trace — Data Read w/ Sync message

80.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

80.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

80.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

80.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z710n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

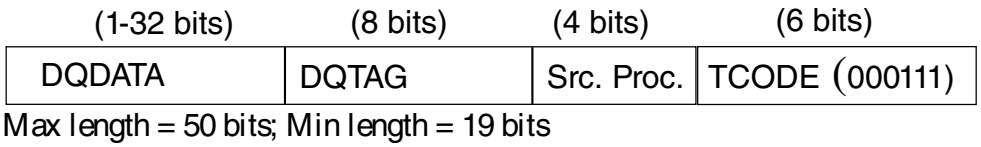

Figure 80-50. Data Acquisition message format

80.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z710n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 80-41 for details on **evto_b**.

Watchpoint information is messaged out in the following format:

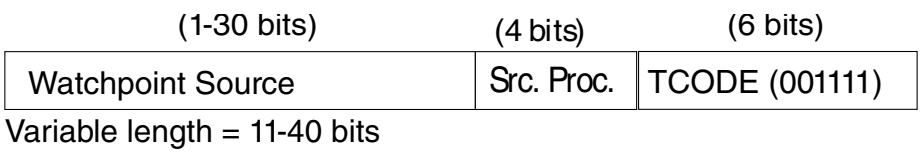

Figure 80-51. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 80-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
000000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	

Table 80-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX	Watchpoint #3 enabled for WTM

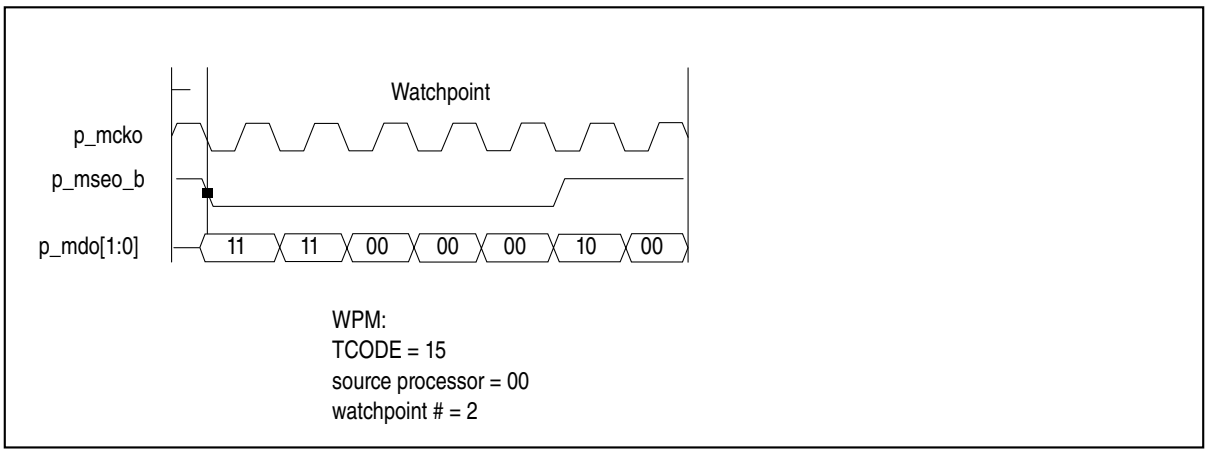

Figure 80-52. Watchpoint Message & Watchpoint Error message

80.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a "window" for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. The following table details the external hardware trigger signals.

Table 80-39. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0 → 1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0 → 1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0 → 1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

80.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/ OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

80.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'1 (write access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data (RWD) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)

4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 80-41 for details) and clears the ERR bit in the RWCS register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once the DV bit has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start**,**nex_err_b**, and **nex_rdy_b** pins, as well as the AC, DV, and ERR bits within the RWCS, provide Read/Write Access status to the external development tool.

80.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block then arbitrates for the AHB system bus and transfers the first data value from the RWD register to the memory-mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output is asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS register. Otherwise, the ERR bit is set and the DV bit is cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Clearing the DV bit indicates that the device is ready for the next access in the block transfer, or that an error has occurred.

3. If the AC bit has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS register are not changed when executing a block write access. The original values can be read by the external development tool at any time.

80.17.3 Single read access

1. Initialize the Read/Write Access Address (RWA)register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'0 (read access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

An Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 80-41 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin

will be asserted, the ERR bit will be set, and the DV bit will be cleared to indicate an error has occurred. The **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit is cleared in either case.

4. The data can then be read from the Read/Write Access Data register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start**, **nex_err_b**, and **nex_rdy_b** pins as well as the AC, DV, and ERR bits within the RWCS register provide Read/Write Access status to the external development tool.

80.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 80-41 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS register, and asserts the **nex_rdy_b** pin (see Table 80-41 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that

the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.

4. The data can then be read from the RWD register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

80.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

80.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

80.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
    a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
    b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

80.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

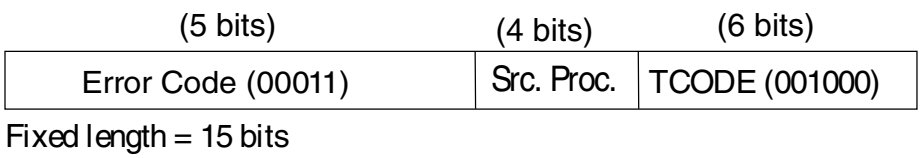

Figure 80-53. Error message format1

80.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

80.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 80-41. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z710n3) Core Debug Support chapter.

Table 80-40. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 80-41.

Table 80-41. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.

Table continues on the next page...

Table 80-41. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_ahb_start	O	AHB Start (**nex_ahb_start**) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one **nex_clk** clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, **nex_ahb_start** remains de-asserted.
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted.
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted.
evto_b	O	Event Out (**evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 80-42. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 80-44.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

80.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 80-43. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 80-43. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 80-54 illustrates the state diagram for single pin MSEO transfers.

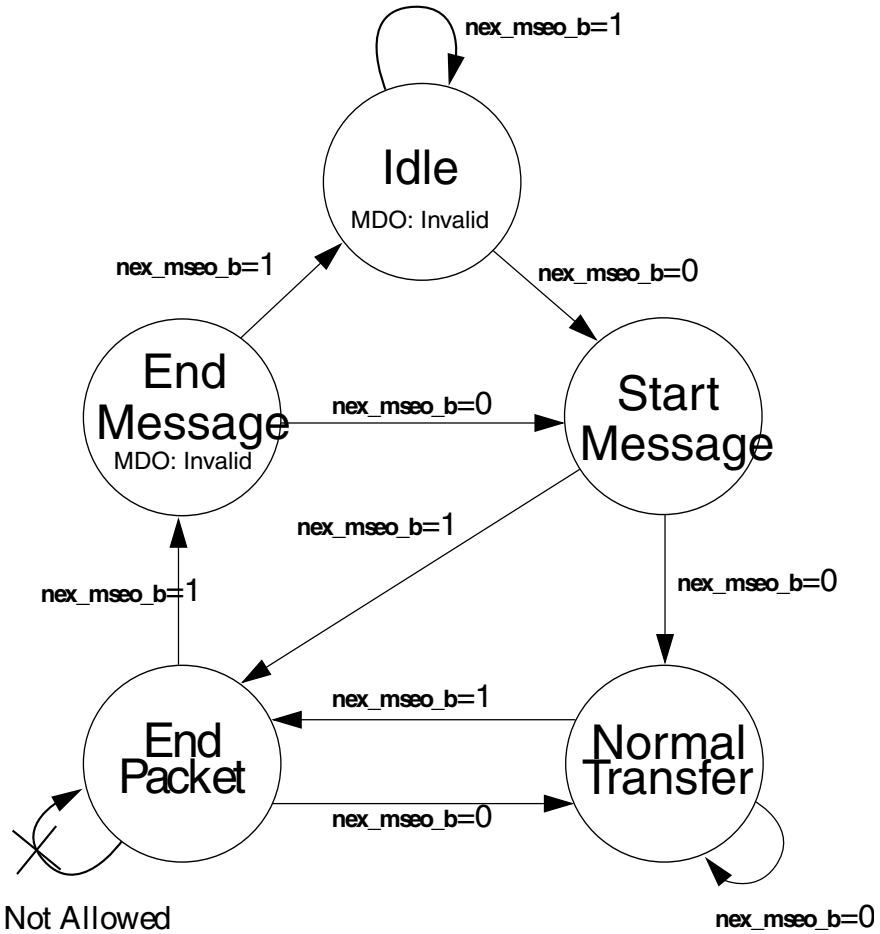

Figure 80-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 80-55 illustrates the state diagram for dual pin MSEO transfers.

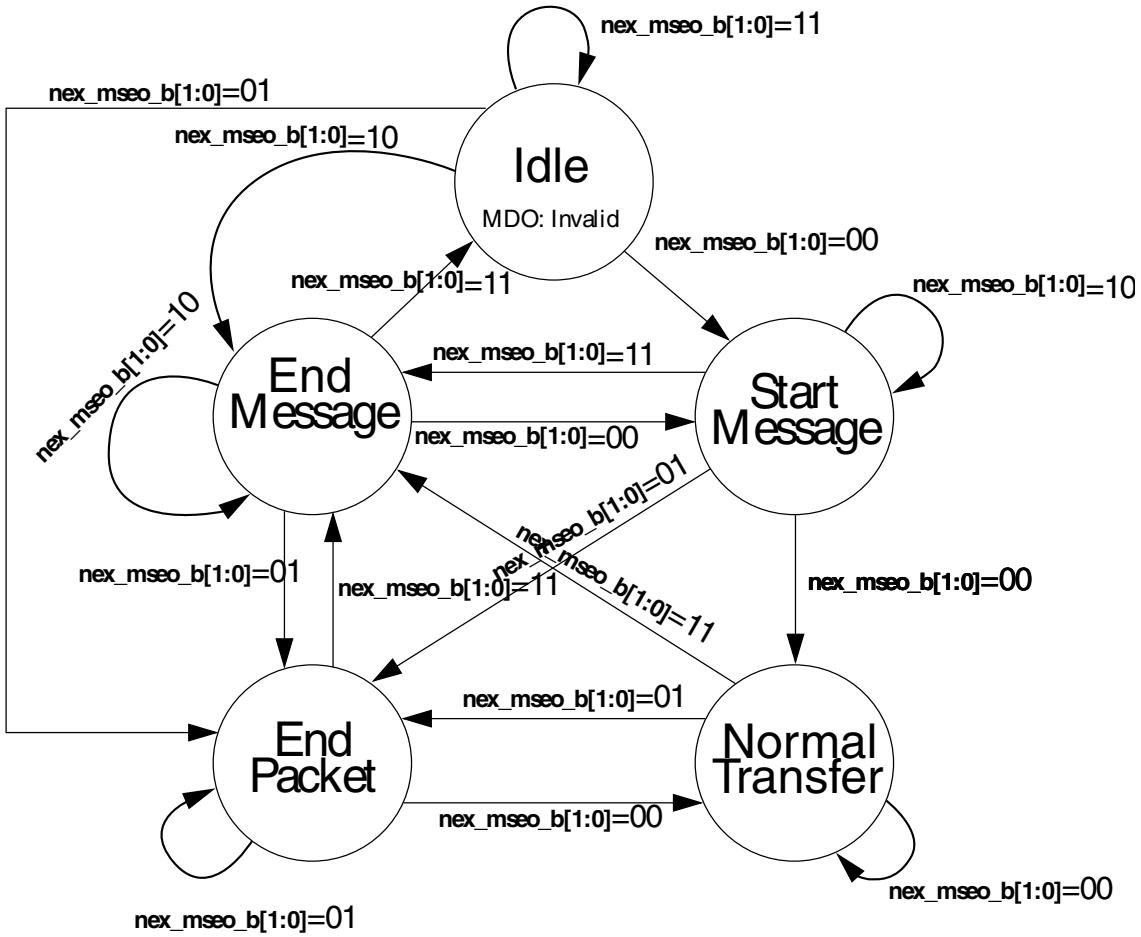

Figure 80-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

80.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

80.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 80-44 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 80-44. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

80.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 80-45 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 80-46 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 80-45. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 80-46. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 80-46. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
						P					
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 80-47 and Table 80-48 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 80-47. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 80-48. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 80-49 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and Table 80-50 illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 80-49. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 80-50. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

80.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

80.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

80.23.1 JTAG sequence for accessing internal Nexus registers

Table 80-51. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

80.23.2 JTAG sequence for read access of memory-mapped resources

Table 80-52. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

80.23.3 JTAG sequence for write access of memory-mapped resources

Table 80-53. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b**or **nex_err_b**pin
8	—	If CNT > 0, go back to Step #5

Chapter 81
Nexus Crossbar Multi-Master Client (NXMC)

81.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools. This also provides the capability of sending user defined messages for the peripherals attached to it.

81.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- HSM master(s) filtering from the tracing function based on external control
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers.

- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

81.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in Table 81-2.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see IEEE 1149.1 (JTAG) Test Access Port for details). A separate JTAG TAP controller is instantiated within the NXMC. The following table describes the JTAG pins.

Table 81-1. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 81-2. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: • one of the internal or external watchpoints has occurred and EOC = 2'b00 • system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see Enabling NXMC operation), assertion initiates data trace synchronization messages (provided data trace is enabled).

81.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 81-3. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 81-4)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 81-4)

Table continues on the next page...

Table 81-3. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 81-5)
	14	14	ECODE	fixed	Error code (See Table 81-6)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 81-4)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 81-4)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See Table 81-22)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier

Table continues on the next page...

Table 81-3. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 81-4. Data trace size (DSZ) encodings (TCODE = 58, 59, 60, 61)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 81-5. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 81-6. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost

CKSRCn	X1XXXXXX	In-Circuit Trace Message(s) Lost
CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

81.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See IEEE 1149.1 (JTAG) Test Access Port for details. The complete list of registers is shown in this table.

Table 81-7. NXMC registers

Nexus register	Nexus access opcode (hex)	Read/ write	Read address (hex)	Write address (hex)
Development Control 1 (DC1)	2	R/W	04	05
Development Control 2 (DC2)	3	R/W	06	07
Watchpoint Trigger (WT)	B	R/W	16	17
Data Trace Control (DTC)	D	R/W	1A	1B
Data Trace Start Address1 (DTSA1)	E	R/W	1C	1D
Data Trace Start Address2 (DTSA2)	F	R/W	1E	1F
Data Trace End Address1 (DTEA1)	12	R/W	24	25
Data Trace End Address2 (DTEA2)	13	R/W	26	27
Breakpoint/Watchpoint Control Register1 (BWC1)	16	R/W	2C	2D
Breakpoint/Watchpoint Control Register2 (BWC2)	17	R/W	2E	2F
Breakpoint/Watchpoint Address Register1 (BWA1)	1E	R/W	3C	3D
Breakpoint/Watchpoint Address Register2 (BWA2)	1F	R/W	3E	3F

81.4.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DC2 is described in this table.

Table 81-9. DC2 register field description

Field	Description	
31:24	$\overline{\text{EVTO}}$ Watchpoint Configuration[1].	
EWC	00000000	No Watchpoints trigger $\overline{\text{EVTO}}$
	1XXXXXXX	External Watchpoint #1 triggers $\overline{\text{EVTO}}$
	X1XXXXXX	External Watchpoint #2 triggers $\overline{\text{EVTO}}$
	XX1XXXXX	Reserved
	XXX1XXXX	Reserved
	XXXX1XXX	Internal Watchpoint #1 triggers $\overline{\text{EVTO}}$
	XXXXX1XX	Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$
	XXXXXX1X	Reserved
	XXXXXXX1	Reserved
23:1	Reserved for future functionality (read as 0)	
0	Peripheral Messaging Enable for the In-Circuit Trace (ICT) feature. [2]	
PME0	0	Peripheral Interface disabled
	1	Peripheral Interface enabled

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

81.4.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable.

The WT bits can be used to produce an address related window for triggering trace messages. This table shows the format of the WT register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	DTS			DTE			0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The WT register is described in this table.

Table 81-10. WT register field description

Field	Description[1]
31:26	Reserved for future functionality (read as 0)
25:23 DTS	Data Trace Start Control. 000 Trigger disabled 001 Use External Watchpoint #1 010 Use External Watchpoint #2 011 Reserved 100 Reserved 101 Use Internal Watchpoint #1 (BWA1 Register) 110 Use Internal Watchpoint #2 (BWA2 Register) 111 Reserved

19:0	Reserved for future functionality (read as 0)

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

81.4.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. This table shows the format of the DTC register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTC register is described in this table.

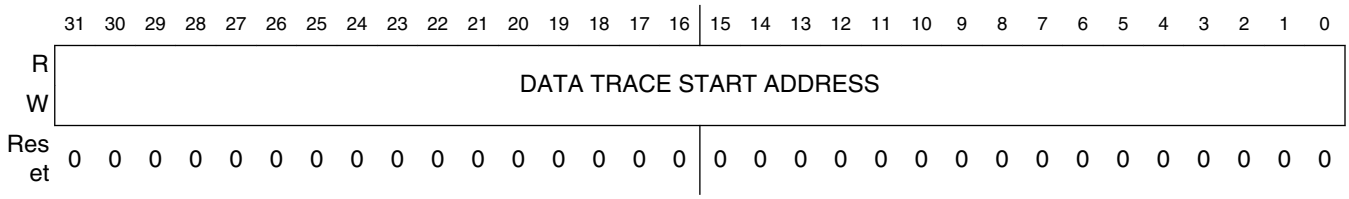
Table 81-11. DTC field description

Field	Description
31:30 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
29:28 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
27:25	Reserved for future functionality
24 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
23:20	Reserved for future functionality
19:16 MID	ID of the system bus Master to be traced[1]
15:8	Reserved for future functionality
7 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
6 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

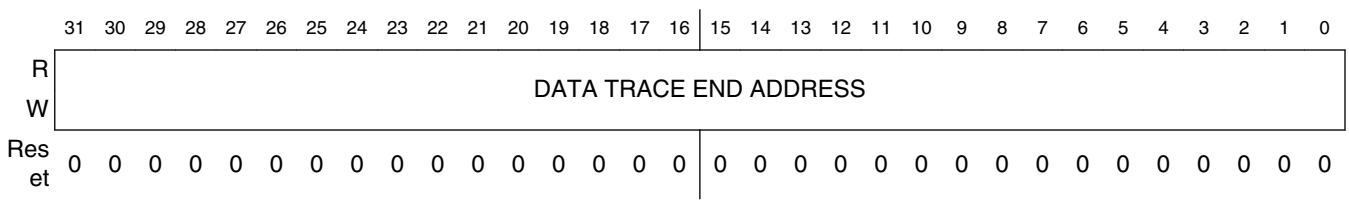
81.4.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. This table shows the format of the DTSA1 and DTSA2 registers.



81.4.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. This table shows the format of the DTEA1 and DTEA2 registers.



This table illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 81-12. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note

DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

81.4.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. This table shows the format of the BWC1 register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The BWC2 register is described in this table.

Table 81-14. BWC2 field description

Field	Description
31:30 BWE2	Breakpoint/Watchpoint #2 Enable. 00 Internal Nexus Watchpoint #2 disabled 01 Reserved 10 Reserved 11 Internal Nexus Watchpoint #2 enabled
29:28 BRW2	Breakpoint/Watchpoint #2 Read/Write Select. 00 Watchpoint #2 hit on read accesses 01 Watchpoint #2 hit on write accesses 10 Watchpoint #2 on read or write accesses 11 Reserved
27:18	Reserved for future functionality (read as 0)
17:16 BWR2	Breakpoint/Watchpoint #2 Register Compare. 00 No Register Compare (same as BWC2[31:30] = 2b00) 01 Reserved 10 Compare with BWA2 value 11 Reserved
15 BWT2	Breakpoint/Watchpoint #2 Type. 0 Reserved 1 Watchpoint #2 on data accesses
14:0	Reserved for future functionality (read as 0)

81.4.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. This table shows the format of the BWA1 and BWA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BREAKPOINT / WATCHPOINT ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

81.4.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 81-7. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

81.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion. The JTAG ID register should be read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

81.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in NXMC register access via JTAG.

81.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

81.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

81.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 81-7.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see Table 81-7), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

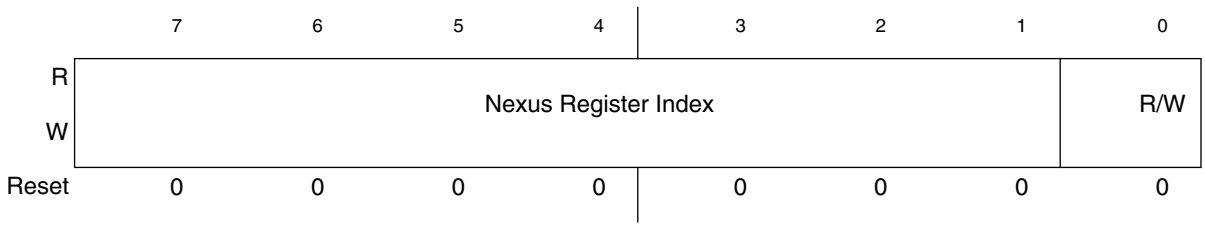

Table 81-15. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 81-7
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

81.6 Functional description

The following sections describe the functionality of the NXMC module.

81.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

81.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

81.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

81.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32 , 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 81-16. DTM message format for DATA width = 64 bits

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

TSTAMP is another optional field which is inserted based on the controls received from the NAR, see Timestamping feature.

81.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

81.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in this figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 81-17. DTM error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

81.6.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see Table 81-19):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.

- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in the following figure. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 81-18. Data write/read with synchronization message format

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Exception conditions that result in data trace synchronization are summarized in this table.

Table 81-19. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).

Table continues on the next page...

Table 81-19. Data trace exception summary (continued)

Exception condition	Exception handling
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

81.6.1.3 Enabling data trace messaging operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

81.6.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).

81.6.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in this figure.

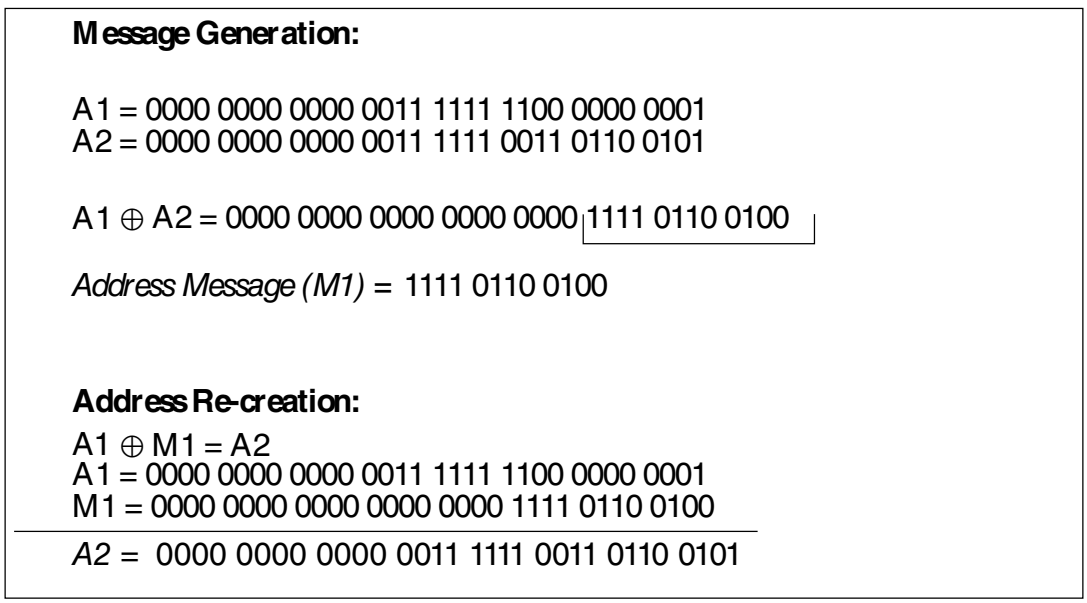

Figure 81-1. Relative addressing example

81.6.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

81.6.1.7 System bus cycle special cases

The system bus cycle special cases are shown in this table.

Table 81-20. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

81.6.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in Data write and data read messages for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

81.6.1.9 HSM master filtering

For security reasons, certain HSM masters need to be disabled or filtered from data tracing operations.

81.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

81.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in System bus multi-master tracing).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in Table 81-21 and Table 81-22.

Table 81-21. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 81-22. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)

Table continues on the next page...

Table 81-22. Watchpoint source description (continued)

Watchpoint source (8-bits)	Watchpoint description
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

81.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in this figure.

Table 81-23. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

81.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

Table 81-24. Peripheral DATA bus fields

MSB	6 bits	(54-6) bits			LSB
CKSRCn		DATAn			
54-1	54-6	54-6-1	2	1	0

n = peripheral number

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

81.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

Table 81-25. Peripheral message format (max length = 60 bits, min length = 17 bits)

1–44 bits	6 bits	4 bits	6 bits
CKDATAn	CKSRCn	SRC	TCODE (100010)

81.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in this figure.

Table 81-26. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE(CKSRCn,ErrCODE)	ETYPE	SRC	TCODE (001000)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in Table 81-5 and Table 81-6.

81.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. This figure shows an example of ICTM message with a TSTAMP field.

Table 81-27. Message with TSTAMP field example

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via TM, PME0 etc. control bits)

Chapter 82
Cyclic Redundancy Check (CRC) Unit

82.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

82.2 Main features

- Single context is supported
- Zero-wait states during the CRC computation (pipeline scheme)
- Three hard-wired polynomials (CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

82.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet (see note below)

NOTE

Although the CRC-32 Ethernet polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the Ethernet protocol (IEEE 802).

82.3 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to the chip configuration chapter for number of contexts in this module.

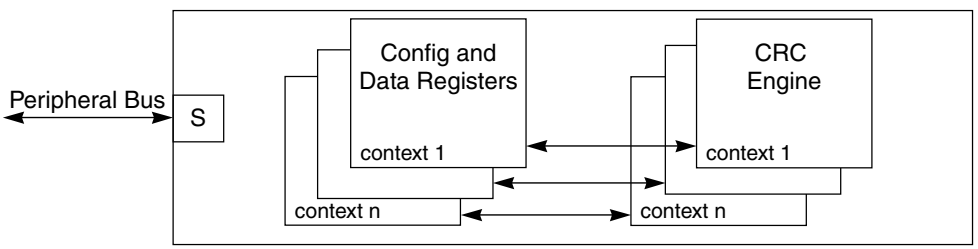

Figure 82-1. CRC top level diagram

82.4 Signal description

The CRC module does not generate any external signals.

82.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:

- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_ CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_ CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

82.5 CRC memory map and registers

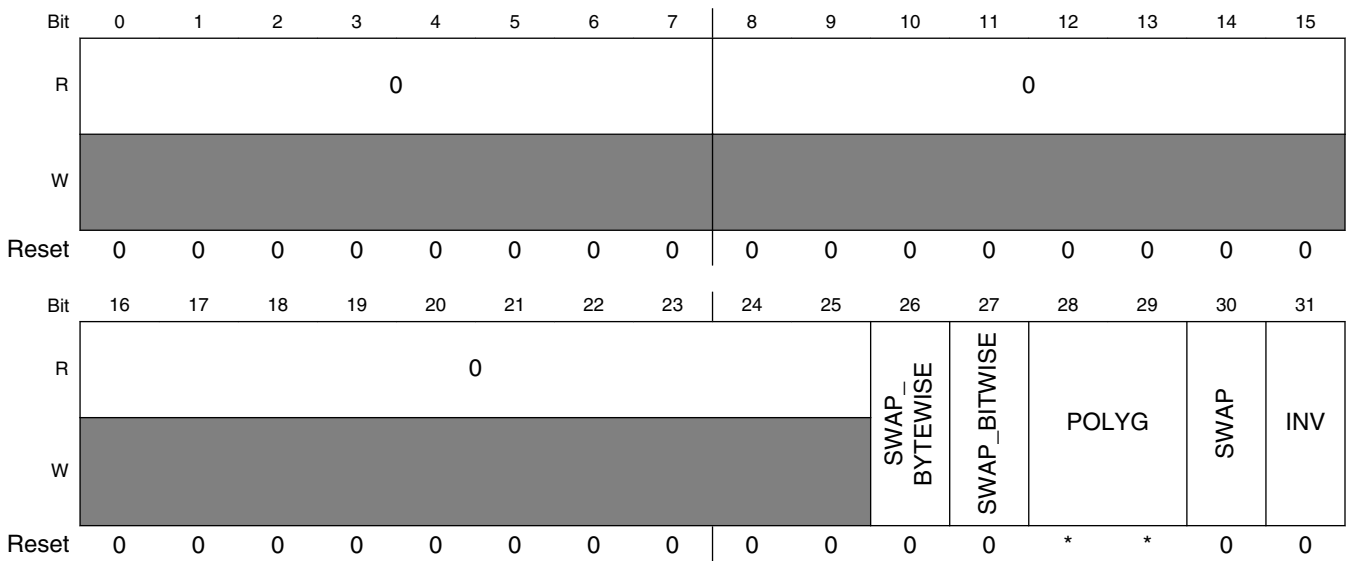
CRC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Configuration Register (CRC_CFG)	32	R/W	See section	82.5.1/4332
4	Input Register (CRC_INP)	32	R/W	0000_0000h	82.5.2/4333
8	Current Status Register (CRC_CSTAT)	32	R/W	FFFF_FFFFh	82.5.3/4334
C	Output Register (CRC_OUTP)	32	R	FFFF_FFFFh	82.5.4/4334

82.5.1 Configuration Register (CRC_CFG)

Access: User read/write.

Address: 0h base + 0h offset = 0h



* Notes:
- POLYG field: Reset value is a function of the number of contexts, N. When N%2 = 0, reset value = 01b. When N%2 = 1, reset value = 00b.

CRC_CFG field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 SWAP_ BYTEWISE	Swap CRC_INP byte-wise **NOTE:** INV and SWAP bits are set to 1 for CRC-32 polynomial calculations. 0 Do not swap 1 Perform byte-wise swap on CRC_INP input data internally for CRC-32 polynomial calculations.
27 SWAP_BITWISE	Swap CRC_INP bit-wise 0 Do not swap 1 Perform bit-wise swap on CRC_INP input data internally for CRC-8 and CRC-16 polynomial calculations.
28–29 POLYG	Polynomial selection

Table continues on the next page...

CRC_CFG field descriptions (continued)

Field	Description
	This bit can be written only during the configuration phase. 00 CRC-CCITT polynomial 01 CRC-32 polynomial 10 CRC-8 polynomial 11 Reserved
30 SWAP	Swap selection This bit can be written only during the configuration phase. The swap operation is a bit-by-bit swapping of the content. 0 No swap selection applied on the CRC_OUTP content 1 Swap selection (MSB to LSB, LSB to MSB) applied on the CRC_OUTP content; in case of CRC-CCITT polynomial, the swap operation is applied on the 16 least-significant bits
31 INV	Inversion selection This bit can be written only during the configuration phase. The inversion operation is a complement (or negation) of the content. 0 No inversion selection applied on the CRC_OUTP content 1 Inversion selection (bit x bit) applied on the CRC_OUTP content In case of CRC-CCITT polynomial, the inversion operation is applied on the 16 least-significant bits.

82.5.2 Input Register (CRC_INP)

Access: User read/write.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CRC_CSTAT field descriptions

Field	Description
0–31 CSTAT	CRC signature status This register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 most-significant bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be written only during the configuration phase.

82.5.4 Output Register (CRC_OUTP)

Access: User read-only.

Address: 0h base + Ch offset = Ch

CRC_OUTP field descriptions

Field	Description
0–31 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

82.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in Equation 81 on page 4335, Equation 82 on page 4335, and Equation 83 on page 4335 for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 81. CRC8 VDA CAN

$$x^{16} + x^{12} + x^5 + 1$$

Equation 82. CRC-CCITT (x.25 protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 83. CRC-32 (Ethernet protocol)

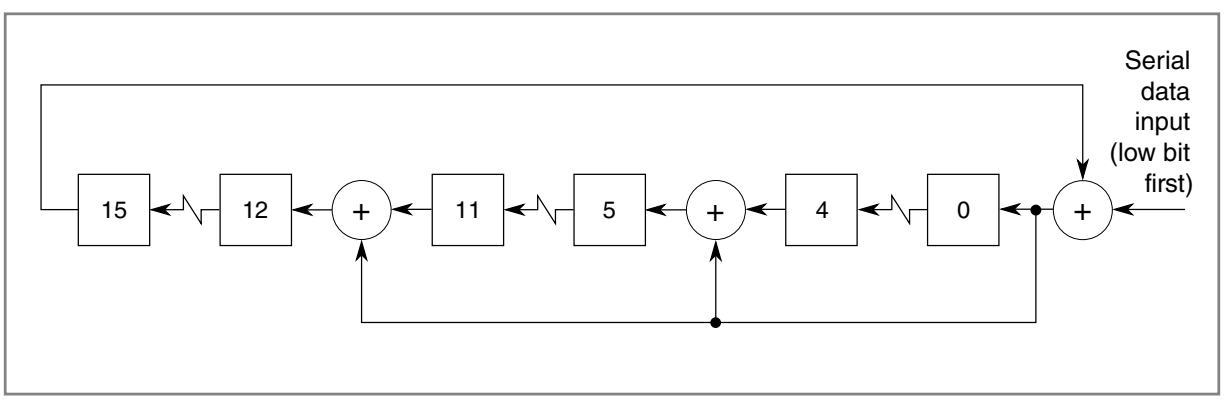

Figure 82-2. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in Figure 82-2 for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in Input Register (CRC_INP), is fed first into the engine. The actual

implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in Figure 82-3.

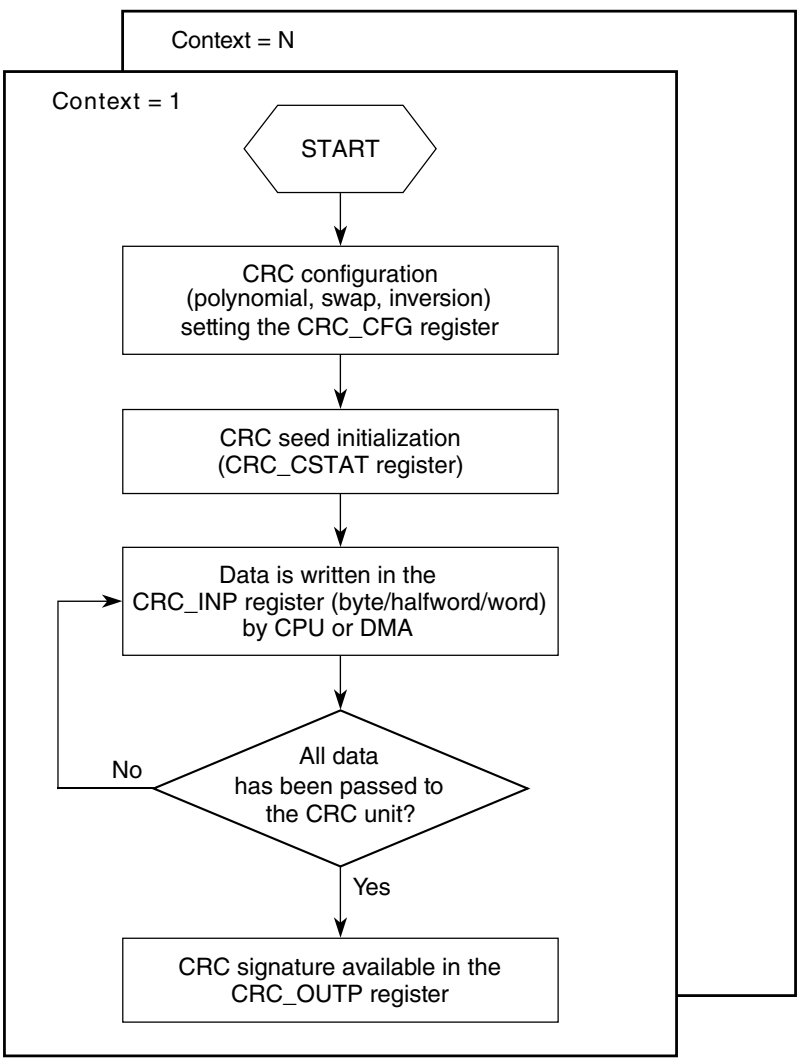

Figure 82-3. CRC computation flow

82.7 Use cases

82.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

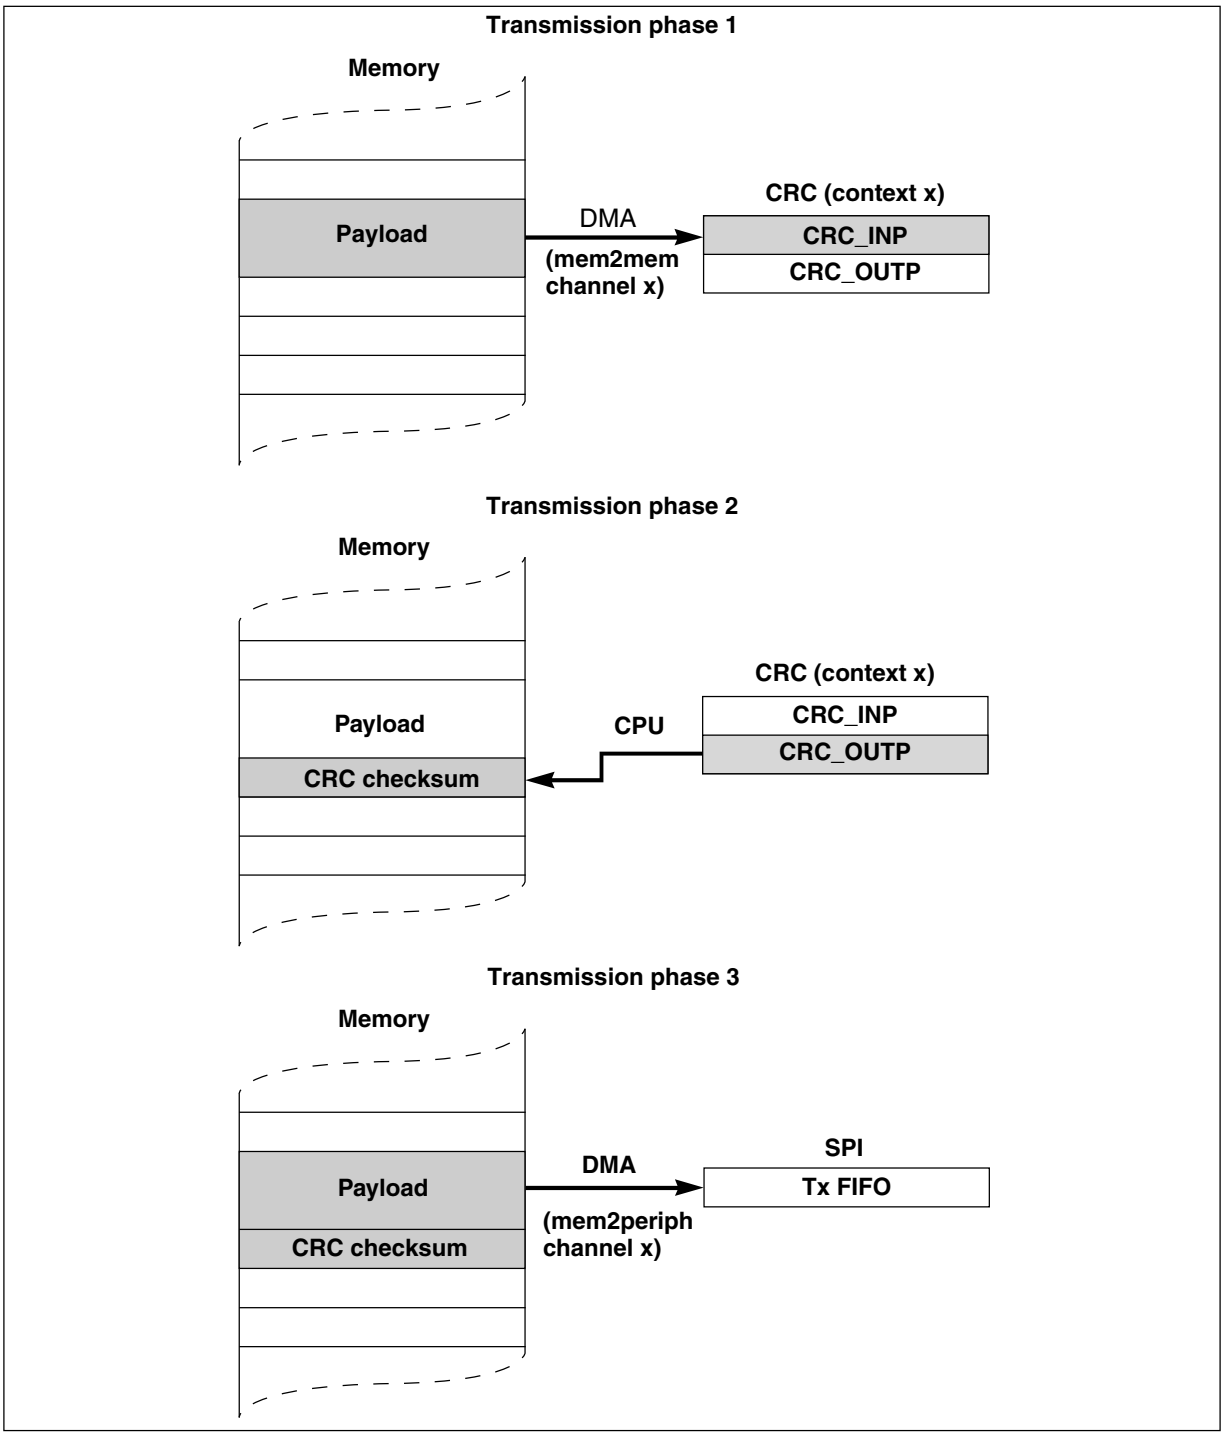

Figure 82-4. DMA-CRC transmission sequence

82.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

Chapter 83
Memory Error Management Unit (MEMU)

83.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM
- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table, and the uncorrectable errors are reported in the other.

See Design overview for the reporting block details.

83.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per the following reporting blocks (the number of error sources are chip-specific; see the chip-specific MEMU information):
  - System RAM ECC and MBIST
  - Peripheral RAM ECC
  - Flash memory ECC
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.

- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

83.3 Block diagram

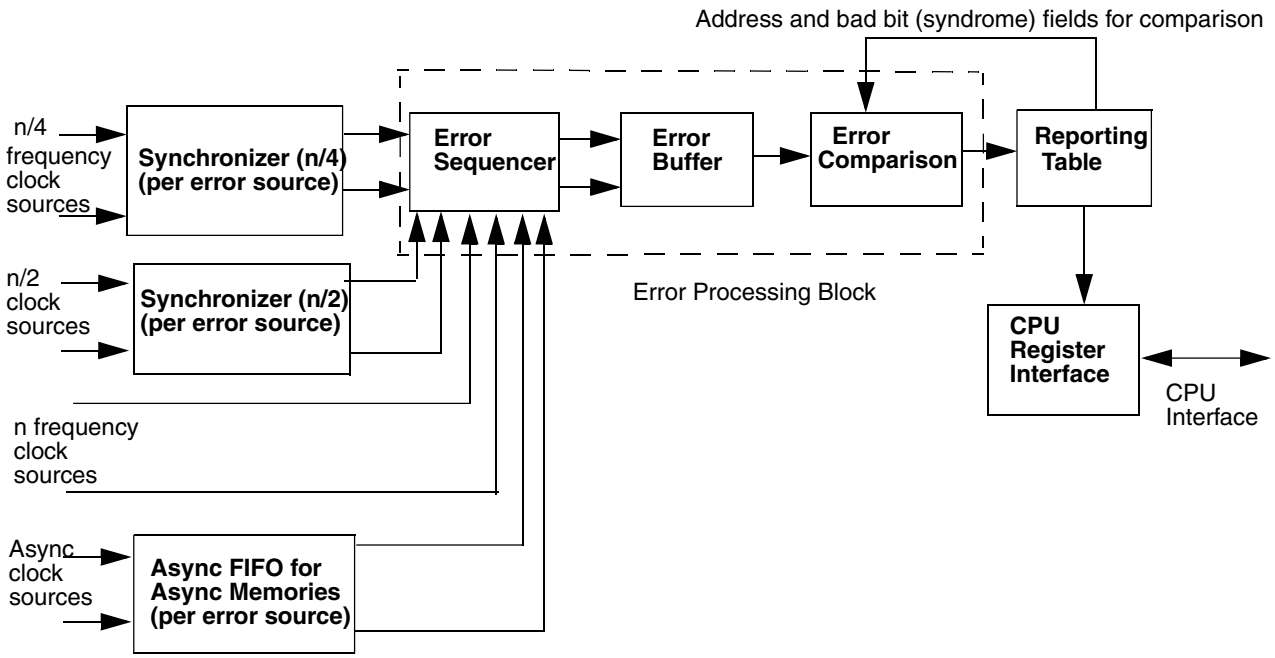

Figure 83-1. MEMU block diagram

83.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See Handling overflows (Multiple error reporting), for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   - Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
   - All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.
   - While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.

- While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique
- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. ..._CERR_STS or ..._UNCERR_STS). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see the chip-specific MEMU information.

4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

   The software, in principle, is not supposed to write VLD to 1 if it is already 1.

   The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

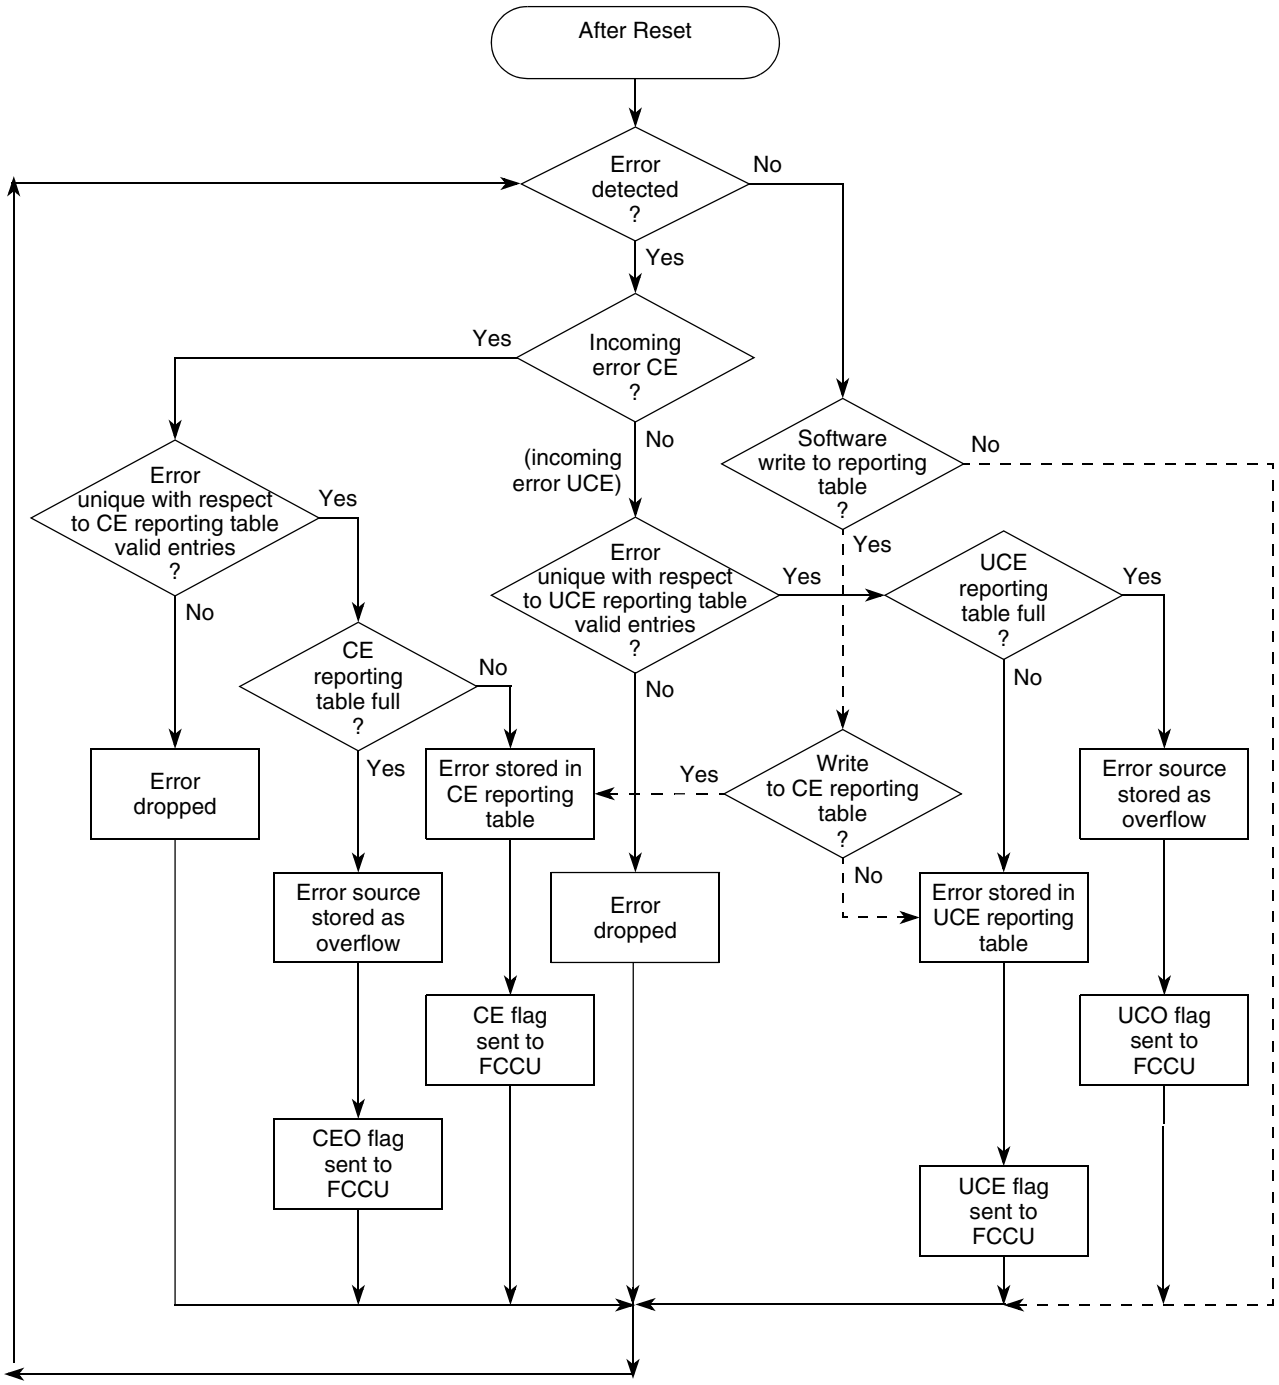

Figure 83-3. MEMU reporting table uniqueness check flow chart

83.5 External signal description

MEMU has no external signals.

83.6 Memory map and register definition

This section describes the registers on this module.

83.6.1 Overview

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

NOTE

The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

NOTE

The memory map in this section shows all the possible registers on this module and the associated offsets (which vary depending on the number of registers actually implemented). The actual availability, number and addresses of registers, and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

MEMU_CTRL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.

Table continues on the next page...

MEMU_CTRL field descriptions (continued)

Field	Description
17–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

83.6.3 Error flag register (MEMU_ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Access: User read/write

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MEMU_ERR_FLAG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: • a new Flash ECC uncorrectable error was detected. • a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SR_CE	System RAM ECCand MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECCand MBISTcorrectable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECCand MBIST Uncorrectable Error Detect flag. Asserted when: • A new System RAM ECCand MBIST uncorrectable error is detected • A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
29 SR_CEO	System RAM ECCand MBIST Correctable error Overflow flag. Asserted when the System RAM ECCand MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECCand MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECCand MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECCand MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECCand MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

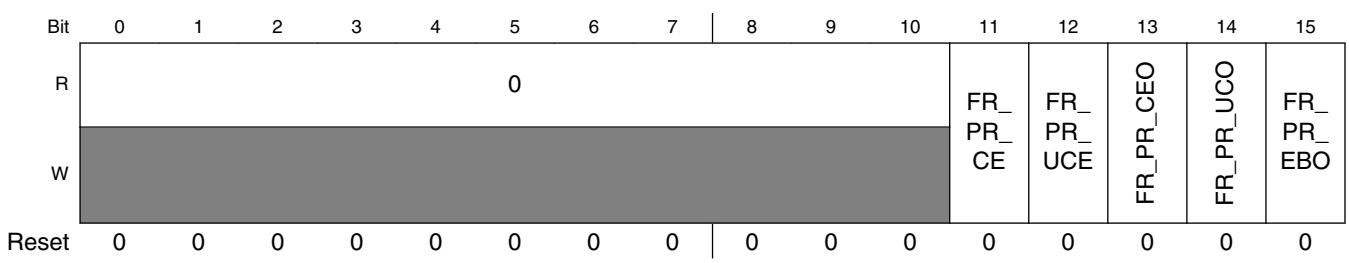
83.6.4 Debug register (MEMU_DEBUG)

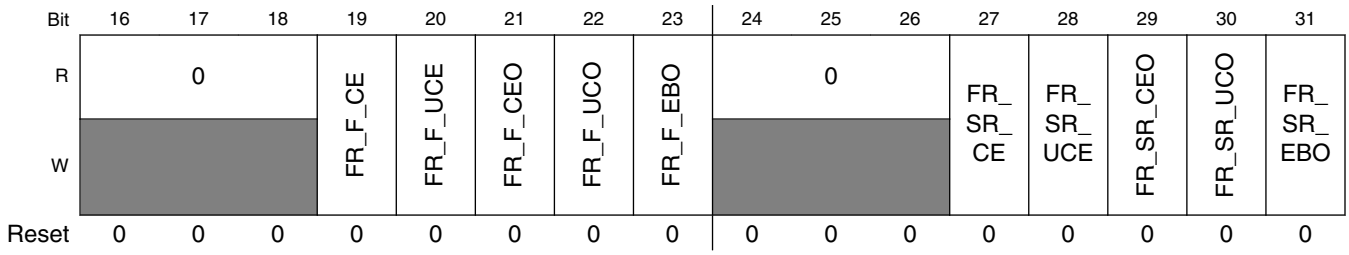
This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Access: User read/write

Address: 0h base + Ch offset = Ch





MEMU_DEBUG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 FR_PR_CE	Force Peripheral RAM Correctable Error detect flag. 0 Forcing is disabled. 1 Forces PR_CE flag going towards FCCU to 1.
12 FR_PR_UCE	Force Peripheral RAM Uncorrectable Error detect flag. 0 Forcing is disabled. 1 Forces PR_UCE flag going towards FCCU to 1.
13 FR_PR_CEO	Force Peripheral RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces PR_CEO flag going towards FCCU to 1.
14 FR_PR_UCO	Forces Peripheral RAM Uncorrectable Error overflow flag. 0 Forcing is disabled. 1 Forces PR_UCO flag going towards FCCU to 1.
15 FR_PR_EBO	Forces Peripheral RAM Error Buffer Overflow Flag. 0 Forcing is disabled. 1 Forces PR_EBO flag going towards FCCU to 1.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 FR_F_CE	Forces Flash Correctable Error detect flag 0 Forcing is disabled. 1 Forces F_CE flag going towards FCCU to 1.
20 FR_F_UCE	Forces Flash Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces F_UCE flag going towards FCCU to 1.
21 FR_F_CEO	Forces Flash Correctable Error overflow flag 0 Forcing is disabled. 1 Forces F_CEO flag going towards FCCU to 1.
22 FR_F_UCO	Forces Flash Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces F_UCO flag going towards FCCU to 1.

Table continues on the next page...

MEMU_DEBUG field descriptions (continued)

Field	Description
23 FR_F_EBO	Forces Flash Error buffer Overflow flag 0 Forcing is disabled. 1 Forces F_EBO flag going towards FCCU to 1.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FR_SR_CE	Forces System RAM Correctable Error detect flag 0 Forcing is disabled. 1 Forces SR_CE flag going towards FCCU to 1.
28 FR_SR_UCE	Forces System RAM Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces SR_UCE flag going towards FCCU to 1.
29 FR_SR_CEO	Forces System RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces SR_CEO flag going towards FCCU to 1.
30 FR_SR_UCO	Forces System RAM Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces SR_UCO flag going towards FCCU to 1.
31 FR_SR_EBO	Forces System RAM Error buffer Overflow Flag 0 Forcing is disabled. 1 Forces SR_EBO flag going towards FCCU to 1.

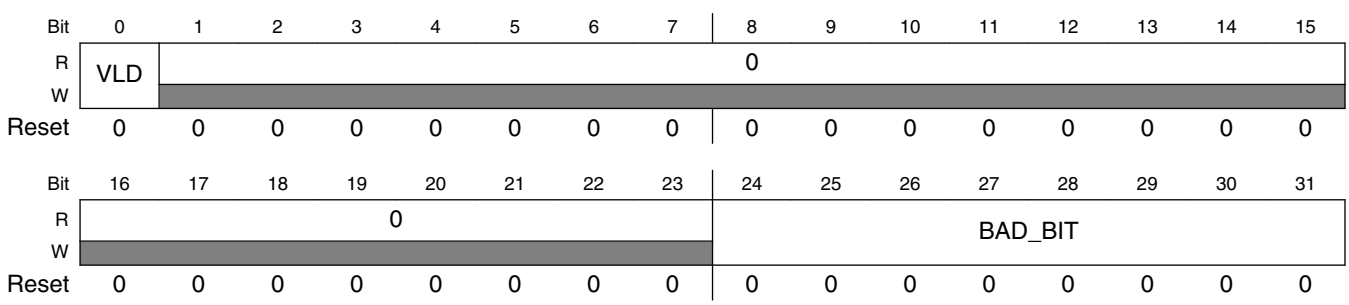
83.6.5 System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS*n*)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 20h offset + (8d × i), where i=0d to 9d



MEMU_SYS_RAM_CERR_STS*n* field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the correctable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BAD_BIT	Bad bit field. Indicates the bit position in RAM where the error is detected. This is also known as the syndrome. For non-BIST type of errors, this field is not used and reads as 0xFF. Any value other than 0xFF - Position of the bit in RAM where error is found. 0xFF - Invalid Bad Bit. This field should not be used when processing errors.

83.6.6 System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR*n*)

Access: User read/write

Address: 0h base + 24h offset + (8d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MEMU_SYS_RAM_CERR_ADDR*n* field descriptions

Field	Description
0–31 ERR_ADD	Error address field Indicates the address on which the error was detected.

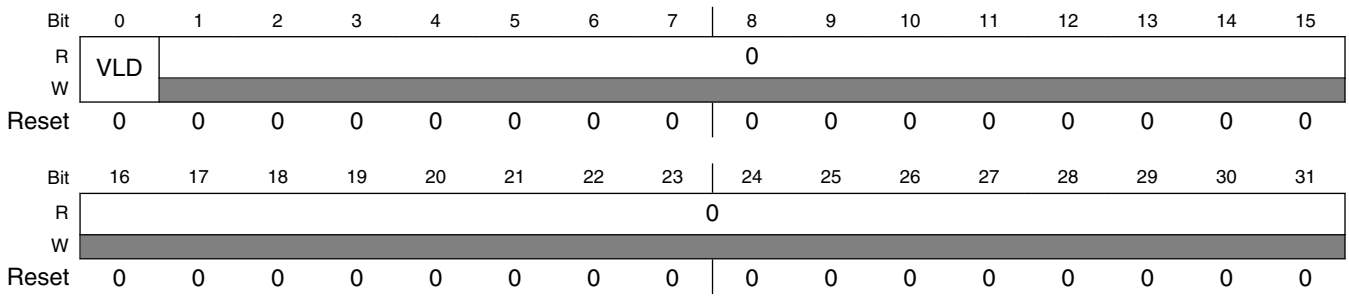
83.6.7 System RAM uncorrectable error reporting table status register (MEMU_SYS_RAM_UNCERR_STS)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 70h offset = 70h



MEMU_SYS_RAM_UNCERR_STS field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the uncorrectable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

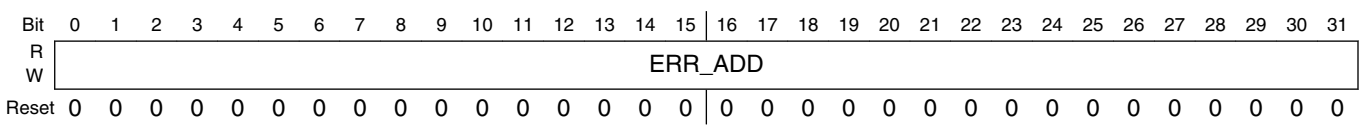
83.6.8 System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 74h offset = 74h



MEMU_SYS_RAM_UNCERR_ADDR field descriptions

Field	Description
0–31 ERR_ADD	Error address field. Indicates the address on which the error was detected. This field must be read-only when its corresponding valid bit (SYS_RAM_UNCERR_STS[VLD]) = 0.

83.6.9 System RAM concurrent overflow register (MEMU_SYS_RAM_OFLW*n*)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 78h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MEMU_FLASH_OFLW*n* field descriptions

Field	Description
0–31 OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in Handling overflows (Multiple error reporting) occurs.

83.7 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

83.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit ='1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (i.e. duplicate entries).

83.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

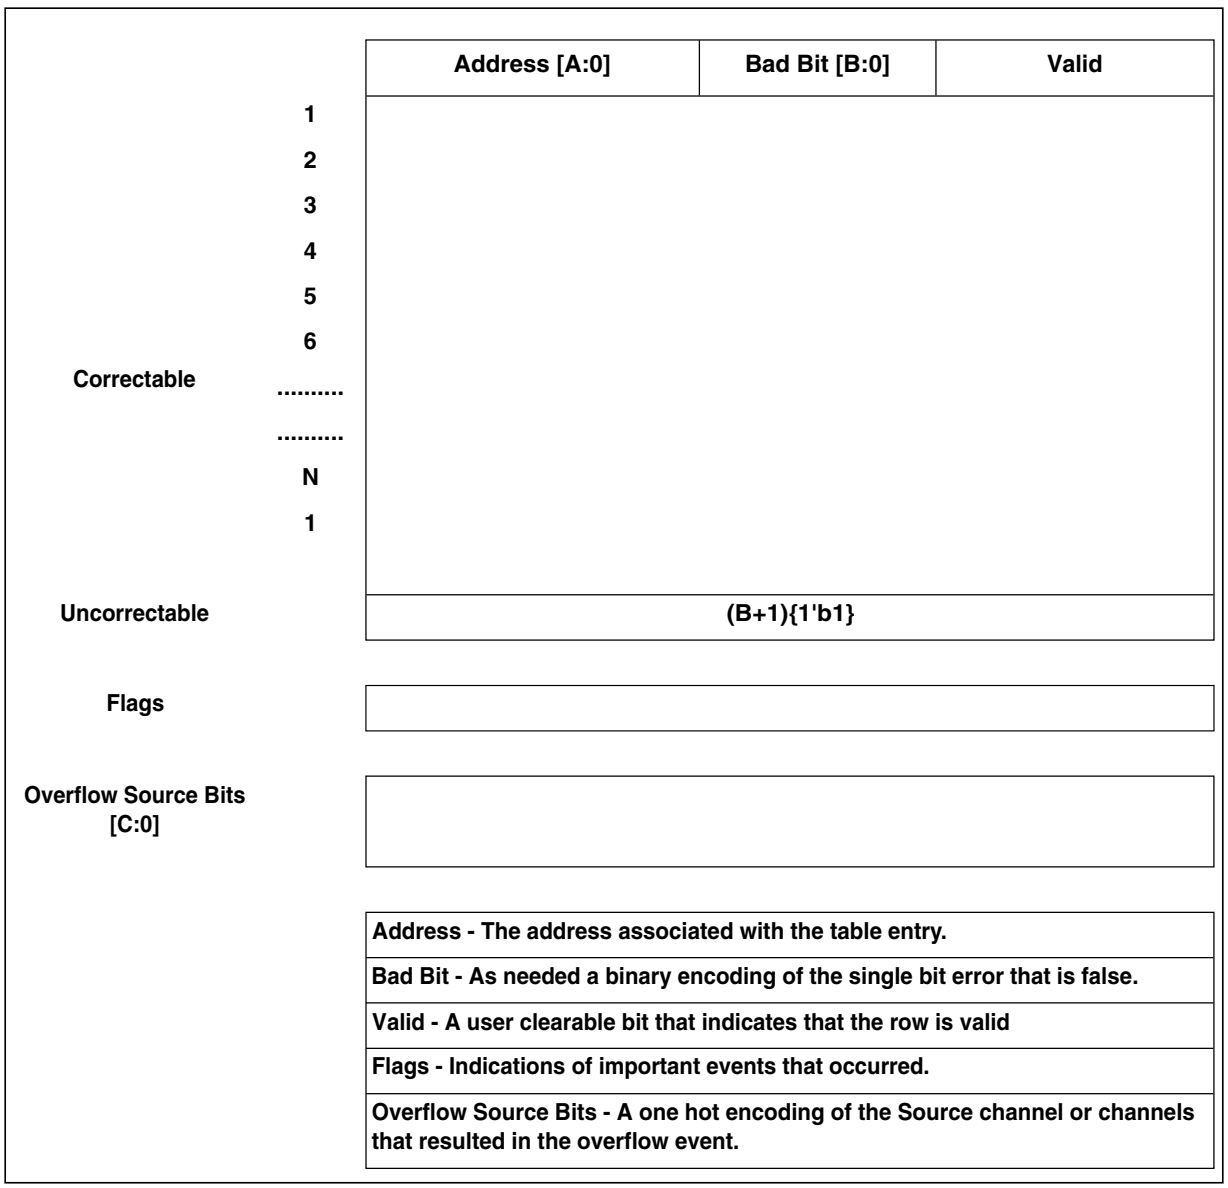

Figure 83-4. Generic representation of the reporting table of one MEMU reporting block

83.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
    - More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not "guarantee" that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
    - An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order i.e., if the error bit 31 reports an error, the bit 31 of the overflow register will be set to '1'.

Chapter 84
Indirect Memory Access (IMA)

84.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading and/or modifying data, including ECC check bits. This capability is useful for test activities, e.g., verifying ECC functionality.

The MPC5777M MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note

Not all SRAM data and ECC bits are accessible. See the Device Configuration chapter for details.

84.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note

All memory accesses by the processor cores are filtered through the MPU. There are no back doors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed—I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

84.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control Register (CDACNTL)
- Cache Debug Access Data Register (CDADATA)

These registers are summarized in the following sections.

84.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control Register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

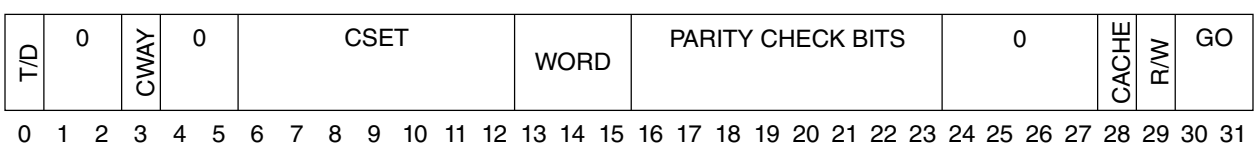

Figure 84-1. Cache Debug Access Control Register (CDACNTL)

The CDACNTL bits are described in Table 84-1.

Table 84-1. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected

Table continues on the next page...

Table 84-1. CDACNTL field descriptions (continued)

Bits	Name	Description
		1 Tag array selected
1–2	—	Reserved - read as zeros
3	CWAY	Cache Way. Specifies the cache way to be selected
4–5	—	Reserved - read as zeros
6–12	CSET	Cache Set. Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13–15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set
16–23	PARITY CHECK BITS	Parity check bits (I or D-cache) D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24–27	—	Reserved - read as zeros
28	CACHE	Cache Select. Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30–31	GO	GO command bits 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

84.2.1.2 Cache Debug Access Data Register (CDADATA)

The Cache Debug Access Data Register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

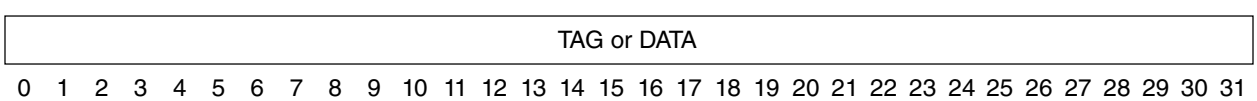

Figure 84-2. Cache Debug Access Data Register (CDADATA)

The CDADATA bits are described in Table 84-2.

Table 84-2. CDADATA field descriptions

Bits	Name	Description
0–31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0-notlocked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23 byte 2 24–31 byte 3

84.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status Register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

84.2.2.1 e2eECC Error Control/Status Register 0 (E2EECSR0)

The e2eECC Error Control/Status Register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

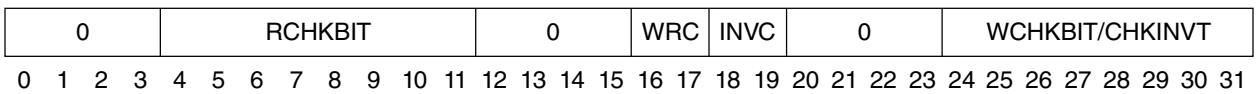

Figure 84-3. e2eECC Error Control/Status Register 0 (E2EECSR0)

The E2EECSR0 bits are described in Table 84-3.

Table 84-3. CDACNTL field descriptions

Bits	Name	Description
0–3	—	Reserved - read as zeros
4–11	RCHKBIT	Read Checkbits. This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12–15	—	Reserved - read as zeros
16–17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18–19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
20–23	—	Reserved - read as zeros

Table continues on the next page...

Table 84-3. CDACNTL field descriptions (continued)

Bits	Name	Description
24–31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask. This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

84.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Please note the following restrictions on memory access via IMA:

- ECC must be disabled prior to IMA write access. If ECC is enabled and a write access is attempted to ECC-bits, the write access is blocked and an error signal is forwarded to the FCCU and the corresponding error flag is set. Read access is always allowed.
- The IMA must be unlocked for reads

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note

Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

84.3.1 Features

The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data.
  - Writes have no effect.
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

84.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it to.

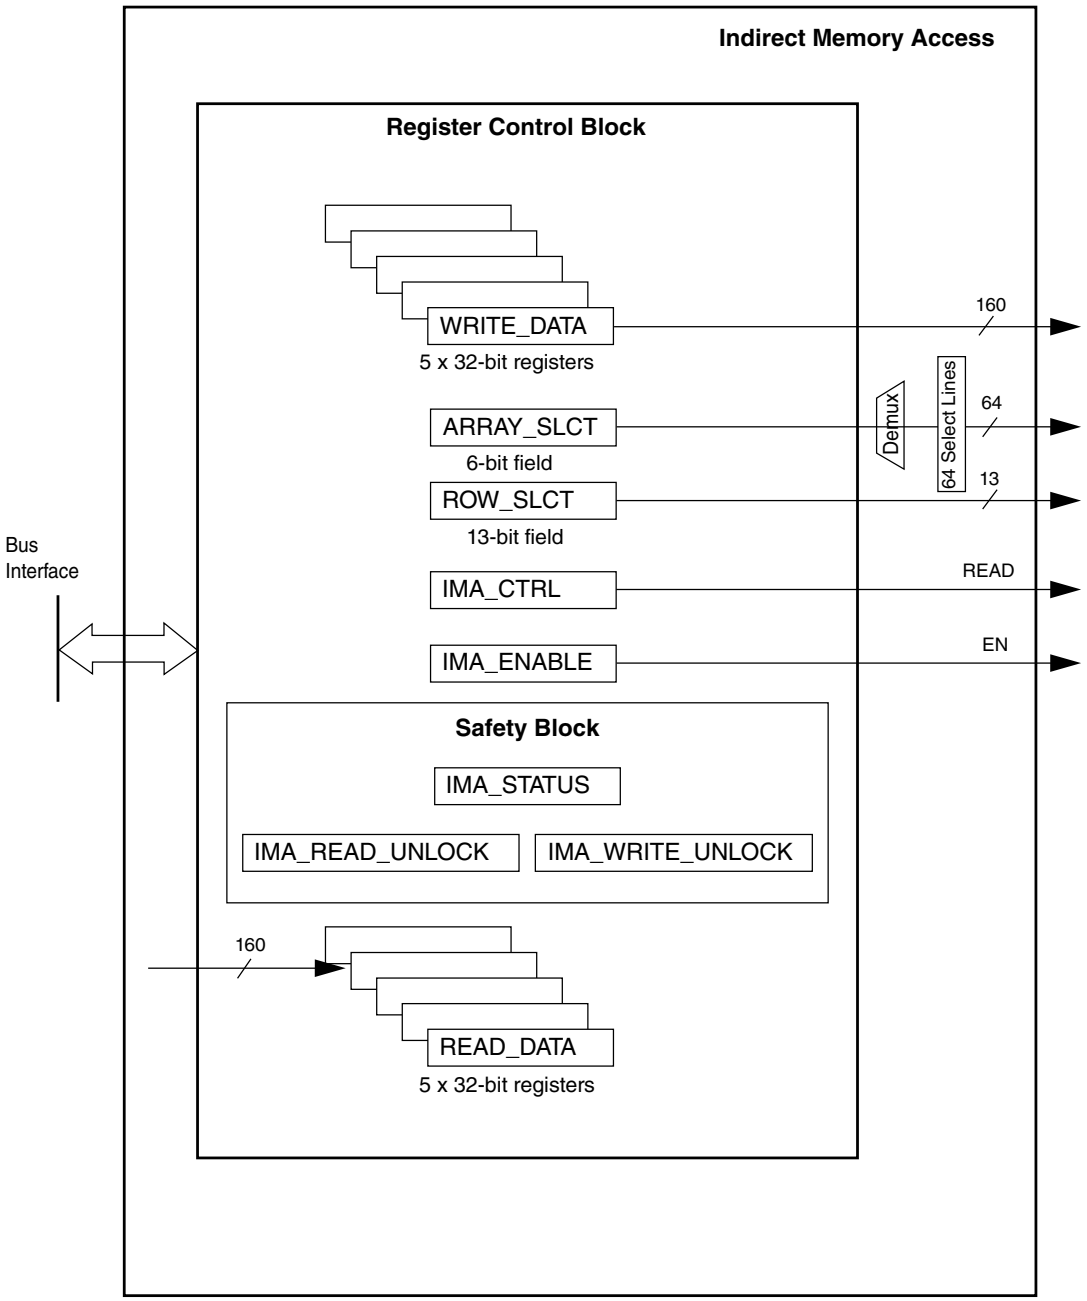

Figure 84-4. IMA block diagram

84.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map .

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

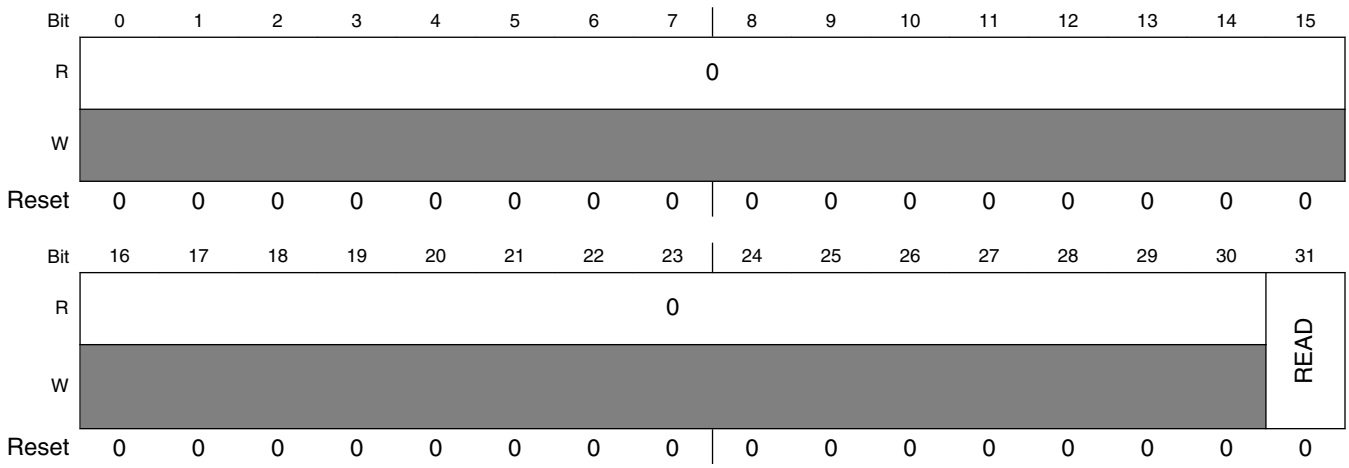
IMA memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control Register (IMA_CTRL)	32	R/W	0000_0000h	84.3.3.1/ 4380
4	Enable Access Register (IMA_ENABLE)	32	W	0000_0000h	84.3.3.2/ 4381
8	Status Register (IMA_STATUS)	32	R	0000_0101h	84.3.3.3/ 4382
C	RAM Select Register (IMA_SLCT)	32	R/W	0000_0000h	84.3.3.4/ 4383
10	Write Unlock Register (IMA_WRITE_UNLOCK)	32	R/W	0000_0000h	84.3.3.5/ 4384
14	Read Unlock Register (IMA_READ_UNLOCK)	32	R/W	0000_0000h	84.3.3.6/ 4384
2C	RAM Write Data Register 4 (IMA_WRITE_DATA_4)	32	R/W	0000_0000h	84.3.3.7/ 4385
30	RAM Write Data Register 3 (IMA_WRITE_DATA_3)	32	R/W	0000_0000h	84.3.3.8/ 4385
34	RAM Write Data Register 2 (IMA_WRITE_DATA_2)	32	R/W	0000_0000h	84.3.3.9/ 4386
38	RAM Write Data Register 1 (IMA_WRITE_DATA_1)	32	R/W	0000_0000h	84.3.3.10/ 4386
3C	RAM Write Data Register 0 (IMA_WRITE_DATA_0)	32	R/W	0000_0000h	84.3.3.11/ 4387
4C	RAM Read Data Register 4 (IMA_READ_DATA_4)	32	R	0000_0000h	84.3.3.12/ 4387
50	RAM Read Data Register 3 (IMA_READ_DATA_3)	32	R	0000_0000h	84.3.3.13/ 4388
54	RAM Read Data Register 2 (IMA_READ_DATA_2)	32	R	0000_0000h	84.3.3.14/ 4389
58	RAM Read Data Register 1 (IMA_READ_DATA_1)	32	R	0000_0000h	84.3.3.15/ 4389
5C	RAM Read Data Register 0 (IMA_READ_DATA_0)	32	R	0000_0000h	84.3.3.16/ 4390

84.3.3.1 Control Register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Address: 0h base + 0h offset = 0h



IMA_CTRL field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 READ	IMA Read. This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

84.3.3.2 Enable Access Register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															0
W																EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

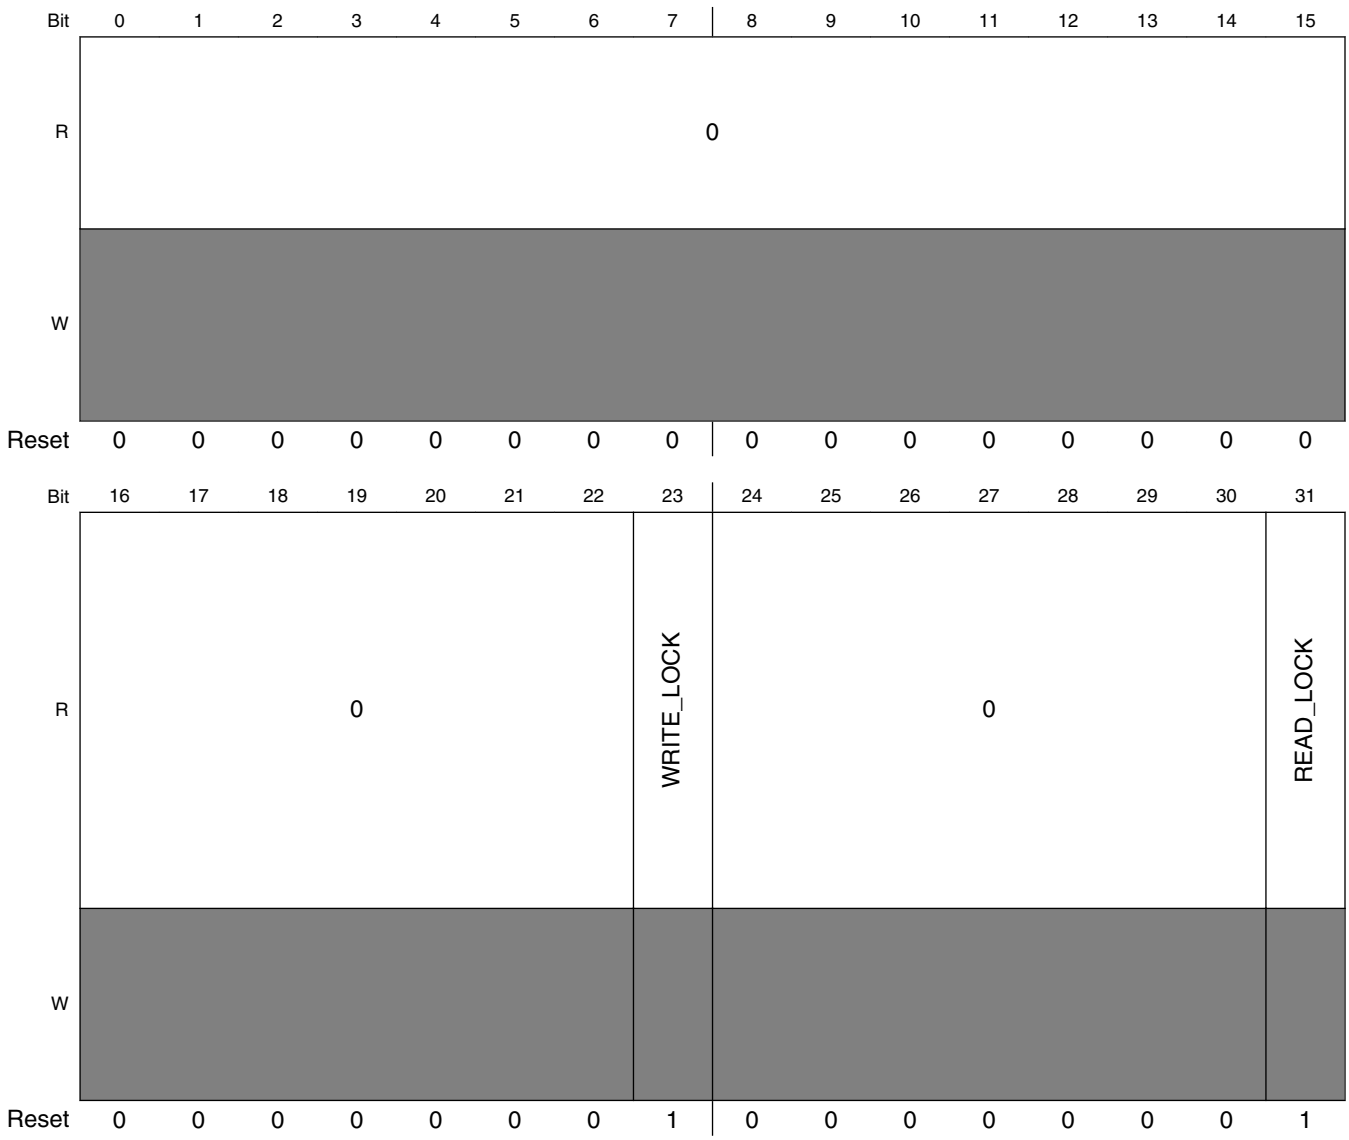
IMA_ENABLE field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 EN	IMA Enable. This bit controls RAM access initiation by the IMA. Once set, this bit is cleared after two clocks to provide an enable pulse. 0 No IMA access will occur or the IMA has finished the previous access. 1 Start an IMA access or an IMA access is occurring.

84.3.3.3 Status Register (IMA_STATUS)

The IMA Status Register shows the current status of the IMA as to which operations are unlocked.

Address: 0h base + 8h offset = 8h



IMA_STATUS field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IMA_STATUS field descriptions (continued)

Field	Description
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

84.3.3.4 RAM Select Register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, i.e., accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

NOTE

Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. See the Device Configuration chapter for details.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			ROW_SLCT													0										ARRAY_SLCT					
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IMA_SLCT field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is an 8 KB word RAM.
16–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IMA_SLCT field descriptions (continued)

Field	Description
26–31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

84.3.3.5 Write Unlock Register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes .

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WRITE_KEY																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IMA_WRITE_UNLOCK field descriptions

Field	Description
0–31 WRITE_KEY	Key to unlock the IMA. • 0x04A43F95 is the first key that has to be written to start the unlock process. • 0xE4A9EBF7 is the second key that has to be written to unlock the IMA.

84.3.3.6 Read Unlock Register (IMA_READ_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The READ_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for reads .

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	READ_KEY																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IMA_READ_UNLOCK field descriptions

Field	Description
0–31 READ_KEY	Key to unlock the IMA Read Access to RAMs. • 0xF06AB5BC is the first key that has to be written to start the unlock process. • 0x14081B56 is the second key that has to be written to unlock the IMA.

84.3.3.7 RAM Write Data Register 4 (IMA_WRITE_DATA_4)

The IMA_WRITE_DATA_n registers hold the data values to be written to the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WRITE_4

IMA_WRITE_DATA_0 field descriptions

Field	Description
0–31 WRITE_0	Contains write data bits[31:0] to be written to RAM.

84.3.3.12 RAM Read Data Register 4 (IMA_READ_DATA_4)

The IMA_READ_DATA_n registers hold the data values read from the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_n registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Address: 0h base + 4Ch offset = 4Ch

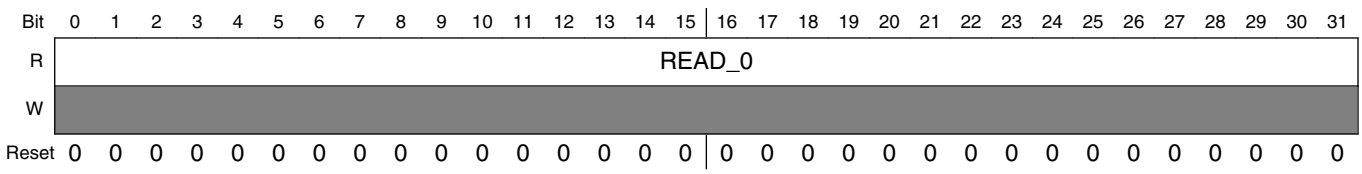
IMA_READ_DATA_1 field descriptions

Field	Description
0–31 READ_1	Contains read data bits[32:63] to be written to RAM.

84.3.3.16 RAM Read Data Register 0 (IMA_READ_DATA_0)

The IMA_READ_DATA_n registers hold the data values read from the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_n registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Address: 0h base + 5Ch offset = 5Ch



IMA_READ_DATA_0 field descriptions

Field	Description
0–31 READ_0	Contains read data bits[31:0] to be written to RAM.

84.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

84.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

84.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

84.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Please consult the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

84.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, please read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

84.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY
2. Write 0x14081B56 to READ_KEY

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY

84.3.4.3.3 Unlocking writes

(The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY
2. Write 0xE4A9EBF7 to WRITE_KEY

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

84.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

84.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections shows the different accesses that are available depending on the options.

84.3.4.5.1 Read access

Read Accesses are to expected to follow the sequence below

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.

2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

84.3.4.5.2 Write access

Write Accesses are to expected to follow the sequence below

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

84.3.5 Application information

warning

The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

Chapter 85
Fault Collection and Control Unit (FCCU)

85.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each RF:
    - No reset reaction
    - IRQ
    - Short functional reset
    - Long functional reset
    - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- The FCCU's configuration is lockable:

  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register.

- One of the error out pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power-on the error out pins have high impedance.[1] FCCU goes to operational state only on software request.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 16.67 ms.
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 safe (IRCOSC) clock cycles**.**

Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when the system clock is faster than the IRC clock.

85.1.1 Acronyms and abbreviations

Table 85-1. Acronyms and abbreviations

Term	Description
UF	Unrecoverable fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRCOSC	Internal RC Oscillator
IRQ	Interrupt request
MC_ME	Mode entry module
RF	Recoverable fault

Table continues on the next page...

1. Actual value depends on device specific setting at pad level.

Table 85-1. Acronyms and abbreviations (continued)

Term	Description
NMI	Non-maskable interrupts
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

85.2 Main features

- Management of recoverable faults
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - long functional reset request pulse
  - short functional reset request pulse
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock

85.3 Block diagram

The following figure is a top-level diagram of the FCCU module.

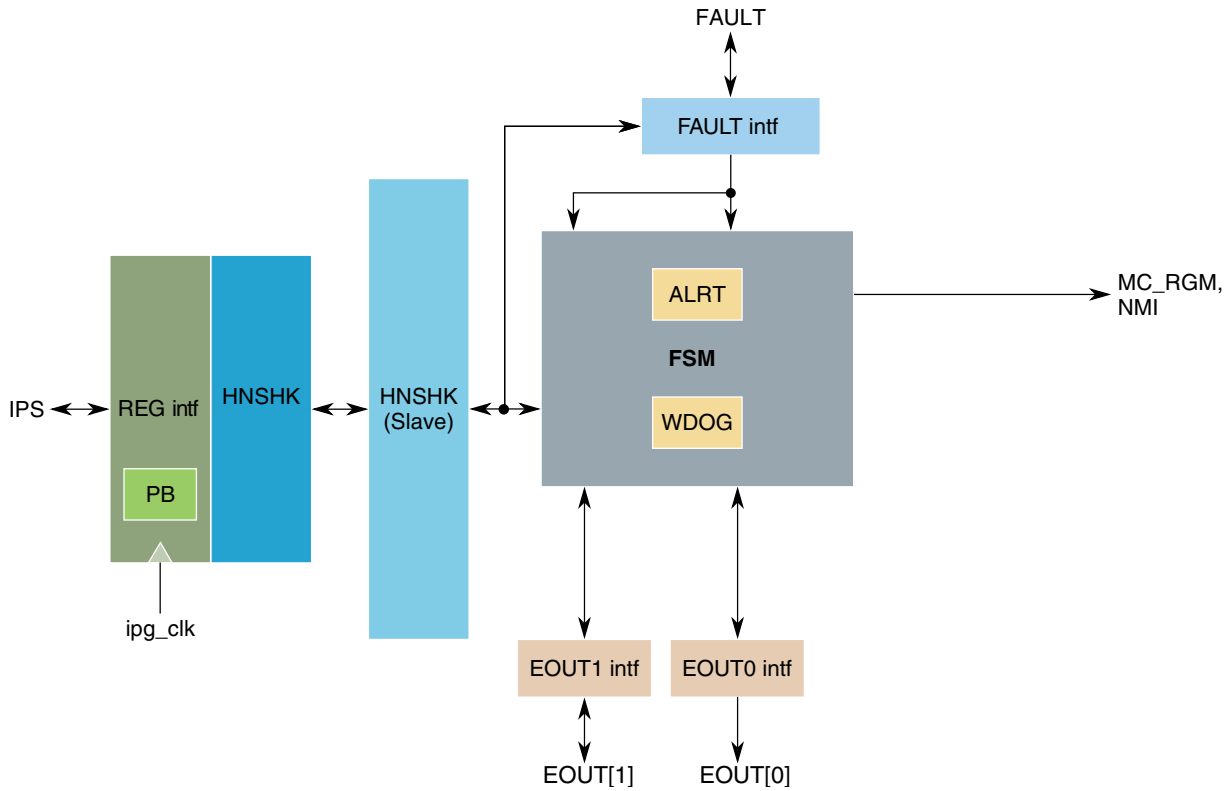


Figure 85-1. FCCU block diagram

The FCCU module includes the submodules listed in Table 85-2.

Table 85-2. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

85.4 Signal description

85.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in EOUT interface.

85.5 Functional description

85.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is '0'. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

The following types of reset are applicable:

- 'Destructive' reset: any type of reset related to a power failure condition that implies a complete system re-initialization
- Long 'functional' reset: implies the digital circuitry (most of it with some exceptions, such as the FCCU, STCU) initialization
- Short 'functional' reset: implies the digital circuitry (most of it with some exceptions, such as the FCCU, STCU) initialization.

For more information on each type of reset, see the MC_RGM and reset chapters.

85.5.2 FSM description

The FCCU module functionality is depicted by the FSM state diagram.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A sub-set of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, time-out, recoverable fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing 0xBC into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU_PERMNT_LOCK register.

  After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a time-out condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in CONFIG mode) are reset to their default values. The movement to NORMAL is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.

- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  - unmasked recoverable faults with the time-out disabled → the FCCU moves to the FAULT state
  - unmasked recoverable faults with the time-out enabled → the FCCU moves to the ALARM state
  - masked recoverable faults → the FCCU stays in NORMAL state

- ALARM: the FCCU moves into the ALARM state when an unmasked fault occurs and the time-out is enabled. The transition to the ALARM state goes along with an interrupt ALARM, if enabled. By definition, this fault may be recovered within a programmable time-out period, before it generates a transition to the FAULT state. The time-out is re-initialized if the FCCU state moves to the NORMAL state. The time-out restarts following the recovery from the FAULT state.
- FAULT: the FCCU moves into the FAULT state when one of the following condition occurs:
  - time-out related to a recoverable fault when the FCCU is in the ALARM state
  - unmasked recoverable faults with the time-out disabled

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

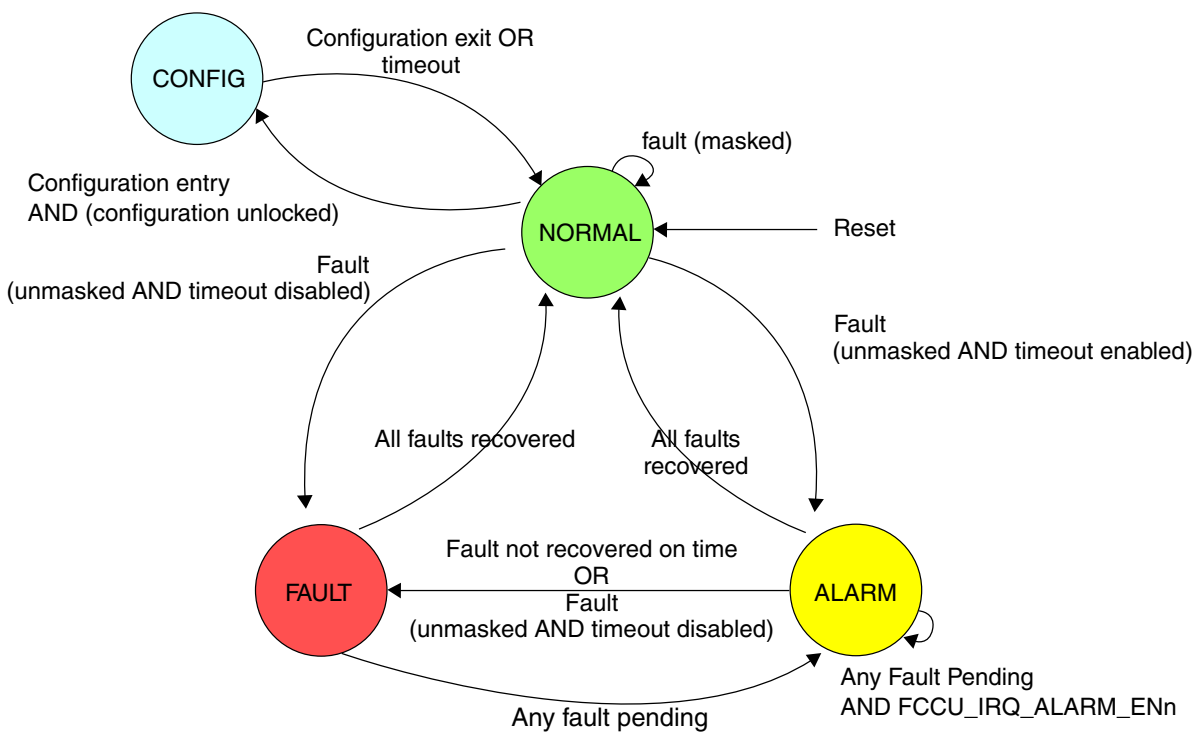

Figure 85-2. FCCU state diagram

85.5.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (recoverable) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a recoverable fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any recoverable fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the recoverable faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

85.5.4 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a recoverable FAULT management (ALARM state), see Figure 85-3 and Figure 85-4, is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)

- FCCU state transition ALARM → NORMAL

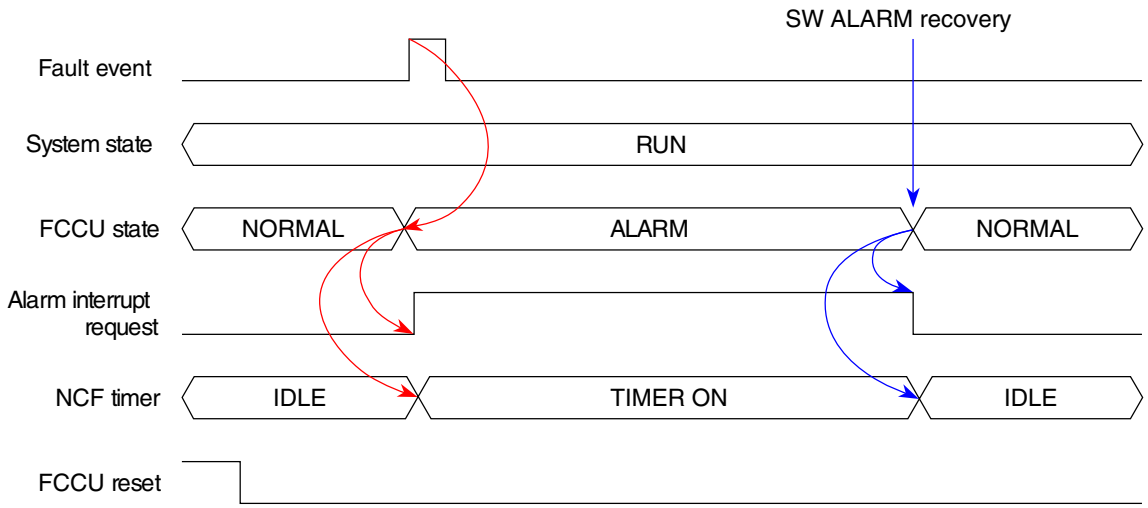

Figure 85-3. recoverable FAULT (ALARM state) recovery (a)

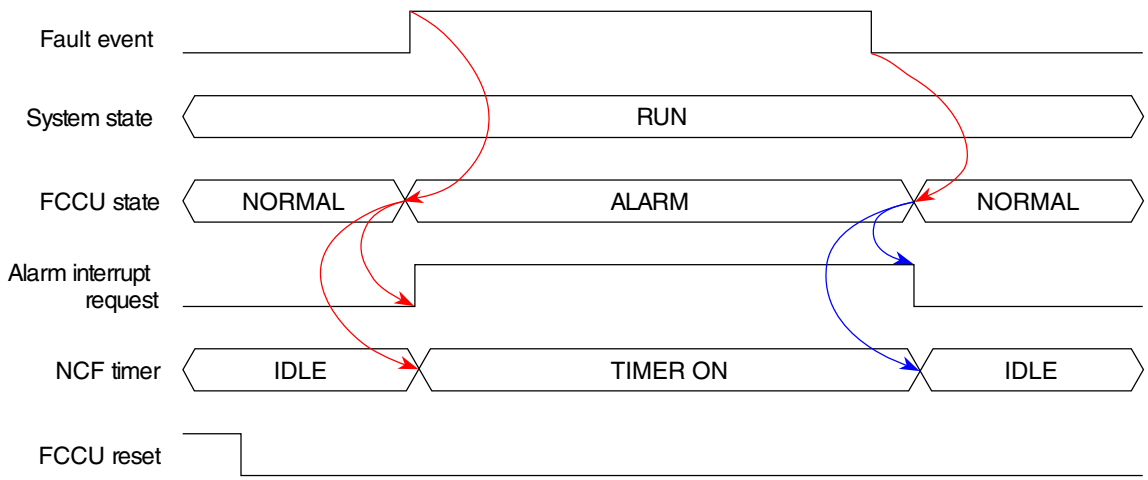

Figure 85-4. recoverable FAULT (ALARM state) recovery (b)

A typical sequence related to a recoverable FAULT management (ALARM → FAULT state), see Figure 85-5, is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)

- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
  - system state transition: SAFE → RUN

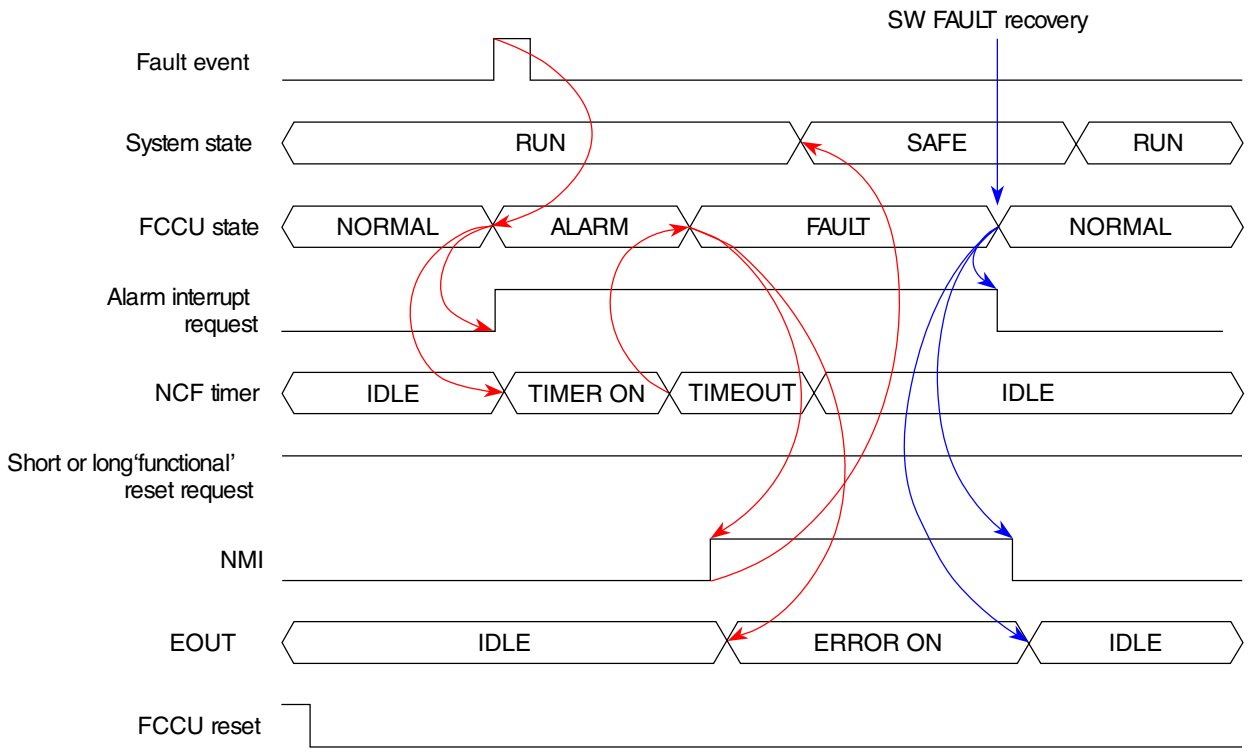

Figure 85-5. FAULT (ALARM → FAULT state) recovery

85.5.5 NMI/WKPU interface

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset is in progress, or
- Chip mode = RESET

and unmasked when:

- a SW change request of the chip mode is triggered

NOTE

The unmasked, internally generated NMI signal is applied to all CPU cores.

The following figure shows the logical scheme.

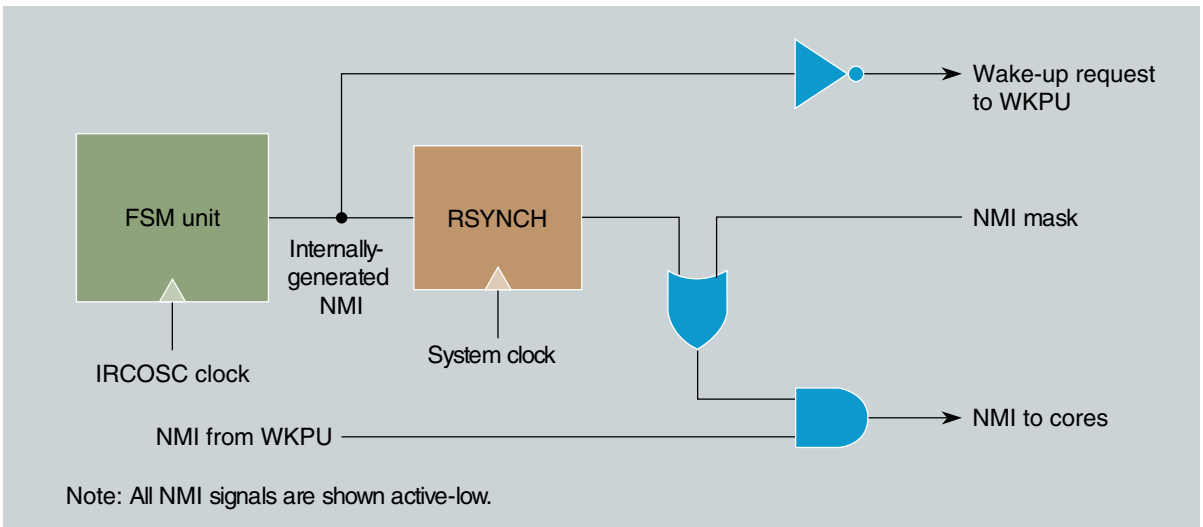

Figure 85-6. NMI/WKPU scheme

85.5.6 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

  The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.

3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable inside the STCU.

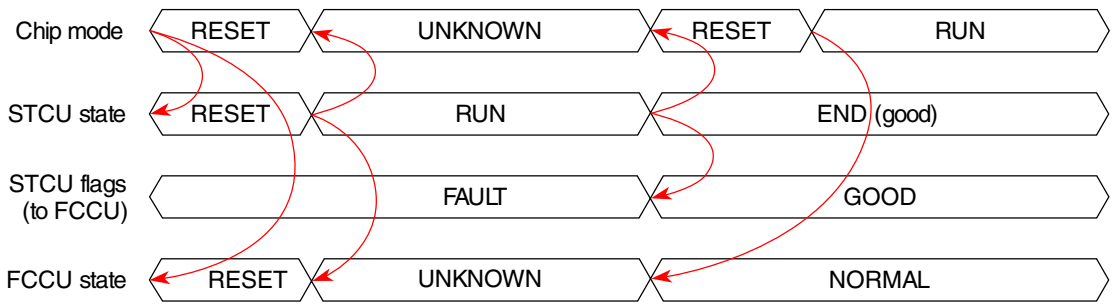

Figure 85-7. STCU-FCCU (case 1)

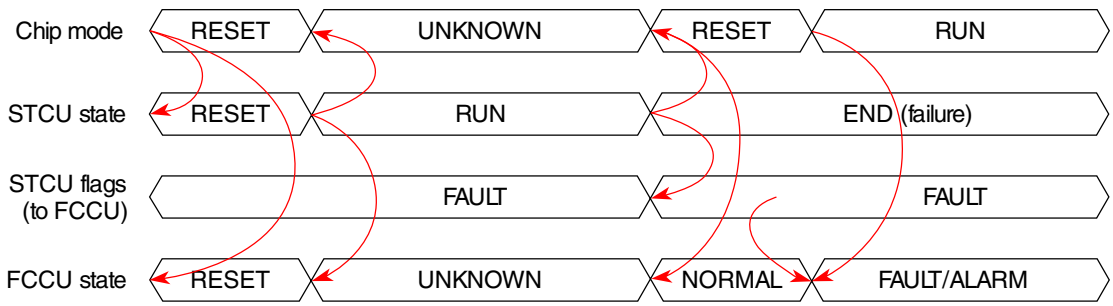

Figure 85-8. STCU-FCCU (case 2)

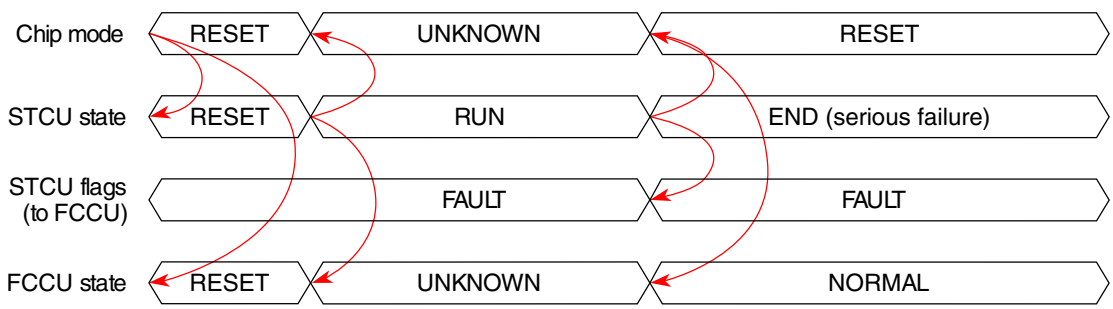

Figure 85-9. STCU-FCCU (case 3)

85.5.7 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world. These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z only when FCCU drives logic '1' else it drives logic '0' (when

FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register.Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual-rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS field in the FCCU_CFG register. For example, for PS = 0, EOUT[0] = 0 and EOUT[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0). In case of inverted polarity (FCCU_CFG.PS = 1) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual-rail or time-switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or viceversa and CONFIG to NORMAL). The EOUT protocol transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.
- fast switching mode: The EOUT protocol transition (NORMAL to FAULT or viceversa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occur in fast switching mode. It implies a frequency violation of the EOUT protocol.

With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual-rail or time-switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK, such as an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself

in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state.

The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

These resets influence the state of the failure indication pins:

- Power on reset
- Destructive reset
- FOSU time-out reset
- Pin reset (RESET_b)

Other resets should not influence the state of the failure indication pins.

NOTE

The transition from fault to config state is not possible but is shown to display the behavior in all four states — reset, normal, error, and config.

NOTE

FCCU remains in NORMAL state when fault is disabled; hence, "NA" (Not Applicable) appears in the following table.

NOTE

The following table is valid only after SW has written fccu_set_after_reset bit to 1.

Table 85-3. FCCU error pin behavior on STATE transitions

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

NOTE

During first configuration phase, EOUT pads will be hi-z state and thereafter, it will follow the configured EOUT protocol encoding.

85.5.7.1 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 85-4 and the related timing diagram is given in Figure 85-10 and Figure 85-11.

Table 85-4. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedence[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

Note

Figure 85-10 and Figure 85-11 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

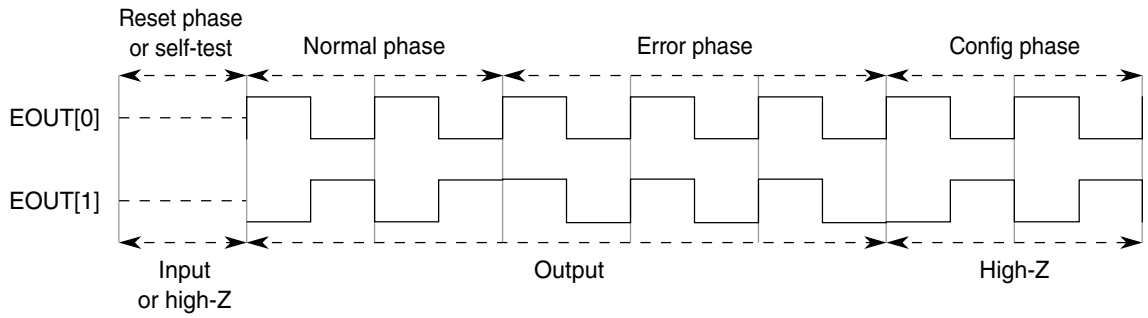

Figure 85-10. Dual-rail protocol (slow switching mode)

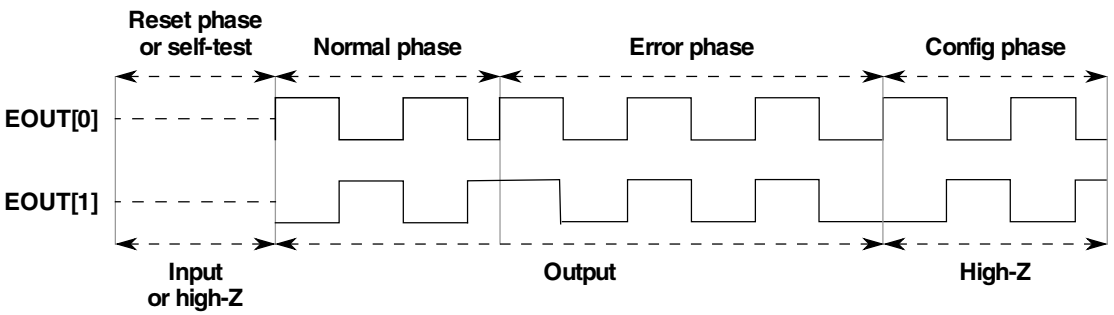

Figure 85-11. Dual-rail protocol (fast switching mode)

85.5.7.2 Time-switching protocol

The encoding scheme is given in Table 85-5 and the related timing diagram is given in Figure 85-12.

Table 85-5. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[2]

Note

Figure 85-12 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

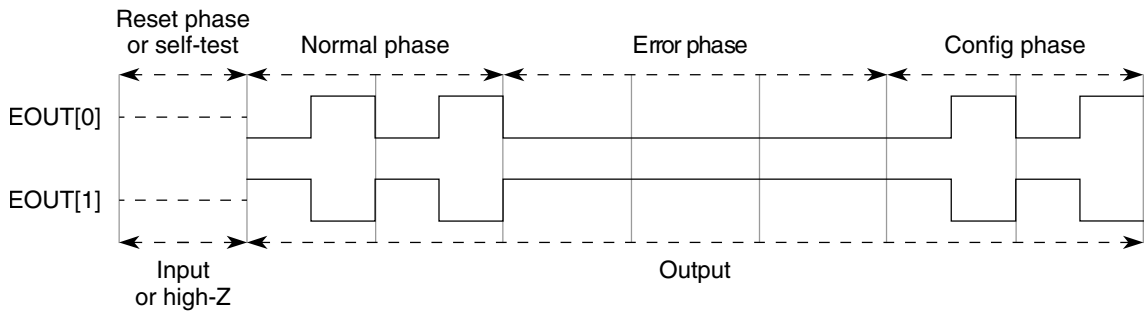

Figure 85-12. Time-switching protocol

85.5.7.3 Bi-stable protocol

The encoding scheme is given in Table 85-6 and the related timing diagram is given in Figure 85-13.

Table 85-6. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[3]

2. Actual value depends on device specific settings at pad level.
3. Actual value depends on device specific settings at pad level.

Note

Figure 85-13 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

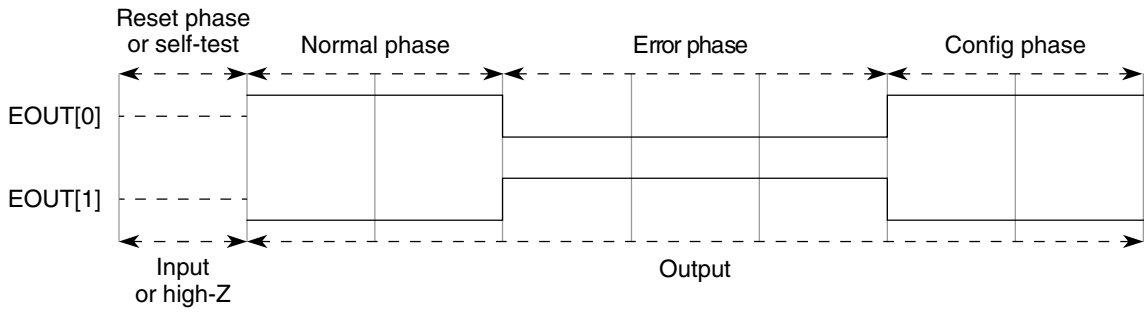

Figure 85-13. Bi-stable protocol

85.5.8 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

85.6 Register description

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

The FCCU generates an access error in the following cases:

- any write/read access to a reserved address
- any write access to the configuration registers not executed in the CONFIG state
- any write access to the Transient and Permanent Lock Register in any mode other than supervisor access mode

With the exception noted above, the FCCU registers are accessible (read/write) in both user and supervisor mode.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

85.6.1 Control Register (FCCU_CTRL)

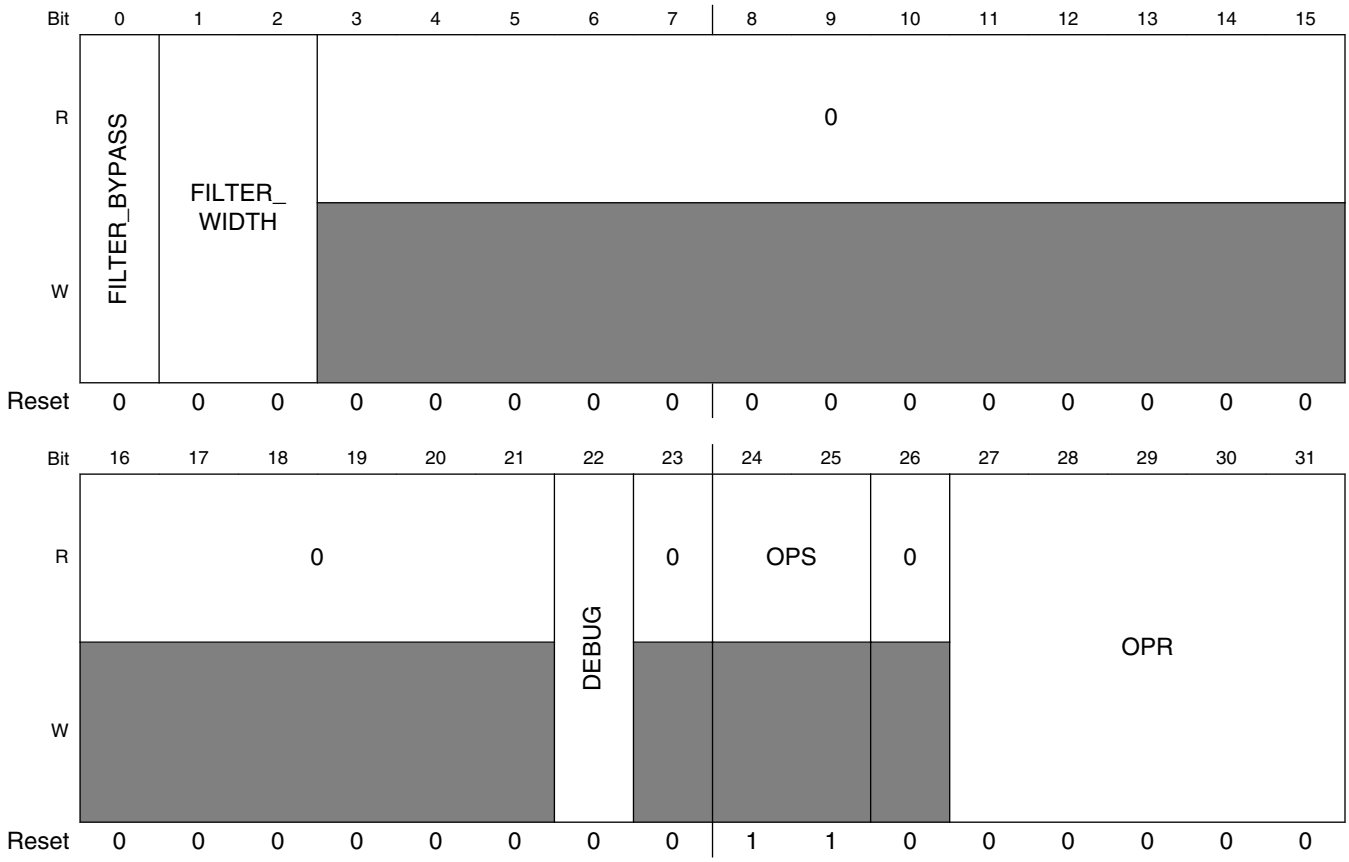
The FCCU_CTRL register allows the following operations to be executed:

- moving the FCCU state from the NORMAL state into the CONFIG state
- moving the FCCU state from the CONFIG state into the NORMAL state
- reading or to clear the RF status register
- reading the FCCU FSM status register
- reading or to clear the FCCU freeze registers
- reading the ALARM timer
- reading the Watchdog timer

Some critical operations require a key as defined in the FCCU_CTRLK register.

Register description

Address: 0h base + 0h offset = 0h



FCCU_CTRL field descriptions

Field	Description
0 FILTER_ BYPASS	Filter bypass 0 glitch filter not bypassed 1 glitch filter bypassed
1–2 FILTER_WIDTH	Filter width 00 filters glitches up to 50 µs 01 filters glitches up to 75 µs 10 filters glitches up to 100 µs 11 filters glitches up to 100 µs
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug mode entry When debug signal is asserted and this bit is set, FCCU moves into debug state and FCCU's FSM remains in the same state. 0 Normal operation 1 Put FCCU into debug mode
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation run. The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP12 must not be programmed. The OPR field is automatically set to OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The operations OP21-OP30 are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: • wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) • wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) • OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked 00000 No operation [OP0] 00001 Set the FCCU into the CONFIG state [OP1] 00010 Set the FCCU into the NORMAL state [OP2] 00011 Read the FCCU state (see the FCCU_STAT register) [OP3] 00100 Read the FCCU frozen status flags (see the N2AF_STATUS register) [OP4] 00101 Read the FCCU frozen status flags (see the A2FF_STATUS register) [OP5] 00110 Read the FCCU frozen status flags (see the N2FF_STATUS register) [OP6] 00111 Read the FCCU frozen status flags (see the F2AF_STATUS register) [OP7] 01000 Reserved 01001 Reserved 01010 Read the RF status register (see the FCCU_RF_S register) [OP10] 01011 Reserved 01100 RF status clear operation in progress (see the FCCU_RF_S register) [OP12] 01101 Clear the freeze status registers (see the freeze registers) [OP13] 01110 CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111 Clear the operation status (OPS=Idle) [OP15] 10000 Reserved 10001 Read the ALARM timer (see the FCCU_XTMR register) [OP17] 10010 Reserved

	10011 Read the CFG timer (see the FCCU_XTMR register) [OP19] 10100 Read the Error Pin low counter value (see XTMR Register (FCCU_XTMR)) [OP20] 10101-11110 Forbidden 11111 Reserved

85.6.2 CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

NOTE

The FCCU_CTRLK and FCCU_CTRL registers must be written with consecutive instructions. Both registers must be written as 32-bit values. Do not use read-modify-write instructions, such as bit field instructions, to modify these registers.

The FCCU_CTRLK register is not readable, a 0000_0000h value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Address: 0h base + 4h offset = 4h

* Notes:

- Reserved field: ("Reserved") Read-Only (RO)

FCCU_CFG field descriptions

Field	Description
0–6 Reserved	This field is reserved.
7 FCCU_SET_ AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts. After power-on the error out pins shall be in high impedance. **NOTE:** Actual value depends on the SoC settings at pad level. They will go to normal state only on software request, that is, this bit is set to '1'. It is SW's responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning. 0 FCCU's Error indication stops functioning and error pins are in HI-Z state. (note: actual value depends on the SoC settings at pad level) 1 Write to start FCCU functioning.
8–9 FCCU_SET_ CLEAR	Error pin state can be controlled by these bits These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z. **NOTE:** Actual value depends on the SoC settings at pad level. Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 or by going to CONFIG state. 00 FCCU acts independent of above SW control 01 Error Pin goes in Faulty state. 10 FCCU acts independent of above SW control. 11 write: Error Pin goes OK state (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault).
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved.
17–18 Reserved	This field is reserved.
19 OD	Open Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s) 0 push-pull 1 OD
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SM	Switching mode. SM has no effect on the bi-stable protocol. 0 EOUT protocol (dual-rail, time-switching) slow switching mode. 1 EOUT protocol (dual-rail, time-switching) fast switching mode.
22 PS	Polarity selection

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non-toggling in Error phase. 0 EOUT[1] active high, EOUT[0] active low 1 EOUT[1] active low, EOUT[0] active high
23–25 FOM	Fault Output Mode selection. **NOTE:** In Test *x* mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock. 000 Dual-Rail (default state) [EOUT[1:0]= outputs] 001 Time Switching [EOUT[1:0]= output to be used] 010 Bi-Stable 011 Reserved 100 Reserved 101 Test0 (controlled by FCCU_EOUT register) [EOUT[0]= input, EOUT[1]= output] 110 Test1 (controlled by FCCU_EOUT register) [EOUT[0]= output, EOUT[1]= output] 111 Test2 (controlled by FCCU_EOUT register) [EOUT[0]= output, EOUT[1]= input]
26–31 Reserved	This field is reserved.

85.6.4 RF Configuration Register (FCCU_RF_CFG*n*)

NOTE

The reset value is chip-specific. See the chip-specific FCCU information.

FCCU_RF_CFGx registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 85-7 shows FCCU RF configuration register channels.

Table 85-7. FCCU RF configuration register channels

Address offset	Register name	Channel range (x) (bit location [0:31])

FCCU_RF_CFG*n* field descriptions

Field	Description
0–31 RFCx	Recovereable fault configuration. The recoverable fault configuration defines the fault recovery mode. HW recoverable faults are self recovered (status flag clearing and related) if the root cause (input fault) has been removed. SW recoverable faults are recovered (status flag clearing) by SW clearing of the related status flag. See Table 85-7 for register offset to channel number relationship. 0 HW recoverable fault 1 SW recoverable fault

85.6.5 RFS Configuration Register (FCCU_RFS_CFG*n*)

NOTE

The reset value is chip-specific. See the chip-specific FCCU information.

The FCCU_RFS_CFGx registers contain the configuration of each recoverable fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.

Table 85-8 shows FCCU RFSNCFS configuration register channels.

Table 85-8. FCCU RFS configuration register channels

FCCU_RFS_CFG*n* field descriptions

Field	Description
0–31 RFSCx	Recovereable fault state configuration See Table 85-8 for register offset to channel number relationship. **NOTE:** The reset value is chip-specific. See the chip-specific FCCU information for details. 00 No reset reaction 01 Short functional reset request pulse (FAULT state reaction) 10 Long functional reset request pulse (FAULT state reaction) 11 No reset reaction

85.6.6 UF Status Register (FCCU_RF_S*n*)

The FCCU_RF_Sx register contains the latched fault indication collected from the recovereable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the time-out (FCCU_TO register) is elapsed before recovering from the fault.

The time-out is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register.
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_RF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_RF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_RF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable fault

Table 85-9 shows FCCU RF status register channels.

Table 85-9. FCCU RF status register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
80h	FCCU_RF_S0	RFS[31:0]
84h	FCCU_RF_S1	RFS[63:32]
88h	FCCU_RF_S2	RFS[95:64]
8Ch	FCCU_RF_S3	RFS[127:96]

FCCU_RF_S*n* field descriptions

Field	Description
0–31 RFSx	Recoverable fault status. The status bits related to the recoverable fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. See Table 85-9 for register offset to channel number relationship. 0 No "recoverable" fault latched 1 "Recoverable" fault latched

85.6.7 RF Key Register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

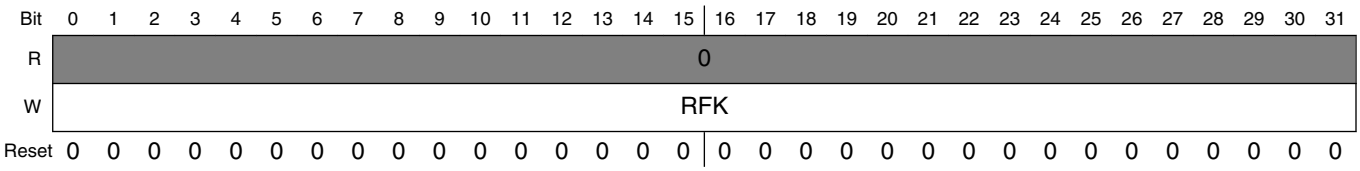
1. Write the key into the FCCU_RFK register.

2. Clear the status (flag) bit RFSx .

The key must be written for each FCCU_RF_Sx clear operation.

The FCCU_RFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h



FCCU_RFK field descriptions

Field	Description
0–31 RFK	recoverable fault key = AB34_98FEh

85.6.8 RF Enable Register (FCCU_RF_E*n*)

NOTE

The reset value is chip-specific. See the chip-specific FCCU information.

The FCCU_RF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Table 85-10 shows FCCU RFE enable register channels.

Table 85-10. FCCU RF enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
94h	FCCU_RF_E0	RFE[31:0]

FCCU_RF_E*n* field descriptions

Field	Description
0–31 RFEx	Recoverable fault enable See Table 85-10 for register offset to channel number relationship. **NOTE:** The reset value is chip specific. See the chip-specific FCCU information for details. 0 No actions following the respective recoverable fault assertion 1 FCCU moves to ALARM or FAULT state

85.6.9 RF Time-out Enable Register (FCCU_RF_TOE*n*)

NOTE

The reset value is chip-specific. See the chip-specific FCCU information.

The FCCU_RF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective time-out is disabled (RFTOEx is cleared) and the recoverable fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related recovereable fault is asserted. The timer (preset with the time-out value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 85-11 shows FCCU RF timeout enable register channels.

Table 85-11. FCCU RF timeout enable register channels

FCCU_RF_TOE*n* field descriptions

Field	Description
0–31 RFTOEx	Fault time-out enable See Table 85-11 for register offset to channel number relationship. **NOTE:** The reset value is chip specific. See the chip-specific FCCU information for details. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

85.6.10 RF Time-out Register (FCCU_RF_TO)

The RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state. The alarm time-outs value should be programmed less than the FOSU_COUNT, elsedestructive resets may be generated by FOSU time-out.

NOTE

This register is writable only when the FCCU is in the CONFIG state.

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_RF_TO field descriptions

Field	Description
0–31 TO	Recoverable fault timeout Timeout = (TO) × $T_{RC16MHz}$

85.6.11 CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the time-out, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. The description for a configuration register will contain a NOTE that it is writable only in the CONFIG state. The watchdog time-out is clocked with the IRCOSC clock (16 MHz). The default time-out value is 4.096 ms.Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

NOTE

The FCCU_CFG_TO register is writable in any state excluding the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog time-out the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

Address: 0h base + B8h offset = B8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

85.6.12 IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)
- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 85-12 shows Bi-stable encoding.

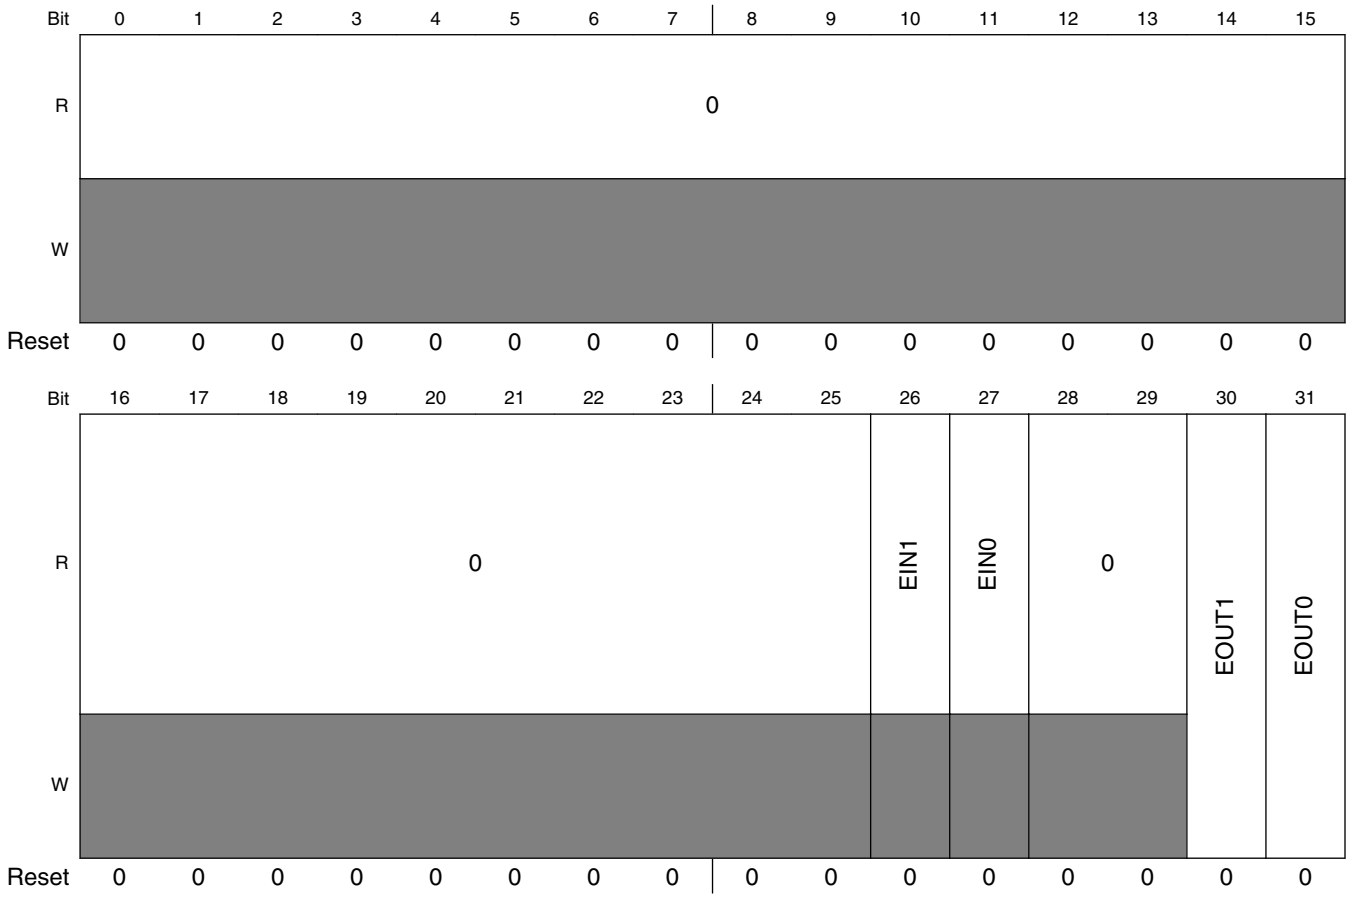
Table 85-12. Bi-stable encoding

Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/ read operation of the FCCU_EINOUT register.

Address: 0h base + BCh offset = BCh



FCCU_EINOUT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIN1	Error input 1. The EIN1 captures the respective fccu_ein[1] input signal. While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[1] pin. 0 when fccu_ein[1] = 0 1 when fccu_ein[1] = 1
27 EIN0	Error input 0.The EIN0 captures the fccu_ein[0] input signal. While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[0] pin. 0 when fccu_ein[0] = 0 1 when fccu_ein[0] = 1
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. 0 force EOUT[1] = 0 1 force EOUT[1] = 1

Table continues on the next page...

FCCU_EINOUT field descriptions (continued)

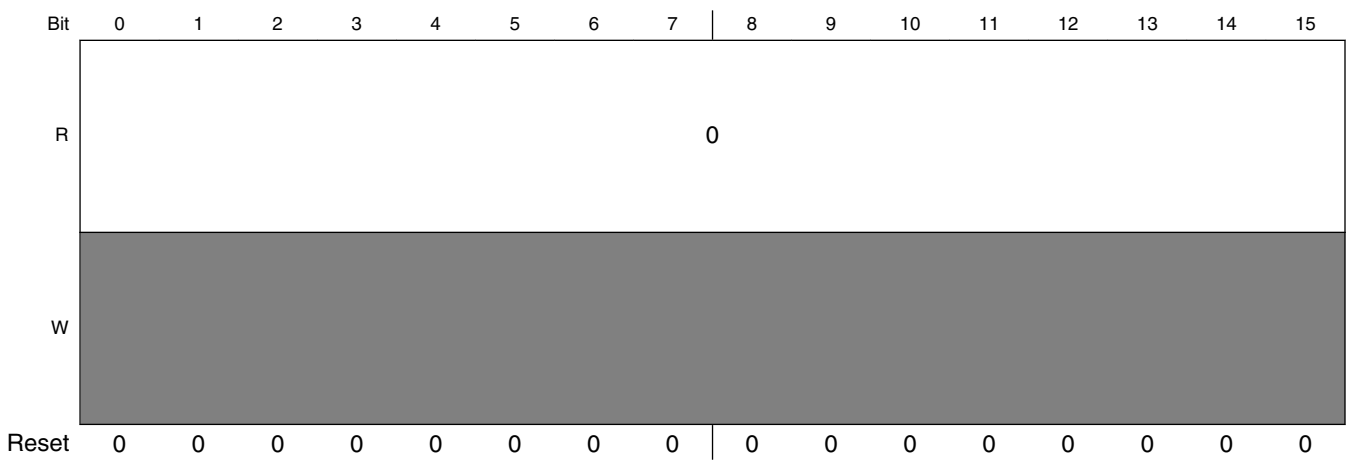
Field	Description
31 EOUT0	Error out 0 (significative only if the FCCU_CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value. 0 force EOUT[0] = 0 1 force EOUT[0] = 1

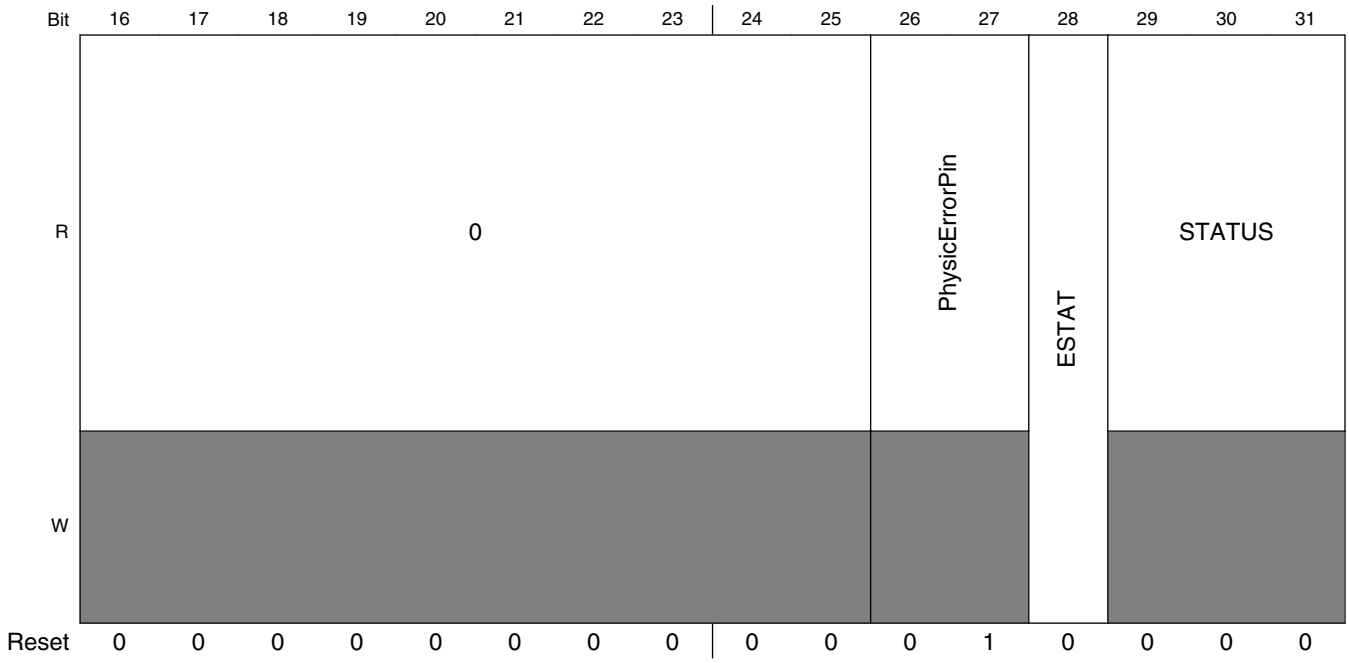
85.6.13 Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Address: 0h base + C0h offset = C0h





FCCU_STAT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PhysicErrorPin	PhysicErrorPin : Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0 1: Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol. 0 Error Pin is at logical 0 1 Error Pin is at logical 1
28 ESTAT	Current Error Pin Status. SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in non-faulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and SW can write it to 0 and after one cycle the bit reads 1 again. 0 System is OPERATIONAL (OK). 1 System is in FAULT state. This state is taken from the FCCU Eout logic (that is, as late as possible).
29–31 STATUS	FCCU Status 000 NORMAL state 001 CONFIG state 010 ALARM state 011 FAULT state 100 Reserved

Table continues on the next page...

FCCU_STAT field descriptions (continued)

Field	Description
	101 Reserved 110 Reserved 111 Reserved

85.6.14 NA Freeze Status Register (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "recoverable" source (fccu_rf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

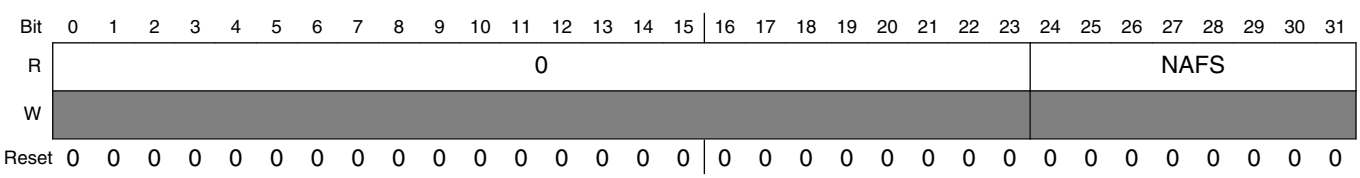
The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h



FCCU_N2AF_STATUS field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 NAFS	Normal to Alarm Frozen Status **NOTE:** This field can be read and written but writing 1 has no effect. 00000000 No transition from NORMAL to ALARM state 00000001 NORMAL to ALARM state transition cause => fccu_rf[0] fault

85.6.15 AF Freeze Status Register (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the time-out trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

Address: 0h base + C8h offset = C8h

85.6.16 NF Freeze Status Register (FCCU_N2FF_STATUS)

The N2FF_STATUS register contains a unique code to identify the source of the recoverable fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + CCh offset = CCh

85.6.18 RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a recovereable fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

Address: 0h base + DCh offset = DCh

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 FRFC	FRFC : Fake recoverable fault code **NOTE:** Only writing to this register, fake fault injection occurs, writing 00 and default value being zero give different results. 00h: Fake recoverablefault injection at recoverablefault source 0 01h: Fake recoverablefault injection at recoverablefault source 1 02h: Fake recoverablefault injection at recoverablefault source 2 ... 7Fh: Fake recoverablefault injection at recoverablefault source 127

85.6.19 IRQ Status Register (FCCU_IRQ_STAT)

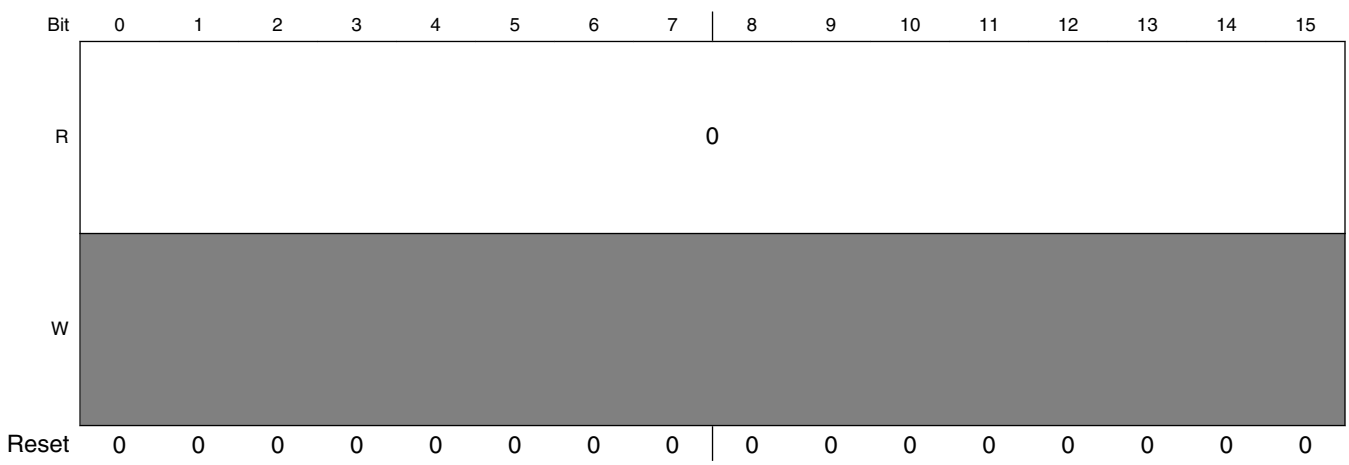
The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:

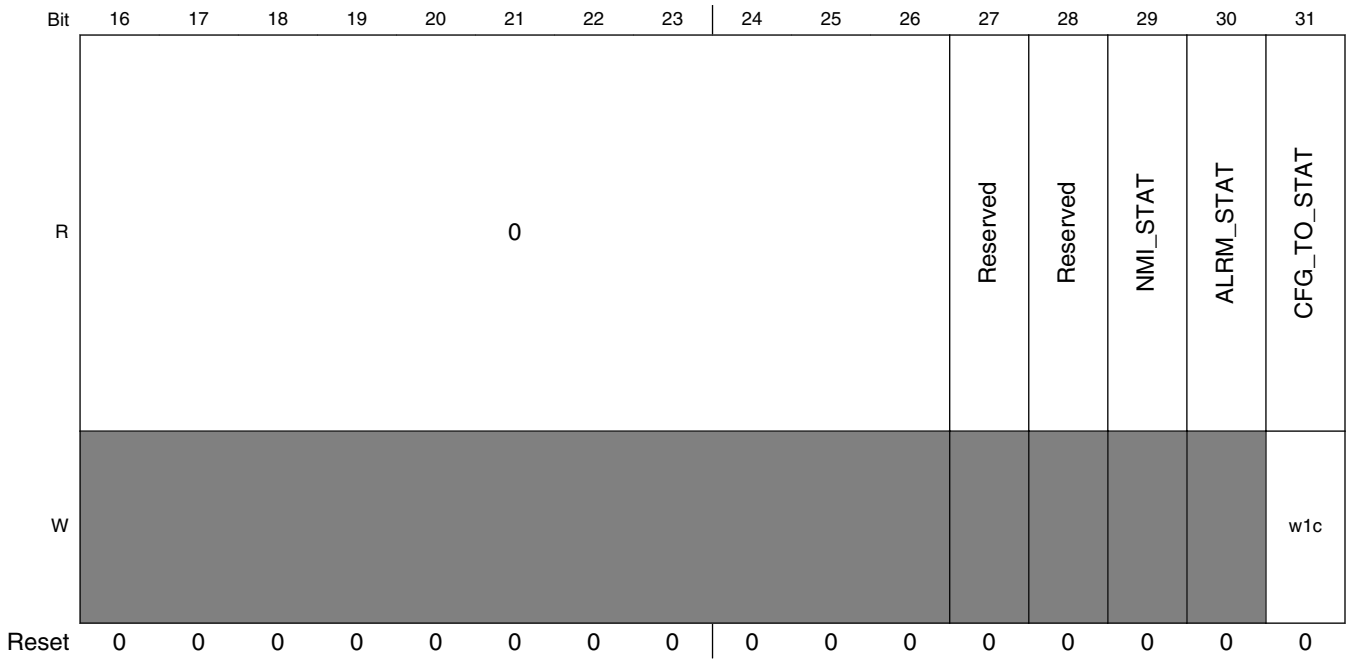
- Configuration time-out error
- Alarm interrupt
- NMI interrupt

The configuration time-out interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h





FCCU_IRQ_STAT field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved.

29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CFG_TO_IEN	Configuration Time-out Interrupt Enable 0 Configuration time-out interrupt disabled 1 Configuration time-out interrupt enabled

85.6.21 XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked on the IRCOSC clock.

[BLG_FCCU_0045][Covers: Saf3554]ETMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it goes high at the end of the T_min period from the last fault trigger.[end]

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   - OP17

- OP19
- OP20

2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 85-13 shows Timer state/value.

Table 85-13. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh
ETMR	00000000h	00000000h	00000000h	Running

Address: 0h base + E8h offset = E8h

FCCU_XTMR field descriptions

Field	Description
0–31 XTMR	Alarm/Watchdog/Safe request timer The current timer value is measured in IRCOSC clock cycles. These bits can be read by the software.

85.6.22 MCS Register (FCCU_MCS)

NOTE

The reset value is chip-specific. See the chip-specific FCCU information.

The FCCU_MCS register contains a queue of the last four chip modes as defined by the Mode Entry module (MC_ME). MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the chip mode has been captured. The chip mode is provided by the MC_ME synchronous to the system clock whereas the FCCU captures the mode with the IRCOSC clock; therefore some uncertainty must be considered regarding the FAULT state indication.

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

FCCU_MCS field descriptions

Field	Description
0 VL3	Valid It indicates that the correspondent MCS3 and FS3 fields are valid. 0 MCS3, FS3 fields are not significative 1 MCS3, FS3 fields are significative
1 FS3	Fault status It indicates that the correspondent MCS3 field has been captured when the FCCU is in FAULT state. 0 MCS3 field captured in any state different from the FAULT state 1 MCS3 field captured in FAULT state
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MCS3	MCS3: State of MC modules The MCS3 is the state of MC modules . MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual .
8 VL2	Valid It indicates that the correspondent MCS2 and FS2 fields are valid. 0 MCS2, FS2 fields are not significative 1 MCS2, FS2 fields are significative
9 FS2	Fault status It indicates that the correspondent MCS2 field has been captured when the FCCU is in FAULT state. 0 MCS2 field captured in any state different from the FAULT state 1 MCS2 field captured in FAULT state
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

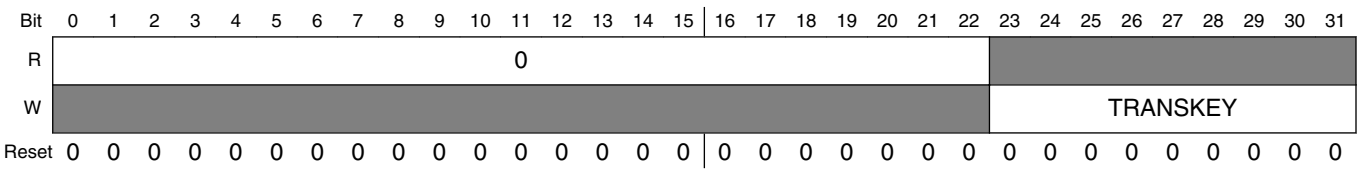
FCCU_MCS field descriptions (continued)

Field	Description
12–15 MCS2	MCS2: State of MC modules The MCS2 is the state of MC modules. MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual.
16 VL1	Valid It indicates that the correspondent MCS1 and FS1 fields are valid. 0 MCS1, FS1 fields are not significative 1 MCS1, FS1 fields are significative
17 FS1	Fault status It indicates that the correspondent MCS1 field has been captured when the FCCU is in FAULT state. 0 MCS1 field captured in any state different from the FAULT state 1 MCS1 field captured in FAULT state
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 MCS1	MCS1: State of MC modules The MCS1 is the state of MC modules. MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual.
24 VL0	Valid It indicates that the correspondent MCS0 and FS0 fields are valid. 0 MCS0, FS0 fields are not significative 1 MCS0, FS0 fields are significative
25 FS0	Fault status It indicates that the correspondent MCS0 field has been captured when the FCCU is in FAULT state. 0 MCS0 field captured in any state different from the FAULT state 1 MCS0 field captured in FAULT state
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MCS0	MCS0: State of MC modules The MCS0 is the state of MC modules. MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual.

85.6.23 Transient Lock Register (FCCU_TRANS_LOCK)

The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.

Address: 0h base + F0h offset = F0h



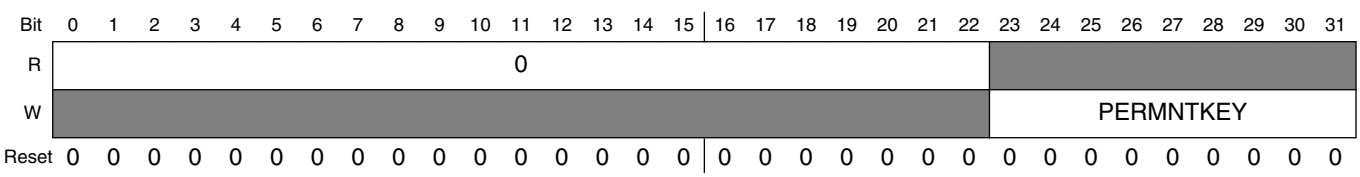
FCCU_TRANS_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 TRANSKEY	Transition Unlocking Key value BCh: Configuration Unlocked Any other value:FCCU gets transiently locked again.

85.6.24 Permanent Lock Register (FCCU_PERMNT_LOCK)

The FCCU_PERMNT_LOCK register is used for locking configuration permanently by writing FFh. This register is available only in supervisor mode. The permanent lock can only be removed by applying a reset (not necessarily power on reset). This register is write only.

Address: 0h base + F4h offset = F4h



FCCU_PERMNT_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FCCU_PERMNT_LOCK field descriptions (continued)

Field	Description
23–31 PERMNTKEY	Transition Locking Key value FFh: Configuration Locked Any other value: No Change

85.6.25 Delta T Register (FCCU_DELTA_T)

The FCCU_DELTA_T register is used for programming the value of delta_T constant, in microseconds.

NOTE

This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved		Reserved													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 Reserved	This field is reserved.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	DELTA_T: Value of Delta_T in microseconds Max. value can be 16,666 microseconds (16.67 ms)

85.6.26 IRQ Alarm Enable Register (FCCU_IRQ_ALARM_EN*n*)

These registers enable the corresponding IRQ alarm.

Table 85-14 shows FCCU IRQ alarm enable register channels.

Table 85-14. FCCU IRQ alarm enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
0FCh	FCCU_IRQ_ALARM_EN0	IRQENE[31:0]
100h	FCCU_IRQ_ALARM_EN1	IRQENE[63:32]
104h	FCCU_IRQ_ALARM_EN2	IRQENE[95:64]
108h	FCCU_IRQ_ALARM_EN3	IRQENE[127:96]

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IRQENx																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_IRQ_ALARM_EN*n* field descriptions

Field	Description
0–31 IRQENx	IRQ alarm enable See Table 85-14 for register offset to channel number relationship. 0 Alarm is disabled for error source x. 1 Alarm is enabled for error source x.

85.6.27 NMI Enable Register (FCCU_NMI_EN*n*)

These registers enable the NMI.

NOTE

Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.

Table 85-15 shows FCCU NMI enable register channels.

Table 85-15. FCCU NMI enable register channels

Address offset	Register name	Channel range (x) (bit location [0:31])
10Ch	FCCU_NMI_EN0	NMIENE[31:0]
110h	FCCU_NMI_EN1	NMIENE[63:32]
114h	FCCU_NMI_EN2	NMIENE[95:64]
118h	FCCU_NMI_EN3	NMIENE[127:96]

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + 10Ch offset + (4d × i), where i=0d to 3d

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0–31 EOUTENx	EOUT signaling enable. See Table 85-16 for register offset to channel number relationship. 0 EOUT signaling is disabled for error (RF) source × for bistable protocol. Error pins are as if in non-faulty state. 1 EOUT signaling is enabled for error (RF) source × for bistable protocol.

85.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by the IRCOSC. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU, which is asserted on power-on, 'destructive', and external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

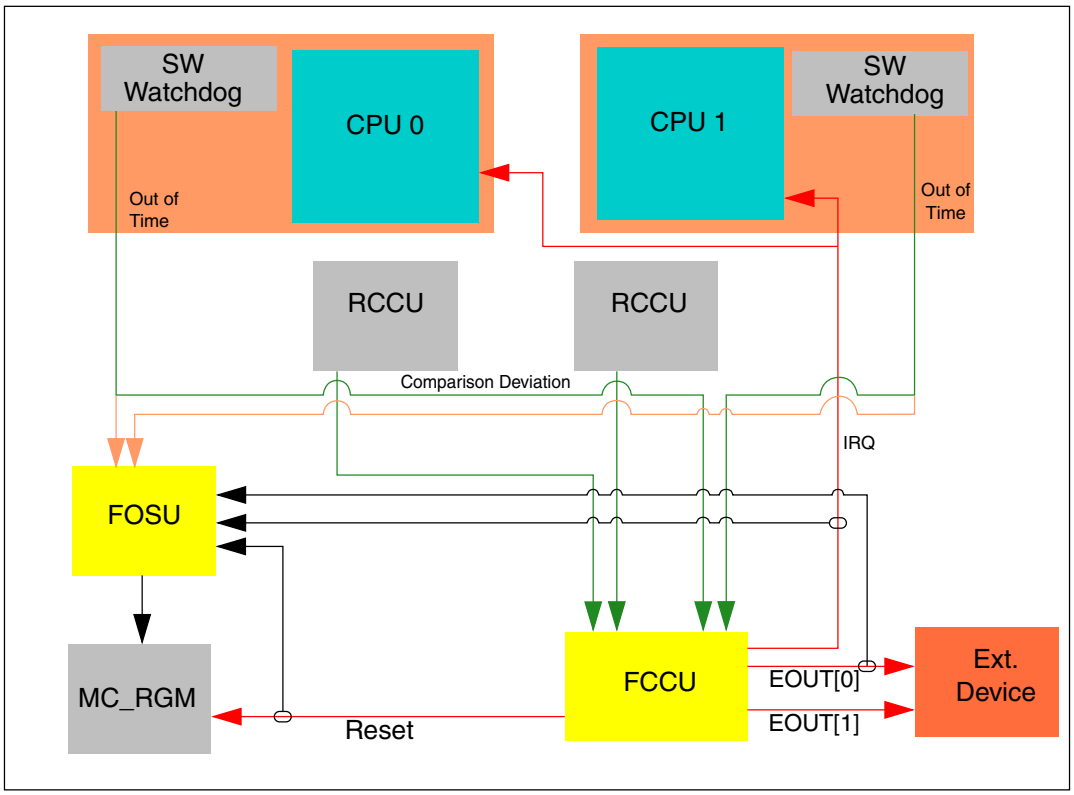

Figure 85-14. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

85.8 Use cases and limitations

85.8.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enabling a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario

   Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.
4. If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and, as a result, FOSU will generate destructive reset request on its timeout.

85.8.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out Tmin to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and Tmin expires
   d. Verify FCCU is in NORMAL state, else repeat step(a) above
   e. Read and verify value in FCCU_NCF_Ex
   f. Reconfigure FCCU, if necessary

Chapter 86
Self-Test Control Unit (STCU2)

86.1 Introduction

Self Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the self test sequence applied both during the Off-Line and/or On-Line conditions. It is able to manage by hardware the device's Logic Built-In Self Test (LBIST) and the SRAM/ROM Built-In Self Test (MBIST) blocks. The STCU2 includes the SSCM DCF bus to load the Self-test parameters (L/MBIST scheduling activity, LBIST setup, Unrecoverable/Recoverable faults management, CRC and MISR expected values, PLL management, and so on) from flash memory during the Off-Line Self-Test phase. This interface is able only to write the configuration parameters and start the Self-Test execution once after the STCU2 global reset has been applied. The register access by software is granted by an IPS interface with the purpose to check the results of the Off-Line Self-Test but also to load/check the execution of the On-Line Self-Test.

The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the Self-Test run to increase the STCU2's Self-Checking capability
- A programmable Watchdog timer (WDG) to check the Self-Test operations (both LBIST and MBIST) have been completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out
- The PLL direct control during the Off-Line Self-Test sequence
- Interrupt lines enabled only during the On-Line Self-Test to simplify the software handling of Self-Test execution end
- Two sets of Result registers to collect the L/MBIST result during Off/On-Line Self-Test separately

To increase the security capability of this module, a different Security Key sequence is also required during Off/On-Line Self-Test in order to unlock the write access to the STCU2 registers. The STCU2 also implements two power-saving mechanisms to switch off:

- The global STCU2 clock after Self-Test sequence is completed
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

86.2 Main features

- Double registers interface (SSCM DCF with priority over IPS)
- SSCM DCF write one time register interface
- IPS read and write (depends on SSCM enable parameters and STCU2_CFG.WRP bit) register interface
- Programmable scheduler for LBIST/MBIST execution
- LBIST concurrent/sequential execution
- MBIST concurrent/sequential execution
- Programmable LBIST delayed concurrent start
- Hardware capability to enable/disable the execution of hardware selected L/MBIST
- 32-bit CRC for STCU2 Self-Checking capability (enabled by STCU2_CFG.CRCEN bit)
- On-Line hardware Self-Test sequence abort capability
- On-Line software Self-Test sequence abort capability
- Programmable Internal clock prescaler to reduce Internal and MBIST/LBIST TCK clocks
- Programmable PLL direct control during Off-Line Self-test sequence
- PLL Lock signal monitoring during Off/On-Line Self Test
- L/MBIST dedicated On-Line interrupt source generation
- Programmable WDG Timer for Self-Check M/LBIST Time Execution
- Hard Coded WDG time-out to flag off-line initialization faults

- Hard Coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence
- LBIST and SRAM/ROM MBIST Off-Line status flags
- STCU2 internal errors Off-Line status flag
- LBIST and SRAM/ROM MBIST On-Line status flags
- STCU2 internal errors On-Line Status flag
- On-Line hardware abort status flag
- On-Line software abort status flag
- LBIST and SRAM/ROM MBIST Off/On-Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 internal errors Off-On/Line programmable failure severity - unrecoverable fault/recoverable fault (UF/RF)
- STCU2 errors (UF/RF) lines for FCCU signaling
- Redundant UF/RF generation logic to improve reliability
- FCCU UF/RF faults injection mechanism
- CRCE register access to perform redundant check by software
- LBIST MISRE registers access to perform redundant check by software
- Self-Test Bypass capability
- Global write register's protection mechanism based on Double Security Key
- STCU2 Global Auto Power-saving when Self-Test is completed, bypass mode is selected or WDT time-out is detected
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)
- STCU2 ITF/WDG Auto Power-saving when Hard Coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU2_CFG.WRP bit is active)

86.3 Block diagram

The top level diagram of the STCU2 module is given in Figure 86-1.

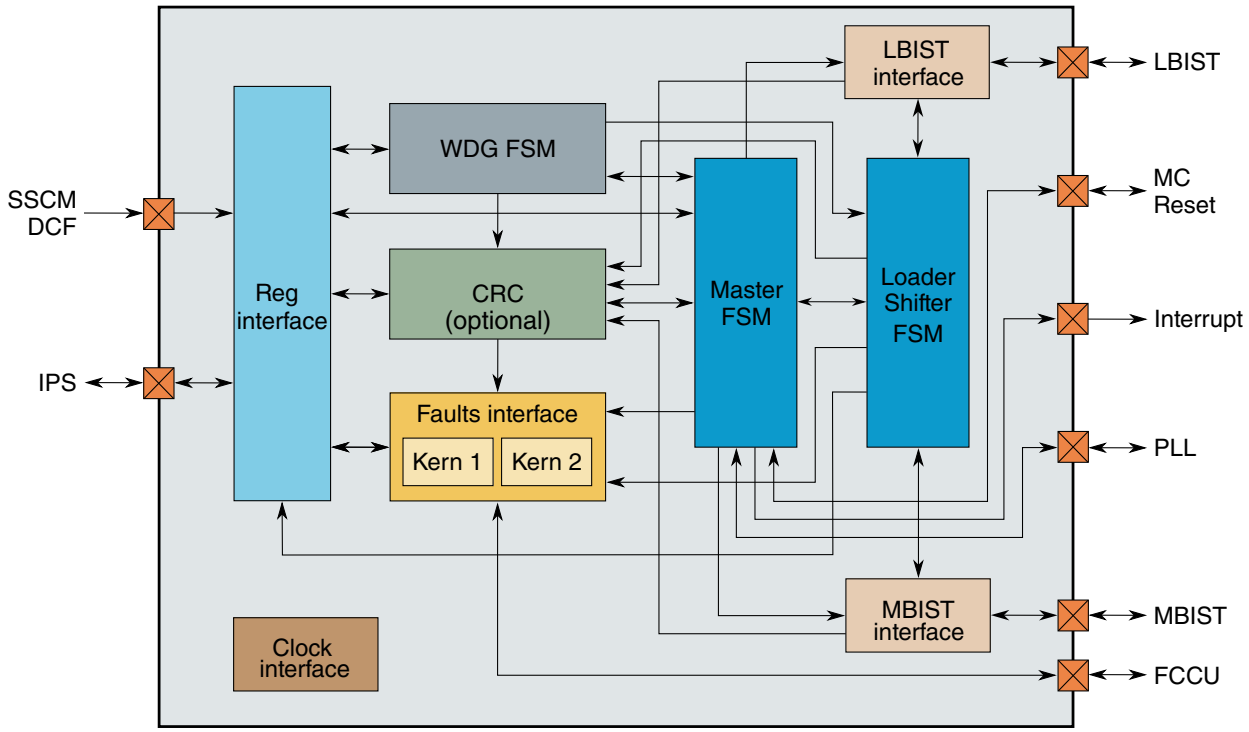

Figure 86-1. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- ***Reg interface***: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- ***CRC***: This module is the core of the Self-Checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- ***Fault interface***: This module collects the fault conditions related to L/MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each one of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set/Clear injection mechanism provided by the FCCU. To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
- ***Clock Interface***: This module manages the internal and the L/MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.
- ***WDG FSM***: This module includes two different Watchdogs. The first one is Hard Coded and is used to Auto Lock the STCU2 access forcing a reset condition on the Double Security Key registers while the second one has a double functionality. After a reset event initializes the STCU2, it is used as Hard Coded Watchdog time-out while during L/MBIST run it is used as programmable Watchdog timer to check the L/MBIST have been completed in the assigned L/MBIST time slot.

- ***STCU2 Master FSM***: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- ***STCU2 Load Shifter FSM***: This module includes the common shifter register and the related state machine used to program the L/MBIST registers and read back the data to be checked at the end of each Test operation.
- ***LBIST interface***: This module includes the interface between the device's LBIST engines and the STCU2 controllers.
- ***MBIST interface***: This module includes the interface between the MBIST controller and STCU2 controllers.

86.4 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on a specific register is allowed by software only when the bit STCU2_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2_CFG.WRP, STCU2_ERR_STAT.UFSF and STCU2_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral

- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

86.5 Functional description

86.5.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

86.5.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the LBRMSW register.

86.5.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

86.5.2.2 On-Line reset generation (only MBIST)

The On-Line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences related to the write operations performed by the MBIST execution other than preventing any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

86.5.2.3 On-Line reset generation (LBIST enabled)

The LBRMSW register should be configured to generate a global functional reset after LBIST online self-test. It is not recommended to use a dedicated reset due to random data injected by the LBIST Controller.

Note

In case there is an ABORT condition detected by STCU2 during the On-Line Self-Test execution, independently of the value of the LBRMSW register, only the related reset line stcu2_rst_lbist_core_b[NLBIST-1:0] is pulsed to prevent any potential dangerous system level operations.

86.5.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/ coverage constraints. The limitation in the programming flexibility is described in Design implementation information.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped at the address 10h, the second on 11h and so on. The additional pointers are in the bitfield STCU2_LB_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU2_MB_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2_LB_CTRL.CSM and STCU2_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list setting the NIL pointer. For more details, see STCU2 LBIST Control Register (STCU2_LB_CTRL*n*) and STCU2 MBIST Control Register (STCU2_MB_CTRL*n*).

NOTE

Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.

86.5.4 ABORT management

The STCU2 module provides two mechanisms to perform the On-Line Self-Test execution abort. When the abort is detected in both cases, the On-Line Self-Test operation stops running and the status of the currently running MBIST or LBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run. In case of LBIST run, see Reset management, for more details about reset specific management when abort is detected.The following sections describe the differences between these two modalities.

86.5.4.1 Hardware ABORT management

The STCU2 enters the hardware abort condition as a consequence of a Functional reset which causes Self-Test execution to abort .

When hardware abort is detected the bit ABORTHW of the STCU2_ERR_STAT register is set. This flag allows the software to diagnose what has happened during the On-Line Self-Test execution run.

86.5.4.2 Software ABORT management

The STCU2 enters in the abort condition because the software set the bit RUNSW_ABORT in the STCU2_RUNSW register. In order to allow the software to understand when STCU2 has completed the abort sequence, this bit will be maintained active until the abort sequence is completed. At that time the STCU2 will clear this bit as described in STCU2 Run Software Register (STCU2_RUNSW).

When software abort is raised the bit ABORTSW of the STCU2_ERR_STAT register is set. Even if the abort condition is forced by software operation, this flag allows to diagnose what has happened during the On-Line Self-Test execution run.

86.5.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2_RUN[MBPLLEN] and STCU2_RUN[LBPLLEN].

When STCU2_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2_PLL_CFG register.

When the STCU2_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

Same behavior will be applied when STCU2_RUN[LBPLLEN] is active and LBIST is currently selected.

86.5.6 Interrupt interface

Interrupt sources:

- Triggered by MBIST (enabled by programming STCU2_RUNSW[MBIE] = 1)
- Triggered by LBIST (enabled by programming STCU2_RUNSW[LBIE] = 1)

As described in the STCU2 Run Software Register (STCU2_RUNSW) description, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential run in the same session, the number of interrupts generated is equivalent to the number of the sequential session providing in such a way a fine granularity with respect to the completed run.

The LBIFLG bit and MBIFLG bit in the STCU2 Interrupt Flag Register (STCU2_INT_FLG) register flag interrupt conditions and allow the clearing of interrupt requests. Interrupt bits are cleared by writing the related flag bit to 1 to enable the next interrupt request.

86.5.7 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

86.5.8 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

86.5.8.1 Initialization watchdog timer

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting the bit STCU2_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

86.5.8.2 Built-in self-test watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Register Granularity (STCU2_WDG), to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU2_ERR_STAT.WDTO and STCU2_MBEL/M/H or STCU2_LBE registers while in case of On-Line Self-Test into STCU2_ERR_STAT.WDTOSW and STCU2_MBELSW/MSW/HSW or STCU2_LBESW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in Reset management.

86.5.8.3 Register write-access watchdog timer

The access on the STCU2 registers during the self-test configuration phase (both online/offline) is protected by a key mechanism to prevent any unwanted access, as described in the STCU2_SKC register description. In addition to this malicious access protection feature, there is a hardware watchdog timer that, after AUTOLOCK_VALUE STCU2 clock cycles, lock the access requiring to apply again the STCU2_SKC keys.

NOTE

Each DCF record takes 8 STCU2 clock cycles for write completion. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK Value divided by 8. To refresh the hardware watchdog timer, the user must write key 2 into the STCU2_SKC register.

This feature is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration since in this case the software application might enable the write access to the STCU2 registers.

86.5.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomial to evaluate the signature of the most important and critical internal signals. This feature is by default switched off but it can be turned on setting the bit STCU2_CFG.CRCEN. Once this bit is set the expected signature has to be programmed into the STCU2_CRCE register; at the end of the Self-Test execution the STCU2 updates the content of the STCU2_CRCR register with the evaluated signature and compares this value with the expected one previously programmed into STCU2_CRCE. In case of mismatches a UF/RF condition is flagged depending on the fault mapping selected into the STCU2_ERR_FM register.

NOTE

The CRC calculation depends on the internal state of the STCU2 when the online/offline self test is started. The STCU2's internal state is dependent on DCF values and their programming sequence for offline selftest. The calculated CRC value can be determined by running an LBIST test under known conditions. The CRC unit produces a stable and predictable result but is dependent on several stimuli (including programming order and the initial internal state of the STCU2 design) during online self test. To calculate a CRC value, run an LBIST test on known good silicon with a predefined software programming sequence. Record the CRC result value. Then provide the STCU2 programming sequence and the initial register vlaues for further runs if the CRC feature is to be used. Once a known good CRC value is determined, the CRC value will not change from one run to another so long as the user does not change the STCU2 programming sequence or any of the values used to program STCU2 registers. To obtain a consistant CRC calculated value, the STCU must start from the same state compared to the state when the CRC was originally evaluated.

86.5.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

86.5.11 L/MBIST execution restriction

The STCU2 provide the capability of preventing the execution of selected L/MBIST. The list of the L/MBIST with this restriction is Hardware defined at design phase STCU2_LBIST_SYS_ENSTCU2_MBIST_SYS_EN) and cannot be changed by software. The activation of the restriction is controlled by system signal sys_lmbist_restriction_en which has to be carefully generated in order to fulfill the system requirements.

86.6 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

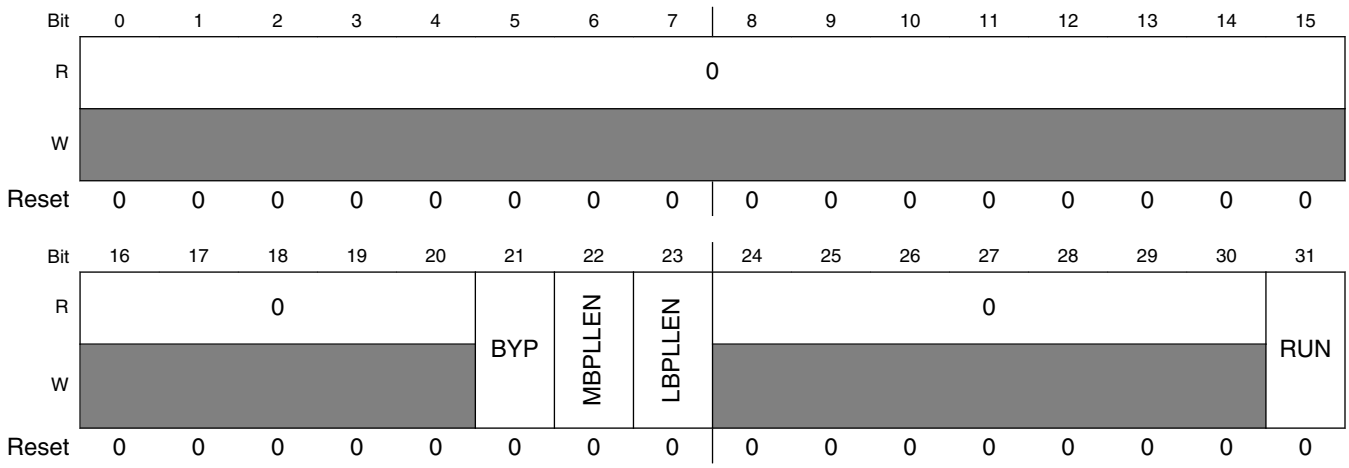
86.6.1 STCU2 Run Register (STCU2_RUN)

The STCU2_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Register description

Address: 0h base + 0h offset = 0h



STCU2_RUN field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BYP	Bypass mode 0 Off-Line Self-Test is active. In case the RUN bit into the STCU2_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU2_ERR_STAT register. 1 Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU2_SCK register is written according to the request access mode.
22 MBPLLEN	Off-Line MBIST with PLL Enabled 0 Off-Line MBIST is executed without using the on-chip PLL. 1 Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
23 LBPLLEN	Off-Line LBIST with PLL Enabled 0 Off-Line LBIST is executed without using the on-chip PLL. 1 Off-Line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUN	RUN: RUN The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed. 0 Idle 1 Off-Line Self testing procedure is running

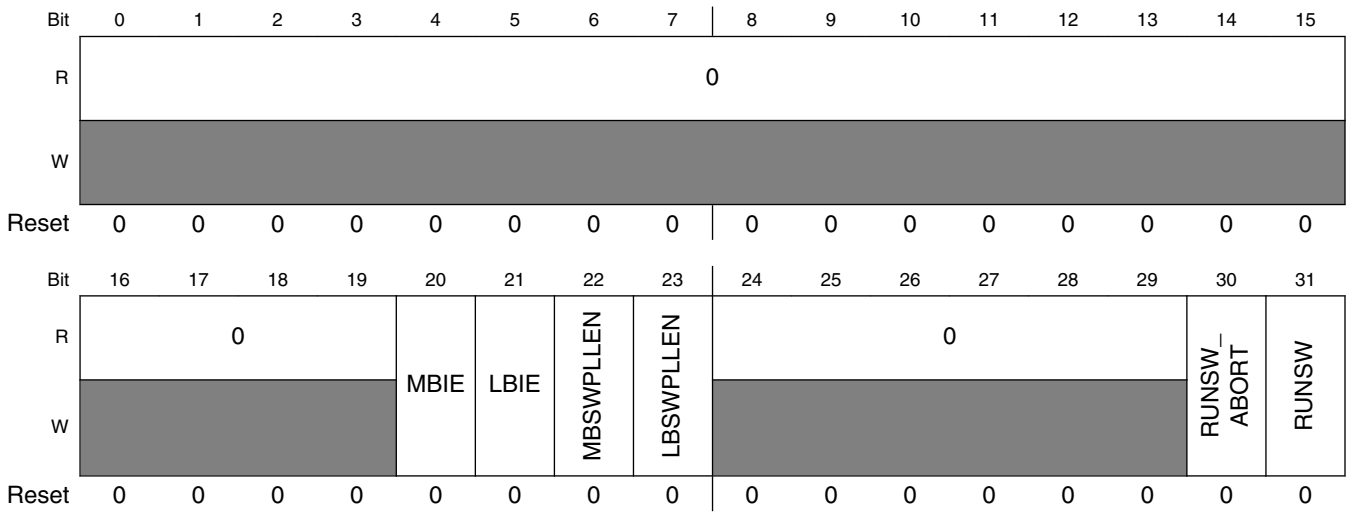
86.6.2 STCU2 Run Software Register (STCU2_RUNSW)

The STCU2_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

Address: 0h base + 4h offset = 4h



STCU2_RUNSW field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories the STCU2 forces an interrupt request to notify that MBISTs of concurrent selected memories are over. In case there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent runs provided that the software will clear the STCU2_INT_FLG[MBIFG] bit in between.
21 LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST the STCU2 forces an interrupt request to notify that LBISTs of the concurrent selected partitions are over. In case there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software will clear the STCU2_INT_FLG.LBIFG bit in between.
22 MBSWPLLEN	On-Line MBIST with PLL Enabled 0 On-Line MBIST is executed without using the on-chip PLL. 1 On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.

Table continues on the next page...

STCU2_RUNSW field descriptions (continued)

Field	Description
23 LBSWPLLEN	On-Line LBIST with PLL Enabled 0 On-Line LBIST is executed without using the on-chip PLL. 1 On-Line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 RUNSW_ABORT	Software abort of the self-test currently running This bit is automatically cleared by the STCU2 when the software self-test abort sequence has been completed. 0 On-line self-test abort is not requested. 1 On-line self-test abort is requested.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed. 0 Idle 1 On-line self testing procedure is running

86.6.3 STCU2 SK Code Register (STCU2_SKC)

The STCU2_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus) or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2_SKC register
- write the key2 into the STCU2_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2_SKC register is not readable. The value 00000000h is always returned in case of read operation.

86.6.4 STCU2 Configuration Register (STCU2_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

MBIST can be run in three different test types according to how the STCU2_CFG register bits 27 and 28 are set.

The following table describes the test algorithm and coverage of the different test types.

Table 86-1. MBIST algorithm and coverage according to test type

MBIST Type	STCU2_CFG[PMOSEN]	STCU2_CFG[MBU]	MBIST Algorithm	Internal Nodes/ Circuits Additionally Covered by Test	Usecase	Test Cycle
Full Test	1	0	Test memory using all built in algorithms. Open PMOS algorithm included	Address Decoder and Bitcell as well as resistive defects in the address decoder	Used by FSL production test. Recommended to use in the field for MBIST online self-test.	About 3 to 4x more than Auto Test
Reduced Test	0	0	Test memory using all built in algorithms except the open PMOS algorithm.	Address Decoder and Bitcell	Recommended to use in the field for MBIST online self-test if the Full Test takes too long.	About 10% less than Full Test
Auto Test	x	1	A smaller set of algorithms which target latent defect mechanisms.	Latent defects such as NBTI of the PMOS transistors in the bitcells	Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage.	About 3 to 4x faster than Full Test

STCU2_CFG field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
8–15 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are the following: 00h: No delay 01h: 1 x16 STCU2 Core clock cycles 02h: 2 x 16 STCU2 Core clock cycles 03h: 3 x 16 STCU2 Core clock cycles ... FDh: 253 x 16 STCU2 Core clock cycles FEh: 254 x 16 STCU2 Core clock cycles FFh: 255 x 16 STCU2 Core clock cycles Note that in case the Frequency of the STCU2 core clock is 16 MHz, the delay parameters is expressed in µs. **NOTE:** This field should be written with 0xFF for self test run. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
23 WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 CRCEN	CRCEN: CRC Enable comparison You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0 The CRC comparison is not performed and the STCU2_ERR_STAT.CRCS[SW] and STCU2_ERR_STAT.UF/RF global flags are not updated in case of mismatches between STCU2.CRCE and STCU2.CRCR values 1 The CRC comparison is performed and the status is updated into the related flags of the STCU2_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable When MBU is 1 then "Auto test" MBIST test type will be selected regardless of the setting of this field.. 0 When MBU is 0 then selects the "Reduced test" MBIST test type. 1 When MBU is 0 then selects the "Full test" MBIST test type.
28 MBU	MBIST MBU Test Enabled 0 Either "Full test" or "Reduced test" MBIST test type will be selected according to the PMOSEN value. 1 Selects "Auto test" MBIST test type regardless of the PMOSEN value.
29–31 CLK_CFG	Logic, Memory Bist and STCU2 core CLK Clock configuration CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following: 000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8 You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

86.6.5 STCU2 PLL Configuration Register (STCU2_PLL_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_PLL_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU2_RUN[MBPLLEN] = 1 or STCU2_RUN[LBPLLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_PLL_CFG field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 PLLODF	PLL Output Division Factor The value of this field drives the Output Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the related PLL's Output Division factor.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 PLLIDF	PLL Input Division Factor The value of this field drives the Input Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the related PLL's Input Division factor.
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PLLLDF	PLL Loop Division Factor The value of this field drives the Loop Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the related PLL's Loop Division factor.

86.6.6 STCU2 Watchdog Register Granularity (STCU2_WDG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or end-less conditions during the Self-Test procedure. When the Off-line Self-Test sequence is not run and the BYP bit of the STCU2_CFG register is not set, the bits 15...0 defines the time-out before the bit WDTO of the STCU2_ERR register is set and the STCU2 core clock is switched off.

In case Off/On-line Self Test sequence is run, it defines the time-out of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

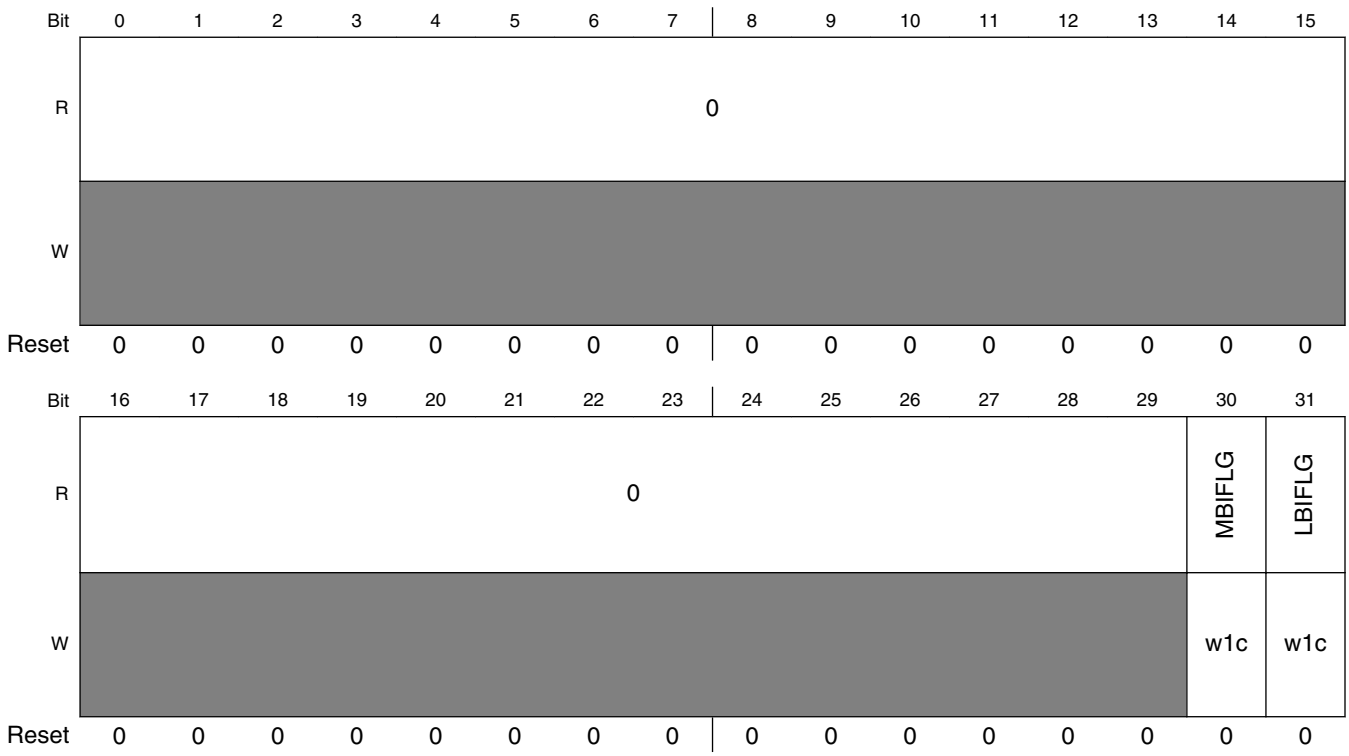
STCU2_WDG field descriptions

Field	Description
0–31 WDGEOC	Watchdog End of Count Timer This value has to be set in order to define the time budget related to the Off/On-Line Self Test execution and check that everything is correctly working within this slot of time. The allowed delay time are the following: 0000 0000h: 1 x 16 STCU2 Core clock cycles 0000 0001h: 2 x 16 STCU2 Core clock cycles 0000 0002h: 3 x 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 x 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 x 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 x 16 STCU2 Core clock cycles

86.6.7 STCU2 Interrupt Flag Register (STCU2_INT_FLG)

The STCU2_INT_FLG register includes an MBIST interrupt pending bit and an LBIST interrupt pending bit. Each bit is effective only during the On-Line Self-Test phase and is managed only when the related control bit in the STCU2_RUNSW register (MBIE or LBIE) is enabled.

Address: 0h base + 18h offset = 18h



STCU2_INT_FLG field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 MBIFLG	MBIST Interrupt Flag 0 No interrupt is pending 1 An interrupt, highlighting that the On-Line execution of the concurrent scheduled MBIST is completed, is pending. Write 1 to clear the bit.
31 LBIFLG	LBIST Interrupt Flag 0 No interrupt is pending 1 An interrupt, highlighting that the On-Line execution of the concurrent scheduled LBIST is completed, is pending. Write 1 to clear the bit.

86.6.8 STCU2 CRC Expected Status Register (STCU2_CRCE)

NOTE

See the chip specific information for the default reset value of this field.

The STCU2_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU2_CRCE_RES and computes the CRC signature of the STCU2's critical signals and when STCU2_CFG[CRCEN] = 1, it is able to provide the Self-Check capability of the STCU2 managing the CRCS[SW] bits of the STCU2_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1$

CRC-32 [ethernet protocol]

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

- x = Undefined at reset.

STCU2_CRCE field descriptions

Field	Description
0–31 CRCE	CRC expected signature

86.6.9 STCU2 CRC Read Status Register (STCU2_CRCR)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CRCR register reports the value obtained at the end of the Off/On-line Self-Test sequence. It might be used for diagnoses and also as additional check with respect to the CRCS[SW] bit of the STCU2_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

STCU2_CRCR field descriptions

Field	Description
0–31 CRCR	Read CRC signature

86.6.10 STCU2 Error Register (STCU2_ERR_STAT)

The STCU2_ERR_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.

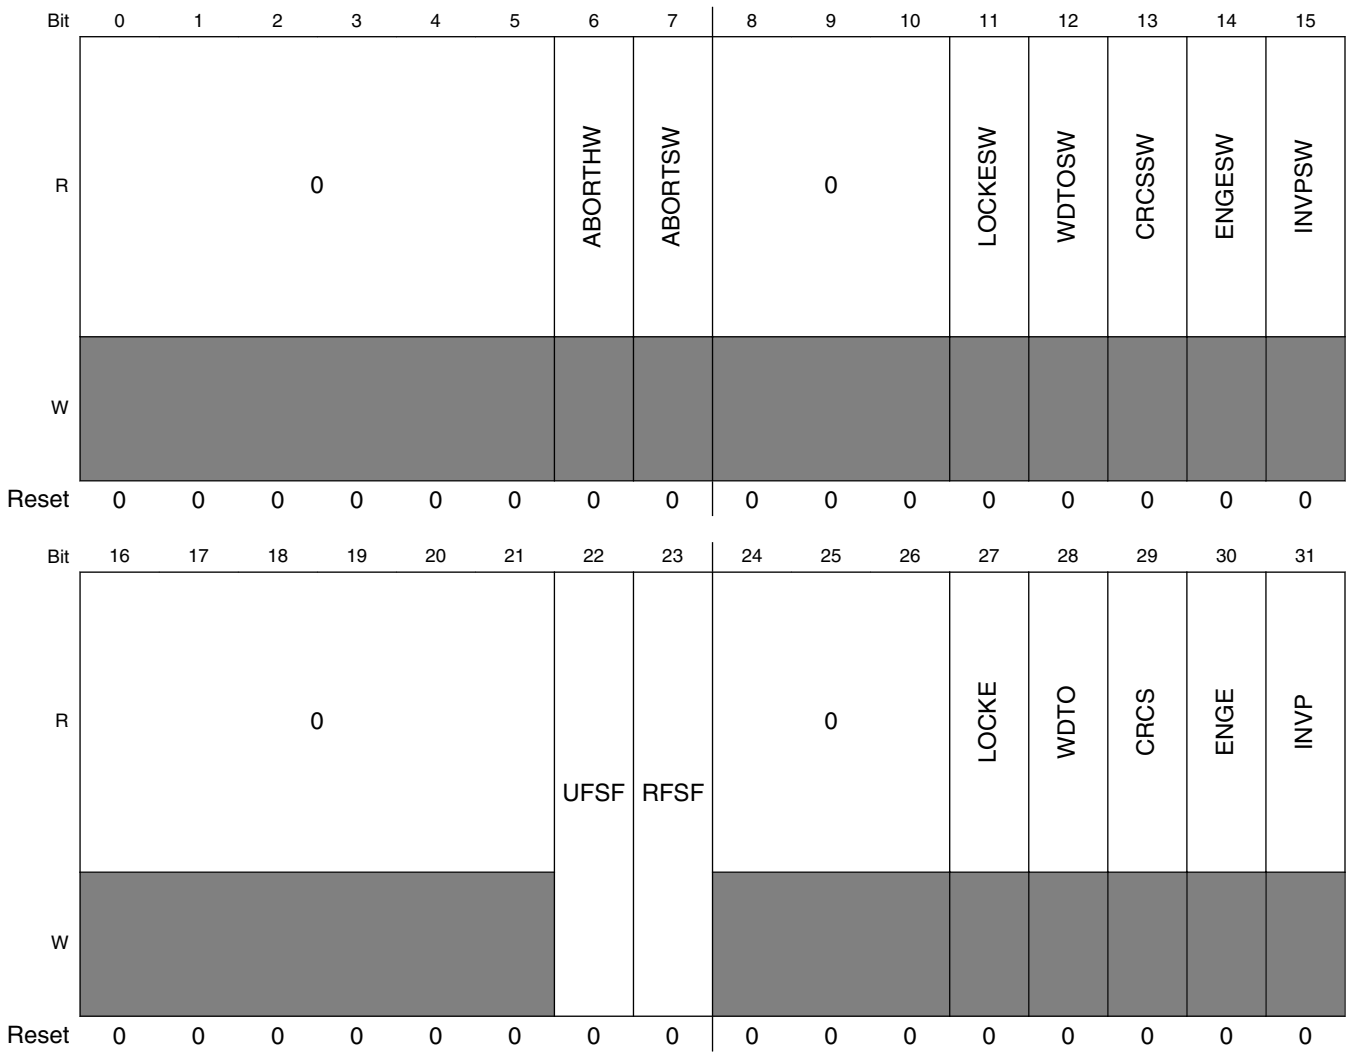
The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Register description

Address: 0h base + 24h offset = 24h



STCU2_ERR_STAT field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ABORTHW	On-line hardware abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No hardware abort was requested during the On-Life Self-Test sequence 1 A hardware abort was detected during the On-Life Self-Test sequence
7 ABORTSW	On-line software abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No software abort was requested during the On-Life Self-Test sequence 1 A software abort was detected during the On-Life Self-Test sequence

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 LOCKESW	On-Line LOCK Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 In case PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUNSW.LBSWPLLEN is set and/or during the MBIST run when STCU2_RUNSW[MBSWPLLEN] = 1.
12 WDTOSW	On-Line Watchdog time-out You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
13 CRCSSW	On-Line CRC Status This flag is activated ONLY when On-Line Self Test is performed and STCU2_CFG.CRCEN is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU2_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU2_CRCR register report the current evaluated CRC. You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Successful CRC comparison or comparison has been masked (STCU2_CFG.CRCEN set to 0) 1 Failed CRC comparison
14 ENGESW	On-Line Engine Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	On-Line Invalid Pointer You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit:

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	• Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
23 RFSF	Recoverable Faults Status Flag 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKE	Off-Line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The Off-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUN[LBPLLEN] = 1 and/or during the MBIST run when STCU2_RUN[MBPLLEN] = 1.
28 WDTO	Off-Line Watchdog time-out 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • The STCU2_RUN[RUN] bit or the STCU2_CFG[BYP] bit are not set before the Watchdog reach the End of Count • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Off-Line CRC status This flag is activated ONLY when Off-Line Self Test is performed STCU2_CFG[CRCEN] is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU2_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU2_CRCR register report the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU2_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
30 ENGE	Off-Line Engine Error 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	• Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Off-Line Invalid pointer 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)

86.6.11 STCU2 Error FM Register (STCU2_ERR_FM)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU2_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h

86.6.16 STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

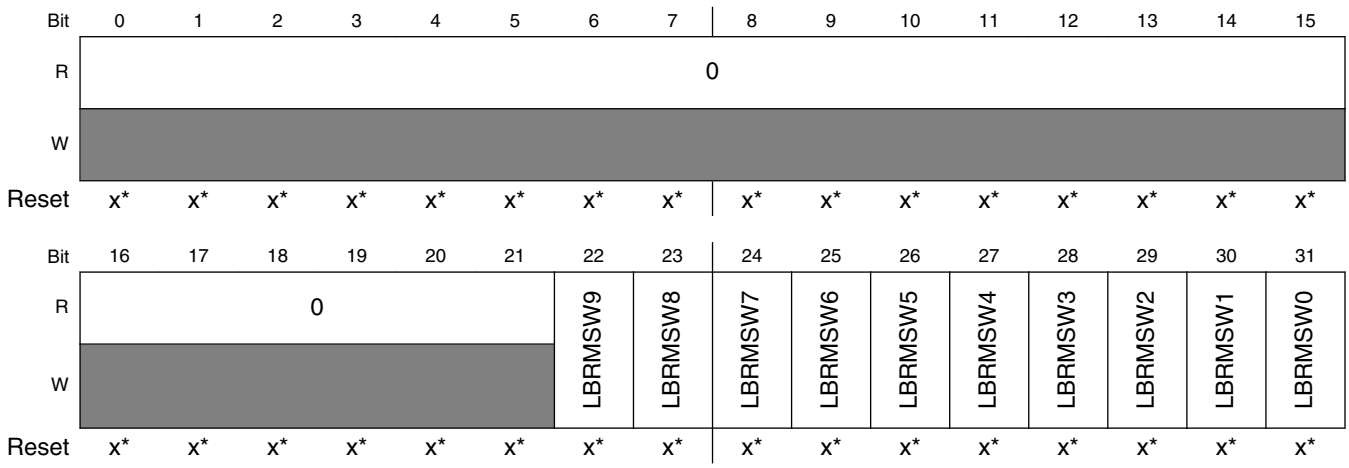
The STCU2_LBRMSW register defines the On-Line reset mapping for each LBIST. Global reset can be programmed.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 3Ch offset = 3Ch



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LBRMSW field descriptions

86.6.17 STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 40h offset = 40h

86.6.29 STCU2 On-Line MBIST End Flag High Register (STCU2_MBEHSW)

The STCU2_MBEHSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

86.6.30 STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFML register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 74h offset = 74h

86.6.33 STCU2 LBIST Control Register (STCU2_LB_CTRL*n*)

NOTE

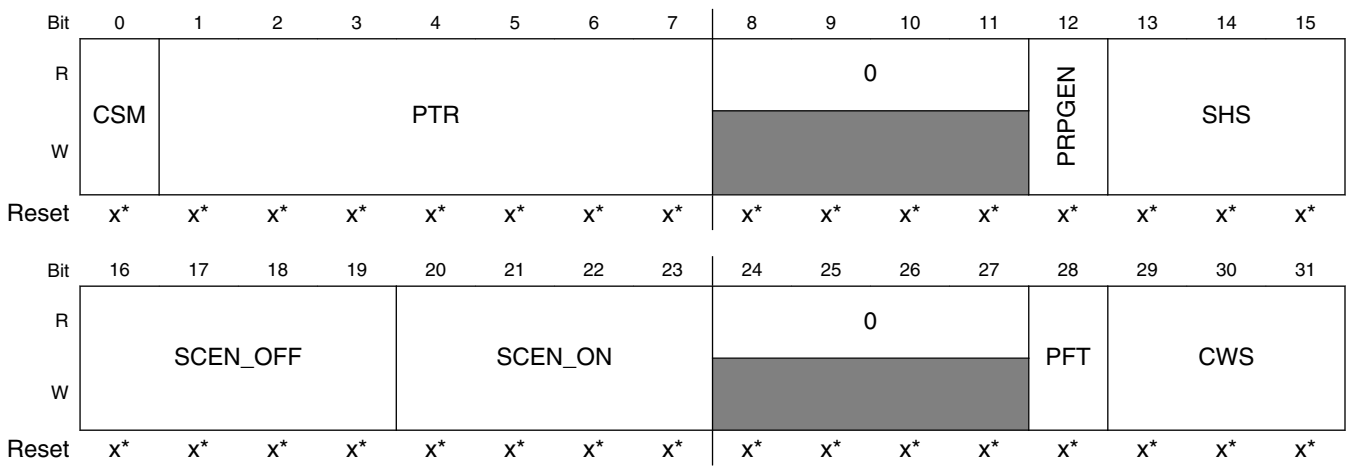
The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 100h offset + (64d × i), where i=0d to 9d



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode The next LBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise, it is scheduled sequentially to the completion of the current LBIST execution.

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
	0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST pointer PTR defines the logical pointer to the next LBIST. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current LBIST has been completed. LBIST POINTERS 0000b - pointer to LBIST partition 0 0001b - pointer to LBIST partition 1 0010b - pointer to LBIST partition 2 0011b - pointer to LBIST partition 3 0100b - pointer to LBIST partition 4 0101b - pointer to LBIST partition 5 0110b - pointer to LBIST partition 6 0111b - pointer to LBIST partition 7 1000b - pointer to LBIST partition 8 1001b - pointer to LBIST partition 9 ... 0x7F - pointer to NIL, end of LBIST execution Values not defined in this list will result in an error being set in the STCU2_ERR register.
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 PRPGEN	Enable PRPG Loading 0 Default LBIST value of the PRPG is used during LBIST run 1 LBIST PRPG value is initialized with the STCU2_LB_PRPGL/H
13–15 SHS	Shift speed SHS defines the shift speed 000 Shift at full rate of STCU2 core clock 001 Shift at 1/2 rate of STCU2 core clock 010 Shift at 1/3 rate of STCU2 core clock 011 Shift at 1/4 rate of STCU2 core clock 100 Shift at 1/5 rate of STCU2 core clock 101 Shift at 1/6 rate of STCU2 core clock 110 Shift at 1/7 rate of STCU2 core clock 111 Shift at 1/8 rate of STCU2 core clock
16–19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN **NOTE:** Scen_off must be programmed to a value >=1 0000 0 delay cycles 0001 1 delay cycle

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
	0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
20–23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN **NOTE:** Scen_on delay register value must be programmed to a value >=1> 0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 PFT	Past Flush Test The LBIST controller, by default, applies 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence. 0 Apply Flush Test Patterns 1 Skip Flush Test Patterns
29–31 CWS	Capture window size CWS defines the capture window size. 000 illegal

	001 controller waits 1 shift cycle for capture to finish 010 controller waits 2 shift cycles for capture to finish 011 controller waits 3 shift cycles for capture to finish 100 controller waits 4 shift cycles for capture to finish 101 controller waits 5 shift cycles for capture to finish 110 controller waits 6 shift cycles for capture to finish 111 controller waits 7 shift cycles for capture to finish

86.6.34 STCU2 LBIST PC Stop Register (STCU2_LB_PCS*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 104h offset + (64d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LB_PCS*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

86.6.35 STCU2 LBIST PRPG Low Register (STCU2_LB_PRPGL*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PRPGL register defines the LSB part (31-0) of the PRPG start value of the LBIST controller.

The size of the register depends on the number of PRPG bits of the related LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 108h offset + (64d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STCU2_LB_PRPGL*n* field descriptions

Field	Description
0–31 PRPGx	PRPG LBIST Low Bits This field defines the Low part (31-0) of the LBIST PRPG start value.

86.6.36 STCU2 LBIST PRPG High Register (STCU2_LB_PRPGH*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PRPGH register defines the MSB part (63-32) of the PRPG start value of the LBIST controller.

The size of the register depends on the number of PRPG bits of the related LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 10Ch offset + (64d × i), where i=0d to 9d

STCU2_LB_MISRRHSW*n* field descriptions

Field	Description
0–31 MISRRSWx	On-Line MISR Read High Bits This field is equivalent to the Low Bits (63-32) of the MISR obtained at the end of the Off-Line LBIST execution.

86.6.45 STCU2 MBIST Control Register (STCU2_MB_CTRL*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

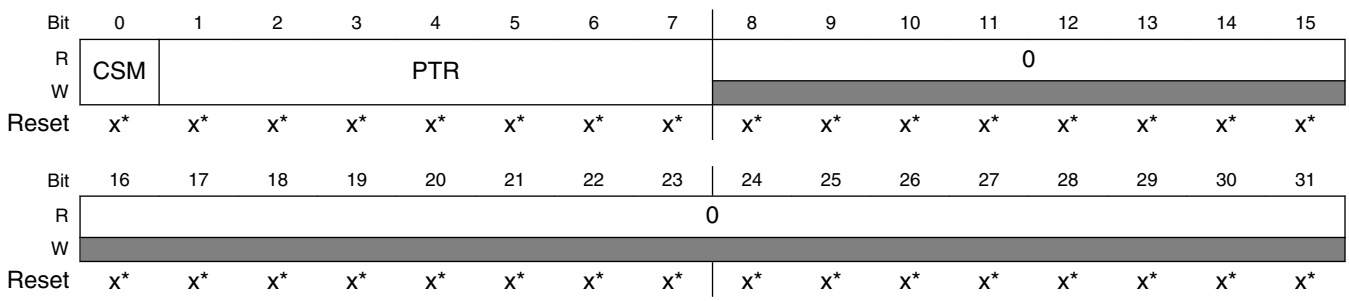
The STCU2_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

The offset of this register is a function of NMCUT .

Address: 0h base + 600h offset + (4d × i), where i=0d to 77d



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_MB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST orMBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure is stopped when the current MBIST has been completed. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2_ERR register.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

86.7 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

86.7.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory.The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU2_LBUFM register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2_ERR_FM register
- Program the STCU2_LB_CTRL, STCU2_LB_PCS, STCU2_MISREL/H registers of each LBIST to be executed. Optionally, also the STCU2_LB_PRPGL/H can be programmed in order to load a specific seed.
- Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU2_CFG register to define: the core and LBIST/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed

- In case the internal CRC comparison has been enabled, program the CRCE value expected at the end of the off-line Self Test sequence into the STCU2_CRCE register
- In case the PLL usage has been enabled, program the STCU2_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2_RUN register to enable the Off-Line Self-Test execution and the L/MBPLLEN bits to enable the PLL during L/MBIST execution according to STCU2_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register.
- The STCU2 switchs off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application reads the STCU2_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.
- The software application reads the STCU2_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
- The software application reads the bits INV, ENGE, CRCS, WDTO, LOCKE of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
- In case the CRCEN bit has been enabled, the software application read the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU2_ERR register.
- The software application reads for each device's LBIST, the STCU2_LBMISREL/H and STCU2_LBIST_MISRRL/H registers to check the coherence with the STCU2_LBS bits.

NOTE

The software application reads operations on the STCU2 CRC and LBIST MISR registers after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

86.7.2 Online self-test sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the L/MBIST execution. Since the On-Line L/MBIST operations clean-up the content of the related Digital Logic (LBIST) or RAM (MBIST) the activation of this mode has to be done carefully. The suggested sequence is the following:

- Unlock the On-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Check and/or clean-up the bit WRP into the STCU2_CFG register to open the IPS access on the STCU2 On-Line Self-Test registers
- The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the Off-Line Self-Test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten setting respectively the registers: STCU2_LBUFM, STCU2_MBUFML/M/H and STCU2_ERR_FM.
- Program the Reset management during on-Line LBIST execution setting the STCU2_LBRMSW register
- The STCU2_LB_CTRL, STCU2_LB_PCS should have been already programmed during Off-Line Self-test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten. The registers STCU2_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU2_MB_CTRL registers of each NMCUT to be executed
- Overwrite/Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution

- Overwrite/Program the STCU2_CFG register in order to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed.
- In case the internal CRC comparison has been enabled, overwrite/program the CRCE value expected at the end of the on-line Self Test sequence into the STCU2_CRCE register
- Program the RUNSW bit into the STCU2_RUNSW register to enable the On-Line Self-Test execution; the L/MBSWPLLEN bits to enable the PLL lock signal monitor during L/MBIST execution and the L/MBIE to enable the related Interrupt requests.
- Start the On-Line Self-Test and depending on PLL management and L/MBIST execution order, also when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register
- In case the L/MBIE have been enabled, an interrupt is generated at the end of all the L/MBIST execution. The software application has to manage these interrupt signals and clean-up the related flag (L/MBIFLG) into the STCU2_INT_FLG register.
- The STCU2 switch-off the core clock at the end of the Self-Test run
- The functional reset activated is managed by the STCU2_LBRMSW.
- In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.
- The STCU2 resets the STCU2_RUNSW[RUNSW] bit. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
- The software application reads the STCU2_LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected
- The software application reads the STCU2_LBESW flag register to check if the LBIST is still on-going when UF or RF is/are detected
- The software application reads the STCU2_MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected

- The software application reads the STCU2_MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected
- In case the CRCEN bit has been enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCSSW of the STCU2_ERR register
- The software application reads for each device's LBIST, the STCU2_LBMISRELSW/HSW and STCU2_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU2_LBS bits

Note

The software application read operations on the STCU2 CRC and LBIST MISR registers after on-line self-test execution has been successfully performed are just an additional reliability layer to be added to improve the already implemented Auto Self-Test feature included in the STCU2.

Note

Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

86.7.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2_SKC register
2. Set the BYP bit in the STCU2_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

86.7.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the online or offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

CAUTION

Do not execute an LBIST on more than one partition at a time.

Chapter 87
Register Protection (REG_PROT)

87.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in the following figure.

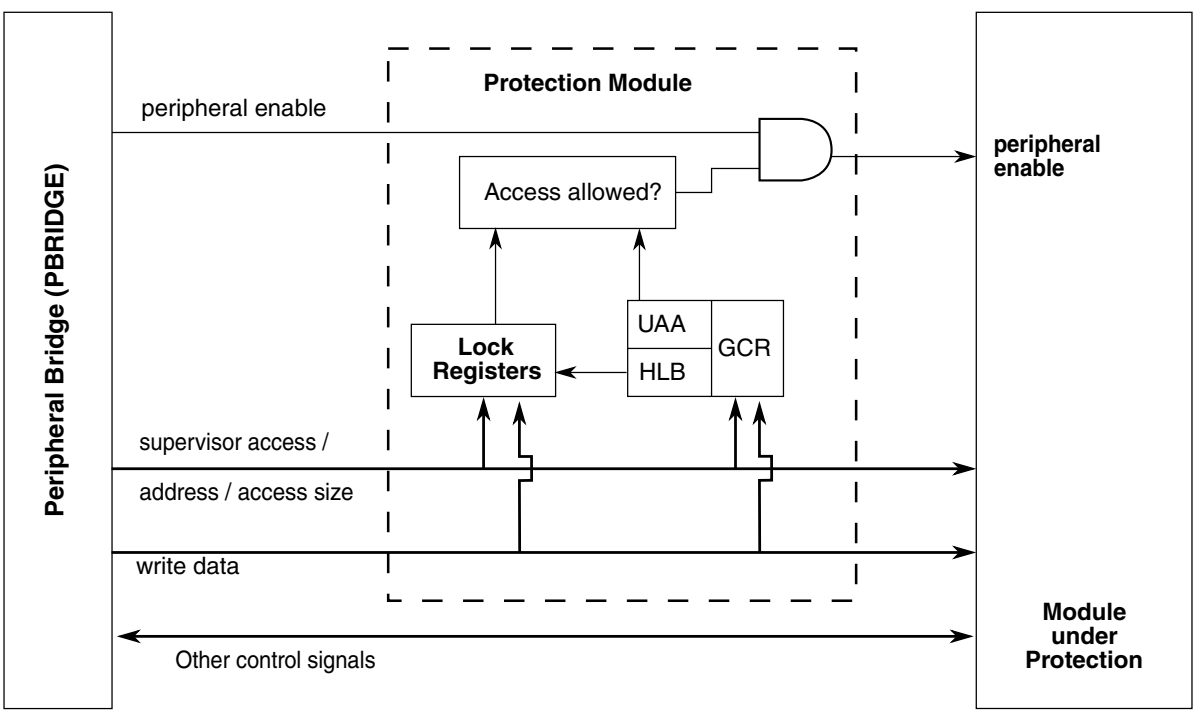


Figure 87-1. REG_PROT Block Diagram

87.2 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

87.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.

87.4 External signal description

There are no external signals.

87.5 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in the following figure.

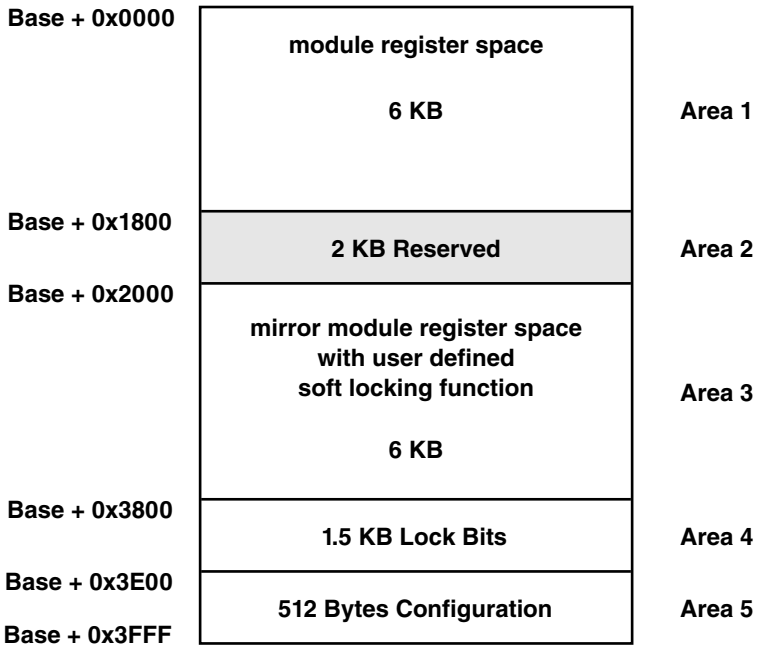

Figure 87-2. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.
- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

87.5.1 Memory map

Following is the memory map for a module which is protected via a REG_PROT module.

Table 87-1. Generic Protected Module Memory Map

Offset	Use
0x0000	Module Register 0 (MR0)
0x0001	Module Register 1 (MR1)
0x0002	Module Register 2 (MR2)
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)
0x1800 - 0x1FFF	Reserved
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 -Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143
0x3E00 - 0x3FFB	Reserved
0x3FFC	Global Configuration Register (GCR)

Note

Reserved registers in area #1 will be handled as specified in the protected module's documentation.

87.5.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

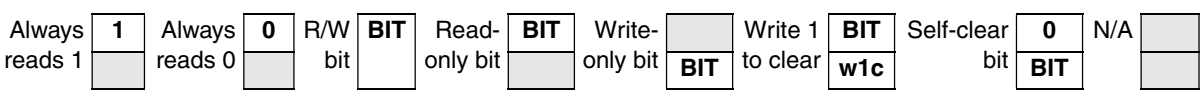

Figure 87-3. Register description

87.5.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

87.5.2.2 Module register and set soft lock bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBRn.SLBm, according to the mapping described in the Soft Lock Bit Register section.

87.6 Memory map and registers

REG_PROT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3800	Soft Lock Bit Register n (REG_PROT_SLBRn)	8	R/W	00h	87.6.1/4575
3FFC	Global Configuration Register (REG_PROT_GCR)	32	R/W	0000_0000h	87.6.2/4577

87.6.1 Soft Lock Bit Register *n* (REG_PROT_SLBRn)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area #1.

Table 87-2. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6

Table continues on the next page...

Table 87-2. Soft Lock Bits vs. Protected Address (continued)

Soft Lock Bit	Protected address
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

NOTE

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3800h offset = 3800h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0	0	SLB0	SLB1	SLB2	SLB3
Write	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

REG_PROT_SLBRn field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB) WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB) WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB) WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB) WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MRn register

Table continues on the next page...

REG_PROT_SLBRn field descriptions (continued)

Field	Description
	SLB0 can block accesses to MR[n *4 + 0] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MRn register SLB1 can block accesses to MR[n *4 + 1] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MRn register SLB2 can block accesses to MR[n *4 + 2] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MRn register SLB3 can block accesses to MR[n *4 + 3] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable

87.6.2 Global Configuration Register (REG_PROT_GCR)

NOTE

Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3FFCh offset = 3FFCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	HLB	0							UAA	0						
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

REG_PROT_GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit This register cannot be cleared once it is set by software. It can only be cleared by a system reset.

Table continues on the next page...

REG_PROT_GCR field descriptions (continued)

Field	Description
	NOTE: Access in User Mode is read-only; in Supervisor Mode access is read/write. 1 All SLB bits are write protected and can not be modified. 0 All SLB bits are accessible and can be modified.
1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

87.7 Functional description

The following sections describe the functional characteristics of the Register Protection module.

87.7.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses that are protected there are SLBRn.SLBm bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBRn.SLBm bit is always 0b0 no matter what software is writing to.

87.7.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn.SLBm directly by writing to area #4
- Set the SLBRn.SLBm bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

87.7.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBRn.SLBm bit has a mask bit SLBRn.WEm which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples. In the left example there is a write access to the SLBRn register specifying a mask value which allows modification of all SLBRn.SLBm bits. The example on the right specifies a mask which only allows modification of the bits SLBRn.SLB[3:1].

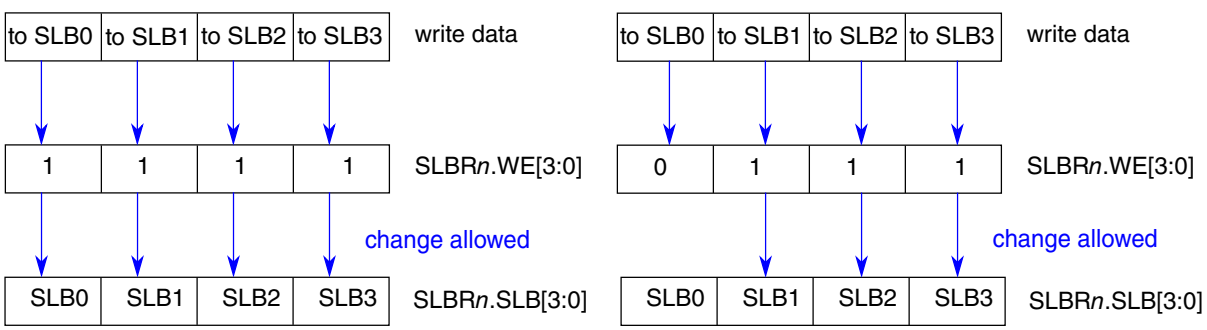

Figure 87-4. Change lock settings directly via Area #4

The previous figure shows four registers that can be protected 8-bit wise. The following figures show registers with 16- and 32-bit protection respectively:

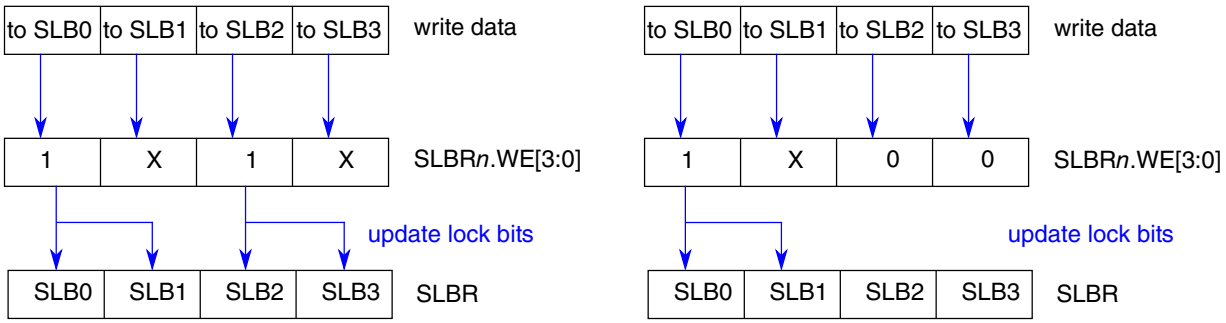

Figure 87-5. Change lock settings for 16-bit protected addresses

On the right side of the previous figure it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of the previous figure the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

The next figure shows a 32-bit wise protected register. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

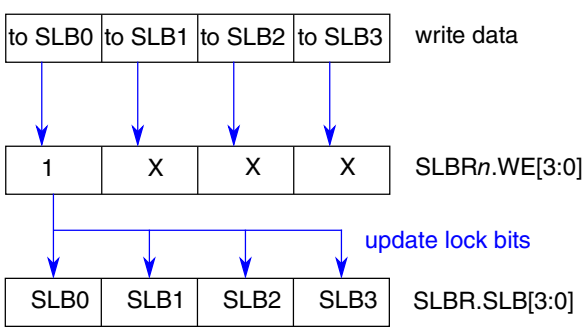

Figure 87-6. Change lock settings for 32-bit protected addresses

The following figure shows a mixed protection size configuration:

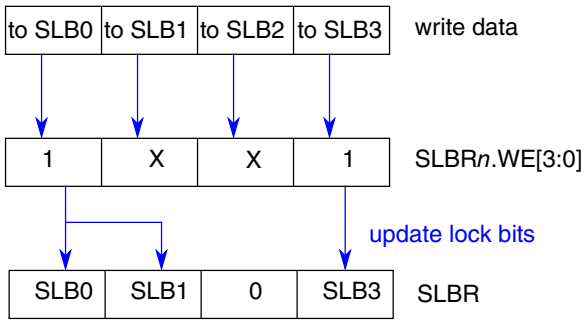

Figure 87-7. Change lock settings for mixed protection

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

87.7.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. For example:

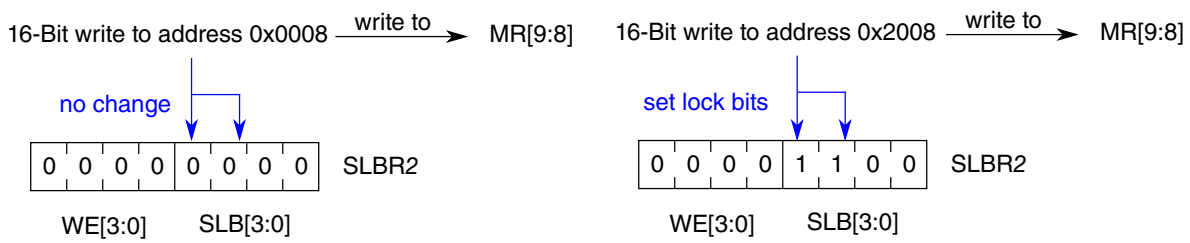

Figure 87-8. Enable Locking Via Mirror Module Space (Area #3)

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of Figure 87-5).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of Figure 87-5).

The following figure shows an example where some addresses are protected and some are not:

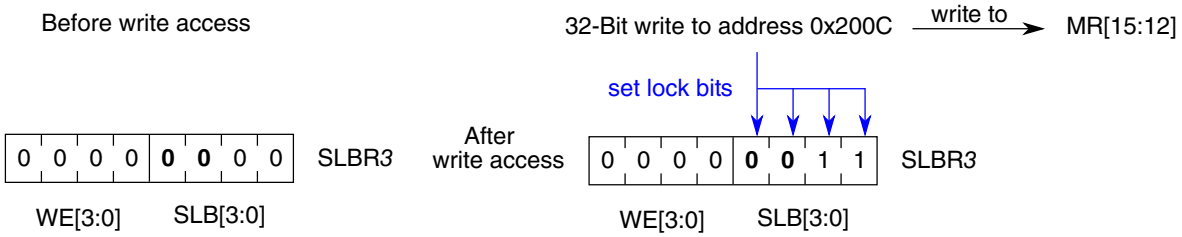

Figure 87-9. Enable locking for protected and unprotected addresses

In the previous figure addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

87.7.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings directly via Area #4 and Enable locking via mirror module space (Area #3) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

87.7.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to Figure 87-2

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.

6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

87.8 Initialization/application information

The following sections contain information relating to initialization and use of the Register Protection module in applications.

87.8.1 Reset

The reset state of each individual bit is shown within the Register Description section. In summary, after reset, locking for all MRn registers is disabled. The registers can be accessed in Supervisor Mode only.

Chapter 88
Password and Device Security Module (PASS)

88.1 Introduction

88.1.1 Overview

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

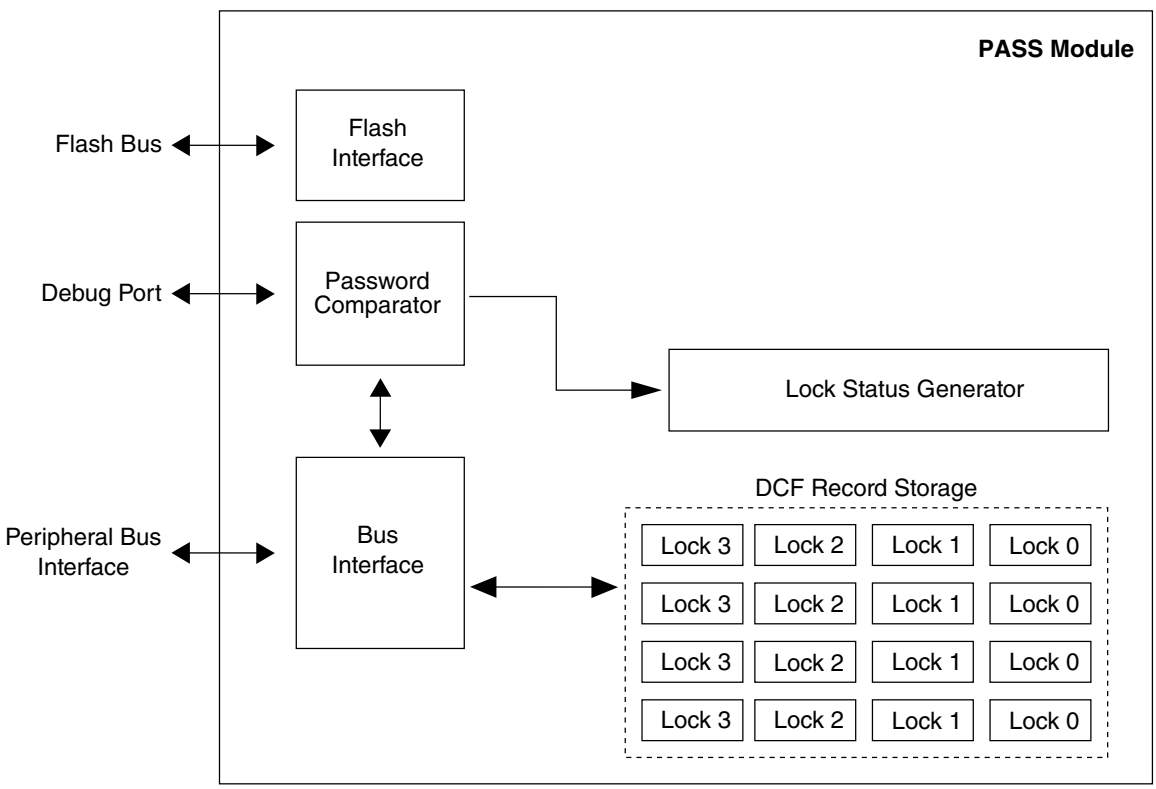

Figure 88-1. PASS module block diagram

88.1.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Production Disable control

88.1.3 Modes of operation

The PASS operates identically in all system modes.

88.2 External signal description

The PASS has 1 external pin that is used for Production Disable control.

88.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

PASS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

88.3.1 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	1	0												
W																
Reset	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								LIFE							
W																
Reset	0	0	0	0	0	0	0	0	*	*	*	*	*	*	*	*

* Notes:
- LIFE field: The reset value derives from a DCF client. If no DCF records have been written, the bit resets to ‘1’.
- CNS field: Reset value depends on the Censorship DCF client

PASS_LCSTAT field descriptions

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA. The bit can be set (or cleared) via DCF Record in UTest Flash. **NOTE:** If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. (In life cycle FA, the JUN bit will always be 0.) Unsuccessful transmission clears this bit.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
3–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 LIFE	This field shows the value of Life Cycle which is decoded by the SSCM module. 1111_110- Customer Delivery 1111_10-- OEM Production 1111_0--- In Field ---0_---- Failure Analysis mode **NOTE:** A dash (-) indicates that the value of the bit is not considered for interpretation of the life cycle.

88.3.2 Challenge Selector Register (PASS_CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CHSEL field descriptions

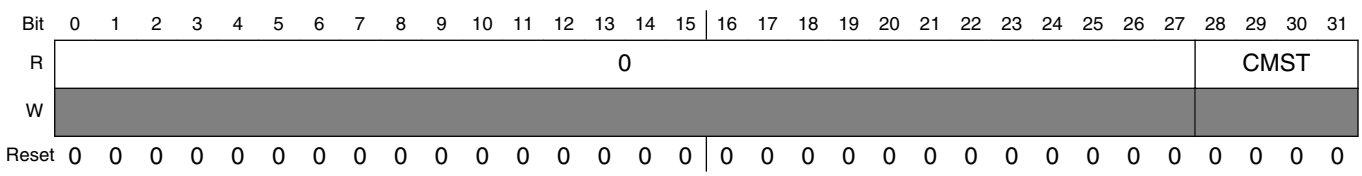
Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 GRP	Password Group to unlock 000 Password Group 0 001 Password Group 1 010 Password Group 2 011 Password Group 3 100 Reserved 101 Reserved 110 Reserved 111 Reserved

88.3.3 Challenge Status Register (PASS_CSTAT)

This register provides status information for the password challenge.

Only the master shown in this register can access the CINn registers - access by other masters result in a comparison fail regardless of the values written.

Address: 0h base + 10h offset = 10h



PASS_CSTAT field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CMST	ID of the master which has last written the CHSEL register

88.3.4 Challenge Input Register (PASS_CIN*n*)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

PASS_CIN*n* field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

88.3.5 Clock Jitter Enable (PASS_CJE)

Software accessible one time writable register. This register stores the jitter enable status for Pseudo Random Clock Divider Module (PRCD). The default value of this register is '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial comms modules include large amounts of psuedo random clock edge jitter, disabling the serial comms modules. For details about which serial comms modules are affected, see the clocking section of the Reference Manual.

For more information on Production disable, see Production disable

Debug access is blocked when Production disable bit[0] (Gated Debug Enable) is asserted, the Chip is In Field and Clock Jitter is not enabled.

Address: 0h base + D0h offset = D0h

PASS_CJE field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
31 CJE	Clock Jitter Enable. 0 Clock Jitter is enabled. The baud rate clock to Serial Comms modules includes large amounts of pseudo random clock edge jitter 1 Clock Jitter is disabled. The baud rate clocks function normally

88.3.6 Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

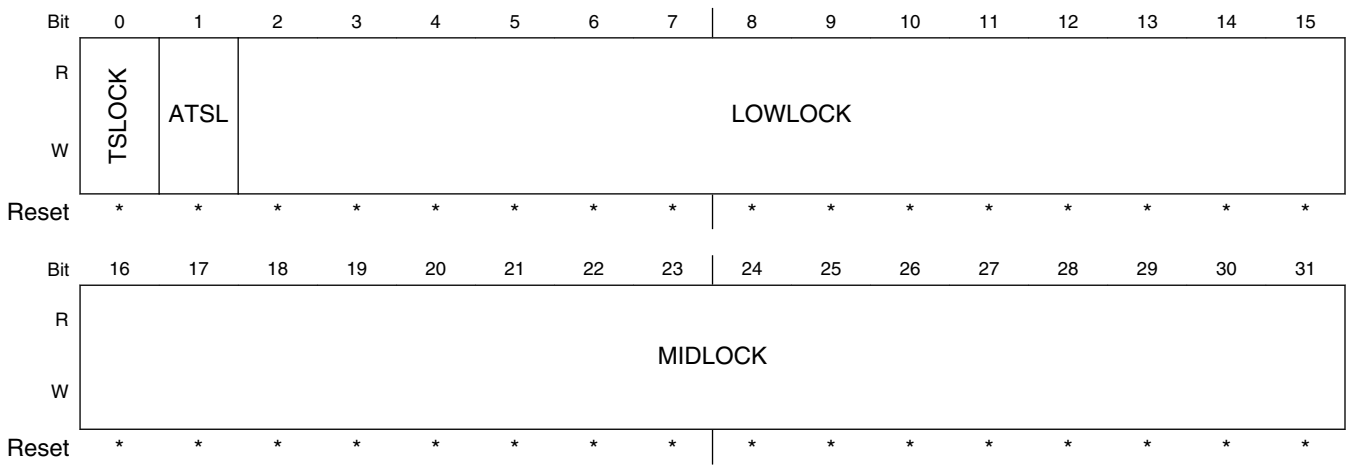
Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

When Production Disable register bit[1](BAF Plock Hardware Interlock enable) is asserted and life cycle is In Field, then the external signal is OR'ed with BAF_plock(low_lock[0]) of LOCK0_PGx.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d



* Notes:

- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- ATSL field: If no DCF records have been written to change the ATSL bit state, the bit will reset to ‘1’.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to ‘1’.

PASS_LOCK0_PG*n* field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTest NVM Lock. This bit is used to lock the UTest NVM block from programs on the alternate interface (erase protection not needed since UTest NVM is OTP and not erasable).
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

88.3.7 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

88.3.8 Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

* Notes:

- L_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to ‘1’.

PASS_LOCK2_PG*n* field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

88.3.9 Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than OEM Production, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

* Notes:

- U_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.

- RL2 field: If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL3 field: If no DCF records have been written to change the RL3 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL4 field: If no DCF records have been written to change the RL4 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- MO field: If no DCF records have been written to change the MO bit lock state, the bit will reset to '1'.
- DBL field: If no DCF records have been written to change the DBL bit lock state, the bit will reset to '1'.
- PGL field: Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

PASS_LOCK3_PG*n* field descriptions

Field	Description
0 PGL	Password Group Lock. This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF load from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface Lock. The default value of this bit would be '1' if not updated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM) 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only. 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MSTR	Master Access. Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 RL4	Read Lock Regison 4 lock bit. The default value of this bit would be '1' if not updated from flash.

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
	0 Region 4 is not protected. 1 Region 4 is protected.
12 RL3	Region 3 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 3 is not protected. 1 Region 3 is protected.
13 RL2	Region 2 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Region 1 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 1 is not protected. 1 Region 1 is protected.
15 RL0	Region 0 is protected. The default value of this bit would be '1' if not updated from flash. 0 Region 0 is not protected. 1 Region 0 is protected.
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

88.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

Table 88-1. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
Censorship					
None	Censorship	None	0x0000_0000	0x00B0	Censorship
Production Disable					

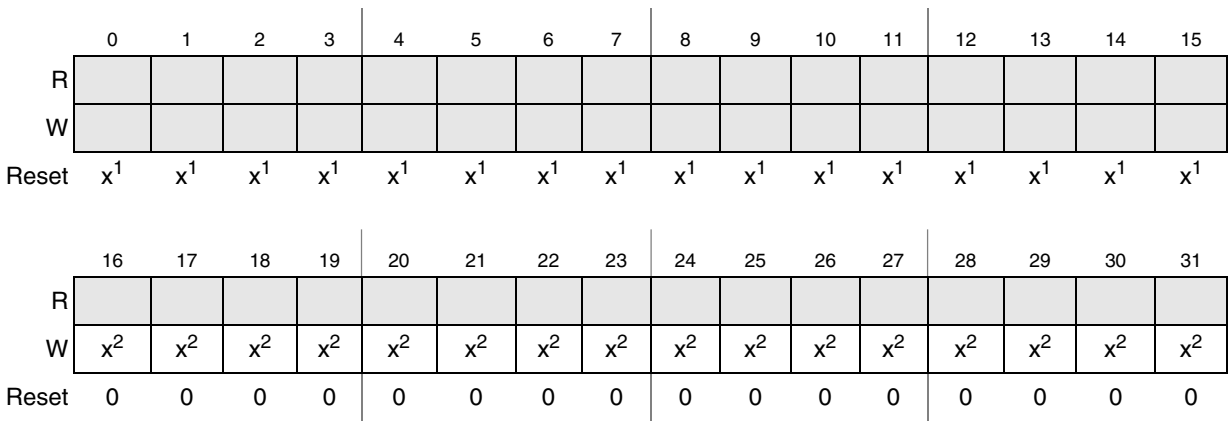
Table continues on the next page...

Table 88-1. PASS DCF clients (continued)

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
None	Production Disable	None	0x0000_0000	0x00C0	Production Disable

88.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.



1 This bit is not defined

2 This value is loaded by DCF Record during reset

Field	Description
16:31	Censorship If this value is 0x55AA the MCU is NOT censored If this value is anything other than 0x55AA, the MCU is censored

88.4.2 Production Disable

Production Disable is a DCF client that is not accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable and Hardware Interlock aspects of the Production Disable feature.

The DCF client implements 2 bits with a default value of ‘0’. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, see Production disable

DCF Client Address: 0x00C0 Production Disable — Access: DCF Record Write Once Only

[1] This value is loaded by DCF Record during reset

Figure 88-2. Production Disable DCF client

Table 88-2. Production Disable DCF Client field descriptions

Field	Description
0-29	This bit is reserved and always has the value 0.
30 HI	Hardware Interlock '0' = BAF flash block programming is controlled by a bit in PASS_LOCK0_PG[LOWLOCK] that controls the BAF (see chip-specific PASS information). '1' = BAF flash block is locked for programming while external hardware pin is asserted '0'
31 DD	Debug disable. '0' = Debug Interface is Enabled and Disabled using Censorship, JTAG password and PASS_LOCK3[DBL] bit (see chip-specific PASS information). '1' = Debug Interface is disabled while Clock Jitter is NOT enabled

88.4.2.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the life cycle is In Field or beyond, overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit. All Debug access is blocked while Clock Jitter is *not* enabled.

Once Clock Jitter *is* enabled, the Debug interface is *not* disabled and can be enabled temporarily or permanently using Censorship, JTAG password or the PASS_LOCK3[DBL] bit.

88.4.2.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the life cycle is In Field or beyond, prevents programming of the BAF Flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

88.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

88.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See Censorship). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

88.5.2 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 registers (See Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)). Both these debug enabling options are further conditioned by life cycle and Production Disable.

The table below describes all options for enabling/blocking Debug Interface access

Table 88-3. Debug Interface Enable Truth Table

Input Conditions						Outcome
Lifecycle	**Production Disable mode**	**Clock Jitter Enable**	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
In Field	Off	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
	On	Jitter Enabled	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
		Jitter disabled	Don't Care	Don't Care	Don't Care	Blocked
Failure Analysis	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled

88.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled until the next destructive reset.

88.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

Table 88-4. Flash Memory Read Protection Truth Table

INPUTS				OUTPUTS	
Life Cycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Don't Care	Locked (1)	Readable	Read Blocked
			Unlocked (0)	Readable	Readable

88.5.4 Production Disable

88.5.4.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (normally CAN and FlexRay). This jitter means those serial communications modules are not able to communicate on the network.

As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted.

88.5.4.2 Enabling

The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. Bit 1 enables the Hardware Interlock pin. See Production Disable for details.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state of both features is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature can not be enabled accidentally.

88.5.4.3 Activation

The BAF code is always the first code executed out of reset. As part of the normal boot sequence, The BAF code copies the ‘Clock Jitter Activation’ constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (See Clock Jitter Enable (PASS_CJE) for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF Flash is 0xFFFF_FFFF (erased state)

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF Flash should be programmed to make the least significant bit ‘0’. After the next reset, the BAF copies this updated value to the Clock Jitter Register and the feature is activated.

The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic ‘0’ the BAF Flash block can not be programmed.

88.5.4.4 Clock jitter Truth table

The following table shows the relationship between Life Cycle, Production Disable & Clock Jitter enable input conditions versus the state of the Baud Rate Clock.

Table 88-5. Clock Jitter Truth Table

Life Cycle	Production Disable[Debug Disable]	Clock Jitter Enable	Baud Rate Clock State
JDP Production Customer Delivery OEM Production In Field	Don't Care	0x0001	Normal - No Jitter
		0x0000	Jitter
Failure Analysis	Off [0]	0x0001	Normal - No Jitter
		0x0000	Jitter
	On[1]	Don't Care	Jitter

88.6 Initialization/application information

88.6.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

88.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 88-6. CS/ADDR Values for Lock Registers

Register	DCF Command Word
PW Group 0	
Lock0	0xxxxx[1] _0100
Lock1	0xxxxx[1] _0104
Lock2	0xxxxx[1] _0108
Lock3	0xxxxx[1] _010C
PW Group 1	
Lock0	0xxxxx[1] _0110
Lock1	0xxxxx[1] _0114

Lock3	0xxxxx[1] _011C
PW Group 2	
Lock0	0xxxxx[1] _0120
Lock1	0xxxxx[1] _0124
Lock2	0xxxxx[1] _0128
Lock3	0xxxxx[1] _012C
PW Group3	
Lock0	0xxxxx[1] _0130
Lock1	0xxxxx[1] _0134
Lock2	0xxxxx[1] _0138
Lock3	0xxxxx[1] _013C

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See chip specific PASS information for the Client Select assignment

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in Table 88-7.

Table 88-7. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00FF	PW Group 1, Lock0
0x0C	0xxxxx[1]_0110	Set MIDLOCK to 0xFF
0x10	0xFFFF_FFFF	Non-Programmed Addresses
0x14	0xFFFF_FFFF	
…	…	

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See Device reference manual for the Client Select assignment

Chapter 89
Tamper Detection Module (TDM)

89.1 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a "diary". At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

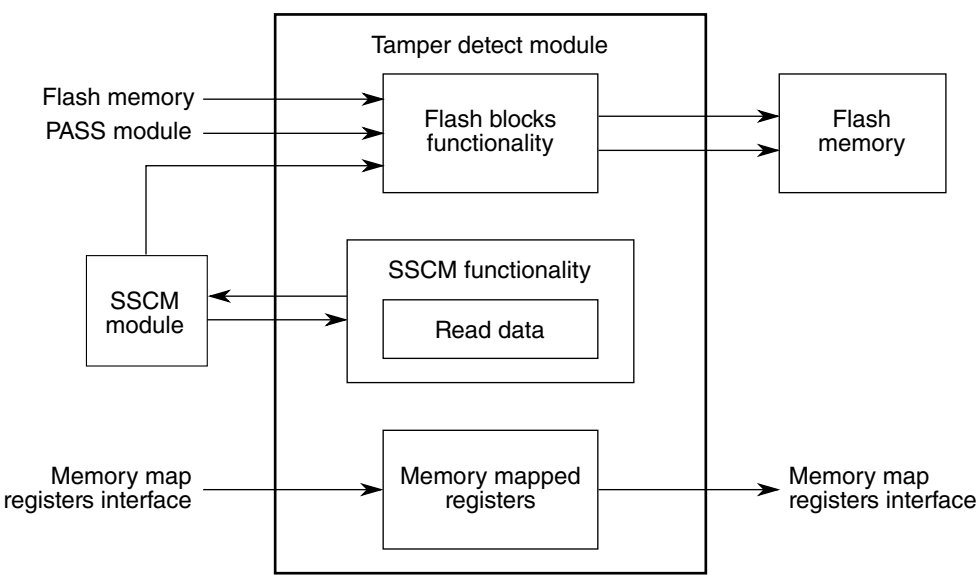

Figure 89-1. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- block assignments for the TDRs
- Tamper region override information (via the DCF bus)
- Software tamper region override

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

89.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[1]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

89.3 External signal description

There are no external signals driving or being driven by the TDM.

89.4 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/ erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

Table 89-1. DCF clients

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
Software Tamper Region Override Disable	Stores information to disable the software mechanism to override the TDR	write once, write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. • n specifies a TDR • m specifies the flash blocks as per the LOCK registers of the flash memory.	write 0 to 1 only

89.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

CAUTION

- This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.
- This DCF client is writable from 1 to 0 only.

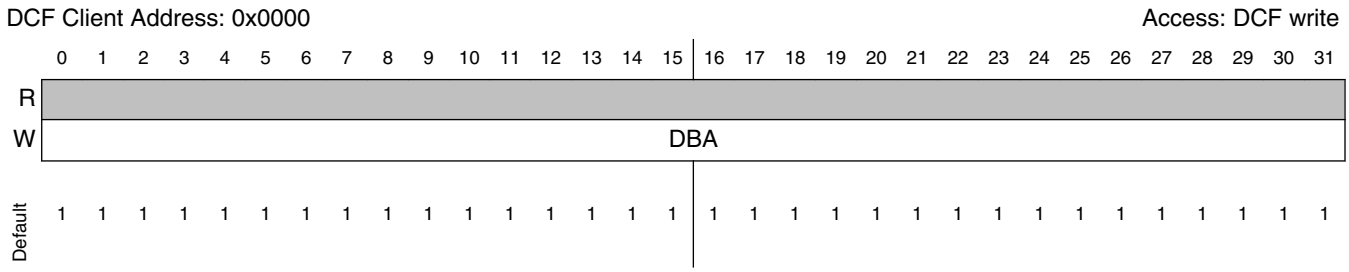

Table 89-2. Diary Base Address (DBA) DCF client field description

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. **NOTE:** Diary Base Address must be on a 16 KB boundary.

89.4.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 89-3. Tamper Region Override (TO) DCF client field descriptions

Field	Description
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the TOE fields.
26–31 TOE5 to TOE0	TDR Override Enable. Each TOE*n* field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written. 1 Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.

89.4.3 Software Tamper Region Override Disable (STO_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

CAUTION

- This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.
- This DCF client is writable from 0 to 1 only.

DCF Client Address: 0x0002 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 89-4. Software Tamper Region Override Disable (STO_DIS) DCF client field descriptions

Field	Description
0–25 Reserved	This field is reserved and should be written with all zeroes when programming the STO_DIS fields.
26–31 STO_DIS5 to STO_DIS0	Software TDR Override Disable TDR*n*. Each STO_DIS*n* field, where *n* represents the TDR number, holds information to disable the software mechanism to override TDR*n*. 0 Software tamper detect override mechanism supported 1 Software tamper detect override mechanism disabled. Any attempt to override TDR*n* by loading a service key value in STO_KEY*n* register is ignored.

89.4.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

16–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in the upper range of 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

89.4.8 Tamper Region Assignment DCF client (TDRn_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn_LOCK0 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 0) Access: DCF write

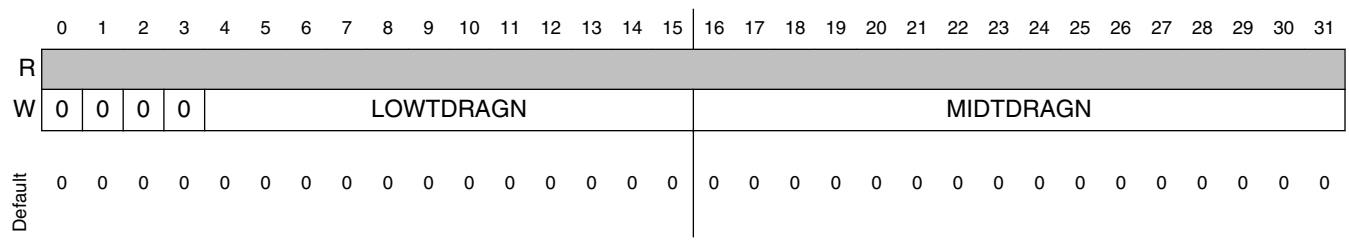

Table 89-9. Tamper Region Assignment DCF client (TDRn_LOCK0)

24	Software Tamper Override Key Region (TDM_STO_KEY5)	32	R/W	0000_0000h	89.5.4/4625

89.5.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

NOTE

1. TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.
2. If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

TDM_STO_KEY*n* field descriptions

Field	Description
0–31 STO_KEY	Software Tamper Override Key Diary n. This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Caution:** The STO_KEYn registers can only be written once.

TDM_STO_KEY*n* field descriptions (continued)

Field	Description

89.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

89.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256 × 64-bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 x 32-bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR diary Location and then unlocks the

blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence, with program completion interrupt enabled (PECIE) or till next reset.

NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This allows erase operations to be performed to the TDR without any diary entry. Alternatively, if another TDR is available it can be defined to contain the same blocks to extend the diary length for that TDR.

The setting from “override tamper region lock” DCF record (Diary) has priority over the settings in the TDRn_LOCK0- 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDR*n*_LOCK*m* settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

NOTE

The settings in the Tamper Region Override Register have priority over the TDR*n*_LOCK*m* registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

89.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDR*n*_LOCK*m* where *n* is the number of a tamper region, that is, 0- 5 and *m* varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- '1' means that the corresponding flash block is assigned to this TDR
- '0' means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

89.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core and from the HSM.

NOTE

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

89.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is ‘1’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xx00_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

89.6.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See TDR Status Register (TDM_TDRSR) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See TDR Status Register (TDM_TDRSR). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See Last Flash Programmed Address Register (TDM_LFPAR).

89.6.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the STO_KEY*n* program-visible register, where n denotes the tamper detect region. By loading the value 0x55AA5A5A into STO_KEYn register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the STO_DISn field of the STO_DIS DCF Client is set.

89.6.7 One time programmable (OTP)

89.6.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

Chapter 90
Wakeup Unit WKPU

90.1 Introduction

The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. This NMI external source can also generate a functional reset event to the MC_RGM. The following figure is a block diagram of the WKPU and its interfaces to other system components.

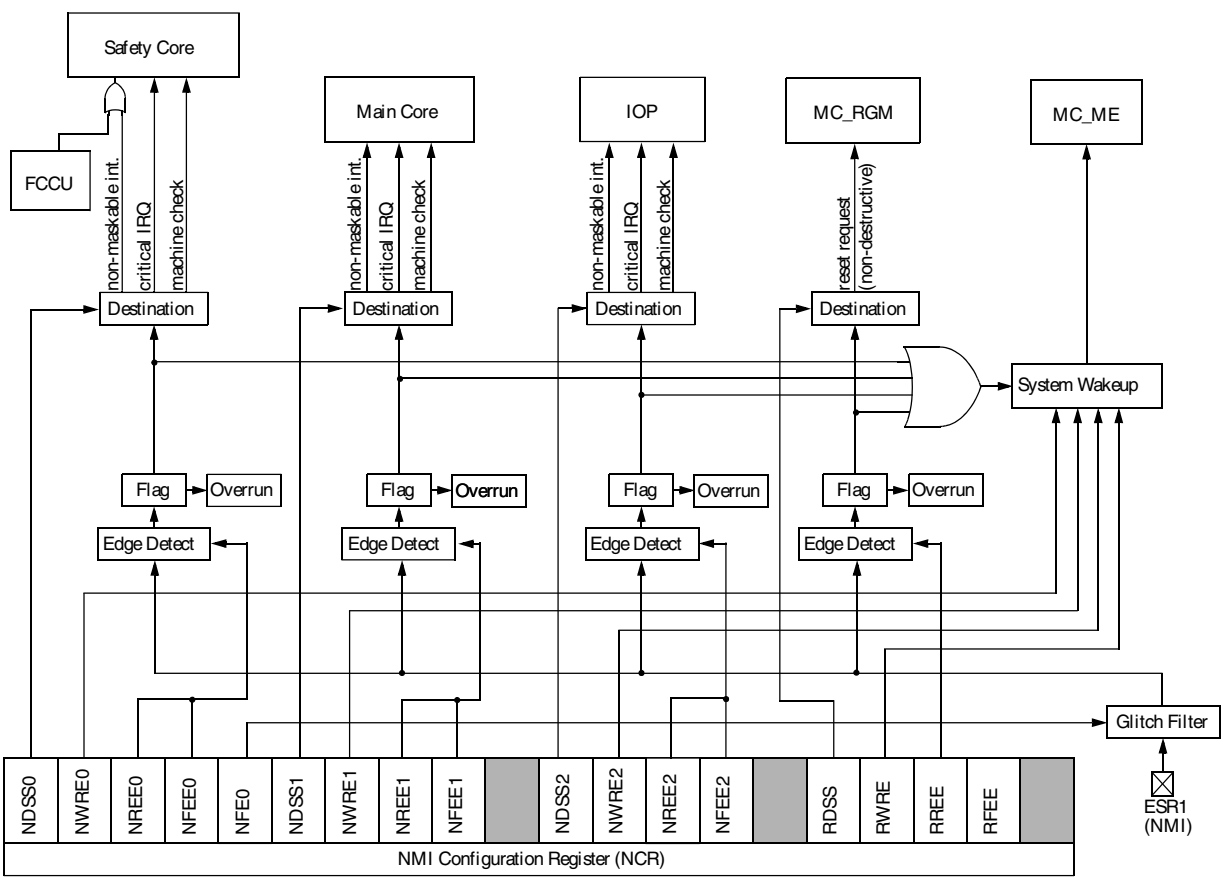

Figure 90-1. WKPU block diagram

90.1.1 Features

The WKPU supports these features:

- One external NMI source
- One analog glitch filter
- Independent interrupt destination for each core (safety core, main core, and IOP):
  - Non-maskable interrupt
  - Critical interrupt
  - Machine check request
- Active edge selection control for events to each core and functional reset event to MC_RGM
- Configurable wakeup event from low-power mode to the MC_ME
- Configurable wakeup event to exit from Stop mode to the MC_ME
- WKPU register configuration lock

90.2 External signal description

There is a single, active-edge selectable, NMI pin on the device that connects to the WKPU block. See this chip's signal description information for details on this pin.

90.3 WKPU memory map and registers

This section provides a detailed description of all registers accessible in the WKPU module.

NOTE

Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

WKPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	NMI Status Flag Register (WKPU_NSR)	32	R/W	0000_0000h	90.3.1/4635
8	NMI Configuration Register (WKPU_NCR)	32	R/W	0000_0060h	90.3.2/4637

90.3.1 NMI Status Flag Register (WKPU_NSR)

This register holds the status flags of the NMI external source pin and reset request. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI or reset request event is detected. The overrun flag is set whenever an NMI or reset request event is detected and the status flag is set (i.e., has not yet been cleared). The reset request overrun is a don't-care since the device will be reset on the first event.

The status flags are set independently of the NDSS/RDSS bits. Therefore, these flags can set but not generate a non-maskable interrupt or system wakeup if NWRE/RWRE = 0 or if NDSS is set to "no request".

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

NOTE

NIF is set when all the following are true:

- NMI Destination Source Select is disabled (NDSS = 11)
- NMI System Wakeup Request is disabled (NWRE = 0)
- An NMI input event is seen

Also see the notes in NMI Configuration Register (WKPU_NCR).

WKPU_NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0 (safety core) If enabled (i.e., NCR[NREE0] or NCR[NFEE0] is set), an NMI input event will set NIF0. NIF0 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS0], and/or a system wakeup request based on NCR[NWRE0]. 0 No event has occurred on the pad 1 An event as defined by NCR[NREE0] and NCR[NFEE0] has occurred
1 NOVF0	NMI Overrun Status Flag 0 (safety core) This field is a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF0 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS0], and/or a system wakeup request based on the NCR[NWRE0] bit configuration. 0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 NIF1	NMI Status Flag 1 (main core) If enabled (i.e., NCR[NREE1] or NCR[NFEE1] is set), an NMI input event will set NIF1. NIF1 causes an interrupt request based on the NMI destination, as configured by NCR[NDSS1], and/or a system wakeup request based on NCR[NWRE1]. 0 No event has occurred on the pad 1 An event as defined by NCR[NREE1] and NCR[NFEE1] has occurred
9 NOVF1	NMI Overrun Status Flag 1 (main core) This field is a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF1 causes an interrupt request based on the NMI destination, as configured by the NCR[NDSS1] bits, and/or a system wakeup request based on the NCR[NWRE1] bit configuration. 0 No overrun has occurred on NMI input 1 1 An overrun has occurred on NMI input 1
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 NIF2	NMI Status Flag 2 (IOP)

Table continues on the next page...

WKPU_NSR field descriptions (continued)

Field	Description
	This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE or NFEE set), an NMI input event will set NIF. NIF causes an interrupt request based on the NMI destination, as configured by the NDSS bit, and/or a system wakeup request based on the NWRE bit configuration. 0 No event has occurred on the pad 1 An event as defined by NCR[NREE2] and NCR[NFEE2] has occurred
17 NOVF2	NMI Overrun Status Flag 2 (IOP) This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short "functional" reset. 0 No overrun has occurred on NMI input 2 1 An overrun has occurred on NMI input 2
18–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RIF	Reset Status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (i.e., if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short "functional" reset. 0 No event has occurred on the pad 1 An event as defined by NCR[RREE] and NCR[RFEE] has occurred
25 ROVF	Reset Overrun Status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short "functional" reset. 0 No overrun has occurred on the NMI reset request input 1 An overrun has occurred on the NMI reset request input
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

90.3.2 NMI Configuration Register (WKPU_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

Writing a '0' to both NREE*n* and NFEE*n* disables the NMI functionality completely (i.e. no system wakeup or interrupt will be generated on any pad activity).

NOTE

Writing to the NCR when NIF = 1 or NOVF = 1 causes an interrupt to the destination source/system wakeup to be generated independent of an NMI wakeup event.

Field	Description
0 NLOCK0	NMI Configuration Lock Register 0 0 Writing 0 to this bit has no effect. 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset.
1–2 NDSS0	NMI Destination Source Select 0 00 A non-maskable interrupt will occur if NSR[NIF0] or NSR[NOVF0] is set. 01 A critical interrupt will occur if NSR[NIF0] or NSR[NOVF0] is set. 10 A machine check request will occur if NSR[NIF0] or NSR[NOVF0] is set. 11 No reaction
3 NWRE0	NMI Wakeup Request Enable 0 0 System wakeup requests from the corresponding NSR[NIF0] bit are disabled 1 A set NSR[NIF0] bit or set NSR[NOVF0] bit causes a system wakeup request
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 NREE0	NMI Rising-edge Events Enable 0 0 Rising-edge event is disabled 1 Rising-edge event is enabled
6 NFEE0	NMI Falling-edge Events Enable 0 0 Falling-edge event is disabled 1 Falling-edge event is enabled
7 NFE0	NMI Filter Enable Enable analog glitch filter on the NMI pad input.

Table continues on the next page...

WKPU_NCR field descriptions (continued)

Field	Description
	0 Filter is disabled 1 Filter is enabled
8 NLOCK1	NMI Configuration Lock Register 1 0 Writing 0 to this bit has no effect. 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset.
9–10 NDSS1	NMI Destination Source Select 1 00 A non-maskable interrupt will occur if NSR[NIF1] or NSR[NOVF1] is set. 01 A critical interrupt will occur if NSR[NIF1] or NSR[NOVF1] is set. 10 A machine check request will occur if NSR[NIF1] or NSR[NOVF1] is set. 11 No reaction
11 NWRE1	NMI Wakeup Request Enable 1 0 System wakeup requests from the corresponding NSR[NIF1] bit are disabled 1 A set NSR[NIF1] bit or set NSR[NOVF1] bit causes a system wakeup request
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 NREE1	NMI Rising-edge Events Enable 1 0 Rising-edge event is disabled 1 Rising-edge event is enabled
14 NFEE1	NMI Falling-edge Events Enable 1 0 Falling-edge event is disabled 1 Falling-edge event is enabled
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 NLOCK2	NMI Configuration Lock Register 2 0 Writing 0 to this bit has no effect 1 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset.
17–18 NDSS2	NMI Destination Source Select 2 00 A non-maskable interrupt will occur if NSR[NIF2] or NSR[NOVF2] is set. 01 A critical interrupt will occur if NSR[NIF2] or NSR[NOVF2] is set. 10 A machine check request will occur if NSR[NIF2] or NSR[NOVF2] is set. 11 No reaction
19 NWRE2	NMI Wakeup Request Enable 2 0 System wakeup requests from the corresponding NSR[NIF2] bit are disabled 1 A set NSR[NIF2] bit or set NSR[NOVF2] bit causes a system wakeup request
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 NREE2	NMI Rising-edge Events Enable 2 0 Rising-edge event is disabled 1 Rising-edge event is enabled

Table continues on the next page...

WKPU_NCR field descriptions (continued)

Field	Description
22 NFEE2	NMI Falling-edge Events Enable 2 0 Falling-edge event is disabled 1 Falling-edge event is enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RLOCK	Reset Configuration Lock Register 0 Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset . 1 Writing a 0 has no effect.
25–26 RDSS	Reset Destination Source Select 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
27 RWRE	Reset Wakeup Request Enable 0 System wakeup requests from NSR[RIF] are disabled 1 A set NSR[RIF] bit or set NSR[ROVF] bit causes a system wakeup request
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 RREE	Reset Rising-edge Events Enable 0 Rising-edge event is disabled 1 Rising-edge event is enabled
30 RFEE	Reset Falling-edge Events Enable 0 Falling-edge event is disabled 1 Falling-edge event is enabled
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

90.4 Functional Description

This section provides a functional description of the WKPU features.

90.4.1 Non-Maskable Interrupts

The WKPU allows the external NMI pin (ESR1) to assert the non-maskable interrupts of the cores on the device. These interrupts include non-maskable interrupts, critical interrupts, or machine check requests to any of the cores including the main core, IOP,

and safety core. The safety core's non-maskable interrupt line from the WKPU is combined with the FCCU internal NMI interrupt event arising due to fault management logic.

The NMI destination interrupt is controlled by the user through the configuration of NCR[NDSS*n*].

The enabling of rising-edge, falling-edge, or either-edge reaction to the NMI pin is independent for each core, and is controlled by NCR[NFEE*n*] and NCR[NREE*n*].

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The NMI supports a status flag, NSR[NIF*n*], and an overrun flag, NSR[NOVF*n*].

90.4.2 Reset management

The WKPU allows the external NMI pin (ESR1) to assert a non-destructive reset request to the MC_RGM module. The ESR1 reset request can be reconfigured in the MC_RGM to generate a SAFE mode or interrupt request (see "Reset Generation Module (MC_RGM)" for details).

The enabling of rising-edge, falling-edge, or either-edge reaction to the NMI pin is independent for the reset request, and is controlled by the RFEE and RREE bits in the NCR register.

Reset request supports a status flag and an overrun flag which are located in the NSR register. See NMI Configuration Register (WKPU_NCR) for more information.

90.4.3 System Wakeup

The WKPU allows the external NMI pin (ESR1) to assert a system wakeup from STOP to the MC_ME module on the chip. The system wakeup is enabled through the NWRE or RWRE bits in the NCR register.

90.4.4 Glitch Filter

An analog glitch filter, between the NMI pin (ESR1) and the WKPU module, is enabled by NCR[NFE0]. See the chip's data sheet for the glitch filter's electrical specifications.

90.4.4.1 Edge Detect

Each NMI and reset request can be enabled or disabled independently. This can be performed using the NCR register, which contains all configuration bits for a given NMI in a single byte. The user can configure interrupts with an active rising edge, an active falling edge, or either edge being active. Disabling both edge events results in no interrupt or reset being propagated from the WKPU block.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits. The active reset request edge is controlled by the RREE and RFEE bits.

NOTE

After reset, all rising-/falling-edge enable bits set to 0, therefore the NMI functionality and reset request is disabled after reset and must be enabled explicitly by software.

90.5 Initialization Information

This section discusses initialization for the following features:

- Glitch Filter and Pad Configuration
- Non-maskable interrupt initialization
- Reset Request

90.5.1 Glitch Filter and Pad Configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NREE, NFEE, RREE, and RFEE, bits in the same register write.

90.5.2 Non-maskable interrupt initialization

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. Mask interrupts by clearing NSR[NIF*n*] and NSR[NOVF*n*].
2. Clear NCR[NFEE*n*] and NCR[NREE*n*], preferably by writing 0 to all bits in the register.
3. Configure the analog glitch filter using NCR[NFE0].
4. Configure the appropriate SIUL2_MSCR register for the desired NMI interrupt pin(s) as follows:
   - Clear the ODC bits to disable output.
   - Set the IBE bit to enable the pin's input buffer.
   - If the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits.

NOTE

NMI interrupt pins should never be configured as outputs, i.e., MSCR[ODC] bits are not zeros, when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
   - NMI source (NDSS*n*).
   - Wakeup request (NWRE*n*).
   - Glitch filter (NFE0)
   - Rising/falling edge events enable (NFEE*n* and NREE*n*).
   - NMI configuration lock (NLOCK*n*).

90.5.3 Reset Request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization, the user must do the following:

1. Mask reset requests by clearing NSR[RIF] and NSR[ROVF].

2. Clear NCR[RFEE] and NCR[RREE], preferably by writing 0 to all bits in this register.
3. Configure the analog glitch filter, as desired, using NCR[NFE0].
4. Configure the appropriate SIUL2_MSCR register for the NMI interrupt pin(s) as follows:
   - Clear the ODC bits to disable output.
   - Set the IBE bit to enable the pin's input buffer.
   - If the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits.

NOTE

NMI reset request pins should never be configured as outputs (i.e., MSCR[ODC] bits are not zeros) when external reset request inputs are desired since false reset requests could be detected (e.g., from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
   - Reset destination source (RDSS]).
   - Reset wakeup request (RWRE).
   - Glitch filter (NFE0)
   - Rising/falling edge events enable (RFEE and RREE).
   - Reset configuration lock (RLOCK).

Appendix A
Release Notes for Revision 4

A.1 General changes

• No substantial content changes

• In the second "Core Debug Support" chapter, added the name of the core (e200z720n3) throughout the chapter.
• In the "IRCOSC Digital Interface" chapter, in the "Functional description" section, deleted the second paragraph and bulleted list pertaining to the power-on reset sequence.
• In the PSI5 chapter:
  • In PSI5S_LINCR2, footnote “Register bit can be read/set by software” changed to a NOTE in the ABRQ field description.
  • In PSI5S_PTD register description, corrected missing cross-reference in the last sentence.
  • In PSI5S_GLSR register, modified bit position of DIRCMD_RDY field.
  • Removed PSI5S_WD_DDTRIG_CLKDIV0, PSI5S_WD_DDTRIG_CLKDIV1, PSI5S_WD_DDTRIG_CLKDIV2, and PSI5S_WD_DDTRIG_CLKDIV3 registers.
  • Added PSI5S_DIRCMD register.
  • In PSI5S_E2SCR_CHn, redundant footnote on start condition removed. (The description is present in the CMD_TYPE field description.)
• Editorial (non-technical) changes and improvements throughout.
• Spelling correction and wording improvements.

A.2 Preface changes

• No substantial content changes

A.3 Introduction changes

In section, Block diagrams, • Updated Periphery allocation figure with two SIPI module. • Updated Block diagram figure with one more LFAST and SIPI block. • Updated Flash size to 8640 KB in sections, Features summary and Feature list.
• In the Software debug and calibration section, changed overlay RAM to 1M byte.

A.4 Embedded Memories changes

• Editorial changes.
• Chip-specific C55FMC flash register information :   • New section contains device-specific C55FMC_LOCKn and C55FMC_SELn register definitions.
• In Flash memory array, changed the flash size (was 8 MB, is 8640 KB).

A.5 Signal Description changes

• No substantial content changes

A.6 Memory Map changes

Editorial changes.

A.7 Functional Safety changes

• In Clock modified cross-reference to MCU clocking details
• In Table 1 deleted column “Recommended recovery: Destructive reset"
• Minor editorial change
• In Online Logical BIST (LBIST), updated the note to, "When Scan mode is entered through LBIST, the flash memory must be in IDLE state, therefore Program or Erase operations must not be either active or suspended."
• Removed section "FCCU failure inputs". This section is now located in the FCCU Device Configuration section of the RM.
• Editorial updates.
• Updated contents of Table 6-2.
• Deleted requirement tag "[Covers: Saf1107]" from topic End-to-End protection on data path. • Changed TT_CAN to M_TTCAN throughout the module. • In Table 6-3 changed DMACHMUX to DMAMUX. • Updated topic Dual-core lockstep • Updated Table 6-5. • In Interface to ECC units, updated paragraogh that starts with "Not all ECC units provide...".

A.8 Device Configuration Changes

• Added Error signal flow diagram.
• In the FCCU bridge topics, FCCU register availability and reset values table, added row for FCCU_MCS register with a reset value of 0x0000_8083.
• In the FCCU Device Configuration, added section "FCCU failure inputs" (FCCU failure inputs).
• In Decorated Storage Memory Controller (DSMC), added footnote to DSMC instances associated with processor cores: "Instances of the DSMC associated with processor core tightly-coupled memory do not protect both ports—only the backdoor port used by other cores or peripherals is protected. Any IMEM or DMEM location expected to be referenced with atomic access should only be accessed by the local processor core via a decorated storage instruction."
• In Interrupt sources, removed Interrupt Sources, 490 and 491. Updated MC_ME3 interrupt source to include ME_IS[I_ICONF] | ME_IS[I_ICONF_CC] | ME_IS[I_ICONF_CU]. • In Table 7-67, updated 'Nominal value expected' for LVD270_C, LVD270_F, LVD295_F, LVD295_A, and LVD400_A.
• In Table 7-23, added extra sources to IRQs 558, 559, 561, and 562.
Changed the following in the DSPI Instantiation table: • Changed DSPI2 value in LVDS column from "Not Available" to "Available." • Added column for CMD FIFO Depth.
Changed the FCCU Channel 5, SSCM_XFER_FLASH_ERR, the "Error reaction path check" cell from "Not testable" to "Testable." Replaced the following in FCCU Channel 53: VDD_HV_IO_JTAG, VDD_HV_IO_FLEX and VDD_HV_IO_MAIN" with "VDD_HV_IO_EBI, VDD_HV_IO_FLEX, and VDD_HV_IO_FLEXE."

• FCCU failure inputs
  • In Table 7-86
  • Changed 'FCCU channel' 27 to Reserved.
  • Changed 'FCCU channel' 28 to Reserved.

• PMC ADC test mode
  • In Table 7-67,
  • Row 6b101101, updated 1.28V to 1.30V in Nominal value field.
  • Row Internal POR on flash HV, updated LVD_Threshold to POR250_Threshold in Nominal value field.
  • Row LVD400_IM, updated LVD_Threshold to LVD400_Threshold in Nominal value field.
  • Rows LVD108_F/P, added footnote for Nominal value expected
  • Added footnote, "bandgap trimmed reference voltage" for all of equations with '~supply X 1.2/*_Threshold'.

• Added CRS register reset values for XBAR_0 and XBAR_1 configurations.
• In PMC ADC test mode updated number of channels to 110 that are used for PMC analog signal monitoring.
• Added Wait time for writing to the online registers.

A.9 Reset and Boot changes

• No changes.

A.10 "Device Configuration Format (DCF) Records

- Revised 4th step in the sequence describing behavior after power is applied in Introduction.
- Added DCF records and UTEST DCF records.
- Miscellaneous DCF registers: Changed title from "DCF registers" to "Miscellaneous DCF registers." Added JTAG Pins table/description. Updated JTAG Pin Configuration DCF Client offset to 000000000000111.
- Reversed order of bit fields in "PMC_REE bits DCF Client" table.
- DCF client table: Content revisions. Added description for DCF order dependency in flash memory.
- DCF records: Changed OTP UTEST flash memory start address to 0x0040_0300.

- Added xref to XOSC Start-up in the Table 9-8 XOSC_LOAD_CAP_ SEL field description.

- Made editorial and technical-content changes to Introduction.
- Made substantial changes to:
  - Table 9-6
  - Miscellaneous DCF registers
- Table 9-8 :
  - Added a note to XOSC_LF_EN description.
  - Changed OSC_EN_40MHZ field description.
  - Changed ESR0_GATE field description.
- Table 9-7 : deleted "Reserved" from XOSC_IBIAS_SEL field.

- Updated "PMC_REE bits DCF Client" table with HVD8_F bit field.

A.11 Power Management changes

- Editorial changes.
- In Checker core disabling, added "(unless user intentionally disables checker clock, e.g. afterrun mode)."
- In Flash power requirements, added content to the last paragraph.
- Revised Table 10-4.
- In VDD_LV conditions and LVD trimming/enabling sequence, changed "After analog delay (tLVDTRIM) has elapsed" to "After a delay (including tLVDTRIM and other system operations) has elapsed".
- In Power-down sequence, added "In the case of an intentional power down of the Low Voltage supply (1.2V), the Auxillary Regulator should be disabled by writing a 1 to the bit VREG1P2_CTRL[VREG1P2_DIS]."
- Updated Figure 10-4.
- Updated Figure 10-6.
- Updated Figure 10-7.
- Updated Figure 10-8.
- Revised VDD_HV conditions and LVD trimming/enabling sequence.

A.12 Security changes

- In Basic security, replaced BAM with BAF.

A.13 Calibration_and_Debug changes

Changed e200z720n3 core name to e200z710n3.
• No substantial content changes.
• Replaced 'DCI cross triggering' entry under the 'Signal' column, to 'Debug Break and Cross Triggering'.
• Added JTAGC ACCESS_AUX block instructions.

A.14 Core_Complex_Overview changes

• No substantial content changes

A.15 Core description module changes

• In Figure 14-1, ensured that the heading "Debug Registers" appears without a subsequent footnote marker.
• Revised Figure 14-1 and Figure 14-2.

• Hardware Implementation Dependent Register 0 (HID0) :
  • New
• Hardware Implementation Dependent Register 1 (HID1) :
  • New

• Register model :
  • Correction to Supervisor Mode Programmer's Model SPRs figure: Added Thread ID register (TIR) and System Information Register (SIR)
  • Correction to Supervisor Mode Programmer's Model DCRs and PMRs figure: Added Thread Management Register TMCFG0
  • Correction to User Mode Programmer's Model SPRs figure: Added System Information Register (SIR)
• Instruction timing :
  • New
• Exceptions :
  • Footnote added to Critical input offset value in Exceptions and conditions table
• Machine Check Syndrome Register (MCSR) :
  • Footnote added to Exception type column heading in field descriptions table
  • Footnote added to DC_DPERR in field descriptions table

A.16 Core description module changes

• Register model :
  • Figure 15-1 : Added Thread ID register (TIR) and System Information Register (SIR)
  • Figure 15-1 : L1CSR2 register deleted
  • Figure 15-2 : Added Thread Management Registers (TMR)
  • Figure 15-2 : Deleted Cache Access Registers

• Figure 15-3 : Added System Information Register (SIR) • Figure 15-3 : Added footnote to Nexus PID • Added "Instruction timing" section.
• DMEM Control Register 0 (DMEMCTL0) : • For DMEMCTL0 register, corrected DSWCE=11b description for local memory partial-width slave write checking • IMEM Control Register 0 (IMEMCTL0) : • For DMEMCTL0 register, corrected DSWCE=11b description for local memory partial-width slave write checking • End-to-End ECC fault injection by software : • In E2EECSR0[RCHKBIT] description, added information about external read accesses that receive an error response.
• End-to-End ECC fault injection by software : • Changed "error generation" to "fault injection" • Added description for external read accesses that receive an error response
• Added "Cache" section and subsections.
• In Table 15-18 of Machine Check Syndrome Register (MCSR) • In table footnote about MEA, corrected core name • Added footnote for exception type
• Machine State Register (MSR) : • Bits added to register figure and field descriptions table: • SPV (SP/Embedded FP/Vector available) • WE (Wait State (Power management) enable) • FP (Floating-Point Available) • FE0 (Floating-point exception mode 0) • FE1 (Floating-point exception mode 1) • IS (Instruction Address Space) • DS (Data Address Space) **NOTE:** None of the above bits are functional. They were previously shown as reserved bits but are redefined to clearly show any deviations from Book III-E of the Power ISA version 2.06 specification.
• Register model : • Correction to Supervisor Mode Programmer's Model SPRs figure: "LSP" removed from EFPU Registers section • Correction to Supervisor Mode Programmer's Model DCRs and PMRs figure: Thread Management Register (TMR16) name changed to TMCFG0 (was DMEMCTL0)
• Hardware Implementation Dependent Register 0 (HID0) : • New • Hardware Implementation Dependent Register 1 (HID1) : • New
• DMEM Control Register 0 (DMEMCTL0) : • First sentence of DSWCE field value 11 description changed to, "Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte) writes." (was "...(1-, 2-, or 3-byte) writes.")

A.17 SIUL2 module changes

• Updated number of external interrupts (EIRQs) to 10, 341 pads and 22 ports throughout. • Updated SIUL2 block diagrams. • In Section, External interrupt request: Added EIRQ 3 to 'interrupt request 0'.

A.18 XBAR changes

- In XBAR Priority Registers Slave (XBAR_PRS*n*), added the note "See Chip Configuration section for this device's reset values." at the beginning of the section.
- In XBAR Control Register (XBAR_CRS*n*), changed the reset value (was 0000_0000h, is 00FF_0000).

A.19 XBIC module changes

- No substantial content changes

A.20 Peripheral Bridge changes

- General operation :
  - Following note added: “FlexRay access to peripherals via the peripheral bridge is not supported“.

A.21 SMPU changes

- No changes.

A.22 IAHBG changes

- In Timing modes, removed "32 -> 64 interface" and "64 -> 32 interface" sections.

A.23 SEMA42 module changes

- Added AUTOSAR definition to Introduction.

- Corrected register prefix to SEMA42 throughout chapter.
- Made editorial and/or technical changes to:
  - Gate Register (SEMA42_GATE*n*) register description.
  - Reset Gate Write (SEMA42_RSTGT_W) register description.
  - RSTGDP field description.
  - Reset Gate Read (SEMA42_RSTGT_R) replaced register description with a sentence referring to SEMA42_RSTGT_W description.

• RSTGSM description for value 10. • Functional description : minor edit. • Multi-core programming 101: software gates : Changed "writes" to "accesses" in the first paragraph. While one processor updates/writes data, another one must not read it.
• Edited two citations in Multi-core programming 101: software gates.

A.24 INTC module changes

• Completely replaced Examining LIFO contents. • In Raised priority preserved, replaced the timing diagram and associated table of event descriptions.
• In Raised priority preserved, deleted the text "Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in INTC_CPRn."
• In Interrupt sources, changed "chapter that describes how modules are configured and connected" to "chip-specific INTC information".
• In INTC Master Protection Register (INTC_MPROT), in the ID field description, added "Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error."
• In Block diagram, revised the stem sentence and figure title to indicate that the diagram is an example of a four-processor configuration, and that the actual number of supported processors is given in the chip-specific INTC information. • In Features, ensured that the bulleted list shows only those processors supported on this chip. • Revised Memory map and register definition to show only those registers and fields actually present on this chip.
• In Memory map and register definition, changed "Although INTC_SSIn are 8 bits wide..." to "Although INTC_SSCIRn are 8 bits wide...".
• In INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*), changed "... can write to the CLR bit and not the SET bit, otherwise ..." to "... can write to the CLR bit, otherwise ...".

• In Memory map and register definition :
  • Added Figure 23-2 and surrounding text explaining write restrictions for PSR*n* and SSCIR*n*.
  • In INTC Priority Select Register (INTC_PSR*n*) and INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*), added "See Figure 23-2 for limitations on writing to this register."

A.25 eDMA changes

• In Enable Error Interrupt Register High (eDMA_EEIH) and Interrupt Request Register High (eDMA_INTH), deleted the extraneous text "[[MAT+MCK]]".
• In TCD Control and Status (eDMA_TCD*n*_CSR), changed “XBS” to “XBAR“ in BWC field description. • In Control Register (eDMA_CR), the reset value was changed from 0x0000_0000 to 0x0000_E400. • In Control Register (eDMA_CR), bit 31 was changed from read-only to read-write.

A.26 DMAMUX module changes

• Updated note in the register description for Channel Configuration register (DMAMUX_CHCFGn) as follows: "Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0)."

- In the section "Enabling and configuring sources," changed code examples, from #define DMAMUX_BASE_ADDR 0xFC084000/* Example only ! */ to #define DMAMUX_BASE_ADDR 0x40021000/* Example only ! */.

A.27 Clocking changes

- Updates to Figure 26-1 in Clock generation :
  - Added PSI5-S (PSI5_S_BAUD_CLK) to AUX Clock 0 Divider 4
  - Added footnote for PSI5_S_BAUD_CLK: "Referred to as ipg_baud_clk in the PSI5-S chapter."
  - Minor non-technical changes
- Update to Table 26-1 in MC_CGM registers :
  - New output clock added to CGM_AC0_DC4, CGM_AC0_SC regusters: PSI5-S (PSI5_S_BAUD_CLK)
- Update to Table 26-2 in System clock frequency limitations :
  - Added PSI5_S_BAUD_CLK (PSI5-S) to divider logic list for Aux Clock 0 Selector (Divider 4)

- Updated XOSC_CTL register reset value to 0030_8000h
- Updated IRCOSC_CTL register reset value to 0000_0000h

- Updated Divider1(DIV1) value from '1...1024' to '1...256' in figure, Figure 26-2

- Added explanation of PSI5-S clock in PSI5 clock dividers.

- Loss of IRCOSC clock
  - Updated Figure 26-11, adding the FCCU and FOSU modules and their connections.

A.28 PLLDIG changes

- DTHDIS
  - Added note (Important) "This field must be written 00b" to the DTHDIS field description.

- Features
  - Removed bullets showing PLL input/output frequencies. Duplicate information that is the Data Sheet.

- PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)
  - Added the requirement ID PLLDIG_BLG_005 (enclosed in square brackets) to the beginning of the LOLIE field description.
  - Added "end" in square brackets to the end of the LOLIE field description.
  - Updated reset value of reserved field 21, and changed access to RO.
- PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)
  - Added the requirement ID PLLDIG_BLG_006 (enclosed in square brackets) to the beginning of the LOLF field description.
  - Added "end" in square brackets to the end of the LOLF field description.
- PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)
  - Added the requirement ID PLLDIG_BLG_007 (enclosed in square brackets) to the beginning of the LOLIE field description.
  - Added "end" in square brackets to the end of the LOLIE field description.
- PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)
  - Added the requirement ID PLLDIG_BLG_008 (enclosed in square brackets) to the beginning of the LOLF field description.
  - Added "end" in square brackets to the end of the LOLF field description.

- Added new topic Maximum lock time.

- Clock configuration
  - Updated equation for f_{PLL0_VCO} by adding a x2 multiplier in numerator.

- Editorial updates throughout.
- Clock configuration

• Updated equations in section.
• PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)   • Updated 'PLL0' to 'PLL1' in Register description, "...effective after PLL1 is disabled, then reenabled."

• PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)
  • Replaced the sentence, "The values of PREDIV and MFD..." with "PLL0DV can be modified at anytime..." in the register description.
• PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)
  • Updated register description.
• PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  • Removed the sentence, "Changing the values of PLL1FM[MODEN] and PLL1FM[MODSEL] fields..." in the register description.
• Clock configuration
  • Add equation headings and titles to equations.
• Frequency modulation
  • Added "Equation" titles to formulas.
  • Updated Figure 27-1 to show that MD is a peak-to-peak value.

• PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  • Removed the text ", however, the output clock from PLL..." from the last sentence in the register description.
• Normal mode with reference, PLL0 or both PLLs enabled
  • Replaced "output divider (Reduced Frequency Divider) and whether PLL modulating is enabled" with "and modulation enable are" in second paragraph.
  • Updated the end of the first sentence, "In normal mode, PLL0 receives..."
• Introduction
  • Removed "The chip provides a user interface and control over" from the first sentence which now reads "The Dual PLL system composed of..."

• PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)
  • Added updated content to the register description.
• PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)
  • Added updated content to the register description.
• PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)
  • Removed the text "the binary equivalent of" from the field descriptions of INCSTP and MODPRD.

• Removed the section "Acronyms and Abbreviations". • Frequency modulation   • Updated the equation in the Note, from "$f_{max} = f_{sys} \times (1 + (MD\%)$." to "$f_{max} = f_{sys} \times (1 + (MD\% / 100))$."
• Frequency modulation   • Updated the sentence "If center modulation is selected..." to "If center modulation is used..." in the Note "The device maximum operating frequency..."
• Register PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)   • Replaced the register description with updated content.
• PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)   • Updated MODSEL bitfield value descriptions for both 0 and 1.

A.29 CMU changes

• CMU Interrupt Status Register (CMU_ISR)   • Added NOTE to the OLRI field description, "While entering STOP mode, OLRI may be triggered. To avoid this when the system is running on the PLL, disable the XOSC before entering STOP mode."

• Introduction
  • Added NOTE "See the 'Clocking' chapter for chip-specific sources used by the CMU."
• CLKMN1 supervisor
  • Added the NOTE "An example of determining the..."

• CLKMN1 supervisor

- Updated NOTE to read "($HFREF_{Actual}$ = ($HFREF_{Ideal}$ ÷ 0.95)" instead of "($HFREF_{Actual}$ = ($HFREF_{Ideal}$ + 2) × 1.05)".
- Added "The actual LFREF value will be 762 when the accuracy is taken into consideration ($LFREF_{Actual}$ = ($LFREF_{Ideal}$ ÷ 1.05)." to the NOTE.

A.30 MC_CGM module changes

- In Memory map and register definition,
  - added MC_CGM_AC5_CDC23 register.
  - Updated reset values of registers, MC_CGM_AC5_CDC0, MC_CGM_AC5_CDC1, MC_CGM_AC5_CDC2, MC_CGM_AC0_SS, and MC_CGM_AC0_SC.

- Editorial changes.
- Added note to the DIV_FMT value in the MC_CGM_AC0_DC3 register to select the correct DIV_FMT value.

- Updated MC_CGM_AC10_SC[SELCTL] field description.
- In Memory Map and Register Definition, Updated note, 'All registers will be accessible in "User mode"... only if SSCM_ERROR[RAE] is set'.

A.31 XOSC changes

- Functional description
  - Added "(from MC_ME)" in the first column of heading row of Table 30-1.

- Added note to clarify bypass operation.

- XOSC Control Register (XOSC_CTL)
  - Split the Reserved bitfield at offset 7 into two Reserved fields of 5 bits and 2 bits.

A.32 IRCOSC changes

- No substantial content changes

A.33 PRAMC module changes

- Reliability considerations
  - Changed "Safety considerations" in section title and content to "Reliability considerations"
- Transaction monitor
  - Changed the sentence, "Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies...." to "Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies...."

- SRAM controller memory map and register definition:
  - Changed the first sentence from, "The RAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot" to "...programming model mapped to a standard on-platform peripheral slot".

• SRAM controller memory map and register definition :
  • Note added regarding caution required when reconfiguring platform RAM controller during device operation
• Hsiao ECC algorithm :
  • Reformatted RAM controller basic H-matrix definition table. Added new column, XOR Sum, as placeholder for calculated checkbit. The XOR sum checkbit for each row is calculated by XORing all values in the positions marked with an asterisk in that row.

• Less than 64-bit writes :
  • Added single bit and multi bit error signals to Read-modify-write data path figure
  • Changed hardware signal names to names that describe signal function more clearly

• Optional read wait-state :   • All references to the PRCR1 register changed to "PRCRx". This is only an editorial change--there is no change to any register name or function.

A.34 Flash memory controller module changes

• Reliability considerations :
  • Section renamed to "Reliability considerations" (was "Safety considerations")
  • Text added: "This section summarizes mechanism to enhance the reliability of Flash by correcting and detecting faults."

• Flash address generation check :   • Clarification: "Functional safety" changed to "Fault detection"
• Overlay RAM feedback check :   • Clarification: "Functional safety" changed to "Fault detection"
• Reliability considerations on overlay accesses :   • Section renamed to "Reliability considerations on overlay accesses" (was "Safety considerations on overlay accesses")
• PFlash calibration remap to RAM :   • Editorial fixes (no technical changes)
• Censorship :   • "Security flash blocks" added to list of flash regions

• Error termination :
  • "...returns an error response on an attempted access ", changed to, "returns an error response on an attempted access to a partition that is unavailable."
  • Link to Embedded Flash Memory chapter added

• Platform Flash Remap Control Register (PFLASH_PFCRCR) :   • Caution note added explaining that the use of overlay remap functions has a potential for causing data coherency issues *when used with line read buffers enabled*. To prevent issue, clear line read buffers prior to enabling any remap region.
• Functional description :   • Deleted from first sentence: "As shown in the block diagram"

• ECC on data flash accesses :
  • Editorial changes
  • Clarification: Following note added: "EEPROM should be avoided for storage of executable code."

• Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRDn_Word0) :
  • Clarification: Previously the LSTARTADDR field was shown as a 32-bit field with read/write access. The address is a 32-bit address but the least significant 4 bits are always 0 and are now shown as a reserved read only zero field.
• Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRDn_Word1) :
  • Clarification: Previously the PSTARTADDR field was shown as a 32-bit field with read/write access. The address is a 32-bit address but the least significant 4 bits are always 0 and are now shown as a reserved read only zero field.

• Platform Flash Configuration Register 1 (PFLASH_PFCR1) :   • Clarification: All "1xx" values in the APC field have the same effect. Previously, the values, 100, 101, 110, and 111 in the APC field were listed individually and had identical descriptions. They are now condensed into a single entry, "1xx" in the value list to reduce the possibility of confusion.
• Platform Flash Configuration Register 1 (PFLASH_PFCR1) :   • Note added to PFLASH_PFCR1[APC] field description: "A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup."

A.35 c55fmc module changes

• Added note about reset value to Alternate Module Configuration Register (C55FMC_MCRA) description: "Reset values are dependent on chip configuration. See the Chip Configuration chapter for specifics."
• Clarified information about chip-specific reset value of:
  • Extended Module Configuration Register (C55FMC_MCRE)
  • Over-Program Protection 0 register (C55FMC_OPP0)
  • Over-Program Protection 1 register (C55FMC_OPP1)
  • Over-Program Protection 2 register (C55FMC_OPP2)
  • Over-Program Protection 3 register (C55FMC_OPP3)

Features • Clarification: Feature "Triple Voted Flops for safety critical flash functions" changed to "Triple Voted Flops for flash functions requiring high reliability".
Test mode disable seal • Detail added: "UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written."
Features • Clarification: Feature "Triple Voted Flops for flash functions requiring high reliability" changed to, "Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control"

A.36 DSMC module changes

• No substantial content changes

A.37 Flash Memory Programming and Configuration changes

• Removed incorrect content from the "Creating password groups" section.

A.38 EBI module changes

- In Modes of Operation, replaced EBI_BR3 with EBI_BR2.
- Memory Map and Register Definition,
  - Module Configuration Register (EBI_MCR): Updated reset value to 0000_0800h. Updated bit field access EBI_MCR[20:19] to RW.
  - Updated the numbers of instances for EBI_BR[0:2] and EBI_OR[0:2] registers.

A.39 ADC Configuration changes

- In Table 38-21, changed input channel 119 from a writeable field to Reserved in the following registers:
  - TCIPR
  - TCIMR
  - TCDSR
  - TCNCMR
  - TCJCMR
  - TCWSELR2
  - TCWENR
  - TCAWORR
- In Table 38-22, renamed 'SARADCB_ECIPR0' register to 'SARADC_ECDSDR'.

- Simultaneous start of multiple Sigma-Delta converters : Updated diagram Figure 38-4.

- Internal voltage monitor channel assignments
  - Added footnote "When doing conversions on this channel, it is recommended to mask the corresponding HVD/LVD from generating a reset for the duration of the conversion when this channel is enabled." to the column "SARADC_B input channel" and rows with channels 112...118, Table 38-16.

- Internal voltage monitor channel assignments
  - Updated the row of channel 111 row making this channel Reserved, in Table 38-16.

- In Table 38-1, removed unused pins from the entry for the SARADC_B instance.

- Expanded Table 38-20 to show channels 64..87 for ICWSELR, ICAWORR, and ICWENR.

- SARADC_0 register definitions
  - In table, updated the row of SARADC0_WTHRHLR0-WTHRHLR3 to SARADC0_WTHRHLR[0:3].
  - In row SARADC0_ICWSELR0, changed width of fields WSEL_CH7, WSEL_CH6, WSEL_CH5, WSEL_CH4 from 3 bits to 2 bits.
- SARADC_1 register definitions
  - In table, updated the row of SARADC1_WTHRHLR0-WTHRHLR3 to SARADC1_WTHRHLR[0:3].
  - In row SARADC1_ICWSELR1, changed width of fields WSEL_CH15, WSEL_CH14, WSEL_CH13, WSEL_CH12, WSEL_CH11, WSEL_CH10, WSEL_CH9, WSEL_CH8 from 3 bits to 2 bits.
- SARADC_2 register definitions
  - In table, updated the row of SARADC2_WTHRHLR0-WTHRHLR3 to SARADC2_WTHRHLR[0:3].
  - In row SARADC2_ICWSELR3, changed width of fields WSEL_CH23, WSEL_CH22, WSEL_CH19, WSEL_CH18, WSEL_CH17, WSEL_CH16 from 3 bits to 2 bits.
- SARADC_3 register definitions
  - In table, updated the row of SARADC3_WTHRHLR0-WTHRHLR3 to SARADC3_WTHRHLR[0:3].
  - In row SARADC3_ICWSELR3, changed width of fields WSEL_CH31, WSEL_CH30, WSEL_CH29, WSEL_CH28, WSEL_CH27, WSEL_CH26 from 3 bits to 2 bits.
- SARADC_4 register definitions
  - In table, updated the row of SARADC4_WTHRHLR0-WTHRHLR3 to SARADC4_WTHRHLR[0:3].
  - In row SARADC4_ICWSELR4, changed width of fields WSEL_CH32, WSEL_CH33, WSEL_CH34, WSEL_CH35 from 3 bits to 2 bits.

A.40 SDADC module changes

- Module Configuration Register (SDADC_MCR)
  - Notes added to SDADC_MCR[PGAN] field description and SDADC_CDR register description noting that when programmable gain is 16 (MCR[PGAN]=111), the least signficant bit is always 0.

- In field-setting descriptions for VCOMSEL in Module Configuration Register (SDADC_MCR)
  - For the field setting 0, changed the description from "Negative input terminal is biased with VREFP/2 (half-scale bias)" to "Negative input terminal is biased with VREFN"
  - For the field setting 1, changed the description from "Negative input terminal is biased with VREFN" to "Negative input terminal is biased with VREFP/2 (half-scale bias)"
- In the table in the description of ANCHSEL in Channel Selection Register (SDADC_CSR)
  - For the case when MODE is 1 and VCOMSEL is 0, changed the "INM (negative terminal)" from VREFP/2 to VREFN
  - For the case when MODE is 1 and VCOMSEL is 1, changed the "INM (negative terminal)" from VREFN to VREFP/2

- Changes to SDADC_MCR register :
  - Reserved field containing bits 0-2 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bit 8 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 25-26 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_CSR register :
  - Reserved field containing bits 0-7 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 16-20 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 24-28 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_RKR register :
  - Reserved field containing bits 0-15 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_SFR register :
  - Reserved field containing bits 0-12 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 16-22 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 24-26 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Clarification: Added following note to DFFF field description: "Whenever MCR[EN] is cleared in order to stop the SDADC or change the channel configuration, it is necessary to also clear the RSER[DFFDIRE] bit alongwith. Similarly if DMA or software is too slow in not reading the FIFO datawords resulting in DFFF condition it is advisable to stop the SDADC by clearing the MCR[EN] followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation."
- Changes to SDADC_RSER register :
  - Reserved field containing bits 0-13 (most significant bit is numbered 0) is read-only zero (was R/W)
  - Reserved field containing bits 17-27 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_OSDR register :
  - Reserved field containing bits 0-23 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_STKR register :
  - Reserved field containing bits 0-15 (most significant bit is numbered 0) is read-only zero (was R/W)
- Changes to SDADC_CDR register :
  - Register access changed to Read-only
  - Reserved field containing bits 0-15 (most significant bit is numbered 0) is read-only zero (was R/W)

- Status Flag Register (SDADC_SFR) :
  - Added detail to WTHH field describing how field is cleared by DMA transfer
  - Added detail to WTHL field describing how field is cleared by DMA transfer
  - Clarification: Rephrased description of condition after which CDVF field is set. Field is automatically set when an internal timer counts a number of output clock fd clock cycles specified by the value of SDADC_OSDR[OSD].
- Data conversion :
  - Complete rewrite of first part of section up to the paragraph that describes wraparound control, to clarify the description of the output settling time required after startup. To account for delays related to latency and output settling time an internal timer counts down from a start value determined by the value of the SDADC_OSDR[OSD] field.

- External signal description :

- Replaced: "At the chip integration level, some of the digital and analog signals might share pins or may not be available external to the chip" replaced with "See the chip-specific details about SDADC signals and package pinouts for information about signal muxing and availability external to the chip."
- Gain calibration support :
  - Formatting changes: Binary number format changed to general form of 0000_1111_0000_1111b (was in form 0b0000_1111_0000_1111)
  - Formatting changes: Sequence of three notes changed to numbered list under one note heading (no technical change to content)
- Offset calibration support :
  - Correction: For step configuring SDADC_CSR[ANCHSEL] field value to '101', "single ended mode with negative input=VDD_HV_ADR_D–VSS_HV_ADR_D" changed to "single ended mode with negative input = $(V_{DD\_HV\_ADR\_D} – V_{SS\_HV\_ADR\_D}) / 2$"
  - Clarification: Fields are referred to using the notation, SDADC_*register_name*[*field_name*], e.g., SDADC_CSR[ANCHSEL]
  - Formatting change: Binary number format changed to general form of 0000_1111_0000_1111b (was in form 0b0000_1111_0000_1111)

- Throughout: Changed hexadecimal numbers prefixed with "0x" to "h" suffix
- Features :
  - Clarification: The programmable FIFO structure can store up to 16 datawords
  - Correction: Interrupt/DMA request generation condition for a data buffer threshold event occurs when the data buffer is *above* the threshold (previously stated "Data buffer *at or above* threshold")
- Differential input mode :
  - Clarification: Fields are referred to using the notation, SDADC_*register_name*[*field_name*], e.g., SDADC_CSR[ANCHSEL]
  - Clarification: Differential input mode is entered when the SDADC_MCR[MODE] field is set to '0' and the SDADC_MCR[EN] field is set to '1' (previously stated: "After system reset exit, this is the default mode of operation if SDADC is enabled by asserting MCR[EN]. This mode is entered by negating MCR[MODE]")
- Single-ended input mode :
  - Clarification: Fields are referred to using the notation, SDADC_*register_name*[*field_name*], e.g., SDADC_CSR[ANCHSEL]
  - Clarification: Single-ended input mode is entered by setting the SDADC_MCR[MODE] and SDADC_MCR[EN] fields to '1'. (previously stated: "Single-ended input mode is entered by asserting MCR[MODE]")
- FIFO Control Register (SDADC_FCR) :
  - Correction: The SDACD_FCR[FTHLD] field is 4 bits wide (bits: 20–23)
  - Correction (in the FTHLD field description): When the number of datawords in the data FIFO is greater than the value in FTHLD field, the FIFO full event is flagged (previously stated FIFO full event occurred when the number of datawords in the FIFO is *equal to or greater* than the value in FTHLD field)
- Data conversion :
  - Correction: Fixed typo ("SDADC" in following note was "SDADCD"):

    Care should be taken while programming the TRIGEN/ TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

- Output Settling Delay Register (SDADC_OSDR)
  - In OSD field description, added note "Refer to the tsettling and tLATENCY parameters in the device datasheet for the minimum allowed output settling delay values."
- Data conversion step
  - Added sentence “Refer to the $t_{settling}$ and $t_{LATENCY}$ parameters in the device datasheet for the minimum allowed output settling delay values.“ into the note.

A.41 SARADC changes

- Start of normal conversion :

• Following note added: "An appropriate gap should be maintained between any two consecutive triggers such that next trigger is received only after the completion of ongoing conversion. This gap value can calculated as a sum of total conversion time as programmed using the CTR0-3 registers for each channel in the chain." • Injected channel conversion : • Following note added: "An appropriate gap should be maintained between any two consecutive injected triggers such that next injected trigger is received only after the completion of ongoing injected conversion. This gap value can calculated as a sum of total conversion time as programmed using CTR0-3 registers for each channel in the injected chain."
• Main Configuration Register (SARADC_MCR) • Updated MCR reset value to 0x0000_8001 from 0x0000_0001.

A.42 Temperature Sensor changes

• In Temperature threshold detection (digital output generation) section, changed "..... if any of the three specified temperature thresholds are crossed" to "..... if any of the specified temperature thresholds are crossed"
• Replaced terms "bandgap voltage" and “reference voltage” with "bandgap reference voltage" across chapter • In Calculating device temperature, “$T_{TSENS\_CODE}(T)$” corrected to “$V_{TSENS\_CODE}(T)$”.
• In Temperature threshold detection (digital output generation) section, removed “or 165°C” in reference to hot insertion test temperature.
• In Temperature formula, removed the "Calibration Points" figure and its introductory sentence.

A.43 STM module changes

• In STM Control Register (STM_CR), added the note "The reset value is implementation specific. See the Configuration information." at the beginning of the section.
• In STM Control Register (STM_CR) description, removed the note "The reset value is implementation specific. See the Configuration information."
• In Functional description • Incorporated minor edits
• For reserved fields of following registers, added text to each field description: "This field is reserved." • STM Control Register (STM_CR) • STM Channel Control Register (STM_CCR*n*) • STM Channel Interrupt Register (STM_CIR*n*)

A.44 SWT module changes

• In Introduction, changed "timer" to "window watchdog timer".
• In SWT Control Register (SWT_CR), added the note "The reset value for the SWT_CR is implementation specific. See the configuration information." at the beginning of the section. • In SWT Time-out Register (SWT_TO), added the note "The reset value for this register is implementation specific. See the chip configuration section." at the beginning of the section.
• Memory Map and Registers: incorporated various edits • In SWT Control Register (SWT_CR) description, revised note:

• From: "The reset value for the SWT_CR is implementation specific. See the configuration information." • To: "The reset value of this register is implementation specific. See the chip-specific SWT information." • In SWT Time-out Register (SWT_TO) description, revised note: • From: "The reset value for this register is implementation specific. See the chip configuration section." • To: "The reset value of this register is implementation specific. See the chip-specific SWT information."
• In SWT_CR register • In section title, changed SWR to SWT • Edited text in section, including in footnote
• In Servicing operations incorporated minor editorial/formatting changes
• In SWT Control Register (SWT_CR) changed Reserved from read-only and always zero to read/write
• In SWT Service Register (SWT_SR) description of WSC field, changed beginning of second sentence from "If the SWT_CR[KEY] bit is set" to "If the SWT_CR[SMD] field is 01b" • In SWT Service Key Register (SWT_SK) description of SK field, changed beginning of second sentence from "If SWT_CR[KEY] is set" to "If SWT_CR[SMD] is 01b"

A.45 PIT module changes

• No substantial content changes

A.46 GTMINT changes

• Extensive revisions and improvements throughout the entire chapter.

A.47 GTM104 changes

• No substantial content changes

A.48 GTMDI changes

• Editorial changes. • Added About this module. • In External signal description, deleted the "Message data out (MDO)" and "Message start/end out (MSEO[1:0])" sections. • Added GTM-IP Debug / Halt mode description. • Revised Debug enable logic.
• In Device Identity register (DID), updated MPC5777M DID_PIN. • In Device Identity register (DID), added values of DID_PRN, DID_DC. • Revised the note after TIM-TOM-ATOM selection and control logic.

A.49 CAN Subsystem chapter changes

• In Core Release Register (M_CAN_CREL), added the note "The coding of revisions depends on the module version used in the device." at the beginning of the section. • In Core Release Register (M_TTCAN_CREL), added the note "The coding of revisions depends on the module version used in the device." at the beginning of the section.
• In Fast Bit Timing and Prescaler Register (M_TTCAN_FBTP), updated the bit field width for TDCO, FBRP bits and updated bit offset of TDC bit.

A.50 DSPI changes

• In DSPI DSI Configuration Register 1 (DSPI_DSICR1) :
  • Updated bit-width of TSBCNT bit from [2:7] to [3:7].
  • Updated bit 3 as Reserved.
 	
• In DSPI Status Register (DSPI_SR) : Updated reset value from 0xDEAD_BEEF to 0x0201_0000h.

• Changed access for all the reserved bit fields in the DSICR0 register to R/W. • Updated DSI serialization
• In section, Continuous Serial Communications Clock, Updated sentence, “Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status” to “Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low".

• All reference to DSPI DSI 64bit Mode removed from the RM as this mode is not supported by the device.
  • In Memory Map and register definition
  • DSPI_CTAR0: Updated FMSZ field description to remove DSI64 support.
  • DSPI_CTAR_Slave: Removed FMSZ5 bitfield and Updated FMSZ field description to remove DSI64 support.
  • DSPI_DSICR0: Removed FMSZ5 bitfield.
  • DSPI_SDR0: Updated description to remove DSI64 support.
  • DSPI_ADSR0, COMPR0, DDR0, SSR0, DIMR0, DPIR0: Updated description to remove DSI64 support.
  • Updated bitfield description DSPI_DSICR1[TRGPRD.]
  • Updated bitfield description DSPI_DSICR1[DSE1] to remove DSI64 support.
  • Deleted DSPI_DSICR1[DSI64E] bitfield.
  • Deleted registers, DSPI_SDR1, DSPI_ADSR1, DSPI_SSR1, DSPI_COMPR1, DSPI_DDR1, DSPI_DIMR1, DSPI_DPIR1.
  • Revised following sections to remove DSI64 Support
  • Timed Serial Bus (TSB)
  • MSC Dual Receiver Support with PCS Switch Over
  • Interleaved TSB (ITSB) Mode
  • Features
  • DSI serialization
  • DSI deserialization
  • DSI configuration
  • Deserialized Data Match Interrupt or DMA Request
  • Deserial Serial Interface (DSI) configuration
  • CSI deserialization
  • CSI serialization
  • Change in data control
• Hidden unimplemented PISR0-7 registers

A.51 Zipwire module changes

• Write performance   • Updated the 'SIPI to write an address' time to 310 ns.

• In Introduction :
  • Updated the paragraph text from "In streaming mode Zipwire has a transfer rate of approximately 32 MB/second" to "In streaming mode Zipwire has a high transfer rate".
• In Read performance :
  • Updated the paragraph text from "64-bit Read response takes 278 ns" to 64-bit Read response takes 278 ns (=89 x 3.13 ns)".

• Editorial changes
• In Zipwire interconnections : Updated bullet from "Tx and Rx connections to the pads via the SIUL and the MSCR registers" to "Tx and Rx configuration is controlled by LFAST Control registers". • Removed "LFAST clocking" section.
• In Architecture : Removed paragraph text "The LVDS pads are shared with other I/O and GPIO.".

A.52 SIPI module changes

• Reserved
  • Added note (Important), "Always write the default value to this field." to the Reserved field description (bit 1).
  • Changed bit 1 to Read/Write from Read Only.

• In In ARR register added a note "This register is writeable only when SIPI_MCR[INIT] = 1." Also removed sentence, "This register can be read or written anytime." from register description.
• In CCR0[WRT], removed a note "Only transfers with channel 2 can write 1 to this bit. All other channels forces SIPI_CCRn[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming.” from the WRT bit field of CCR0-CCR3 registers. • Added bit field brief description of WRT bit in CCR2 register.

A.53 LFAST module changes

• Editorial changes.

• Removed reference to 312/320 MHz and referred to as high data rate. Updated in:
  • External signals section.
  • LFAST operating data rates section.
  • Features section.
  • Auto correlation section.
  • Figure 52-6 figure.
  • LFAST Speed Control Register (LFAST_SCR) : Updated description for bit-value 1 of RDR and TDR bit.
• Editorial changes.
• Removed table from LFAST operating data rates section.
• Changed the base address of LFAST register set from 1h to 0h.

• LVRXOP bit in LFAST LVDS Control Register (LFAST_LCR) is split into 3 individual bits: • LVRXOP[2] changed to LVRXOP_TR.

• LVRXOP[1] changed to Reserved. • LVRXOP[0] changed to LVRXOP_BR. • Updated the access value of LVLPEN bit to Read/Write in LFAST LVDS Control Register (LFAST_LCR).
• Updated the description of [LVCKSS] bit in LFAST LVDS Control Register (LFAST_LCR).

A.54 FEC module changes

• In MII Management Frame Register (FEC_MMFR), added the note "Does not reset" at the beginning of the section.
• In Memory map and register definition, changed the base address appearing above each register figure (is 0h).

• In Features, changed the footnote to "For interface selection options, see the chip-specific FEC information."
• In Interface options, changed the footnote to "For interface selection options, see the chip-specific FEC information."
• In MII Management Frame Register (FEC_MMFR), changed the reset value to X (indicating that the reset value is undefined, as mentioned in the description).
• In Memory map and register definition :
  • Added a new section, Using the RMON and IEEE registers.
  • Revised all the RMON and IEEE register definitions to match the information in this new section.

• In MII Management Frame Register (FEC_MMFR), deleted the text "Does not reset" associated with the reset value, and ensured that the register reset value information is correctly presented.
• In Physical Address High Register and Type Field (FEC_PAUR), changed the reset value of the TYPE field (was 0000h, is 8808h) to match what is already written in the register and field description. • In Opcode/Pause Duration (FEC_OPD), changed the reset value of the PAUSE_DUR field (was 0000h, is undefined at reset) to match what is already written in the register and field description.
• Added Clocking requirements.
• In Frames received with CRC error (FEC_IEEE_R_CRC), ensured that the reset value is shown as Undefined.

A.55 FlexRay module changes

• Glossary : Minor editorial update.
• Minor editorial updates in few sections. • Features : Clarified features for SECDED ECC.
• Changed "Memory Content Error Detection" section title to "Memory Content Fault Detection". • Changed "Memory Error Injection" section title to "Memory Fault Injection". • Changed "Memory Error Injection out of POC:default config" section title to "Memory Fault Injection out of POC:default config" and changed references of "error" to "fault" in this section.

• Added the note "After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section)." at the beginning of the following sections:
  • Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*)
  • Message Buffer Frame ID Register (FR_MBFIDR*n*)
  • Message Buffer Index Register (FR_MBIDXR*n*)
  • Message Buffer Data Field Offset Register (FR_MBDOR*n*)
  • LRAM ECC Error Test Register (FR_LEETR*n*)

• Memory map and register definition : Editorial updates.
• Slot Status Counter Condition Register (FR_SSCCR) : In FR_SSCCR[STATUSMASK[3:0]] bit field name, removed the text [3:0].
• StopWatch Count Register (FR_STPWR) : corrected the width of FR_STPWR register and FR_STPWR[STPW] from 16-bits to 32-bits

• FR_MCR[CHB]: In FlexRay channel selection table, Dual channel Device Modes CHB=1 and CHA=0 settings are updated as "reserved"
• In Features, added "Dual Channel Support" feature.

A.56 I2C changes

• In I2C Bus Data I/O Register (I2C_IBDR), added the note "When the I^2C is configured ... should be different".
• Editorial changes.

• Editorial changes.
• In I2C Bus Data I/O Register (I2C_IBDR), deleted the note "When the I^2C is configured in master mode ... should be different".
• In Figure 55-13, changed "Set TXAK =1" to "Set NOACK = 1".
• In Generating START, changed IBVR to IBCR.
• Revised Transmit/receive sequence to show the correct procedures for all four cases.
• In Exiting DMA mode, system requirement considerations :
  • Revised the information about DMA channel linking and DMA scatter/gather process.
  • Added an example for a 150 MHz system.

• In Memory map and register definition, added register access level information (indicating that registers can be accessed in supervisor mode only).
• Editorial changes. • In I2C Bus Interrupt Config Register (I2C_IBIC), added the BYTERXIE field. • In Table 55-15 and Table 55-16, deleted the first step ("Use the IBFD register to select...") and adjusted the remaining step letters accordingly. • In Loss of arbitration, changed "generate an interrupt to CPU and set the IBAL to indicate that the attempt to engage the bus is failed" to "generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration."
• In I2C Bus Frequency Divider Register (I2C_IBFD), revised the IBC field description to show the correct bit encoding. • In I2C Bus Interrupt Config Register (I2C_IBIC), added "To program BIIE = 1, you must ensure that IBCR[MDIS] = 0." • In Table 55-11, changed the "SCL Hold (stop)" entry for IBC = 6F (was 96, is 962).
• In Register accessibility, added "Address location 0x0007 is a reserved location, but access to this location will not generate any bus error."
• In Figure 55-1, changed the SCL and SDA lines to appear bidirectional. • In Arbitration procedure and Loss of arbitration, changed "slave receive mode" to "slave mode".

A.57 PSI5 module changes

• Updated DSR_RST fields of CHn_DOBCR registers with current value of DEFAULT_SYNC field. • Changed the reset value of Global Control Register (PSI5_GCR) register from 0000 to 0001. • In the PSI5_GCR register GLOBAL_DISABLE_REQ field description, removed sentence “When PSI5_PDIS_RST = 0 then the reset value is "0"(PSI5 module is enabled after reset). • Editorial change.
• A note added in DMA support section: DMA master ID replication mode is not allowed together with PSI5. • Removed "Clock and Reset" section.
• Changed S3SBR+ to S3SBR in all channels in SnEBR resgiters' description.
• Added T-bit handling and all its sub-sections.
• In Features section, removed "DMA transfer through bullet list" feature from the features' list. • In Operating modes section, updated the "Operating Modes" diagram.

• In External signal description section, removed the duplicate footnote from the "PSI5 Port List" table. • Changed the location of table footnote to page footnote. It now appears in the description of PSI5_GCR register. • Updated the description of NDS field of PSI5_CHn_NDSR registers. • Updated the description of DSR field of PSI5_CHn_DSRL and PSI5_CHn_DSRH registers.

• In Data Output Block Configuration Register (PSI5_CH0_DOBCR) register section,
  • Deleted duplicate footnotes from "DOBCR bit configurations and the related output states" table.
• In Data Output Block Configuration Register (PSI5_CH1_DOBCR) register section,
  • Deleted duplicate footnotes from "DOBCR bit configurations and the related output states" table.
• In Data Output Block Configuration Register (PSI5_CH2_DOBCR) register section,
  • Deleted duplicate footnotes from "DOBCR bit configurations and the related output states" table.

• In PSI5_CHn_DSR[IS_DMA_PM_DS_FIFO_FULL] description, changed "the DMA request ipd_psi5_dma_req_pm_ds" to "DMA request"
• In PSI5_CHn_GICR description, reorganized second half of sentence into list format

• In each CHn_DOBCR register, in the "CMD_Type" table:
  • Made formatting updates in the heading row
  • Combined redundant footnotes and edited footnote text
• In CH0_DOBCR register, removed "DPR" after "State 5" in "DOBCR bit configurations and the related output states" table.

A.58 PSI5-S module changes

-
• Editorial change.
• In PSI5-S Watchdog Operation corrected cross-references to register descriptions of WD_CFGR_CH and WDGTSSR
• Updated field width of IFD field in PSI5-S UART Tx Idle Delay Time Register (PSI5S_PTD) register to 4-bit, in place of 5-bit earlier.

• Added PSI5-S ECU to Sensor Direct Command Write register (PSI5S_DIRCMD).
• Moved position of DIRCMD_RDY field in PSI5-S Global Status Register (PSI5S_GLSR) from 12 to 11.
• Removed the following registers:
  • WD_DDTRIG_CLKDIV0
  • WD_DDTRIG_CLKDIV1
  • WD_DDTRIG_CLKDIV2
  • WD_DDTRIG_CLKDIV3

A.59 SRX/SENT module changes

• In Global Control Register (SRX_GBL_CTRL) description:
  • Changed FMDUIE field to Reserved
  • Changed SMDUIE field to Reserved

• In Global Status Register (SRX_GBL_STATUS) description, changed abbreviated name of Fast Message DMA Underflow field from FDMU to FMDU
• Minor editorial updates • In section Low power modes added a note to show that the message read registers will appear to lose their contents in certain conditions. • In section Initialization sequence added a note to explain that NUM_EDGES_ERR status flag is getting set randomly at the falling edge of the first Calibration pulse (start of status and communication nibble) which comes after an IDLE phase, even without the occurence of the event related to this flag and still the receiver is able to receive the message. Because of this other error status flags may get masked.

- In Fast Message Ready Status Register (SRX_FMSG_RDY) added a note in SRXx_FMSG_RDY register to show that under certain conditions, the Single Edge Nibble Transmission (SENT) Receiver (SRX) stalls and the Fast Message Data Ready bit for the SENT channel (FMSG_RDY[F_RDYn]) will no longer get set to indicate that a fast message is available. Reads of any of the fast message registers by the MCU core will stall and not complete.
- In section Adjustment for variation in sensor (Tx) clock note added as a workaround for Length of Calibration pulse 25% higher
- In section CRC check note added as a workaround for SENT module that creates errors when the actual calibration pulse is shorter than nominal value
- In section Pause pulse diagnostic added details as a workaround for unexpected behavior of SENT Calibration equal to pause pulse
- Deleted heading "Register Classification for Safety"

- In table “Table 58-2" ID [15:12] changed to Data Field [15:12]

- In Features changed sentence from "Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift and jitter in the Transmitter and Receiver clocks per channel" to "Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel".
- In Slow Serial Message Ready Status Register (SRX_SMSG_RDY) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Fast Message Ready Status Register (SRX_FMSG_RDY) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Initialization sequence, Note removed as it was taken care of via ERR007425
- In Fast Message DMA Control Register (SRX_FDMA_CTRL) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Slow Serial Message DMA Control Register (SRX_SDMA_CTRL) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Fast Message Ready Interrupt Control Register (SRX_FRDY_IE), changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Slow Serial Message Ready Interrupt Enable Register (SRX_SRDY_IE) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
- In Input programmable filter updated value of FIL_CNT for the example shown and updated the diagram
- In CRC check removed Note
- In Fast Message Ready Status Register (SRX_FMSG_RDY) removed a Note
- In Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL) added a Note to the field CM_PRSC
- In Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL) changed sentence from "The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock" to "The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock".
- In Channel 'n' Status Register (n=0 to (CH-1)) (SRX_CH*n*_STATUS) changed SMSG_OFLW bitfield description.
- In Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CH*n*_CONFIG) changed description of field values of bitfield SRX_CHn_CONFIG[FCRC_TYPE] and SRX_CHn_CONFIG[SCRC_TYPE].
- In Adjustment for variation in sensor (Tx) clock deleted note that starts with "At ambient ...".
- In Receiver diagnostics changed bullet point from "Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or XOR-based" to "Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.".
- In Nibble value check changed intoductory sentence from "As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:" to "As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):".
- In CRC check changed text in introductory paragraph from "XOR-based CRC implementation" to "new recommended CRC implementation".
- In Pause pulse diagnostic update changed table caption and deleted FMSG_OFLW row.
- In High frequency receiver clock (protocol clock) requirements modified entire content within this heading.

- In Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CH*n*_CLK_CTRL), changed access of CM_PRSC field from read/write to read-only.

- In Time stamp logic changed text:
  - Was: "For example, if the high frequency receiver clock is 59 MHz, the required prescaler value to generate a time stamp clock of 1 µs resolution is 60"
  - Now: "For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1 µs resolution"

• In DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3) changed field name SRX_DMA_SMSG_BIT3[ID7_4_D3_0] to SRX_DMA_SMSG_BIT3[ID7_4_ID3_0].
• Minor editorial changes.

A.60 LINFlexD module changes

• In the description of LINFlexD_UARTSR[RMB], changed LINESR to LINSR
• In the LINFlexD_LINCR1 register description, added note: "When accessing the LINFlexD_LINCR1 register, each reserved bit should be written to its original reset value." • In the LINFlexD_UARTCR register description, added note: "When accessing the LINFlexD_UARTCR register, reserved bits should always be written to zero." • In the LINFlexD_LINCR2 register description, added note: "When accessing the LINFlexD_LINCR2 register, each reserved bit should be written to its original reset value."
• In UART mode section, added "13-bit frames" to second bullet item.
• Updated the reset value note: "When slave = 0, this field always reads ‘0’.." and the bit field description: "If generic slave.." for IOPE bit of LINCR2 register. • Added notes to UARTCR and LINTCSR register descriptions • In section: Use cases and limitations, deleted list item, "When IPG_STOP is requested..."
• Updated the reset value note for HTO bit of LINTOCR register • Added note to RDFL_RFC and TDFL_TFC bit description of UARTCR register
• Added note to reset value of MME bit of LINCR1 register

• In Timeout error section
  • Changed ocr_1 to ocr_2 in headings: 'Master mode' and 'Slave mode'.
  • Changed OC1 to OC2 in figure: 'No response'
• In LINFlexD_UARTSR register, removed text from descriptions of DRFRFE and DTFTFF fields: "Register bit is read-only field."
• In LINFlexD_LINOCR register description, changed LINTOCR value to LINTCSR:CNT value
• In LINFlexD_LINTOCR register, clarified HTO footnote

• Editorial updates in the following sections:
  • Slave mode
  • Identifier filtering
  • Start detection and break delimiter detection in receiver
  • UART receiver
  • UART transmitter

• Clarified baud rate calculation equation/formula to have two cases: ROSE=0 and ROSE=1 in section Baud rate generation.
• Added list item, "When IPG_STOP is requested..." in section: Use cases and limitations which was previously deleted.
• Deleted the note: "When the MODE bit is 0, any activity on the transmit ..." written in the register description of LINTCSR. • Updated the reset value note written in the IOPE bit reset value of register LINCR2.

• In section: Master mode, changed 'BDR[0:7]' to 'BDRL and BDRM'
 	
• In section: Memory map and register description,
  • Updated the note: "In Master mode, the registers IFCR0 – IFCR15...". Added table: "Offsets of the register from offsets 8C to 9C", below the note.
  • Minor editorial updates in register 'LINFlexD_LINCR1', bit field 'LASE'

• Changed "For proper functionality, OSR can only take values" to "Allowed values are:" in register 'LINFlexD_UARTCR', bit field 'OSR' • Removed phrase "Parity sent is Even" from the bit field description of bits 'WL0' and 'WL1' of register LINFlexD_UARTCR
• In section: LIN mode features and UART mode features : Updated the baud rate calculation relationship. • In section: Memory map and register description, • Removed reset value of register 'LINFlexD_LINSR' and added the following note to the bit reset value of bit field 'RDI: • "Reset value of RDI reflects the RX pin state" • Updated the bit field description of bit fields 'Reserved' and 'DTE' of register 'LINFlexD_DMATXE'. • Updated the bit field description of bits fields 'Reserved' and 'DRE' of register 'LINFlexD_DMARXE'.
• In section: Timeout error, • Changed 'At the end of the ID, ocr_2 is loaded with 36 (maximum possible response space)' to 'At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT]' • Changed 'ocr_2' to 'OC2'
• In section: Memory map and register description, • Removed sentence "The reset value is the 2Dh = 45 ... the LIN specification." from the description of 'HTO' bit of register 'LINTOCR' • In section: Interrupts, added note: "Rx interrupt due to ... LSIE is enabled." in the figure: 'Interrupt diagram'
• In section: Memory map and register description, • In register LINSR, • Changed the access of bit field 'LINS' to ROWO (was RO) • Added note 'The value of this bit field doesn't change ... LIN state event. to the bit field description. ' • In register, UARTSR, updated the bit field description of bit DRFRFE. • In register, UARTSR, updated the bit field description of bit DTFTFF: 'This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.' to 'This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set.' • In register LINTOCR, clarified the reset value note of bit field HTO.
• Updated section: Header error
• In section: References", removed note: 'FBRR will not be usable ... in UART mode.' • In section: Baud rate generation, updated sentence 'When reduced oversampling is enabled, LINFBRR is not used and LDIV contains only the integer part of LINIBRR.' to 'When reduced oversampling is enabled, LINFBRR should not be used and programmed to zero and LDIV contains only the integer part of LINIBRR.' • In section: Memory map and register description, • In register UARTCR, enhanced the bitfield description of bits WL0, WL1, PC0, and PC1.
• In section: Memory map and register description, • Updated the bitfield descriptions of: • Bitfields 'SLEEP' and 'INIT' of register 'LINCR1' • Bitfields 'DTU_PCETX' and 'TDFL_TFC' of register 'UARTCR' • Bitfields 'EN' and 'IFD' of register 'PTD' • Updated the register description of register 'PTD' • Reduced the width of bitfield 'IFD' from 5 to 4 of register 'PTD'
• Updated section: Baud rate generation
• In section: Memory map and register description, • In register 'LINESR' updated the bitfield description of 'OCF'
• Added section: LINFlexD Clock Tolerance

A.61 MC_RGM module changes

• Added MC_RGM_FERD[D_SOFT_FUNC] field.

- In Memory Map and Register Definition, Updated note, 'All registers will be accessible in "User mode"... only if SSCM_ERROR[RAE] is set'.
- Editorial update to MC_RGM_FERD[D_TSR_FUNC] field description.
- Added note to MC_RGM_FES, 'When ESR0 gate is disabled via ... ESR0 reset has also occurred.'

A.62 BAF module changes

- Download start address, VLE bit and code size
  - Removed the paragraph "The NO_ECHO bit is used to indicate..."
  - Table Table 61-19
    - Replaced the row in table that has VLE at bit0, and now have a CODE_LENGTH of 15 bits (CODE_LENGTH[30:16])and no NO_ECHO bit.
- Protocol summary
  - Table Table 61-21
    - Removed the contents of row 'Protocol steps' 4, column 'BAF response message' and replaced with '—'. NO_ECHO bit is not used.

- BAF image header
  - Removed the device specific 'BAF version number' address, replacing it with text, "BAF version number". Customer is referred to the 'BAF memory map' table in the configuration section.
- BAF image version
  - Removed the device specific BAF start address, and referred customers to the "BAF memory map" table in the configuration section.
- Optionally perform serial boot
  - Switched the output of the "Password Valid" decision block, 'no' to 'Static mode' and 'yes' to 'Receive START address' in Figure 61-3

- Bullet point describing "Serial Boot" in Boot modes section is updated.
- Flow of control image in Flow of control section is updated.
- Table 61-4 is updated for clarity.
- Note added in Soft DCF clients section and Table 61-5 is updated.
- Note added in Security Watchdog CPU select (SEC_SWT_CPU) section.
- Caution is added in BAF DCF client - DATAX section.
- New section added - CALIBRATION_PD_DELAY_ENABLE – BAF calibration PD delay enable DCF client.
- In second paragraph of Production disable activation protocol and implementation section, modified the value to enable jitter.
- New section added - TDM Diary Operation.
- Download start address, VLE bit and code size section is updated as:
  - The statement mentioning about 3 LSB bits in download address is updated in the paragraph starting as "The start address...".
- Protocol summary section is updated as:
  - Table 61-21 is updated.
  - Row for protocol step 2 in Table 61-22 is updated.
- Resources is updated as:
  - Bullet point mentioning PFLASH is updated.
  - New bullet point - FCCU is added.
  - New bullet point - TDM is added.

- Added "or JDP/FSL Production" to the first paragraph of Optionally perform serial boot section.
- Updated Download start address, VLE bit and code size section:
  - cross link from 1st paragraph changed to Table 61-19.
- Changed figure title in Implementation details of BAF supplied remap function section to "BAF flowchart default implementation".

- Added a DCF client, IVPR2_CPU2 in Table 61-5
- Added a new section - IVPR2_CPU2 - BAF set IVPR2 for CPU2 DCF client

- Updated Introduction section.
- Added Caution note in BAF DCF client - DATAX section.

• Added new section Clock Settings under Serial boot configuration. • Updated reference to baud rate frequency in LINFlexD configuration section. • Updated the baud rate frequency in the paragraph under section - Baud rates and in Table 61-20.
• Updated Figure 61-1. • Added a new row in Table 61-17 for "Production Disable flash Driver SRAM area".

A.63 SSCM module changes

• Life Cycle   • Added NOTE at end of section "When programming Life Cycle, ensure that..."
• ECC error monitoring   • Reformatted the list of possible error reactions to a bullet list for better readability.

• SSCM System Status (SSCM_STATUS)
  • Removed the NOTE "Reset value depends on the device status after leaving reset." from the BMODE field description.
• BAF configuration
  • Updated the paragraph "In BAF mode..."

• In the SSCM memory map table, changed the access for LCSTAT register from "R/W" To "R" • For LCSTAT register reserved bits 22/23, added footnote ("Reset Value is...") and changed reset value to undefined
• Modified footnote in Table 62-5

• In Life Cycle Status Register (SSCM_LCSTAT) description of LC field settings
  • Changed "FAIL_ANALYSIS" to "Failure Analysis"
  • Changed "Undefined" to "Reserved"
  • Changed "PROD_OEM" to "OEM Production"
  • Changed "CUST_DELIV" to "Customer Delivery"
  • Changed "JDP_PROD" to "JDP Production"
  • Changed "IN_FIELD" to "In Field"

• In Table 62-5 updated the abbreviated names of LC slot table to match the updated ones in SSCM_LCSTAT[LC].
• Updated Features list
• Added PWCMPH register. • Added PWCMPL register.
• In SSCM System Status (SSCM_STATUS) register updated the reset value and description of bit 6 (Reserved)
• In CER removed "(with PARITY enabled)" from the bit description.

• In SSCM System Status (SSCM_STATUS) register's CER field description, changed first sentence and added sentence:
  • was: "This field indicates that the SSCM has detected a configuration error during reset while loading DCF clients."
  • now: "This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error."

A.64 PMC_DIG Changes

• Introduction   • Editorial updates. • Pending Gauge Status Register (PMCDIG_GR_P)

- Added "This bit is indeterminate after reset..." to the VD10_A, VD9_IF, VD9_IJ, MD9_IM, VD9_F, and VD9_C bitfield descriptions.
- Added "This bit is indeterminate after reset..." to the VD10_F and VD9_O bitfield descriptions.

- Analog PMC interface
  - Removed the text " (both active high and active low, but only active low are used)" from the paragraph "The signals from the PMC..."
  - Replaced the sentence "This time can vary from 5 µsec to 11.4 µsec." with "This time can be ≥ 5 µsec."
- Temperature Sensor interface logic
  - Editorial updates.
  - Removed the text "The test interface is discussed in the test section."
- Standby RAM regulator interface logic
  - Removed the paragraphs "Another control signal, vrefsel, is controlled..." and "There are a few test signals that are also used..."
- Power On Reset (MC_RGM phase gates)
  - Added "(and other system time counts)" to the paragraph "During the POR phase 3 exit, the..."
  - Editorial updates.
- Flash memory interface (DCF client usage)
  - Removed the sentence "Please see the Reset Event Enable (REE_TD) register for more information regarding REE/RES bits loading from flash."
  - Updated the content of the paragraph "These trim bits that are loaded..."
  - Editorial updates.
- Other module interfaces
  - Added "LVD295_A" to the LVD bullet list.
- Interrupt Enable Pending Register (PMCDIG_IE_P)
  - Added NOTE "Special care must be taken with..." to register description.
- Reset Event Select Registerr (PMCDIG_RES_VD8)
  - Added description details for the HVD8_F bitfield.
- LVD270 Event Pending Register (PMCDIG_EPR_VD9)
  - Added the NOTE "These bits are cleared out of initial..." to the register description.
  - Added the paragraph "This field is indeterminate..." to the LVD9_O, LVD9_IF, LVD9_IJ, LVD9_IM, LVD9_F, and LVD9_C field descriptions.
- LVD295 Event Pending Register (PMCDIG_EPR_VD10)
  - Added the NOTE "These bits are cleared out of initial..." to the register description.
  - Added the paragraph "This field is indeterminate..." to the LVD10_F and LVD10_A field descriptions.
- Temperature Sensor Configuration Register (PMCDIG_CTL_TD)
  - Added the text "For instance, 111b (-7) could be written to the..." to the end of the second paragraph in the register description.
  - Added NOTE "Care must be taken to include a timeout..." to the register description.
  - Added "This signal behavior has changed. The..." to the DOUT_EN field description.
- Voltage Detect User Mode Test Register (PMCDIG_VD_UTST)
  - Updated the register description.
- Module Control Register (PMCDIG_MCR)
  - Updated the register description.
  - Replaced the ADC_CHSEL_EN field with a Reserved field.

- In last paragraph of Other module interfaces corrected title of referenced document: MPC5700 Family Microcontroller Security Reference Manual

- In the Analog PMC Interface section, added a new paragraph about POR initialization.
- In the Temperature Sensor interface logic section, added a new paragraph describing the entry for Temp Sensor User Trim Adjust registers to prevent accidental resets.
- In the Temperature Sensor interface logic section, added a note at the end of section to describe the flag behavior and status bits.

A.65 MC_PCU module changes

- No substantial content changes

• In Memory Map and Register Definition, Updated note, 'All registers will be accessible in "User mode"... only if SSCM_ERROR[RAE] is set'.

A.66 MC_ME module changes

• In the Register description section, added MC_ME_CADDR2 register.
• In Memory map and register definition section: Updated access of MC_ME_SAFE_MC[PWRLVL] field from RO to RW
• In the Invalid mode configuration interrupt section: Removed the reference to ME_CCTLn and changed ME_CTL to ME_MCTL. • Removed note from CCTLx registers that stated, "A write access to CCTL register during MC_GS[MTRANS]=1, will result in the ICONF_CC flag in the ME_IS register being asserted." • Added note to the DBG_MODE bit in the MC_ME_DMTS register. • Added arrow in MC_ME Mode Diagram from TEST to SAFE. • Changed the description for the DBG_MODE field in the MC_ME_DMTS register. Changed all instances of the DBG_F field to Reserved in the MC_ME_PCTLx registers.
• Added note about the RMC bit to the CADDR4 register.
• In Memory Map and Register Definition, Updated note, 'All registers will be accessible in "User mode"... only if SSCM_ERROR[RAE] is set'.

A.67 Core Debug Support changes

• No substantial content changes

A.68 Core Debug Support changes

• In Hardware Debug Facilities, changed "Standard 1149.1" to "Standard IEEE 1149.1".
• Editorial changes. • In description of DBCR4[DVC1C] in Table 67-5 defined the field value corresponding to "Inverted polarity DVC1 operation" as 1
• Added the core name (e200z710n3) throughout the chapter.

A.69 DCI changes

• In "Software enabled debug and calibration mode" section, minor edit and removed second paragraph of NOTE. • Updated references to IEEE 1149.1 and IEEE 1149.7.

A.70 JTAGC module changes

- No substantial content changes

A.71 CJTAG changes

- Editorial changes.
- In Overview, removed references to SScan.

A.72 JDC changes

- Changed reset description of memory mapped registers to say registers are reset by system destructive reset.
- In Overview, removed sentence "The JTAG accessible registers are provided through an instance of the existing JTAGC module".
- In Memory mapped registers sections, changed base addresses of each register from "FFF3_C000h base" to "0h base".

A.73 SPU changes

- Added State1 offset in L2nSEL0 register.

A.74 JTAGM changes

- In the "Memory mapped registers" section, changed the base address appearing above each register figure (is 0h).

A.75 Zipwire_debug information changes

- No substantial content changes

A.76 SIPI_debug changes

• No substantial content changes

A.77 LFAST_debug changes

• No substantial content changes

A.78 DTS changes

• In the "Memory mapped registers" section, changed the base address appearing above each register figure (is 0h).

A.79 NAR changes

• No substantial content changes

A.80 Core Nexus Module changes

A.81 Core Nexus Module changes

• In Feature list, added bullet item "Indicates to the FCCU whether it becomes active during functional mode."
• Editorial changes.
• Corrected broken link.
• Replaced nex_evto_b with evto_b throughout chapter.
• Added missing TSTAMP sub-row to each Message Name row in Table 80-2 table. • Data Acquisition Trace event : in figure, corrected "TCODE(011011)" to "TCODE(000111)". • Added Timestamp field (TSTAMP). • Data Trace Messaging (DTM) : Changed "in one of three ways." to "in one of the following ways."
• Added the core name (e200z710n3) throughout the chapter.

A.82 NXMC module changes

• Updated Data Trace Size (DSZ) encodings TCODE value

A.83 CRC module changes

• Changed "CPU" to "DMA" in "Transmission phase 3" figure (bottom). • Added note to Standard features bullet regarding Ethernet CRC. • Updated CFG[SWAP_BITWISE] field description for value 1 from "Perform bit-wise swap on CRC_INP input data internally for CRC-16 polynomial calculations.", to "Perform bit-wise swap on CRC_INP input data internally for CRC-8 and CRC-16 polynomial calculations.".

• Removed references to support CRC-8-H2F Autosar polynomial and its impact from:
  • Main features section : Updated the bullet from "Four hard-wired polynomials..." to "Three hard-wired polynomials..."
  • Standard features section
  • Description of POLYG field in Configuration register (CRC_CFGn)
  • Functional description section

• Title corrected for section "Register programming".
• Added information about register access level at the end of each register description.
• Updated Main features section. • Editorial changes.
• In CRC_CFG*n*[SWAP], updated bit description text from "The swap operation is a bit-by-bit rotation of the content" to "The swap operation is a bit-by-bit swapping of the content".

A.84 MEMU changes

• Editorial changes.
• In Figure 83-4, changed "that is in error" to "that is false".
• In Memory map and register definition, added register access level information to all register descriptions.
• Previous errata e8145 integrated into this reference manual: In System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR), in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted." • Previous errata e8145 integrated into this reference manual: In Peripheral RAM uncorrectable error reporting table address register (MEMU_PERIPH_RAM_UNCERR_ADDR), in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted." • Previous errata e8145 integrated into this reference manual: In Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR), in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted."

• Editorial changes.
• In Introduction and Features :
  • Standardized the names of the error-reporting categories for consistency:
  • System RAM

• Peripheral RAM • Flash memory • Changed "see the Device Configuration chapter that describes how modules are configured and connected" to "see the chip-specific MEMU information." • In Design overview, changed "see the Device Configuration chapter that describes how modules are configured and connected" to "see the chip-specific MEMU information." • In Flash memory correctable error reporting table status register (MEMU_FLASH_CERR_STS*n*), in the BAD_BIT field description, changed "bit position in RAM" to "bit position in flash memory".
• Revised Figure 83-2 and Figure 83-3. • In System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR), added "This field must be read-only when its corresponding valid bit (SYS_RAM_UNCERR_STS[VLD]) = 0." to the ERR_ADD field description. • In Peripheral RAM uncorrectable error reporting table address register (MEMU_PERIPH_RAM_UNCERR_ADDR), added "This field must be read-only when its corresponding valid bit (PERIPH_RAM_UNCERR_STS[VLD]) = 0." to the ERR_ADD field description. • In Flash memory uncorrectable error reporting table address register (MEMU_FLASH_UNCERR_ADDR), added "This field must be read-only when its corresponding valid bit (FLASH_UNCERR_STS[VLD]) = 0." to the ERR_ADD field description.
• Revised Memory map and register definition so it shows 2 instances of the PERIPH_RAM_OFLW register.

A.85 IMA changes

A.86 FCCU module changes

• Added note to RF Enable Register (FCCU_RF_E*n*) description: "Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn)." • For Delta T Register (FCCU_DELTA_T) • Added note to description: "Reserved bits should always be written as all 0's." • Changed access for reserved field that was read-only and always 0 to simply read-only • Added text to description of following registers: "These registers can be written only when the FCCU is in CONFIG state." • IRQ Alarm Enable Register (FCCU_IRQ_ALARM_EN*n*) • NMI Enable Register (FCCU_NMI_EN*n*) • EOUT Signaling Enable Register (FCCU_EOUT_SIG_EN*n*)
• Changed the value for Delta_T from 10 ms to 16.67 ms in FCCU_DELTA_T register and also in Introduction Section. • Added note to the FCCU_NCF_EN register description: Any fault that is enabled should be programmed to take some action.
• Changed bit definition for PS bit of the FCCU_CFG register = 0 from "0 - eout[1] active high, eout[0] active high" to "0 eout[1] active high, eout[0] active low" • Changed bit definition for PS bit of the FCCU_CFG register = 1 from "1 - eout[1] active low, eout[0] active low" to "1 eout[1] active low, eout[0] active high"
• Introduction section - Deleted word "redundant" in first line. • Introduction section - In bullet item "The FCCU's configuration is lockable in two ways, deleted "in two ways" • Introduction section - Added footnote to bullet item "After power-on the error out pins have high impedance." Foot note reads "Actual value depends on the design settings at pad level." • Introduction section - In last paragraph, changed "specific FCCU state" to "CONFIG state" • Acronyms section - Added WKPU entry. • Acronyms section - Deleted NVM.

- Main Features section - Reworded first two bullet items "1 to 128 critical/unrecoverable ...." and "1 to 128 non-critical/recoverable ...."
- Fault priority scheme and nesing section - Changed "NCT timer" to "NCF timer"
- NMI/WKPU interface section - Deleted first paragraph beginning with "The wake-up interface includes the following signals: .....".
- Time-Switching Protocol section - Changed all occurrances of "Fccu_eout[1]' to EOUT[1].
- Time-Switching Protocol section - Added foot note: Foot note reads "Actual value depends on the design settings at pad level."
- Bi-Stable Protocol section - Changed all occurrances of "Fccu_eout[1]' to EOUT[1].
- Bi-Stable Protocol section - Added foot note: Foot note reads "Actual value depends on the design settings at pad level."

- Changed "Error" to "Fault throughout chapter.
- Acronyms and Abbreviations section -- removed conditional text tag for "non-critical Fault" in NCF row.
- Bi-stable protocol section -- Added footnote to "High-Z" entry of reset row of Bi-stable encoding table. Also added same footnote in text. "Actual value depends on device specific settings at pad level."
- Dual Rail protocol section -- Added footnote to "High-Z" entry of reset row of Bi-stable encoding table. Also added same footnote in text. "Actual value depends on device specific settings at pad level."
- Time Seitching protocol section -- Added footnote to "High-Z" entry of reset row of Bi-stable encoding table. Also added same footnote in text. "Actual value depends on device specific settings at pad level."
- FOSU section - Made minor non-technical XML coding corrections.
- Fault priority scheme and nesting section: Added text: If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

- FCCU FOSU Output Supervision Unit -- Added following note: -- FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

- Editorial changes.
- Added the note "The reset value is chip-specific. See the Chip Configuration chapter for details." at the beginning of the following sections:
  - RF Configuration Register (FCCU_RF_CFG*n*)
  - RFS Configuration Register (FCCU_RFS_CFG*n*)
  - RF Enable Register (FCCU_RF_E*n*)
  - RF Time-out Enable Register (FCCU_RF_TOE*n*)

- Introduction section -- removed text referring to FCCU circuitry being checked at start up.
- EOUT interface section: removed reference to FCCU failure inputs table.
- Use cases and limitations section -- Added note to bullet item "Software reset is optional." stating that "This reset is not implemented on all devices".

- In Error signal flow, deleted the signal-flow figure and replaced it with a reference to the chip-specific FCCU information (where the figure now exists).

- Editorial corrections

- EOUT interface
  - Reorganized the sentence about resets' effect on failure indication pins as two sentences and a list
  - In the list, added "FOSU time-out reset" as a reset type that influences the state of failure indication pins

- Changed reset value of FCCU_CTRL register from 0x0000_0000 to 0x0000_00C0. (OPS field changed from 00b to 11b.)

- In NCF Fake Register (FCCU_NCFF), changed register description.

- INTRODUCTION SECTION - Change "Internal reactions (independently configurable for each NCF):" to "Configurable internal reactions for each NCF:"
- INTRODUCTION SECTION - Change "External reaction (failure is reported to the outside world via one or more output pins)" to "External reactions via configurable output pins"
- INTRODUCTION SECTION - Change bullet item text to "Configurable fault control" (was "Configurable and graded fault control").
- INTRODUCTION SECTION - Removed phrase "for application/test/debugging purposes"
- INTRODUCTION SECTION - Changed "FCCU is designed for assuming that the system clock is faster than the IRC clock" to "The FCCU is designed to function when the system clock is faster than the IRC clock."

• FSM description - Change "After reset lifts, the state shall be transiently locked (permanent lock ? is unlocked and transient lock ? is locked)." to "After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked." • In the FCCU_CTRLK register description, change note "There should not be any other operation in between the above steps." to "The FCCU_CTRLK and FCCU_CTRL registers must be written with consecutive instructions. Both registers must be written as 32-bit values. Do not use read-modify-write instructions, such as bit field instructions, to modify these registers." • In section FCCU_DELTA_T, FCCU_IRQ_ALARM_ENn, FCCU_NMI_ENn, FCCU_EOUT_SIG_ENn descriptions: Changed, "This register can be written only when the FCCU is in CONFIG state." to Note. • In FCCU_CFG_TO description changed "oscillator" to "IRCOSC". Changed part of description to Note. • In section Self-checking capabilities, removed "Self-checking reaction (reset)" figure.
• For FCCU_NCF_CFGx, FCCU_NCFS_CFGx, FCCU_NCFEx, FCCU_NCF_TOEx and MCS registers: Changed the reset value of the registers from 0x0000_0000 to X. Added the following footnote to each register: The reset value is chip-specific. See the chip-specific FCCU information. Added the following note to register descriptions: The reset value is chip-specific. See the chip-specific FCCU information. For all configuration registers, made the following text into a note: These registers can be written only when the FCCU is in CONFIG state. • INTRODUCTION -- Changed bullet item "Configurable and graded fault control" to "Configurable fault control" • INTRODUCTION -- In bullet item "Permanently locked until next reset ...., Changed "FCCU_TRANS_LOCK" to "FCCU_PERMNT_LOCK" • INTRODUCTION -- Changed "failure indication" to "error out" • MAIN features -- Changed "Failure indication" to "Error indication" • FSM description -- Changed reference to state diagram. • FSM description -- Changed "Following one of the following events" to "Following state transions occur on one of the following event" • Corrected notation for binary numbers. • FCCU state diagram -- Changed block text on CONFIG state from "AND NOT (configuration locked)" to "AND (configuration unlocked)" • FCCU state diagram -- Added block text to ALARM state -- "Actual text in diagram is "Any Fault Pending AND FCCU_IRQ_ALARM_ENn"" • EOUT interface -- Throughout section changed uppercase "ERROR" to "FAULT". • Deleted the text -- "The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^18."
• At the end of EOUT interface section, added NOTE on state of EOUT pads.
• FCCU_MCS register -- added note: The reset value is chip-specific. See the chip-specific FCCU information. • FCCU_CTRL register, FILTER_WIDTH field -- Changed 10 bit description from "filters glitches up to 100 microseconds for 20 Mz IRC clock" to "filters glitches up to 100 microseconds". Changed 11 bit description from "filters glitches up to 100 microseconds for 20 Mz IRC clock" to "filters glitches up to 100 microseconds"
• Added the following note to the FCCU_NCFS_CFGn and FCCU_NMI_ENn register descriptions: Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time. • The following text was added to the EIN1 bit description of the FCCU_EINOUT register -- While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[1] pin. The following text was added to the EIN0 bit description of the FCCU_EINOUT register -- While this field is set to zero by reset, a read of this field always returns the logic value on the fccu_ein[0] pin.
• Acronyms and Abbreviations section: Added IRCOSC entry into the Acronyms and Abbreviations table. • FCCU_CTRL register, removed "configure the glitch filter present on location given by FILTER_POSITION parameter" • FCCU_CTRL[DEBUG] description, changed ipg_debug to debug. • Added the note "The reset value is chip-specific. See the Chip Configuration chapter for details." at the beginning of the following sections: NCF Configuration Register (FCCU_NCF_CFGn), NCFS Configuration Register (FCCU_NCFS_CFGn), NCF Enable Register (FCCU_NCF_En) and NCF Time-out Enable Register (FCCU_NCF_TOEn)
• Minor non-technical grammatical corrections. • FCCU_CFG_TO register description - replaced "See FCCU register set table." with "The description for a configuration register will contain a NOTE that it is writable only in the CONFIG state.”
• Dual Rail Protocol section -- Corrected error phase portion of timing diagram. • FCCU_STAT register, STATUS field -- Changed "UNKNOWN" to "Reserved" in bit field descriptions. • Use Cases and Limitations section, Misconfigurations heading -- removed "Software reset is optional. NOTE: Software reset is not required for all devices."

• In Definitions, after the list of applicable reset types, added this information: *For more information on each type of reset, see the MC_RGM and reset chapters.*

A.87 STCU2 module changes

• Corrected reset value of STCU2_CRCE register from 0x0000_0000 to 0xFFFF_FFFF.
• Block Diagram -- changed "errors" to "faults" and "safety" to "reliability" • Main Features section -- changed "errors" to "faults" and "safety" to "reliability" • Write Access Time Out section -- Changed "safety feature" to "malicious access protection feature" • On Line Self Test Sequence -- Removed "In case the L/MBIE have been enabled, an interrupt is generated." • Changed bit 0 field description for the LBRMSWx bits of the LBRMSW register to "Reserved"
• Added the following note to the IPS bus interface section: "When writing to the online registers, the user must wait for the expiration of the offline key. The time the user should wait is (IPS_CLK)*4096 clock periods. If the IPS_CLK is 66.5 Mhz then the user must wait (1/66.5)*4096 = 61.6 us. • Added footnote to CRCE register for default reset value. "See the chip specific information for the default reset value of this field."

• Added the note "The reset value is chip-specific; see the chapter that describes how modules are configured and connected." at the beginning of the following sections:
  • STCU2 Configuration Register (STCU2_CFG)
  • STCU2 PLL Configuration Register (STCU2_PLL_CFG)
  • STCU2 Watchdog Register Granularity (STCU2_WDG)
  • STCU2 CRC Read Status Register (STCU2_CRCR)
  • STCU2 Error FM Register (STCU2_ERR_FM)
  • STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)
  • STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)
  • STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)
  • STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM)
  • STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)
  • STCU2 LBIST Control Register (STCU2_LB_CTRL*n*)
  • STCU2 LBIST PC Stop Register (STCU2_LB_PCS*n*)
  • STCU2 LBIST PRPG Low Register (STCU2_LB_PRPGL*n*)
  • STCU2 LBIST PRPG High Register (STCU2_LB_PRPGH*n*)
  • STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISREL*n*)
  • STCU2 Off-Line LBIST MISR Expected High Register (STCU2_LB_MISREH*n*)
  • STCU2 Off-Line LBIST MISR Read Low Register (STCU2_LB_MISRRL*n*)
  • STCU2 Off-Line LBIST MISR Read High Register (STCU2_LB_MISRRH*n*)
  • STCU2 On-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELSW*n*)
  • STCU2 On-Line LBIST MISR Expected High Register (STCU2_LB_MISREHSW*n*)
  • STCU2 On-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLSW*n*)
  • STCU2 On-Line LBIST MISR Read High Register (STCU2_LB_MISRRHSW*n*)
  • STCU2 MBIST Control Register (STCU2_MB_CTRL*n*)
• In STCU2 CRC Expected Status Register (STCU2_CRCE), added the note "See the chip specific information for the default reset value of this field." at the beginning of the section.

• Hardware ABORT management section -- Rewrote this section for grammatical clarity.
• In the block diagram, indicated that the CRC block is optional.
• Minor non-technical typographical corrections.
• In Offline self-test sequence, changed *PMOSEN or CHKBRD* to *PMOSEN or MBU*. • In Online self-test sequence, changed *PMOSEN or CHKBRD* to *PMOSEN or MBU*.
• In the value descriptions for the SHS field in the STCU2_LB_CTRL registers, changed *(bist_clk)* to *STCU2 core clock*.
• Specified the reset value of the CRCE register to be undefined at the release of reset.
• In the description for the PTR field in the STCU2_LB_CTRL registers, added this note: *The value of NLBIST is device specific. See the device specific information for the value of NLBIST*

• In the STCU2_LBRMSW register description removed reference to "specific functional reset".
• Added the following note to the Built-in self-test scheduling section: Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.
• Added the following note to the CRC section: "The CRC calculation depends on the internal state of the STCU2 when the online/offline self test is started. The STCU2's internal state is dependent on DCF values and their programming sequence for offline selftest. The calculated CRC value can be determined by running an LBIST test under known conditions. The CRC unit produces a stable and predictable result but is dependent on several stimuli (including programming order and the initial internal state of the STCU2 design) during online self test. To calculate a CRC value, run an LBIST test on known good silicon with a predefined software programming sequence. Record the CRC result value. Then provide the STCU2 programming sequence and the initial register vlaues for further runs if the CRC feature is to be used. Once a known good CRC value is determined, the CRC value will not change from one run to another so long as the user does not change the STCU2 programming sequence or any of the values used to program STCU2 registers. To obtain a consistant CRC calculated value, the STCU must start from the same state compared to the state when the CRC was originally evaluated."
• Added the following to the STCU2_LB_CTRL[CSM] field description: "The next LBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution."
• Removed the following from the STCU2_LB_CTRL[PTR] field description: "The next LBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution." • Reformatted the STCU2_LB_CTRL[PTR] field description.
• In Register write-access watchdog timer, added the following note: *Each DCF record takes 8 STCU2 clock cycles for write completion. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is Value divided by 8. To refresh the hardware Watchdog, the user must write key 2 into the STCU2_SKC register.* • Changed the access type of the STCU2_MBUFML, STC2U2_MBUFMM and STCU2_MBUFMH registers from read-only (RO) to read/write (RW).
• In the register descriptions for STCU2_LB_CTRL, STCU2_LB_PCS, STCU2_LB_PRPGL, STCU2_LB_PRPGH, STCU2_LB_MISREL, STCU2_LB_MISREH, STCU2_LB_MISRRL, STCU2_LB_MISRRH, STCU2_LB_MISRELSW, STCU2_LB_MISREHSW, STCU2_LB_MISRRLSW, and STCU2_LB_MISRRHSW, deleted this text:*The offset of this register is a function of NLBIST.* • Revised the description for the PTR field in the STCU2_LB_CTRL registers.
• In Online self-test sequence, added the following note: *Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.* • In Design implementation information, added the following caution notice: *Do not execute a BIST on more than one partition at a time.*
• In STCU2_CFG register description, added description and table describing three MBIST test types and their coverage. • Modified STCU2_CFG[PMOSEN] and STCU2_CFG[MBU] field descriptions and bit definitions.

• Retitled the Built-in self-test scheduling section.
• In Watchdogs, retitled the following sections:
  • Initialization watchdog timer
  • Built-in self-test watchdog timer
  • Register write-access watchdog timer

• Edited Design implementation information for grammar and style.
• In Design implementation information, changed *Do not execute a BIST* to *Do not execute LBIST*.
• In Design implementation information, corrected the grammar in the caution notice.
• In IPS bus interface, replaced the note with a reference to the chip-specific STCU2 information (which is where the correct contents now appear).

A.88 REG_PROT module changes

- In Memory map and register definition, made editorial changes.

A.89 PASS module changes

- Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*), LOWLOCK and MIDLOCK fields - Removed footnote: Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
- Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*), ATSL reset value - Added "If no DCF records have been written to change the ATSL bit lock state, the bit will reset to ‘1’.
- Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*), HIGHLOCK field - Removed footnote: Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
- Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*), L_256LCK field - Removed footnote: Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
- Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) - Revised the reset-value footnotes.
- Activation Section -- Changed "Jitter Activation constant in BAF Flash should be programmed to make the most significant bit ‘0’. to "Jitter Activation constant in BAF Flash should be programmed to make the least significant bit ‘0’.
- Clock Jitter Truth table -- Corrected bit pattern in Clock Jitter Enable Column to reflect that CJE bit is the LSB.
- Clock Jitter Truth table -- Added "OEM Production" to first row in Lifecycle column.

- In the "Memory map and register definition" section, changed the note "Non-implemented registers generate bus aborts if enabled by the SOC" to "Non-implemented registers generate bus aborts if enabled".

- In Life Cycle Status Register (PASS_LCSTAT), in the CNS field description, deleted the text "See section Censoring and uncensoring the device."

- In Setting lock bits in a password group in Table 88-6 changed the column heading from "DCF CS/ADDR" to "DCF Command Word"

- Changed Reserved bit of LCSTAT register to read-only and always 1
- Added following text to description of JUN bit in LCSTAT register: "(In life cycle FA, the JUN bit will always be 0.)"
- In Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) description, added sentence: "Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle."
- Incorporated minor, non-technical editorial and formatting corrections.

- In Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*) register description, moved paragraph: "LOCK1_PGn register functions are as shown in this section."
- In Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) register, RL0, RL1, RL2 and RL3 field footnotes modified.

- Challenge Selector Register (PASS_CHSEL) description -- Changed “When a master accesses this register, the PASS module stores the number of the master in the LOCK3_PGn register of the selected passgroup and sets the PGL bit in that register.” to “When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.”
- Challenge Selector Register (PASS_CHSEL) description -- Changed “ The ID of the accessing master sets the CMST field of the Challenge Status register.” to “When a master writes this register, its ID sets the CMST field of the Challenge Status register.”
- Challenge Input Register (PASS_CIN*n*) description -- Added following text to second paragraph: “In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as sets the PGL bit of that register.”
- In Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*) description -- changed NOTE to CAUTION
- Revised Table 88-7.
- Incorporated minor, non-technical editorial and formatting corrections

- PASS_LOCK1_PGn register description -- Minor formatting and grammatical changes.

- Added the following note to the Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*) description: note - Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

- Debug Interface Access :
  - Deleted "The HSM can further block Debug Interface Access, even if it enabled by PASS. This allows HSM to granted Debug Interface Access after an encrypted secure challenge/response protocol with an external tool -- see HSM documentation".

- In Challenge Selector Register (PASS_CHSEL), changed GRP field from 2 bits to 3 bits in order to accommodate eight Password Groups.

- Revised Challenge Input Register (PASS_CIN*n*) description to indicate that a successful password comparison "clears the PGL bit of that register" (was "sets the PGL bit...").

A.90 TDM module changes

- Editorial changes.
- Overview :
  - Correction: Added "Software tamper region override" to list of security data passed to the TDM by the SSCM module.
  - Clarification: Reworded note regarding PASS module settings having priority over TDM settings.
- Flash erase counter and tamper detection :
  - Clarification: For each TDR, software must ensure that the tamper diary is not full before writing a diary record. If it is full the TDR can either be overridden or, if an unused TDR is available, a duplicate TDR can be defined.
  - Following extraneous sentence deleted: "A schematic representation of the TDM implementation is depicted in the following figure."
- Tamper Region Override (TO) DCF client :
  - Changed the description for TOE[5:0] in the table: A '1' in the TOE field enables the blocks assigned to a tamper region to be erased without creating a diary record. Previously states that a '1' would allow the diary to be erased.

- In TDR Status Register (TDM_TDRSR), added the note "The reset value for this register is device specific. See the chip configuration chapter." at the beginning of the section.

- Editorial changes.
- Overview :
  - Clarification: The Tamper Detection Module provides a type of flash memory *erase* protection mechanism. (previously stated *write* protection mechanism).
  - Added list of three dedicated signals provided by TDM module.
- Features :
  - Deleted from feature list: "Memory mapped registers interface for reading via software of specific registers."
- DCF clients :
  - Deleted: All content describing the general function of DCF records.
- TDR Status Register (TDM_TDRSR) :
  - Register description rewritten for clarification.
  - Statement deleted: "This register is not defined in all devices. See the chip configuration chapter for details."
- Last Flash Programmed Address Register (TDM_LFPAR) :
  - Statement deleted: "This register is not defined in all devices. See the chip configuration chapter for details."
- Diary Base Address (TDM_DBA) :
  - Footnote added to register: "The reset value of this register is set via DCF record."
- Software Tamper Override Key Region (STO_KEYn) :
  - Correction: This register is write-once. Previously stated as being write once per reset cycle.
  - Clarification: The DCF client associated with this register is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.
- Flash erase counter and tamper detection :
  - Correction: After TDM verifies that a successful double word program to a valid TDR diary location, TDM ensures the blocks assigned to a TDR are unlocked for erase until a successful erase operation is performed.

(previously stated the blocks are unlocked until an erase is performed *with program completion interrupt enabled or till next hard reset*.
• Specifying the diary base address :
  • Clarification: Statement that diary can hold "a maximum of 256 x 8 byte entries" changed to "...each diary region limits the erases of the assigned blocks to 256 erases.
• Diary :
  • Correction: The diary base address DCF client is only writable once (previously stated it is once during reset).
• TDR lock status. :
  • Section title changed (was "Diary Base Address Verification").
• TDR override :
  • Section title changed (was "Diary management").

• Software Tamper Override Key Region (STO_KEYn) :   • Changed access from R(ead only) to RW.
• Updated Figure 89-1. • Removed all references to "C55FMC".
• In DCF clients in Table 89-1 column for Strategy, added "write once" for: • Software Tamper Region Override Disable. • In every subsection of DCF clients changed "Warning" notice to "Caution" notice. Changed introductory descriptions in all One Time Programmable Enable (OTPENn) DCF client sections. • For Software Tamper Override Key Region (TDM_STO_KEY*n*) ensured the correct register array size.
In Specifying the diary base address, in the sentence, "The DCF client is writable once during reset and the default bit state is ‘0’." deleted "during reset" and change default bit state to '1'.

• Editorial changes.
• Changed second Caution bullet in:
  • Diary Base Address (DBA) DCF client.
  • Software Tamper Region Override Disable (STO_DIS) DCF client.
• Edited note re. TDR Status Register (TDM_TDRSR) reset value.

• Overview :
  • Deleted list of three dedicated signals provided by TDM module.
• Features :
  • Added feature list item: "Memory mapped registers interface for reading via software of specific registers."
• Table 89-2 : Added note stating boundary requirement for TDM diary base address.

Table 89-1 : Changed table title to "DCF clients" (was "DCF client address map").

A.91 Wakeup Unit changes

Chapter 1
Emulation and Debug Device Introduction

1.1 Introduction

The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD).

1.2 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications for 4- to 8-cylinder engines. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface—Allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the LFAST, Debug and Calibration Interface (DCI) and JTAG Master Module (JTAGM) functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2012 Nexus Aurora standard)
- 2 MB on-chip SRAM usable as calibration overlay or trace RAM—entire SRAM contents are maintained as long as ED debug supply is maintained

1.3 Feature summary

On-chip modules available on the BD include the following features:

- 2 MB on-chip SRAM
  - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
  - Includes ECC
  - Implemented as 4 × 512 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
  - 64-bit data width with ECC checkbits
  - Supports "Early Write" AHB protocol (AHB-EW) for one clock trace data writes
  - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources—Memory-mapped resources include buddy device SRAM and AIPS resources
- Nexus Aurora auxiliary trace port
  - 1.25 Gbit/s maximum data rate per lane
  - Four lanes supported in ED package
  - Port configurable to operate in 2- or 4-lane width
  - One lane LVDS reference clock in
  - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2012 standard.
- Data Write Processing Unit (DWPU)
  - Filters data trace stream to retain only writes to user selected locations
  - Detects user configured out of range condition on writes to selected locations
- Debug and Calibration Interface—Supports JTAG (IEEE 1149.1 and IEEE 1149.7) mode and LFAST mode
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)

1.4 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

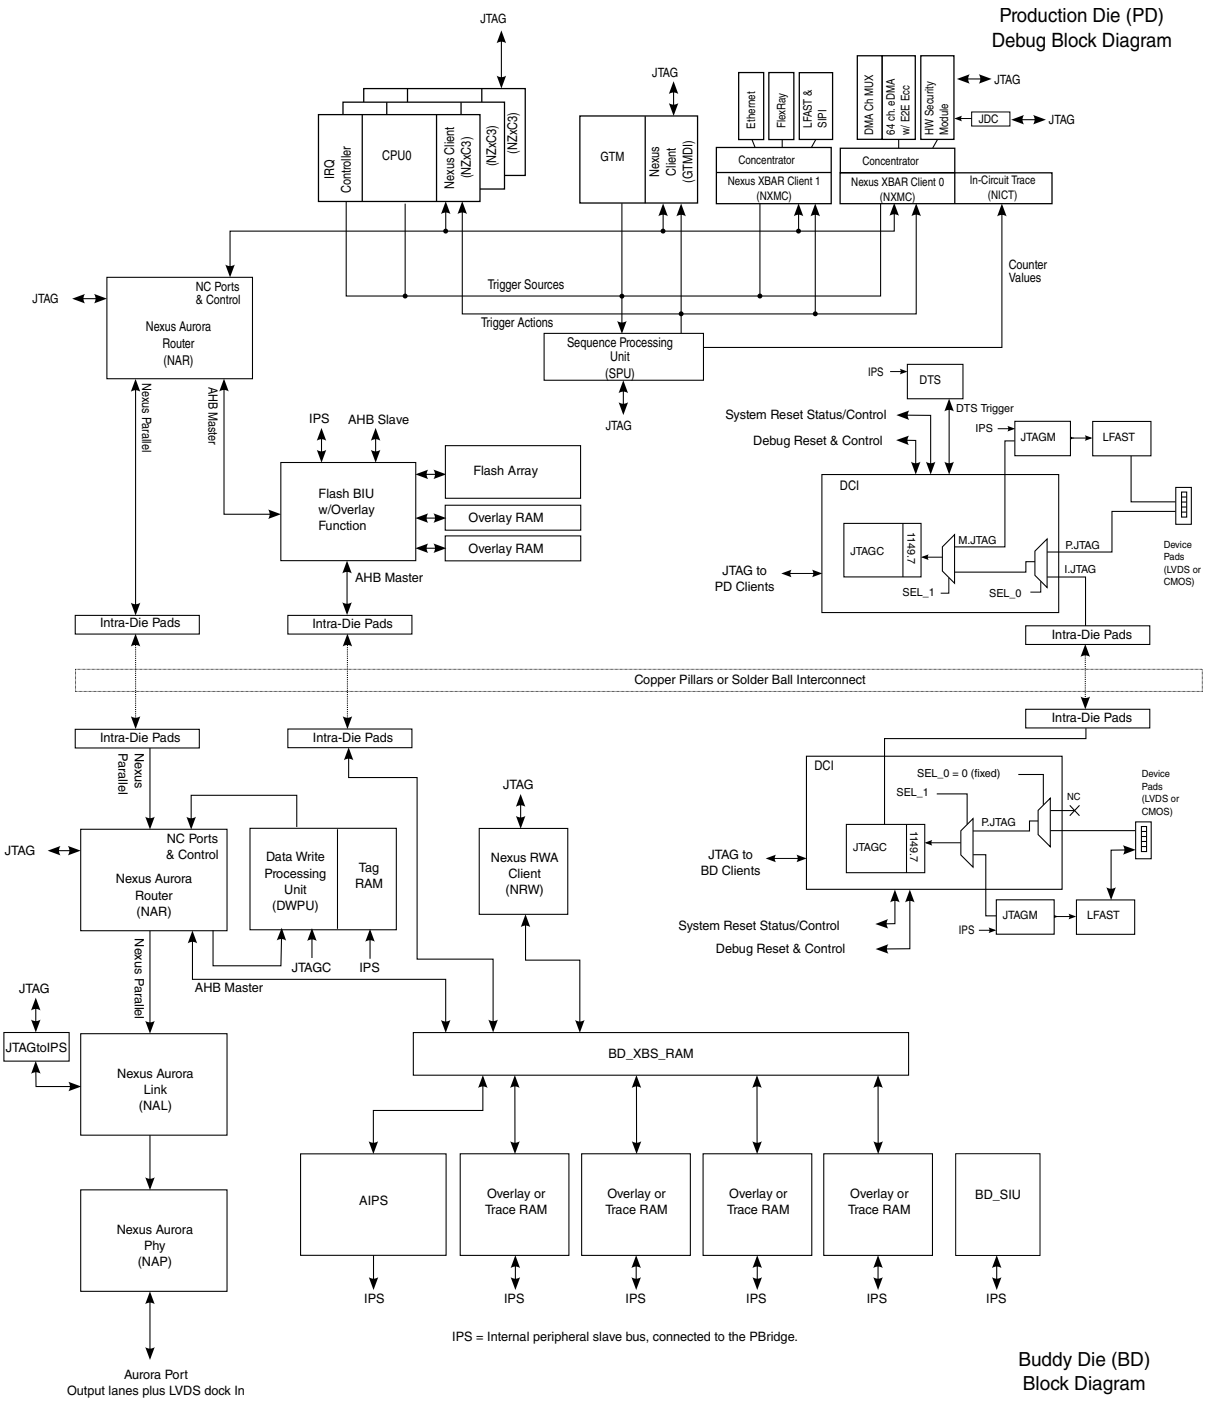

Figure 1-1. Emulation and debug device architecture

1.5 Clocking

The figure below shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- LFAST PLL reference clock coming from the PD (BD LFAST PLL clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Nexus Aurora PHY clock coming from differential LVDS pins in the ED

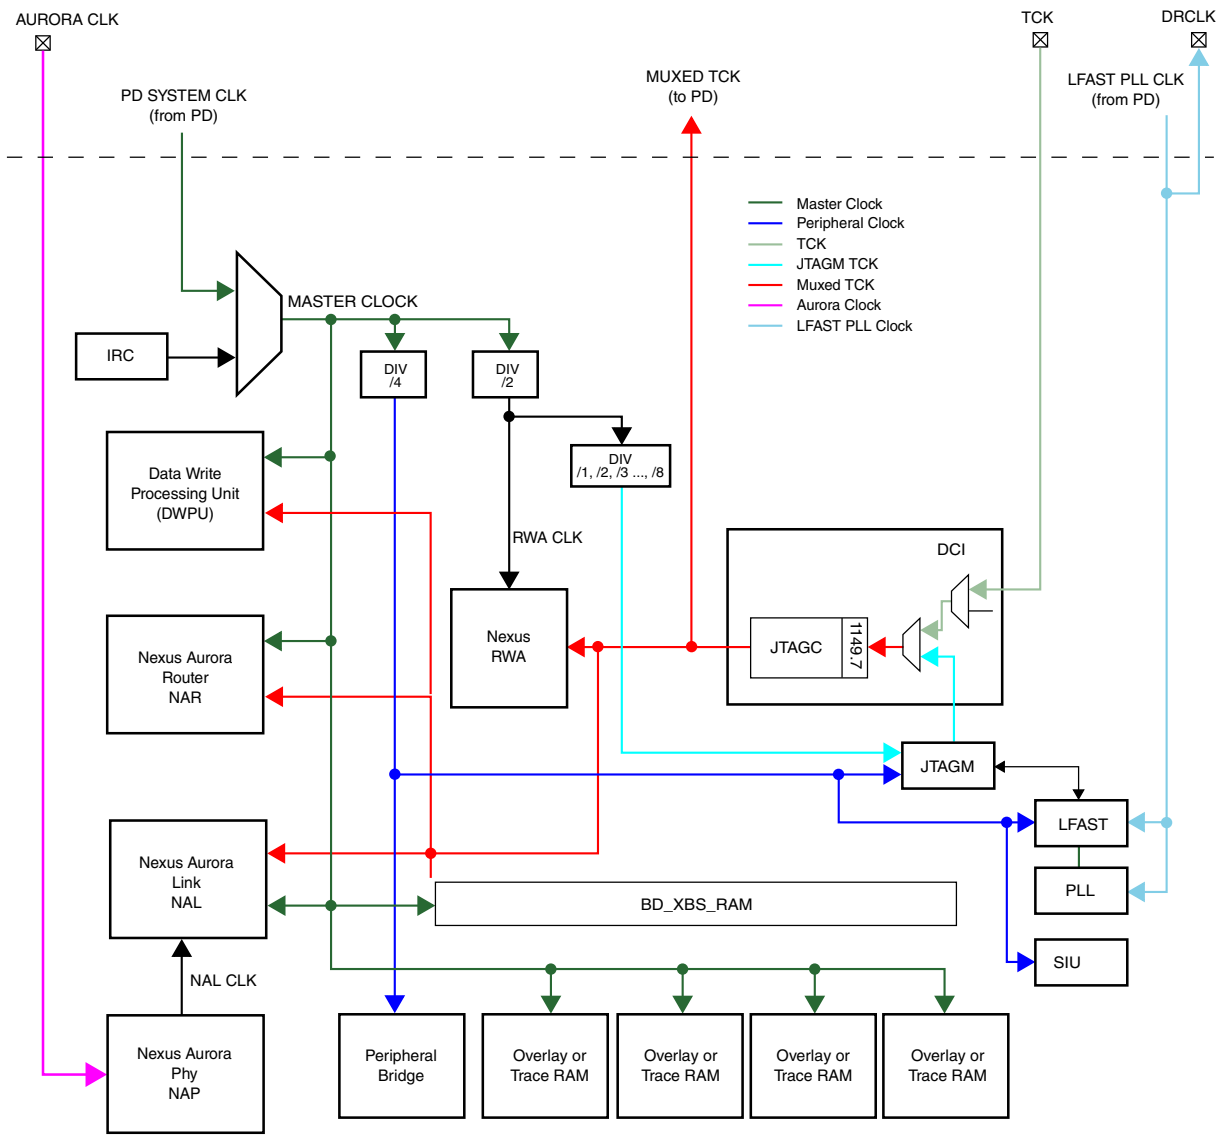

Figure 1-2. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible register and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of ±30%.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 200 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4)—provides the clock to memory mapped registers and other low-speed logic
- Nexus RWA clock (divided by 2)—provides the clock to the Nexus Read Write Access module
- JTAGM TCK (divided by 1, 2, …, 8)—provides a high speed TCK clock to the JTAGM module

The LFAST PLL clock from the PD (also referred to as lfast_sysclk) feeds the LFAST PLL, but it can also directly clock the LFAST in the low data rate mode. This clock is also made available as an output clock to the DRCLK package pin.

The internal TCK clock (referred to as muxed clock in Figure 1-2) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock can come from two sources (see the Buddy Device–Debug and Calibration Interface (DCI) chapter):

- TCK package pin, when using IEEE 1149.1 or IEEE 1149.7 access
- Divided down version of the master clock to be used in LFAST/JTAGM debug accesses

Note

The division factor for the LFAST/JTAGM clock is defined by the TCKSEL field of the JTAGM_MCR (refer to the JTAGM chapter for more details). However the division factor described there applies to an already divided-by-2 clock, as shown in Figure 1-2.

When the PD is unpowered, access through LFAST/JTAGM is not possible. In this case, JTAG accesses can be done only by IEEE 1149.1 or IEEE 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

In the LFAST/JTAGM mode of operation, both RWA clock and internal TCK are synchronous to each other, therefore they can both be the same frequency. This means that TCK frequency can be half of the master clock frequency. This table summarizes the frequency restrictions on the Nexus RWA accesses.

Table 1-1. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	200	200	27.7/50	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns). Otherwise, the maximum Nexus RWA JTAG frequency is internally limited to 50 MHz.
Powered, out of reset, PLL engaged	LFAST/JTAGM	200	200	100	—

1.6 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described in the following table:

1. BD power-on reset—asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset—asserts two clock rising edges after assertion of reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset—asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.

4. JTAG controller reset—asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset—asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In the following table, an 'X' indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins. When the debug interface is running through the LFAST interface or by software through JTAGM, those blocks are not reset by the mentioned reset sources.

Table 1-2. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
JTAGM	X	—	JTAG mode only	JTAG mode only	—
LFAST	X	—	JTAG mode only	JTAG mode only	—
NAR/DWPU	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

NOTE

The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

1.7 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as LFAST, JTAGM, XBAR configuration, etc. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 1-3. BD memory map

Start address	End address	Allocated size (KB)	Description
BD overlay RAM			
0x0C00_0000	0x0C0F_FFFF	1024	Extended overlay RAM
0x0C10_0000	0x0C1F_FFFF	1024	Extended BD overlay RAM
0x0C20_0000	0x0C3F_FFFF	2048	Reserved BD overlay RAM
0x0C40_0000	0x0C5F_FFFF	2048	Reserved BD overlay RAM
0x0C60_0000	0x0C7F_FFFF	2048	Reserved BD overlay RAM
BD registers			
0x0C80_0000	0x0C80_3FFF	16	BD_SIUL2
0x0C80_4000	0x0C80_7FFF	16	LFAST
0x0C80_8000	0x0C80_BFFF	16	JTAGM

0x0C81_C000	0x0C81_FFFF	16	Reserved
0x0C82_0000	0x0CFF_FFFF	8064	Reserved

Chapter 2
Buddy Device—Crossbar and RAM (BD_XBS_RAM)

2.1 Introduction

Within the buddy device (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note

Throughout this description, the term "overlay RAM" is applied to the BD memory, even though this memory can be used for *both* overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
    - Bus masters include the BD's Nexus Aurora Router (BD-NAR), the production device's flash controller (PFLASH) and the BD's Nexus Read/Write Access Client (RWA)
    - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge (AIPS-Lite) bus controller
        - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
        - End-to-End ECC32 address and data protection

- ECC scheme based on 29-bit address and 32-bit data
- Overlay RAM supports a 64-bit "early write" datapath and a 128-bit read datapath

- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note

Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

2.2 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit "early write" datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, m0 > m1 > m2 (PFLASH > BD-NAR > Nexus RWA). Each slave port is "parked" on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

2.3 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

e2eECC64[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0] ^ ecc_data_lower[7:0]

where `ecc_addr` is H-matrix evaluation of the 29-bit access address (addr[31:3]), `ecc_data_upper` is the H-matrix evaluation of the upper data word (data[63:32]) and `ecc_data_lower` is the comparable evaluation of the lower data word (data[31:0]).

For the BD RAM definition, the following (re)definitions apply:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]; data_lower[31:00] = 0

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]; data_upper[63:32] = 0

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 2-1. e2eECC Basic H-Matrix Definition

Checkbits [7:0]	Data Bit[1]																															
	Byte 7								Byte 6								Byte 5								Byte 4

0	*		*	*	*			*	*		*		*	*	*		*		*	*	*			*		*	*		*				

1. Bit numbering is AHB convention, bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

Figure 2-1 through Figure 2-4 show an alternative representation of the ECC32 encode process, written as a C language function.

```
encodeEcc32_upper (addr, data_a2_is_zero)
    unsigned int        addr;                   /* 32-bit byte address */
    unsigned int        data_a2_is_zero;        /* 32-bit data upper, a[2]=0 */

{
    unsigned int        addr_ecc;               /* 8 bits of ecc for address */
    unsigned int        ecc;                    /* 8 bits of ecc codeword */

    /* the following equation calculates the 8-bit wide ecc codeword by examining
    each addr or data bits and xor'ing the appropriate H-matrix value if the bit = 1 */

    addr_ecc
        = (((addr           >> 31) & 1) ? 0x1f : 0x0)       /* addr[31] */
        ^ (((addr           >> 30) & 1) ? 0xf4 : 0x0)       /* addr[30] */
        ^ (((addr           >> 29) & 1) ? 0x3b : 0x0)       /* addr[29] */
        ^ (((addr           >> 28) & 1) ? 0xe3 : 0x0)       /* addr[28] */
        ^ (((addr           >> 27) & 1) ? 0x5d : 0x0)       /* addr[27] */
        ^ (((addr           >> 26) & 1) ? 0xda : 0x0)       /* addr[26] */
        ^ (((addr           >> 25) & 1) ? 0x6e : 0x0)       /* addr[25] */
        ^ (((addr           >> 24) & 1) ? 0xb5 : 0x0)       /* addr[24] */

        ^ (((addr           >> 23) & 1) ? 0x8f : 0x0)       /* addr[23] */
        ^ (((addr           >> 22) & 1) ? 0xd6 : 0x0)       /* addr[22] */
        ^ (((addr           >> 21) & 1) ? 0x79 : 0x0)       /* addr[21] */

```

Figure 2-4. C language encodeECC32_upper function description (Part 4 of 4)

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

Chapter 3
Buddy Device—System Integration Unit Lite (BD_SIUL2)

3.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

These registers are also indirectly accessible by software via BD_JTAGM in software debug mode.

3.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type
- A version field that is changed for every major mask revision of the BD
- A parameterized field that indicates the amount of extended overlay RAM included
    - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants)

3.3 Device status information

This section describes the devices status information.

3.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically
  - BD_INIT is not cleared by external BD reset input
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or calibration software sets BD_INIT
- After PD POR, the BAF executes and reads BD_INIT
  - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap
  - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used.)

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

3.3.2 PD reset status

The IPS accessible BD_SIU_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

3.4 Memory mapped registers

This table gives an overview of the BD_SIUL2 registers.

BD_SIUL2 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C80_0000	Device Identification Register 1 (BD_SIUL2_DIDR1)	32	R	57BD_0000h	3.4.1/32
C80_0004	Device Identification Register 2 (BD_SIUL2_DIDR2)	32	R	0003_0100h	3.4.2/33
C80_0100	Initialization Status Register (BD_SIUL2_ISR)	32	R/W	0000_0000h	3.4.3/34
C80_0104	Reset Status Register (BD_SIUL2_RSR)	32	R	0000_0000h	3.4.4/35

3.4.1 Device Identification Register 1 (BD_SIUL2_DIDR1)

The BD_SIUL2_DIDR1 contains the part number and mask number.

Address: C80_0000h base + 0h offset = C80_0000h

BD_SIUL2_DIDR1 field descriptions

Field	Description
0–15 PARTNUM	Device Part Number. Read-only, mask programmed part number of the device. Reads 0x57BD.
16–23 Reserved	This field is reserved.
24–27 MASKNUM_ MAJOR	Major Mask Revision Number. Read-only, mask programmed mask number of the device. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.
28–31 MASKNUM_ MINOR	Minor Mask Revision Number. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.

3.4.2 Device Identification Register 2 (BD_SIUL2_DIDR2)

The BD_SIUL2_DIDR2 contains a complement to the part number and amount of RAM available.

Address: C80_0000h base + 4h offset = C80_0004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

BD_SIUL2_DIDR2 field descriptions

Field	Description
0–11 Reserved	This field is reserved.
12–15 RAM_SIZE	RAM Size. Read-only, indicates the amount of overlay RAM available in the device, with resolution of 256K byte steps 0000 0.25M byte 0001 0.5M byte 0010 0.75M byte 0011 1M byte 0100 1.25M byte 0101 1.5M byte 0110 1.75M byte 0111 2M byte 1000 2.25M byte 1001 2.5M byte 1010 2.75M byte 1011 3M byte 1100 3.25M byte 1101 3.5M byte 1110 3.75M byte 1111 4M byte
16–23 PARTNUM	Device Part Number. Read-only, mask programmed complement to the part number of the device. For the BD 1M byte part with part number 57BD1, BD_SIUL2_DIDR1.PARTNUM=57BD, and BD_SIUL2_DIDR2.PARTNUM=1. 01 1 (BD1M) 02 2 (BD2M)
24–31 Reserved	This field is reserved.

3.4.3 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset)
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT
- If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap
- If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used)

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

Address: C80_0000h base + 100h offset = C80_0100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

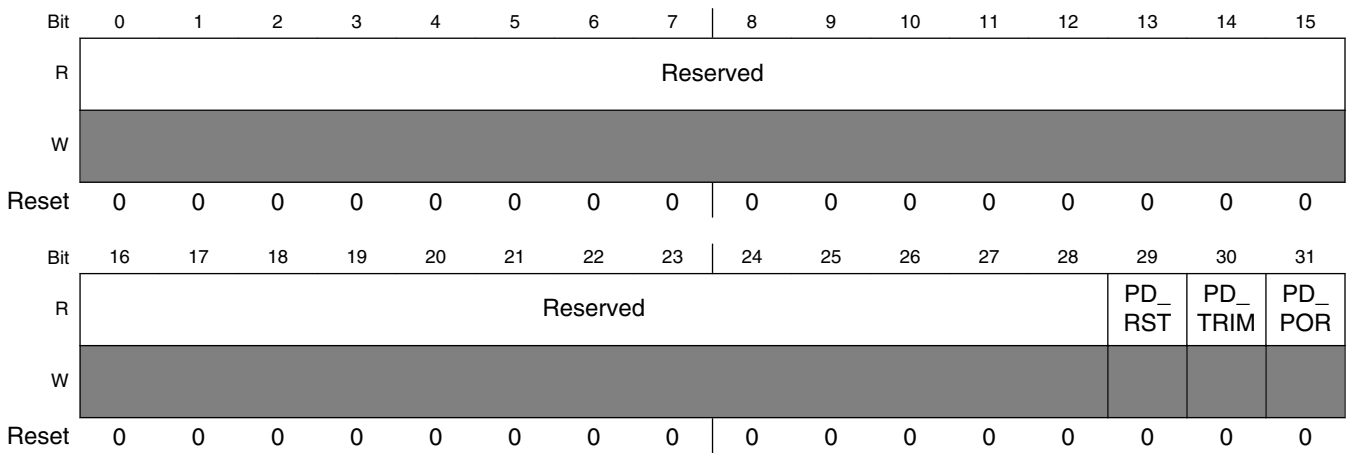
BD_SIUL2_ISR field descriptions

Field	Description
0–30 Reserved	This field is reserved.
31 BD_INIT	Initialization Flag. This is a read/write bit that can be used to indicate that the BD was initialized. Software reset does not affect the flag. Power-on reset clear the flag. 0 BD not initialized 1 BD initialized

3.4.4 Reset Status Register (BD_SIUL2_RSR)

The BD_SIUL2_RSR contains reset status information about the PD.

Address: C80_0000h base + 104h offset = C80_0104h



BD_SIUL2_RSR field descriptions

Field	Description
0–28 Reserved	This field is reserved.
29 PD_RST	PD Reset Flag. Read-only, indicates if PD has finished the reset sequence. 0 PD reset sequence not completed 1 PD reset sequence completed
30 PD_TRIM	PD Trim Flag. Read-only, indicates if PD has finished trimming phase during the reset sequence. 0 PD trimming phase not completed 1 PD trimming phase completed
31 PD_POR	PD POR Flag. Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed 1 PD is powered and power on reset has completed

Chapter 4
Buddy Device—Debug and Calibration Interface (DCI)

4.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard IEEE 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

4.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and IEEE 1149.7 controllers
- Debug break and cross-triggering control

- Synchronous restart control for CPU(s) when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

4.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
    - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
    - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.
- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as timers/ SPU, etc. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

This figure shows the DCI block diagram.

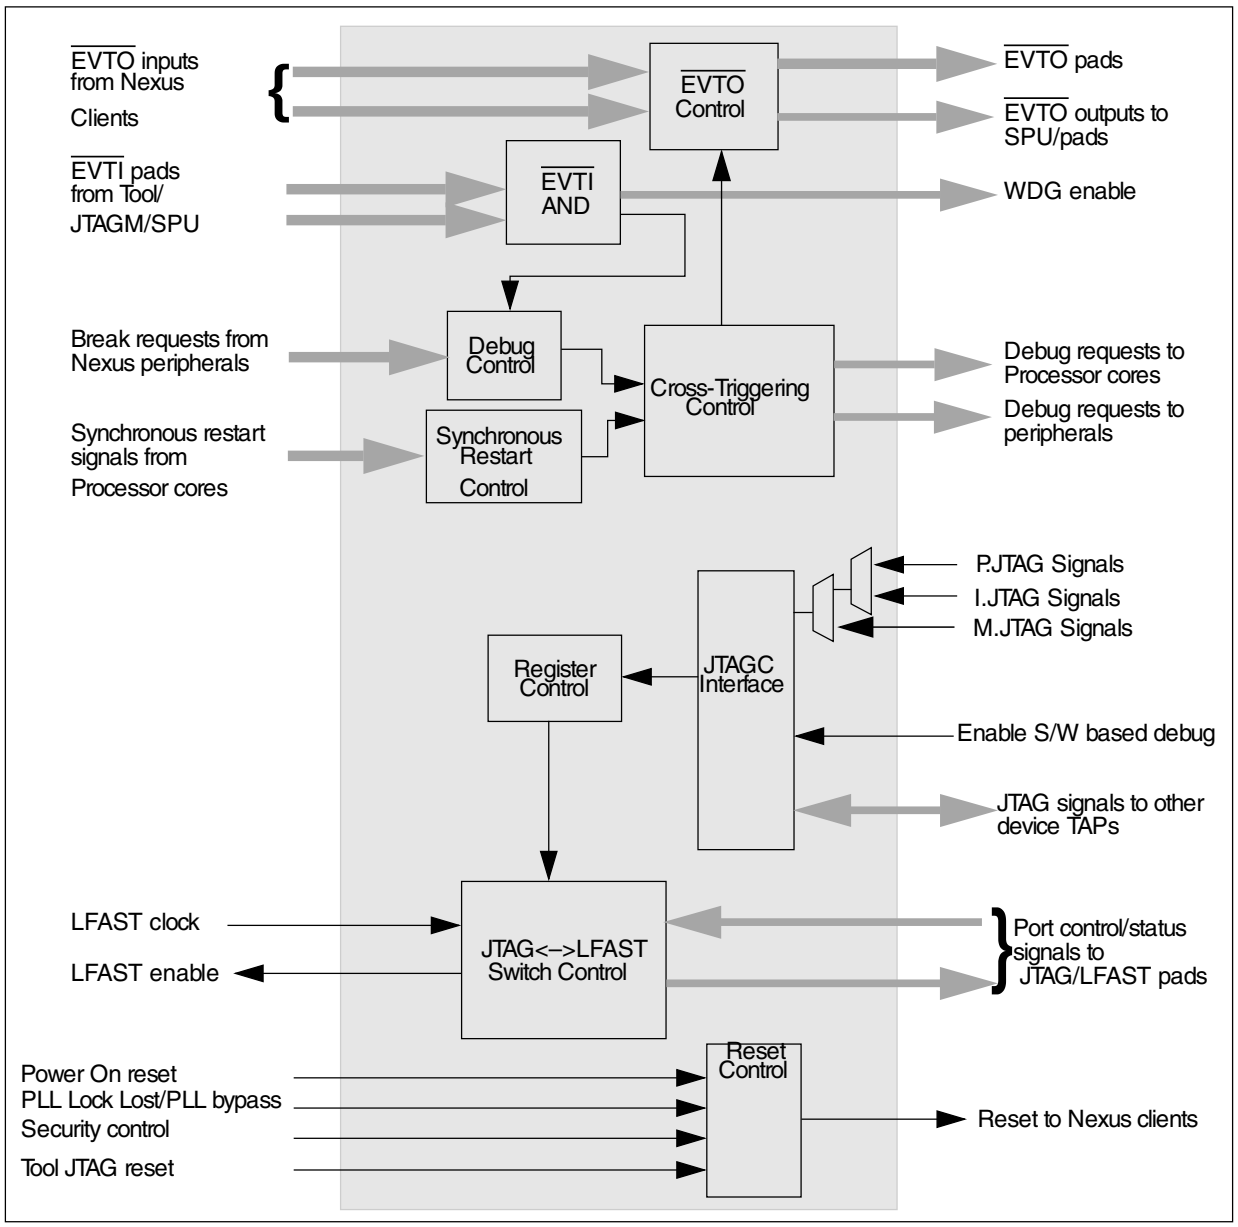


Figure 4-1. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in the following figure. In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

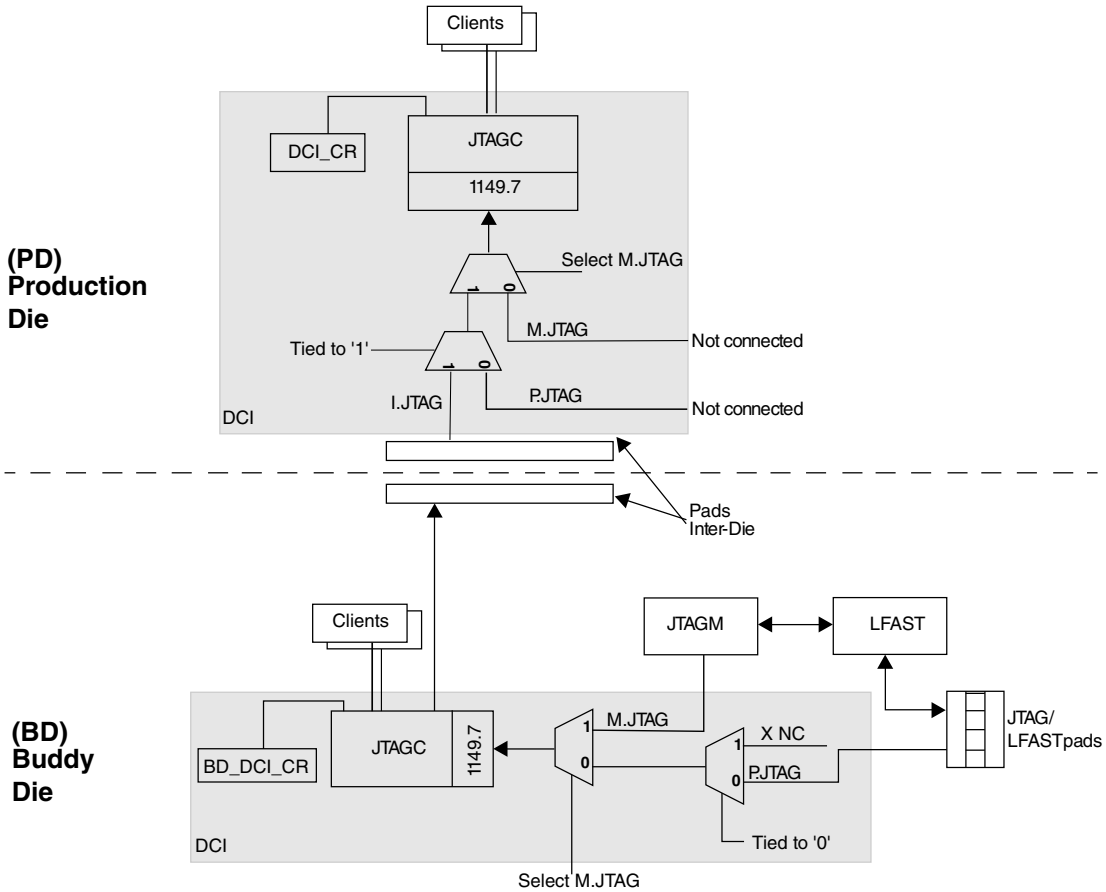

Figure 4-2. DCI in an emulation configuration

4.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

This table shows a summary of the configuration options.

Table 4-1. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the BD LFAST and BD JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed. Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in Port sharing between JTAG and LFAST modes. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. Table 4-2 shows the port mapping.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 4-2. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

This figure shows the DCI mode switching operation.

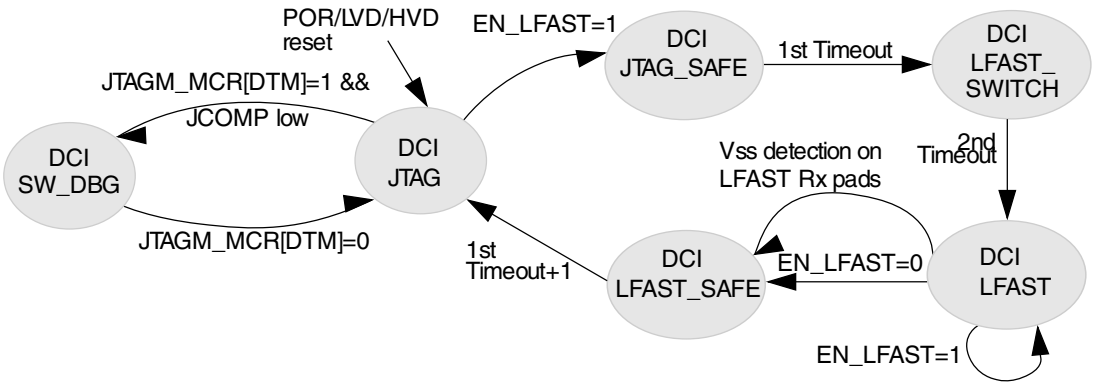

Figure 4-3. DCI operating modes state diagram

Note

JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

This table contains the operating mode descriptions.

Table 4-3. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: • JCOMP is latched inside to control until switching gets completed • The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state • An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

This figure shows a block diagram of the JTAG/LFAST connections.

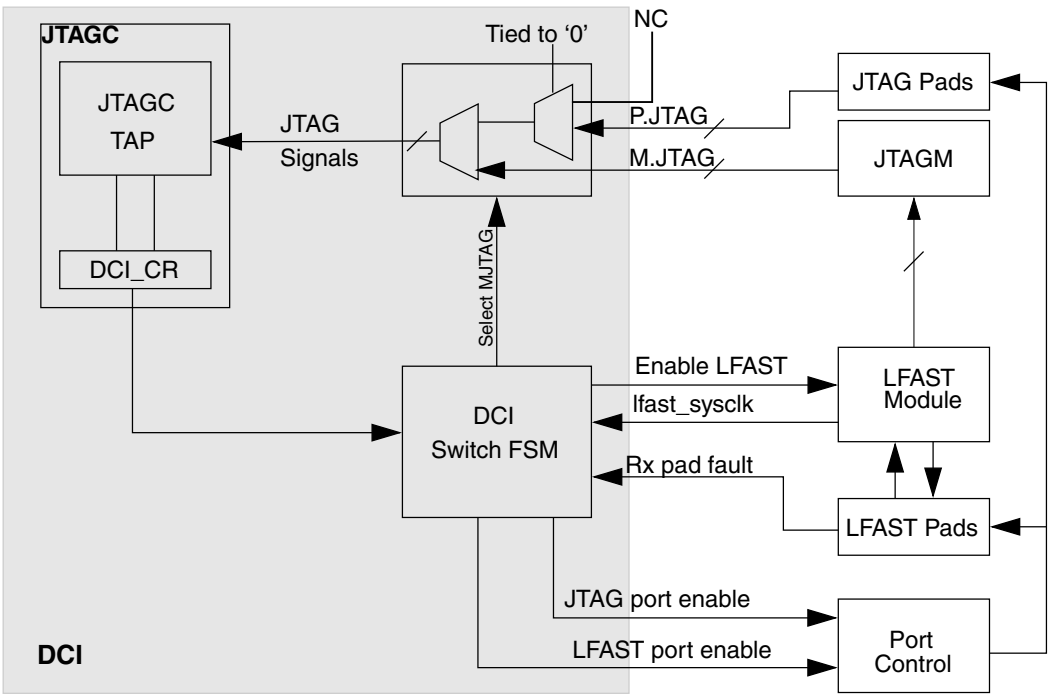

Figure 4-4. DCI JTAG/LFAST switch integration

4.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST

mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in Figure 4-5.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

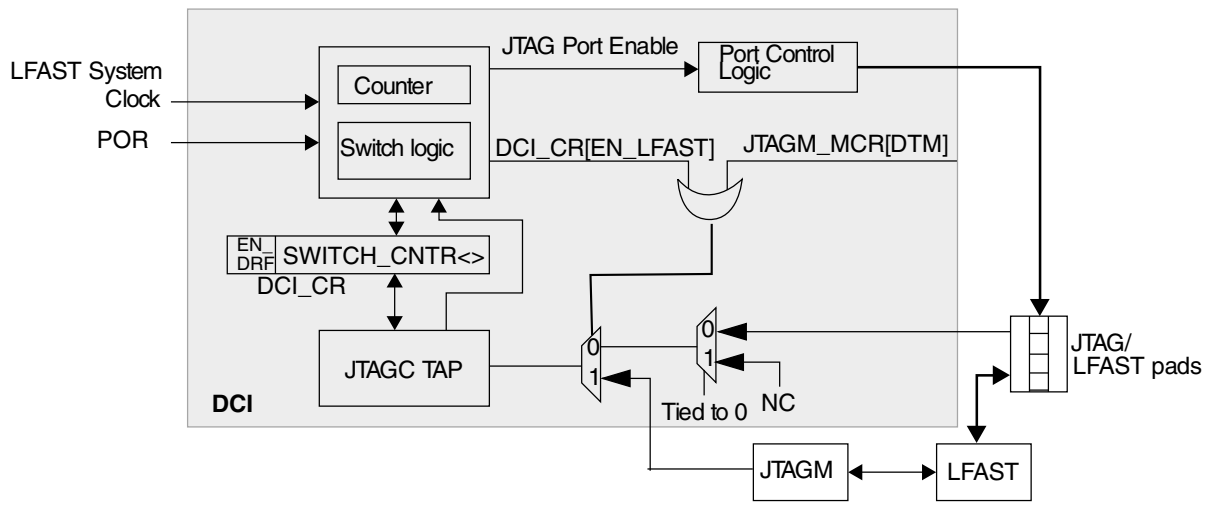

Figure 4-5. DCI switching between JTAG and LFAST modes

4.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The

DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.

5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

This figure shows the timing sequence.

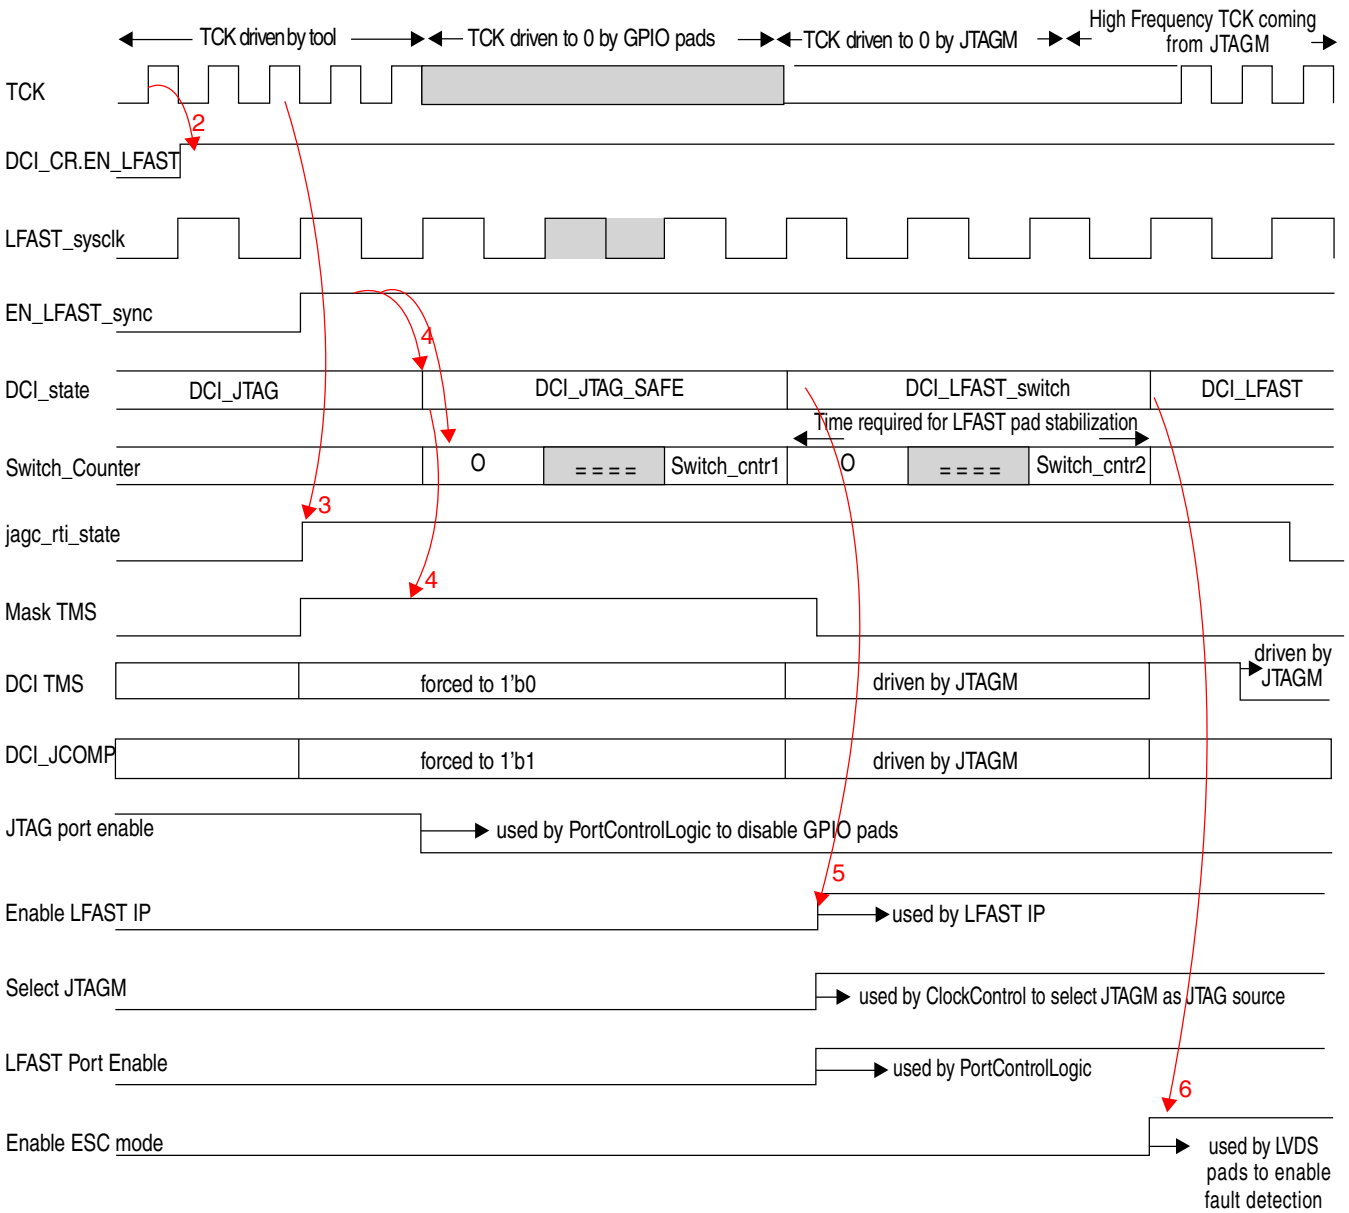

Figure 4-6. DCI JTAG to LFAST switching diagram

4.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.

3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 4-7 and Table 4-9 summarize the MCU and tool behaviors. The following figure shows the timing sequence.

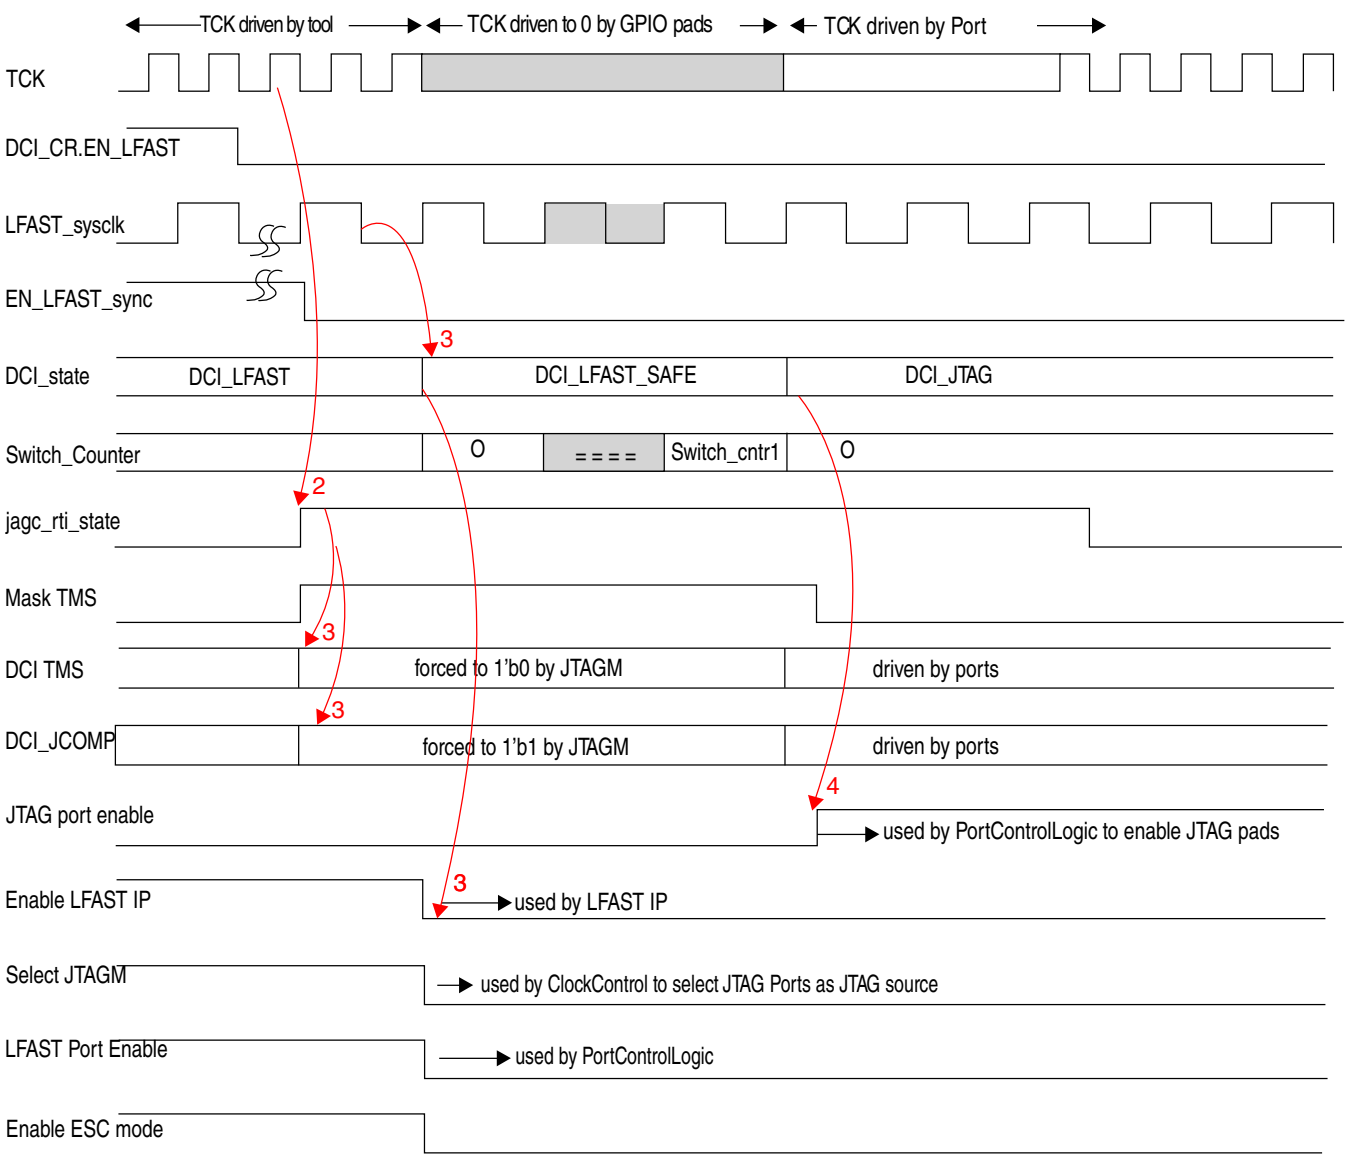

Figure 4-7. DCI LFAST to JTAG switching diagram

4.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

4.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

When MCR[jtagm_JCOMP] is programmed to 0, the JTAGC block reset is asserted, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

NOTE

It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

4.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.

If Debug_Enable is de-asserted by the SoC security modules (HSM or PASS), then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 4-4. Nexus Reset Truth Table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert

Table continues on the next page...

Table 4-4. Nexus Reset Truth Table (continued)

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

4.1.3.5 System watchdog control

The BD DCI does not include the Software Watchdog Timer (SWT) disable feature.

4.1.3.6 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

4.1.3.7 Security

The SoC security logic provides a Debug_Enable signal to the PD DCI. The PD DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the PD DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

4.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

4.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

4.3.1 DCI control register (BD_DCI_CR)

The BD_DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. The following table shows the format of the BD_DCI_CR.

NOTE

The BD version of this register is refered to as DCI_CR in the other sections of this chapter.

In an ED which has both PD and BD instances of the DCI, all bits controlling the switch between LFAST and JTAGM must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

	31	30	29	28	27	26	25	24
R W	SWITCH_CNTR2							
Reset	1	1	1	1	1	1	1	1

	23	22	21	20	19	18	17	16
R W	SWITCH_CNTR2							
Reset	1	1	1	1	1	1	1	1

	15	14	13	12	11	10	9	8
R W	SWITCH_CNTR1					FLVDS_PAD_FLT	Reserved	
Reset	1	1	1	1	1	0	0	0

	7	6	5	4	3	2	1	0
R W	FBD_RESET	FORCE_LFAST	EVTI_1_PAD_EN	EVTI_0_PAD_EN	Reserved		EN_ESC_MODE	EN_LFAST
Reset	0	0	0	0	0	0	0	0

The BD_DCI_CR is described in this table.

Table 4-5. BD_DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2. Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32×T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
7 FBD_RESET	Force Reset 0 Do not force Reset 1 Force Reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5	$\overline{\text{EVTI}}$[1] feature enable

Table continues on the next page...

Table 4-5. BD_DCI_CR field descriptions (continued)

Field	Description	
EVTI1_PAD_EN[1]	0	$\overline{\text{EVTI}}$[1] disabled (default)
	1	$\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN[1]	$\overline{\text{EVTI}}$[0] feature enable	
	0	$\overline{\text{EVTI}}$[0] disabled (default)
	1	$\overline{\text{EVTI}}$[0] enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads	
	0	Fault detect feature not present for LFAST Rx pads (default)
	1	Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST[2]	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset.	
	0	LFAST tool not enabled. DCI operates in JTAG mode (default)
	1	LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

4.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

4.4 Functional description

This section describes the functional description of the DCI.

4.4.1 DCI mode transition

After power-on reset, the BD DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. Table 4-6 and Table 4-7 show the steps and expected

states for the MCU and tool for JTAG to LFAST switching. Table 4-8 and Table 4-9 contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 4-6. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN

TCK	Logic Input	Logic Input	Logic Input	Hi-Z	Logic Output	Logic Output	Logic Output
Mode Escape	Inhibit	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable
LFAST_ SYSCLK _EN	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable	Enable

Table 4-7. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode)[1]	DCI_CR[EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don't Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 4-8. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 4-9. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

4.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the BD LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the BD DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode.Table 4-10 and Table 4-11 contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 4-10. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 4-11. Tool operation (LFAST to JTAGRST switching)

TCK	Logic Input	Don't Care

Chapter 5
Buddy Device—JTAG Controller (JTAGC)

5.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

5.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as Register description for more information about the JTAGC registers.

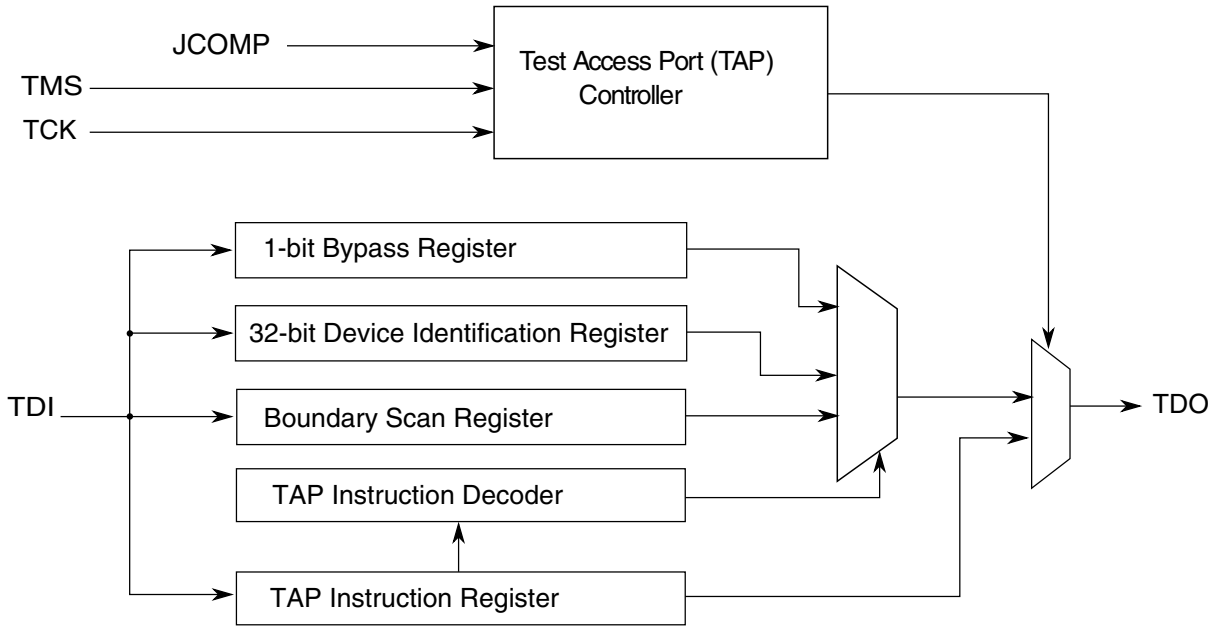

Figure 5-1. JTAG (IEEE 1149.1) block diagram

5.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 5-4 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Bypass register, boundary scan register, data registers, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

5.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

5.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

5.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

5.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

5.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 5-1. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z[1]	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

5.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

5.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

5.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

5.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

5.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

5.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

5.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 5-2. Instruction register

5.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

5.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number					
W

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Part Identification Number				Manufacturer Identity Code											1
W																
Reset	PIN (contd.)				MIC											1

The following table describes the device identification register functions.

Table 5-2. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. 0x381.

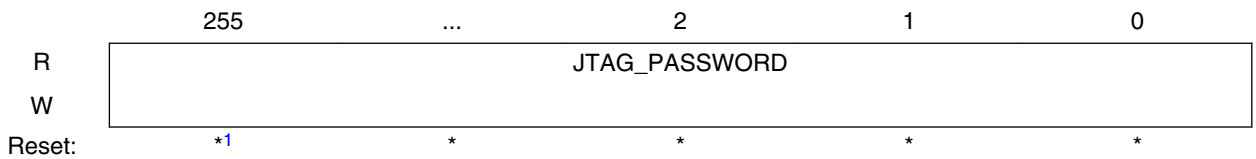
Table continues on the next page...

Table 5-2. Device identification register field descriptions (continued)

Field	Description
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E0x020.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

5.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.



1. The reset value of JTAG_PASSWORD is 256 'b0.

1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 5-3. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

5.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary

scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

5.4 Functional description

This section explains the JTAGC functional description.

5.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

5.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

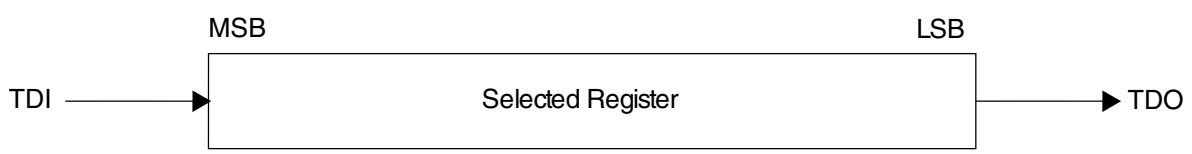


Figure 5-3. Shifting data through a register

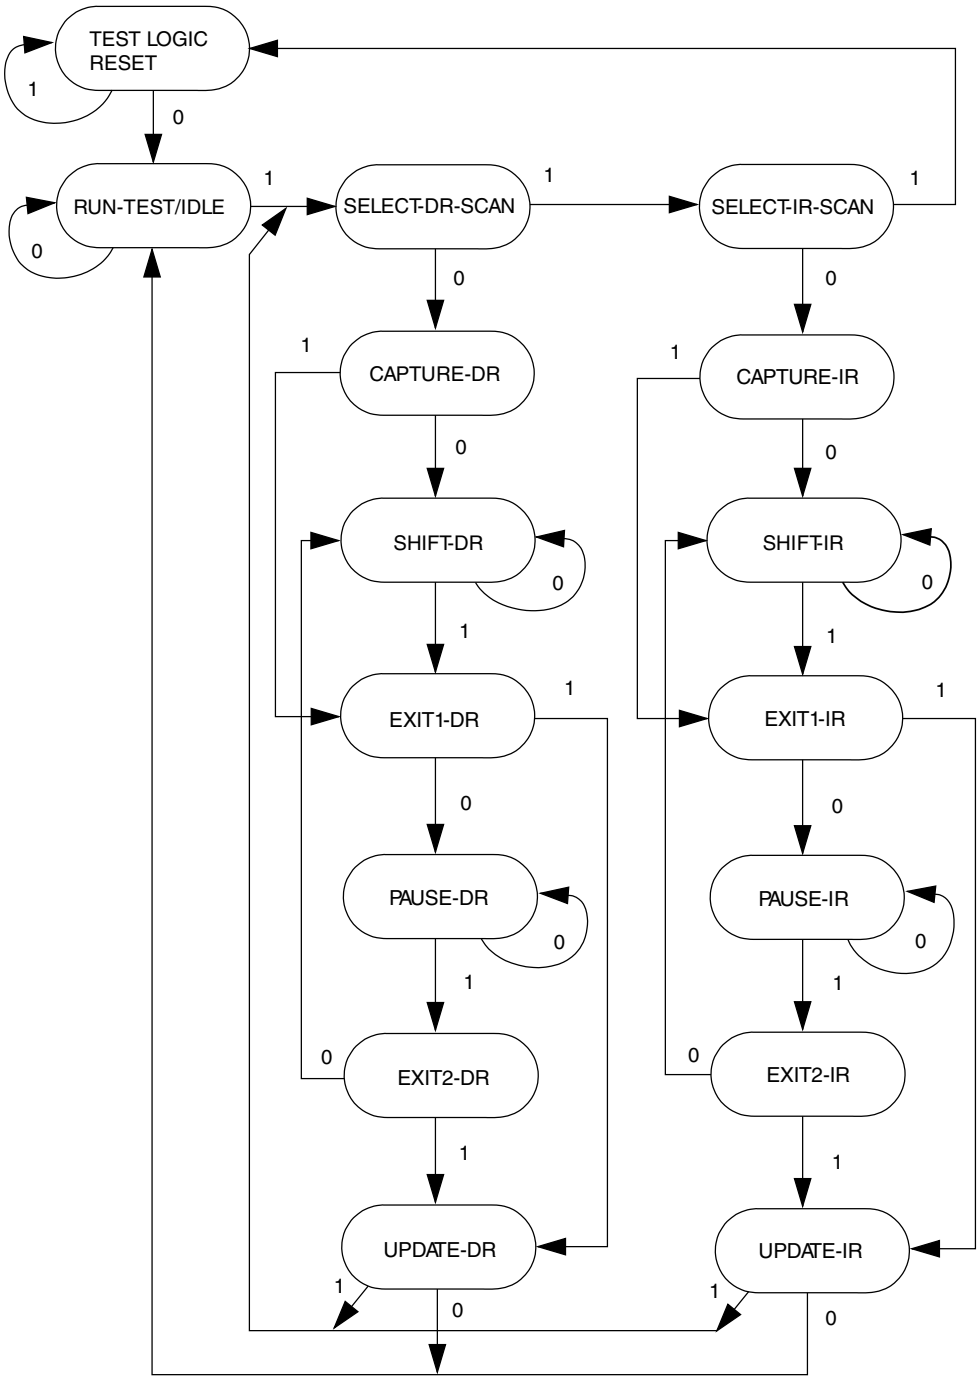
5.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 5-4. IEEE 1149.1-2001 TAP controller finite state machine

5.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

5.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

5.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 5-4. General 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
CLAMP	001100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
ENABLE_DCI_CR	001110	Enables access to DCI CR register

Table continues on the next page...

Table 5-4. General 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	001111	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

5.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

5.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

5.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

5.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

5.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

5.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

5.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

5.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

5.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

5.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

5.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

Chapter 6
Buddy Device—JTAG Master (JTAGM)

6.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

6.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:

- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

This figure shows the block diagram of the JTAGM.

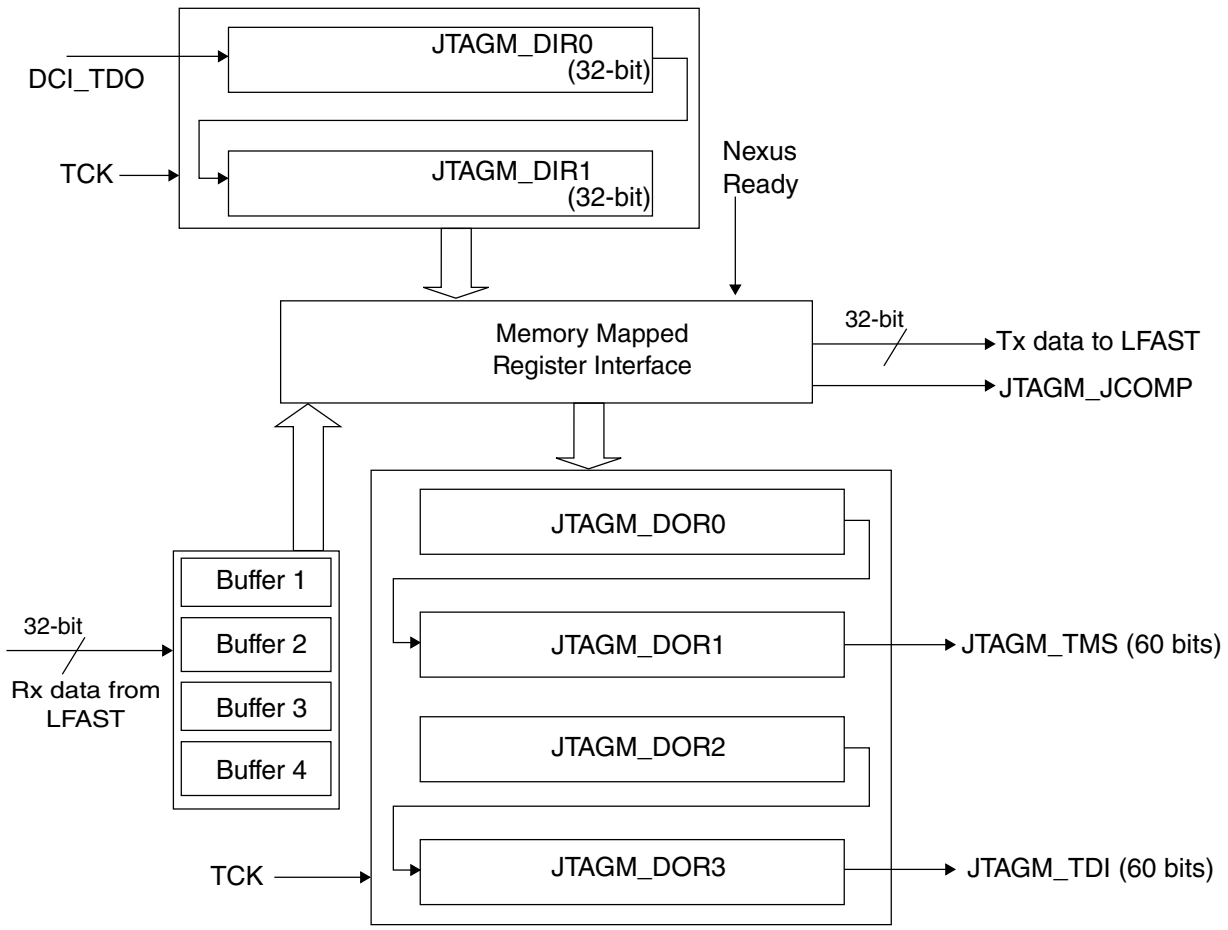


Figure 6-1. JTAGM block diagram

6.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

6.2 Functional description

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

This figure shows the flow diagram of the LFAST to DCI connection.

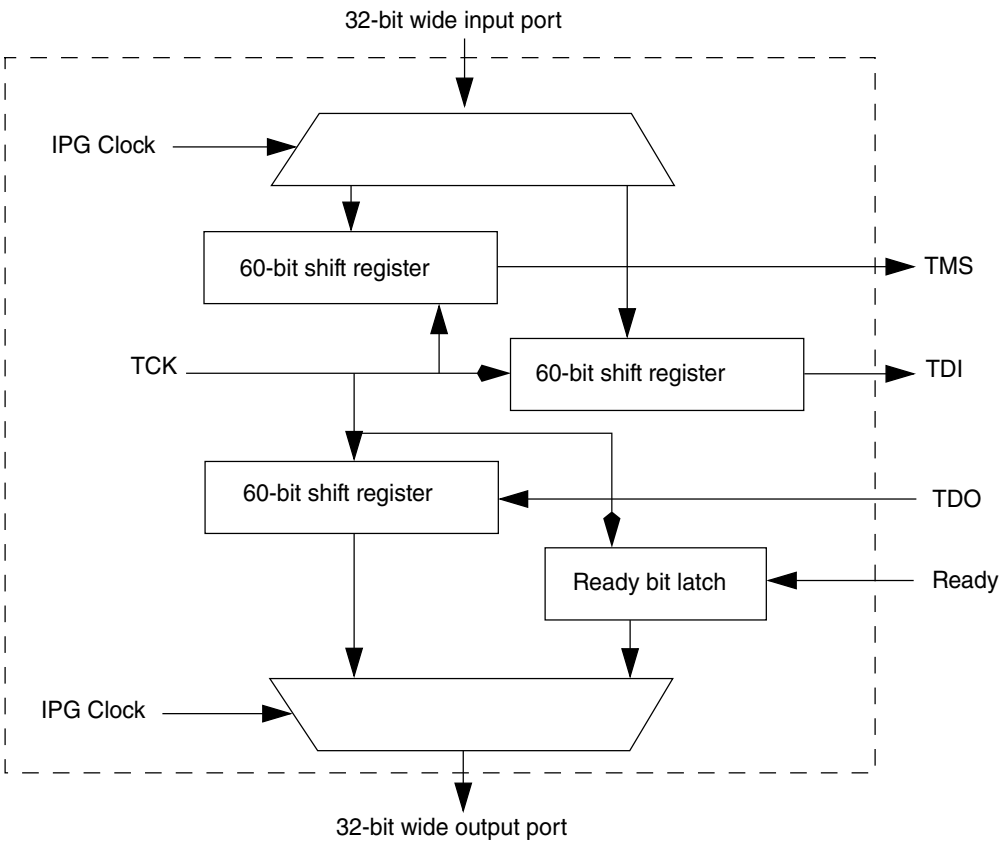

Figure 6-2. LFAST-to-DCI flow diagram

6.2.1 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

NOTE

The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

6.2.2 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the

first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

6.2.3 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

6.2.4 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

6.2.4.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

6.2.4.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

6.2.5 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus $\overline{\text{EVTI}}$ (Event In) and $\overline{\text{EVTO}}$ (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ signals to be embedded into the serial protocol. The $\overline{\text{EVTI}}$0 and $\overline{\text{EVTI}}$1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either $\overline{\text{EVTO}}$0 or $\overline{\text{EVTO}}$1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI.

The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

6.2.6 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in Status register ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).

The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module.

The JTAGM requests data from the LFAST only when at least one internal buffer is free.

6.2.7 JTAGM to DCI serial interface

This figure shows the data transfer timings between JTAGM and DCI.

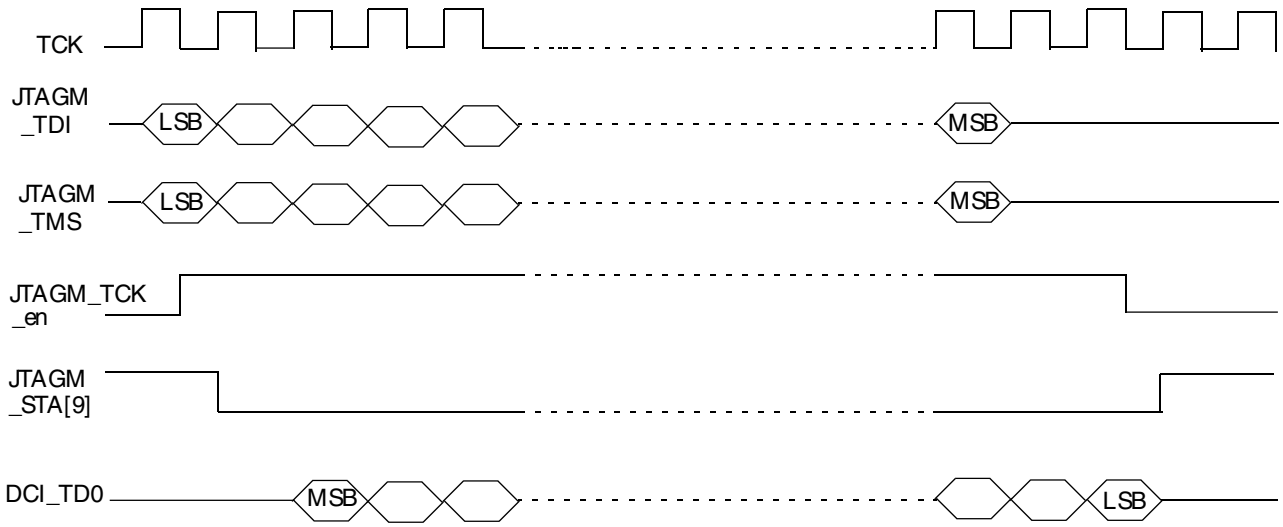

Figure 6-3. JTAGM to DCI serial interface diagram

6.2.8 JTAGM data handling and CRC calculation in LFAST mode

This figure shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

bit 127 to bit 68		bit 67 to bit 8		7	6	5	4	3	2	1	0
TMS (60 bits)		TDI (60 bits)		CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59									
Last TMS bit transmitted by JTAGM	First TMS bit transmitted by JTAGM	Last TDI bit transmitted by JTAGM	First TDI bit transmitted by JTAGM								

Figure 6-4. Bit ordering for LFAST to JTAGM transfer

This figure shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

bit 95 to bit 36		bit 35 to bit 32	bit 31 to bit 8	7	6	5	4	3	2	1	0
TDO (60 bits)		0 pad (4 bits)	JTAGM_SR (24 bits)	CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59	bit 31 to bit 8								
First TDO bit received by JTAGM	Last TDO bit received by JTAGM										

Figure 6-5. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in Figure 6-5).

6.2.9 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

6.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

6.4 Memory mapped registers

JTAGM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JTAGM_MCR)	32	R/W	0300_0002h	6.4.1/83

6.4.1 Module Configuration Register (JTAGM_MCR)

This register contains the status bits for the current transfer. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. (The only exception is the SIE bit, which is only seen in the PD instance of the JTAGM and is therfore not seen in this chapter. The SEI bit always needs to be programmed in the PD instance of the JTAGM, regardless of being ED or not.)

6.4.2 Status Register (JTAGM_SR)

The functionality of some of the SR bits changes depending on the setting of the DTM bit in the MCR. These differences are described in the field descriptions table.

In the ED, all bits of this register need to be accessed in the BD instance of the JTAGM. The exceptions are the bits related to the SPU interrupts (SPU_INT, SPU_INT_CLR), which always need to be accessed from the PD JTAGM, regardless of being ED or not.

JTAGM_SR field descriptions

Field	Description
0 Overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 TXGOOD	Status information from the LFAST to be used by software: Indicates either data frame or ping frame was transmitted successfully
3 TXERROR	Status information from the LFAST to be used by software: Indicates Tx data Interface not enabled and a frame is ready to be transmitted
4 RXOVFL	Status information from the LFAST to be used by software: Indicates Rx data FIFO overflow
5 INVFPS	Status information from the LFAST to be used by software: Indicates reception of frame with invalid frame payload size
6 INVICLC	Status information from the LFAST to be used by software: Indicates reception of frame with invalid ICLC code
7 ILLLCT	Status information from the LFAST to be used by software: Indicates reception of illegal LCT frame
8 Reserved	This field is reserved. Reserved to 0
9 LVDSEN	DCI status: DCI LVDS port enable
10 JTAGEN	DCI status: DCI JTAG port enable
11 LVDSSAFE	DCI status: DCI LVDS safe mode
12 JTAGSAFE	DCI status: DCI JTAG safe mode
13 LVDSESC	DCI status: DCI LVDS escape mode

Table continues on the next page...

JTAGM_SR field descriptions (continued)

Field	Description
14 LFASTEN	DCI status: DCI enable LFAST
15 TOOL	DCI status: DCI tool present, set when a debug tool is connected
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit. 0 No activity sensed on $\overline{\text{EVTO}}$ 0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$ 0
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$ 1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$ 1
18 SPU_INT_CLR	Write 1 clears the SPU_INT. This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. In LFAST mode (DTM = 0), this bit has no effect and should not be used. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24–31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode (DTM = 0): Bit 24:31 contains the CRC. Write has no effect. SW Mode (DTM = 1): • Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. • Writing 1 on bit 24 clears evto0_edge, bit 16 • Writing 1 on bit 25 clears evto1_edge, bit 17

6.4.3 Data Out Register 0 (JTAGM_DOR0)

Address: 0h base + 8h offset = 8h

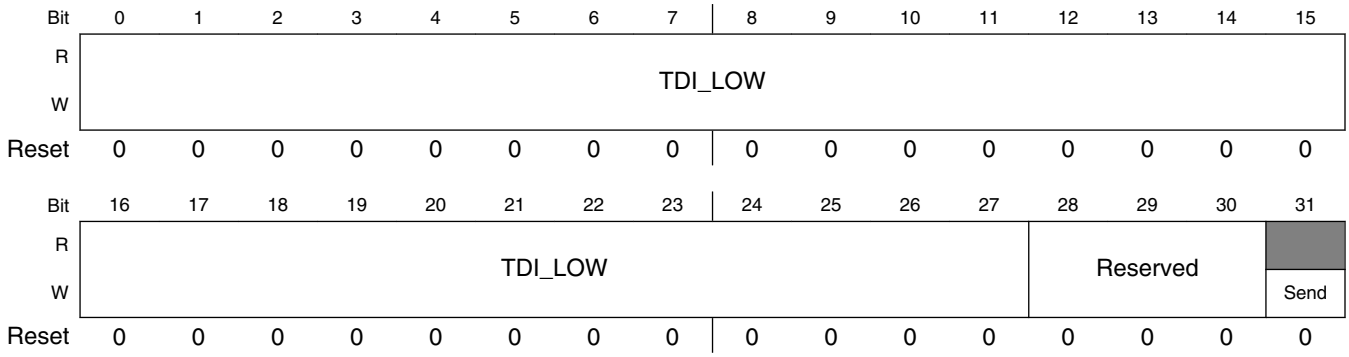
JTAGM_DOR2 field descriptions

Field	Description
0–31 TDI_HIGH	Higher word of data for TDI, bits 59-28. Writable by software only when DTM = 1

6.4.6 Data Out Register 3 (JTAGM_DOR3)

Address: 0h base + 14h offset = 14h

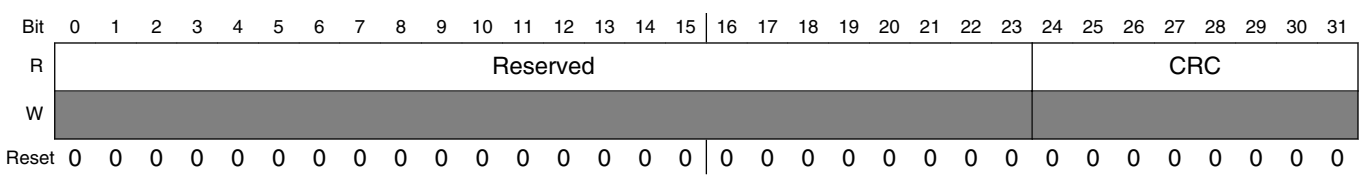


JTAGM_DOR3 field descriptions

Field	Description
0–27 TDI_LOW	Lower word of data for TDI, bits 27-0. Writable by software only when DTM = 1. TDI_LOW[0] is shifted out first
28–30 Reserved	This field is reserved.
31 Send	Send bit. When this bit is set, data is sent to the DCI. It is a self-clearing bit and is always read as 0. Writable by software only when DTM = 1

6.4.7 Receive CRC Register (JTAGM_RxCRC)

Address: 0h base + 18h offset = 18h

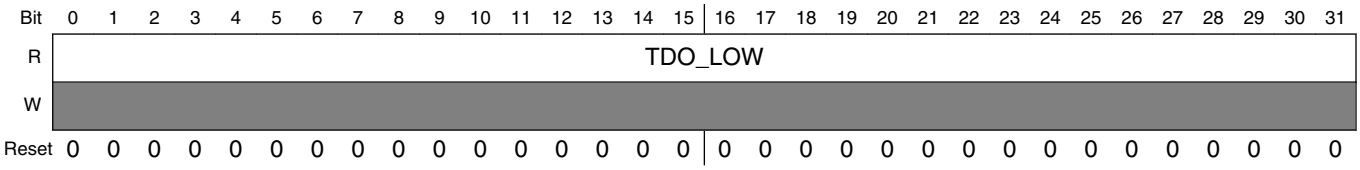


JTAGM_RxCRC field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24–31 CRC	Received CRC. Refers to the CRC of the received LFAST message.

6.4.8 Data Input Register 0 (JTAGM_DIR0)

Address: 0h base + 1Ch offset = 1Ch

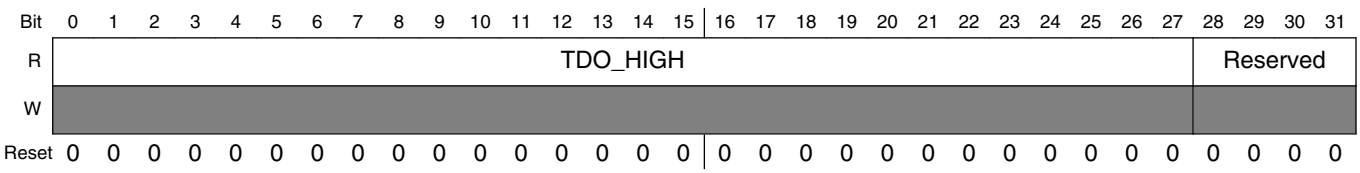


JTAGM_DIR0 field descriptions

Field	Description
0–31 TDO_LOW	Lower word of data received on TDO, bits 0-31

6.4.9 Data Input Register 1 (JTAGM_DIR1)

Address: 0h base + 20h offset = 20h



JTAGM_DIR1 field descriptions

Field	Description
0–27 TDO_HIGH	Higher word of data received on TDO, bits 32-59
28–31 Reserved	This field is reserved.

Chapter 7
Buddy Device—Nexus Aurora Router (NAR)

7.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in the following figure. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

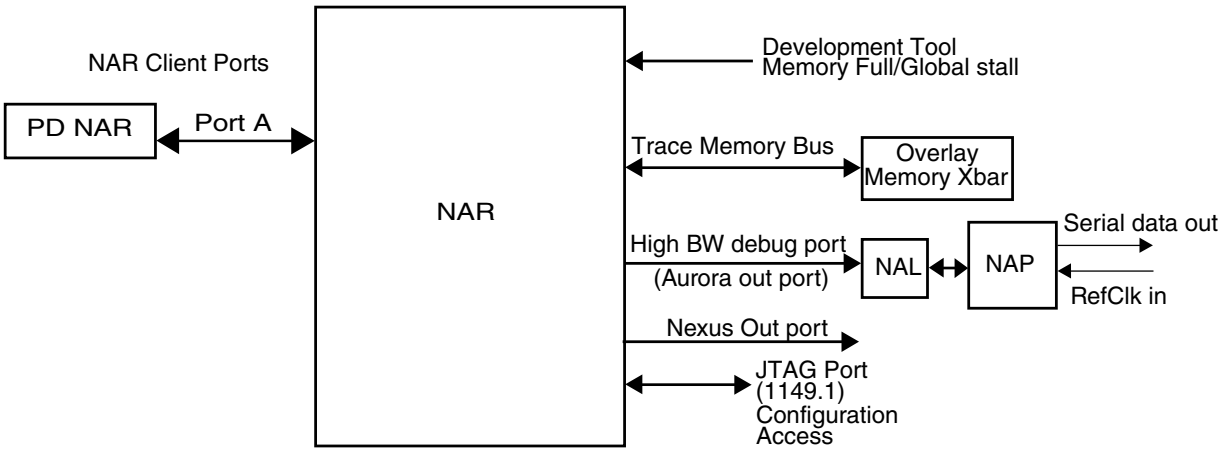


Figure 7-1. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. The Nexus Out port provides additional flexibility to the channel trace data to memory on the Nexus recipient. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

- Aurora type interface with clock domain transfer at the same frequency

7.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (IEEE 1149.1) port.

7.3 Features

The NAR supports the following features:

- Connects 1 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Nexus out port for direct connection to pins (low-speed applications) or to another Nexus port controller
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client

- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

7.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (IEEE 1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 7-1. NAR registers

Register name	Read/Write	JTAG index (NAR relative)
NAR_CR—NAR Control Register	R/W	0
NAR_ST—NAR Status Register	R	1
NAR_SFR—Source Filter Register	R/W	2
NAR_TFR—Type Filter Register	R/W	3
NAR_TBALO—Trace memory port base address, low	R/W	4
NAR_TBAHI—Trace memory port base address, high	R/W	5
NAR_TCR—Trace Memory bus control register	R/W	6
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)
NAR_CSSR–Client Suppress Status Register	R	B
NAR_CDR—Client Disable Register	R/W	C
NAR_NAPCR—Nexus Aurora Phy Control Register	R/W	D
NAR_AHFPAR—Trace memory fill level and partition configuration	R/W	E

7.4.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following table shows the format of the NAR_CR.

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NCD	TEN	TRS	TSG		SED	SRD	TBW	AQP		0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WPE			0	0	MSP		0	ALT		0	AFA	0	FSD	PUS	NSR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 7-2. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See Disabled for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). **Note:** Some clients may only support timestamps on every message. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled

Table continues on the next page...

Table 7-2. NAR_CR field descriptions (continued)

Field	Description
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 1/2 of queue is dedicated to alternate partition 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications. 00 No message select port. 0–1 port is active. 01 HBDP is the MSP 10 Trace memory bus is the MSP 11 Nexus is the MSP
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 HBDP is the ALT 10 Trace memory bus is the ALT 11 Nexus is the ALT
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2 FSD	Frame Serial Data. 0 Framing disabled. Data is streamed through the Aurora out port. 1 Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode

Table continues on the next page...

Table 7-2. NAR_CR field descriptions (continued)

Field	Description
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

7.4.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following table shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				MPF	MLV		APF	ALV		0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 7-3. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24	NAR Config Error.

Table continues on the next page...

Table 7-3. NAR_ST field descriptions (continued)

Field	Description
NCE	See Table 7-18 for coding
23 MPF	MSP Partition Full. 0 MSP partition not full 1 MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled i.e. the main queue is partitioned. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%
20 APF	ALT Partition Full. 0 ALT partition not full 1 ALT partition full
19–18 ALV	ALT Partition Queue Level. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%
17–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)

7.4.3 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See Output arbitration, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

7.4.3.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	FE2	SF2				0	0	0	FE3	SF3				0	ACC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 7-4. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters

Table continues on the next page...

Table 7-4. NAR_SFR field descriptions (continued)

Field	Description
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See Output arbitration for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See Output arbitration for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See Output arbitration for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See Output arbitration for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

7.4.3.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following table. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

Table continues on the next page...

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TFR is described in the following table.

Table 7-5. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See Output arbitration for an example.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See Output arbitration for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See Output arbitration for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See Output arbitration for an example.

7.4.4 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

7.4.4.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following tables show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 7-6. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 7-7. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

7.4.4.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following table shows the format of the NAR_TCR.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BTM	BTS		BTH		0	0	0	TBW	MXFR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

R W	MXFR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 7-8. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
23 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

7.4.5 Suppress mode triggers registers (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in Suppress mode. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress

Trigger Control Register, shown in the following table, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7-A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GST	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	LST															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 7-9. NAR_STCR field descriptions

Field	Description	
31 GST	Global Suppress Trigger. 0 The associated trigger cannot cause NAR to enter global suppress mode 1 The associated trigger is enabled for global suppress mode	
29–16	Reserved	
15–0 LST	Local Suppress Trigger.	
	0000000000000000	The associated trigger is disabled for local suppress mode for all clients
	xxxxxxxxxxxxxxx1	Trigger is enabled for Client 1 local suppress
	xxxxxxxxxxxxxx1x	Trigger is enabled for Client 2 local suppress
	xxxxxxxxxxxxx1xx	Trigger is enabled for Client 3 local suppress
	xxxxxxxxxxxx1xxx	Trigger is enabled for Client 4 local suppress
	xxxxxxxxxxx1xxxx	Trigger is enabled for Client 5 local suppress
	xxxxxxxxxx1xxxxx	Trigger is enabled for Client 6 local suppress
	xxxxxxxxx1xxxxxx	Trigger is enabled for Client 7 local suppress
	xxxxxxxx1xxxxxxx	Trigger is enabled for Client 8 local suppress
	xxxxxxx1xxxxxxxx	Trigger is enabled for Client 9 local suppress
	xxxxxx1xxxxxxxxx	Trigger is enabled for Client 10 local suppress
	xxxxx1xxxxxxxxxx	Trigger is enabled for Client 11 local suppress
	xxxx1xxxxxxxxxxx	Trigger is enabled for Client 12 local suppress
	xxx1xxxxxxxxxxxx	Trigger is enabled for Client 13 local suppress
	xx1xxxxxxxxxxxxx	Trigger is enabled for Client 14 local suppress
	x1xxxxxxxxxxxxxx	Trigger is enabled for Client 15 local suppress
	1xxxxxxxxxxxxxxx	Trigger is enabled for Client 16 local suppress
	All other options	Reserved

7.4.6 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following table, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LSS																0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CSSR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress status, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 7-10. NAR_CSSR field descriptions

Field	Description	
31–16	Local Suppress Status.	
LSS	0000000000000000	No client is in local suppress mode
	xxxxxxxxxxxxxxx1	Client 1 is suppressed
	xxxxxxxxxxxxxx1x	Client 2 is suppressed
	xxxxxxxxxxxxx1xx	Client 3 is suppressed
	xxxxxxxxxxxx1xxx	Client 4 is suppressed
	xxxxxxxxxxx1xxxx	Client 5 is suppressed

	xxxx1xxxxxxxxxxx	Client 12 is suppressed
	xxx1xxxxxxxxxxxx	Client 13 is suppressed
	xx1xxxxxxxxxxxxx	Client 14 is suppressed
	x1xxxxxxxxxxxxxx	Client 15 is suppressed

Table continues on the next page...

Table 7-10. NAR_CSSR field descriptions (continued)

Field	Description	
	1xxxxxxxxxxxxxx	Client 16 is suppressed
	All other options	Reserved
15–0	Reserved	

7.4.7 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following table, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note

Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Register index: C

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.4.8 Nexus Aurora Phy control register (NAR_NAPCR)

The Nexus Aurora Phy control register provides configuration control to number of HBDP lanes of Nexus Aurora Phy and LVDS pad control signals. The following table shows the format of the NAR_NAPCR.

Register index: D

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	NUM_LANE			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0		0	LVDS_TXOPT				LVDS_RX_TERM_EN	LVDS_BIAS_PRG	LVDS_RXOPT					
W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

The NAR_NAPCR is described in the following table.

Table 7-12. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. This field is device specific. For a description of this field see the Calibration and Debug configuration chapter which describes how the modules are configured.
11–8 LVDS_TXOPT	This is an internal characterization field.
7 LVDS_RX_TERM_EN	This is an internal characterization field.
6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

7.4.9 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following table shows the format of the NAR_AHFPAR.

Register index: E

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

The NAR_AHFPAR is described in the following table.

Table 7-13. NAR_AHFPAR field description

FIELD	Description
31-25	Reserved and must be written with 0s
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on dci_evti[1] event to generate a global stall
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See Global (Development tool client) stall control
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** This is used in BD as it has memory ranges from 65K to 983K
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Overlay and internal trace memory full status generation **Note:** This is used in PD as it has memory ranges from 1K to 15K

7.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

7.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/ filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note

The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see Suppress mode. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

7.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in the following table.

Table 7-14. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

7.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

7.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

7.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

7.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

7.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in the following table on the incoming messages before transmitting to one of the output ports.

Table 7-15. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

7.5.3 Data reception and arbitration

The BD NAR supports 1 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the

client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn × 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

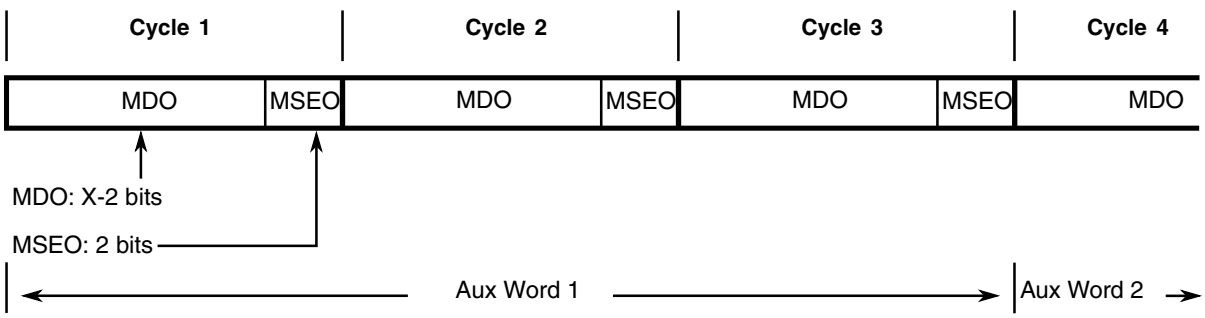

Figure 7-2. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

7.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR

can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

7.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the

message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

7.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Even though the NAR supports three outputs (HBDP, Nexus, and trace memory bus) only two can be used at the same time. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register

(NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

7.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in Figure 7-3. Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

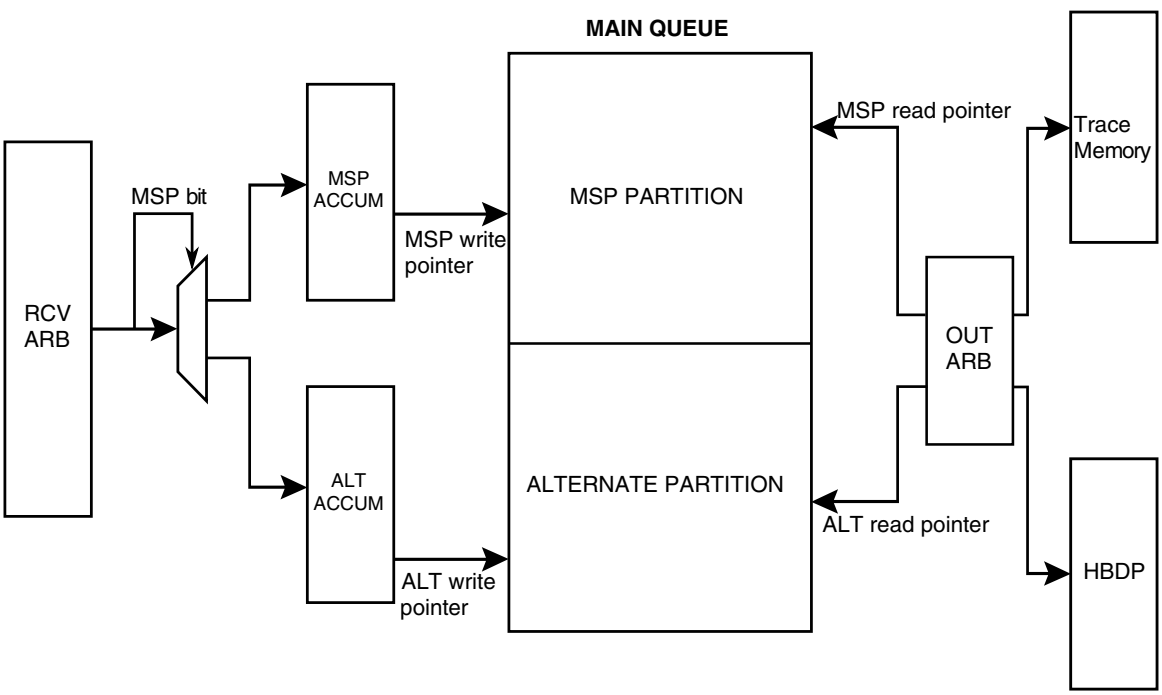

Figure 7-3. Queue partitioning

7.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

7.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

7.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

7.5.8.3 Nexus format

If the Nexus port is used, entries are sent directly out of the queue with no translation or resizing. The Nexus output, Nexus input, and queue are all the same width.

The Nexus port also includes an EVTO output. This allows EVTO signaling functionality to be maintained in systems with multiple NARs. EVTO can also be used as a trigger by an external event processing block, to allow events such as client halt to occur based on

NAR events such as tracebuffer overflow. Currently, the only event that can cause an EVTO assertion is an HBDP hard error/reset, since data is almost certainly lost when the HBDP link goes down, the NAR needs to communicate that back to the clients so that they can generate sync messages.

Many Nexus message types use address/data compression, wherein the compressed data is generated by XORing the current data with the previous data sent. This type of compression can only work if there is no data lost; if data is lost, the client must start over by sending a new sync message which contains the full uncompressed address or data.

7.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

7.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 × 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

7.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.

- Watchpoint—The NAR generates its own watchpoint match message under the circumstances shown in Table 7-19.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 7-16. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message[1]	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC [2]	NAR source ID
	4	4	fixed	ETYPE	See Table 7-17
	12	12	fixed	ECODE	See Table 7-18
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message[3]	6	6	fixed	TCODE	TCODE value = 15
	6	6	fixed	SRC [2]	NAR source ID
	6	6	fixed	WPHIT	See Table 7-19
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2012 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2012 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

7.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in the following table.

Table 7-17. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 7-18.
0011 (h'3)	Trace memory bus port read/ write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.[2]
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 7-18	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 7-18), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1101 (h'D)	Receive Queue Overrun	Minor	Drop message	If a client sends a data word that the NPC cannot accept (due to a full receive queue), the new data word will be dropped2.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.

Table continues on the next page...

Table 7-17. NAR error types (continued)

ETYPE	Description	Classification	NAR action	Comment
1111 (h'F)	Stall error	Minor	—	—

2. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in the following table.

Table 7-18. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

7.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 7-19. Watchpoint hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

7.5.12 Timestamp function

The NAR and its clients may transmit timestamps to allow precise ordering of events. Synchronous or asynchronous clients use the NAR timer value broadcasted over a bus to ensure that all timestamps are in sync as shown in the following figure. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

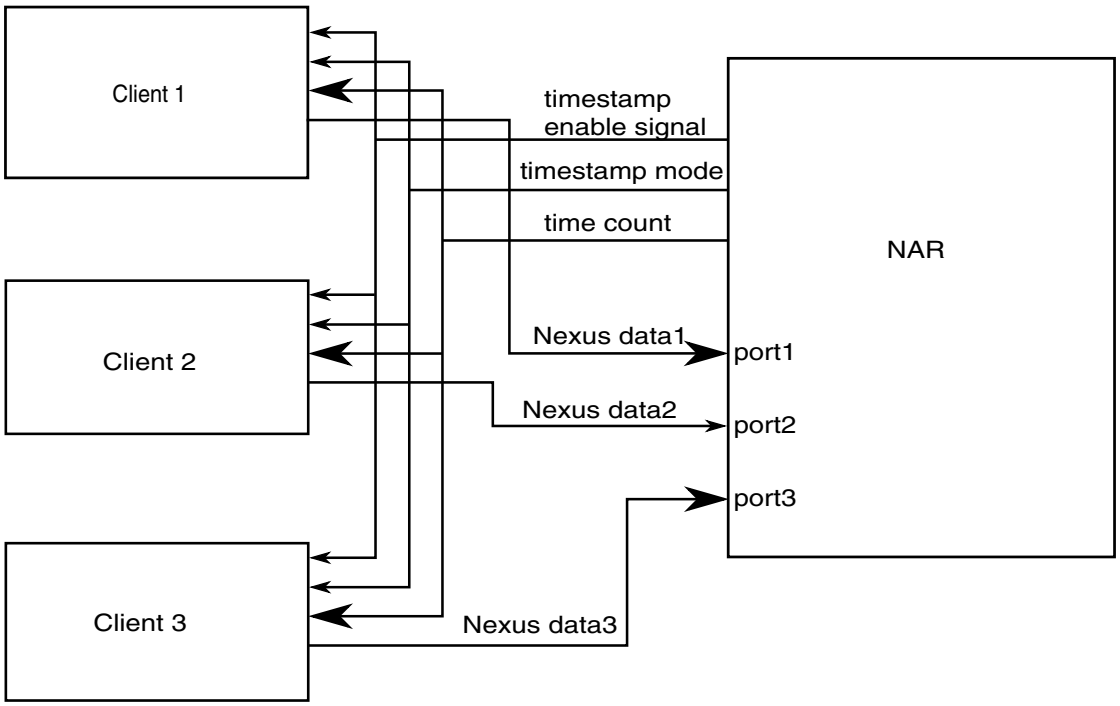

Figure 7-4. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The timestamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode, and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

7.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to NAR block. The dci_evti[1] carries this information. NAR detects the falling edge of dci_evti[1] and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

7.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 × 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

7.5.15 Configuration/debug interface JTAG

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in Table 7-20. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

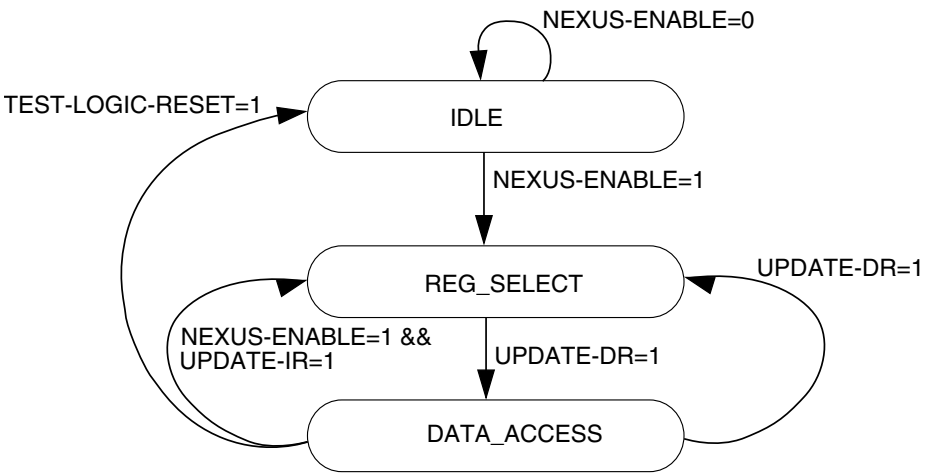

Figure 7-5. Nexus controller state machine

Table 7-20. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

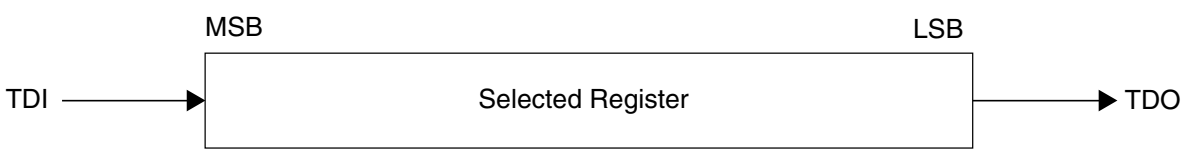

Figure 7-6. Shifting data into register

7.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

7.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 7-5, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 7-21. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

7.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in Table 7-1.

Table 7-22. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 7-23. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

7.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - 32-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR
  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

7.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

7.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

7.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

7.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width × 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as Bn × 32, where 32 = MDO bits + 2 MSEO bits and Bn is the number of beats.

Thus:

Aurora data width = the Nexus client data

Aurora width × 16 = Bn × 32

Aurora width = 2 × Bn

This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block. The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

7.6 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in Output arbitration.

Example flow of NAR configuration for different cases.

Configuration with Two output port enabled

1. For Two port enabled one port must be Message Select (MSP) and other Alternate (ALT); Trace Memory and Aurora ports with multiple clients

   Selection of MSP port depends on user choice. One option could be based on the requirement of Filtering. If Messages from some known sources with some specific type (if any) is required to be sent to a particular port then select user can select that

port as MSP. All other messages will go to the Alternate port. The filter can be used as inverted manner where unmatched messages will go to MSP. (Please see section “Output arbitration” for details)

- Configure the Source Filter register (NAR_SFR), To enable proper filtering of messages based on Message source going to MSP or ALT port
  - Example: for DWPU connected in Nexus out port set the source ID of the core and NXMC in any two source filter type and enable it
- Configure the Type Filter register (NAR_TFR), To enable proper filtering of messages based on Message Type going to MSP or ALT port
  - Example: for DWPU connected in Nexus out port set the Type of messages in any two Type filter type and enable it
- Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
  - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
  - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
- Configure Client disable register NAR_CDR (disable clients which are not required)
- Configure NPC suppress trigger registers NAR_STCR[x] (x=0-3) (suppress the clients for which data is not to be forwarded at output) (Difference between suppressing and disabling is that suppressing can be done dynamically during NAR operation but disabling can’t be done this way which may leads to system hang)
- Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
- Configure the NAR control register for other controls and Enable NAR
  - Set the MSP as Nexus Out and ALT as Trace memory
  - Set AQP for partitioning the Main Queue for ALT and MSP ports
  - Set time stamp controls
  - Enable NAR to start operation
  - Configuration for Single Output port with single partition in NAR central Message Queue

2. Only Trace Memory port is enabled with multiple client
   - Configure Trace Memory port attributes : (This step is not required if Trace memory port is not used)
     - Start Address (base address) in NAR_TBALO & NAR_TBAHI register
     - Transfer mode, Block size, Threshold in %, Wrapping enable and Total size of memory
   - Configure Client disable register NAR_CDR (disable clients which are not required)

- Configure the Event generation register (NAR_AHFPAR) for programmable fill level event generation
- Configure the NAR control register for other controls and Enable NAR
  - Set the Trace Memory port as ALT port (Alternate port is only the main port in single out port application)
  - Set AQP for disabling partitioning
  - Set time stamp controls
  - Set watch point controls
  - Enable NAR to start operation

Chapter 8
Buddy Device—Nexus Aurora Link (NAL)

8.1 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. The following figure details the NAL block diagram. The number of lanes, n, is .

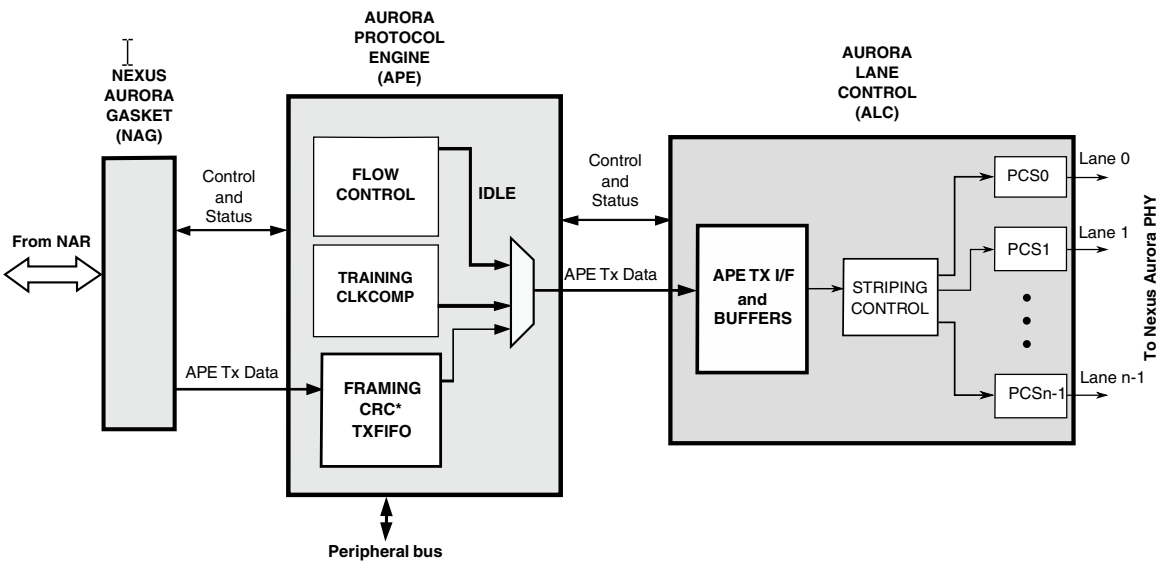

Figure 8-1. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Router (NAR) ; messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS

drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. The table below lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 8-1. NAL and NAP feature summary

Sub-Component	Feature
NAR Aurora Gasket (NAG)	• Transmit FIFO to buffer data as it crosses the NAR/NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. • Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	• Link training • Per the Aurora Protocol specification, clock-compensation, and data framing • Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	• Striping of data stream from the Aurora core across all available lanes in two-byte chunks • PCS functionality for NAL
Nexus Aurora PHY (NAP)	• Physical transmission of serial data to device pins • External clock source for SerDes clock domain

8.2 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each payload is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each end symbol packet transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

NOTE

Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

8.3 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

8.4 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note

Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the

channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

8.5 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 8-2. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0h	NAL General Status Register (NAL_GSR)	32	R	0008_0000h
8h	NAL General Control Register (NAL_GCR)	32	R/W	0000_0000h
Ch	NAL Training Control Register (NAL_TCR)	32	R/W	0000_0000h

8.5.1 Nexus Aurora Link General Status Register (NAL_GSR)

The NAL_GSR is a read only register that describes the status of the NAL.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TXONLY	0		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			TXCFG			0									AS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 8-3. NAL_GSR field descriptions

Field	Description
31–20 Reserved	Reserved This bitfield is reserved.
19	Transmit Only mode. Indicates that Aurora is configured in a transmit-only mode.

Table continues on the next page...

Table 8-3. NAL_GSR field descriptions (continued)

Field	Description
TXONLY	0 Reserved 1 Aurora is configured for transmit-only simplex communication. Training method is configured to use Static Training.
18–13 Reserved	Reserved This bitfield is reserved.
12–10 TXCFG	TX Lane Configuration. Number of enabled TX lanes. These bits are read-only and are controlled external to the NAL. 000 Reserved 001 2 TX lanes 010 Reserved 011 4 TX lanes 100 Reserved 101 Reserved 110 Reserved 111 Reserved
9–1 Reserved	Reserved This bitfield is reserved.
0 AS	Aurora Status. 0 Aurora is not enabled. 1 Aurora is enabled.

8.5.2 NAL General Control Register (NAL_GCR)

The NAL_GCR configures the behavior of the APE. It can be programmed to reset the Aurora channel, or to configure simplex/duplex initialization and to enable debug features.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RST	ALCPD	0												FCM	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	PCRST	0	SLD			0	BOOE	BOOD				CRCEB	CCOEN	0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 8-4. NAL_GCR field descriptions

Field	Description
31 RST	Reset the Aurora Channel. 0 to 1 transition resets the channel and begins the training sequence. 0 normal operation 1 transition from 0 to 1 resets channel and starts training sequence
30 ALCPD	ALC/NAL Power Down. Gate off clocks to the NAL blocks (ALC and APE). 0 NAL is enabled with all clocks running provided other mechanisms of powerdown (such as alc_num_lanes) are not in effect. 1 NAL is powered down and inactive.
29–18 Reserved	Reserved This read-only bitfield is reserved and always has the value zero.
17 FCM	Flow Control Mode. 0 Completion Mode 1 Immediate Mode
16-15 Reserved	Reserved and must be written with zero.
14 PCRST	Protocol Converter Reset. Resets the ALC when asserted.
13 Reserved	Reserved This read-only bit is reserved and always has the value zero.
12–10 SLD	Symbol Lock Delay. 000 Allow 3 characters to accumulate in elastic buffer before starting to read 001 Allow 4 characters to accumulate in elastic buffer before starting to read 010 Allow 5 characters to accumulate in elastic buffer before starting to read 011 Allow 6 characters to accumulate in elastic buffer before starting to read 100 Allow 7 characters to accumulate in elastic buffer before starting to read 101 Allow 8 characters to accumulate in elastic buffer before starting to read 110 Allow 9 characters to accumulate in elastic buffer before starting to read 111 Allow 10 characters to accumulate in elastic buffer before starting to read
9 Reserved	Reserved This read-only bit is reserved and always has the value zero.
8 BOOE	Bond Offset Override Enable. 0 ALC channel bond attempts to determine channel bond offset. 1 ALC uses user override setting for channel bond offset.
7–4 BOOD	Bond offset override data. Only valid when BOOE is set. 0000/1000 use 0-cycle offset 0001 use -7 cycle offset 0010 use -6 cycle offset 0011 use -5 cycle offset

Table continues on the next page...

Table 8-4. NAL_GCR field descriptions (continued)

Field	Description
	0100 use -4 cycle offset 0101 use -3 cycle offset 0110 use -2 cycle offset 0111 use -1 cycle offset 1001 use +1 cycle offset 1010 use +2 cycle offset 1011 use +3 cycle offset 1100 use +4 cycle offset 1101 use +5 cycle offset 1110 use +6 cycle offset 1111 use +7 cycle offset
3 CRCEB	CRC Enable. 0 CRC generation and checking is disabled for TX and RX data. 1 CRC is inserted for TX frames and CRC is checked for RX paths.
2 CCOEN	Clock Compensation Override Enable. This is a debug feature which allows the duration between clock compensation sequences to be reduced to 1280 cycles. 0 Clock compensation counter times out at 7424 cycles 1 Clock compensation counter times out at 1280 cycles
1–0 Reserved	Reserved This read-only bitfield is reserved and always has the value zero.

8.5.3 NAL Training Control Register (NAL_TCR)

The NAL_TCR supports static training as described in Static training.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	STE	AHD	BHD	VHD	Reserved					ATC				Reserved					BTC				Reserved						VTC

	0111 Remain in bond for 192 cycles 1000 Remain in bond for 256 cycles 1001 Remain in bond for 384 cycles 1010 Remain in bond for 512 cycles 1011 Remain in bond for 768 cycles 1100 Remain in bond for 1024 cycles 1101 Remain in bond for 1536 cycles 1110 Remain in bond for 2048 cycles 1111 Remain in bond for 3072 cycles
9–4 Reserved	Reserved This bitfield is reserved.
3–0 VTC	Verify Timer Count 0000 Remain in verify for 16 cycles 0001 Remain in verify for 24 cycles 0010 Remain in verify for 32 cycles 0011 Remain in verify for 48 cycles 0100 Remain in verify for 64 cycles 0101 Remain in verify for 96 cycles 0110 Remain in verify for 128 cycles 0111 Remain in verify for 192 cycles 1000 Remain in verify for 256 cycles 1001 Remain in verify for 384 cycles 1010 Remain in verify for 512 cycles 1011 Remain in verify for 768 cycles 1100 Remain in verify for 1024 cycles 1101 Remain in verify for 1536 cycles 1110 Remain in verify for 2048 cycles 1111 Remain in verify for 3072 cycles

Chapter 9
Buddy Device—Nexus Aurora PHY (NAP)

9.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

The following figure shows a high level block diagram of the High Speed Nexus Interface and the NAP.

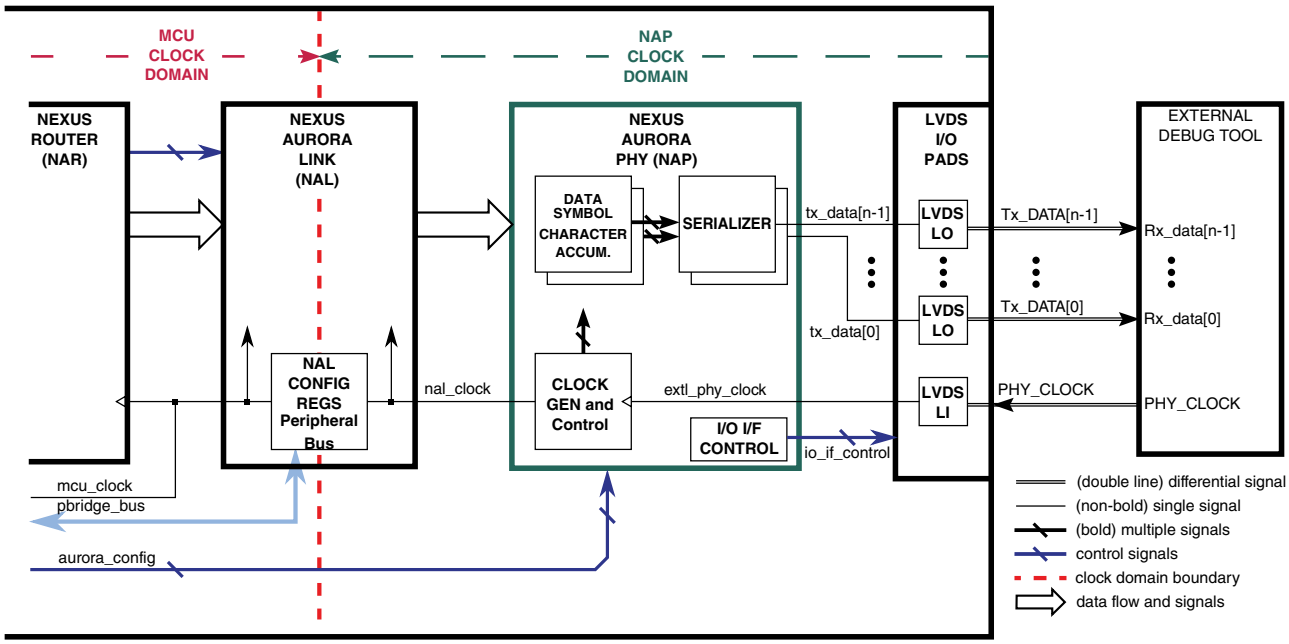

Figure 9-1. High speed Nexus interface block diagram

9.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

9.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

9.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

9.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

9.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 4 transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

9.2 External signal description

The external signals of the NAP are listed in the following table. Each of the NAP signals consists of a positive and negative differential pair.

Table 9-1. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool

Table continues on the next page...

Table 9-1. NAP signals (continued)

Signal Name	Direction	Description
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2 (TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3 (TX3P/TX3N)	Output	NAP Tx data for lane 3

9.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

9.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

9.4.1 Data symbol character accumulator

The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

9.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

The following figure shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

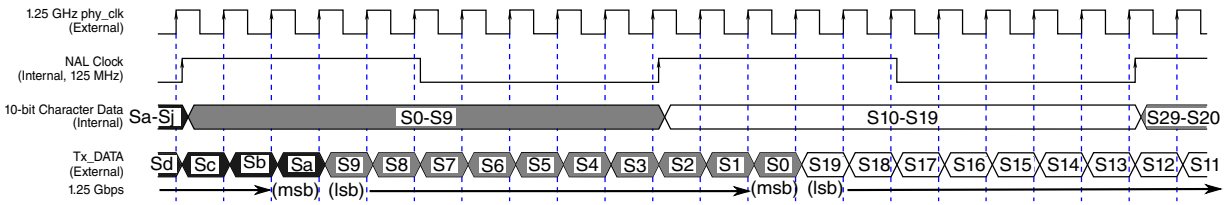

Figure 9-2. Serializer timing diagram

9.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

9.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

Chapter 10
Buddy Device—Data Write Processing Unit (DWPU)

10.1 Introduction

The Data Write Processing Unit (DWPU) supports two specific debug and calibration functions:

- Data trace filtering
- Out of range parameter identification

DWPU takes the Nexus standard messages and processes the data write trace messages to filter out messages based on the tagged addressing schema contained in the Tag RAM. DWPU also generates triggers indicating out of range data values for a set of identified addresses and data ranges.

This figure shows the block diagram of the DWPU identifying various functional block and the data flow.

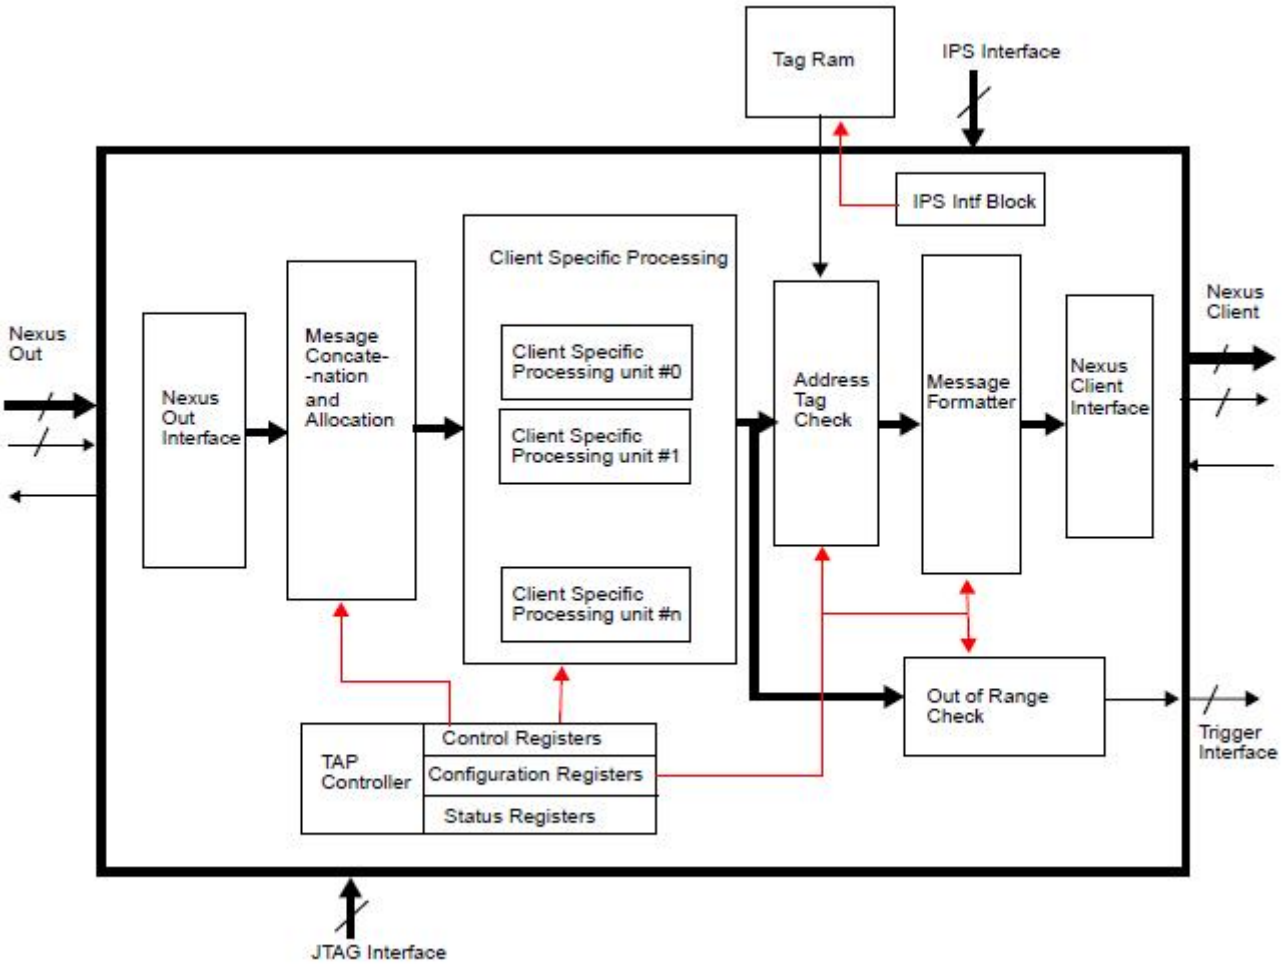

Figure 10-1. DWPU block diagram

10.2 Features

DWPU supports the following features:

- Out of range data value detection and data write trace filtering simultaneously from up to five Nexus clients
- Filtering operation that can be individually enabled or disabled for each 64-bit word in system RAM or data memory
- High bandwidth throughput
- Filtered trace stream is returned to the BD NAR to allow routing to the trace port or overlay RAM
- Detection of out of range data values writes within data write trace stream

10.3 Functional description

DWPU includes the following functional blocks:

- Nexus Out Interface (NOI)
- Message Concatenation and Allocation (MCA)
- Client Specific Processing (CSP)
- Address Tag Check (ATC)
- Out of Range Check (ORC)
- Message Formatter (MF)
- Nexus Client Interface (NCI)

10.3.1 Nexus Out Interface (NOI)

The Nexus Out Interface (NOI) enables DWPU to receive Nexus message for data write filtering from NAR. NOI maintains a minimum queue of two buffers to accommodate incoming messages. The NAR only initiates a transfer to the DWPU when it has all the beats of a messages. The incoming messages are buffered and then forwarded to the Message Concatenation and Allocation (MCA) for message concatenation and allocation. NOI ensures the temporal order of the incoming messages while forwarding to MCA. NOI also acknowledges the processing of data write messages by MCA.

The format for incoming message with NEXUS_WORD = 32 and NUM_BEAT_IN = 8 is shown below.

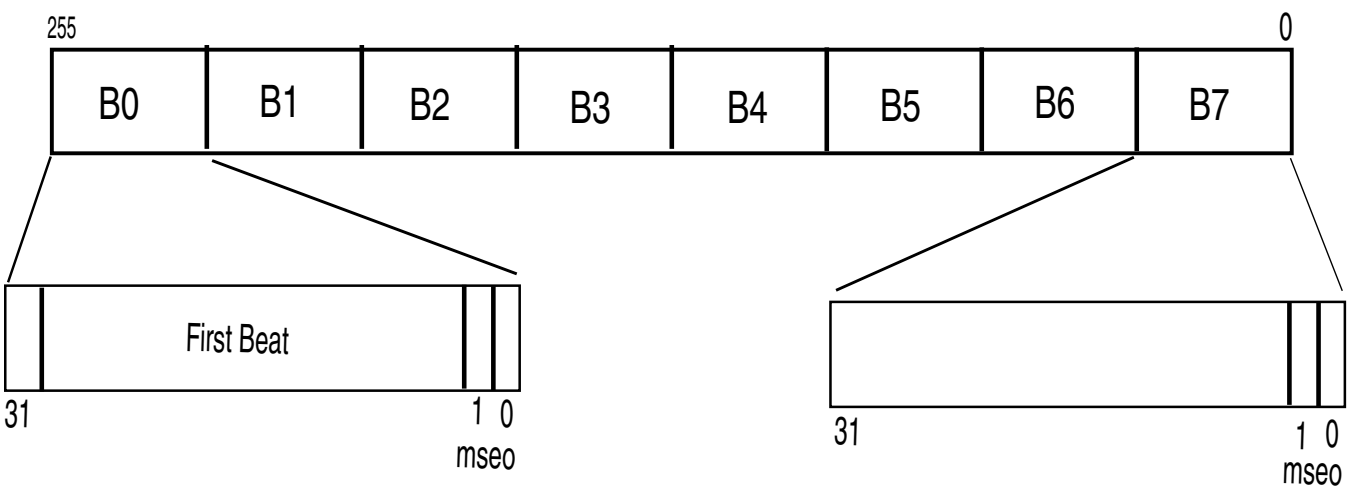

Figure 10-2. Incoming message format

10.3.2 Message Concatenation and Allocation (MCA)

Message Concatenation and Allocation (MCA) starts concatenating message beats once the NOI has a valid input messages to form a complete message. Concatenated messages with selected source IDs contained in within Nexus messages are passed over to appropriate Client Specific Processing Unit (CSPU) for further processing. The following messages are dropped by MCA:

- Messages that do not have a selected source ID
- IDLE messages
- Messages with number of beats larger than defined beats for data-write messages

MCA has the capability of providing one fully concatenated message to a CSPU each clock.

10.3.3 Client Specific Processing (CSP)

The Client Specific Processing (CSP) block receives the messages from MCA. The received message are processed after extracting all the relevant fields. Different types of message from various clients are received and processed differently based on their type by a specialized unit called the Client Specific Processing Unit (CSPU).

The CSPU receives concatenated data write messages (including synchronization messages) from MCA and provides the following for the Out of Range Check (ORC) and Address Tag Check (ATC) logic to perform filter checks:

- Reconstructed address
- Data value
- Source ID
- Master ID
- Timestamp

CSPU also confirms that each message is a data write message. All other message types are dropped.

There are two CSPU types, one associated with Core Nexus clients and another associated with NXMC clients. Each CSPU simultaneously supports data write messages with up to four different source IDs. Data write with synchronization message is always required to start an address thread for a particular source ID, then each subsequent data write message associated with that source ID contains an encoded address. This table shows the CSPU type encoding to be used while mapping the source IDs to a CSPU type using SRC_MAP_CTLR.

Table 10-1. CSPU encoding

CSTU type	Encoding
Standard	01
NXMC	10

10.3.3.1 Input message formats

DWPU supports various message formats from different source clients. These formats are further processed by the CSPU. The following message formats are supported by the CSPUs, as also described in details the sub-sections:

- Standard data write message format (SDWM)—Includes sync and non-sync type. This is used by most of the clients, i.e., e200 peripheral and e200 main cores.
- AHBMM (modified) data write message format (MDWM)—Includes both sync and non-sync type of messages. Used by NXMC clients only.

10.3.3.1.1 Standard data trace write message format

The standard data trace write messages are of two types, sync and non-sync. The non-sync type contains the data write value and the address of the write access, relative to the previous data trace message. The address and DATA field is considered variable. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

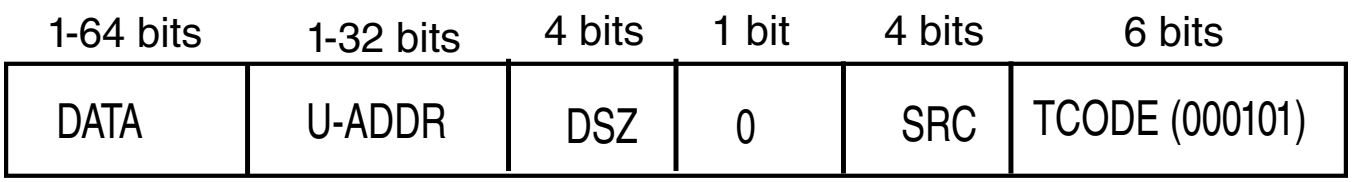

Figure 10-3. Non-sync data trace write message format

The TSTAMP field not shown is an optional variable field upto 26 bits, is inserted optionally by the core clients based on controls received from the BD NAR.

The second type is the DWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly.

Synchronization messages provide a reference address for subsequent DWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

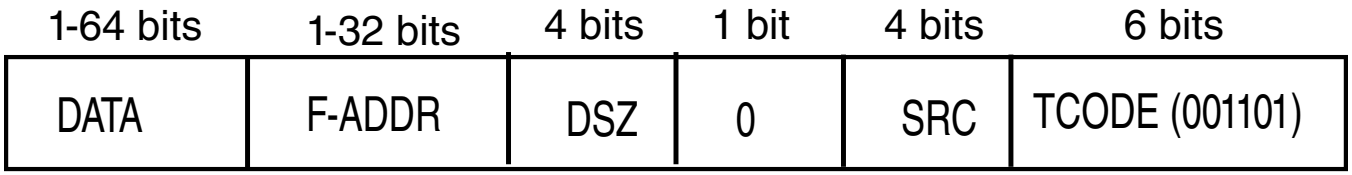

Figure 10-4. Sync data trace write message format

The table below shows the data size (DSZ) encoding for standard data trace messages.

Table 10-2. Standard DSZ encoding

DSZ	Data size
0000	0-byte
0001	1-byte
0010	2-byte
0011	3-byte
0100	4-byte
0101	5-byte
0110	6-byte
0111	7-byte
1000	8-byte
1001-1111	Reserved

10.3.3.1.2 NXMC (modified) data trace write message format

The NXMC (modified) data trace write non-sync messages contain the data write value and the address of the write access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encoding to either 8, 16, 32 or 64. The TSTAMP field is 26 bits. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

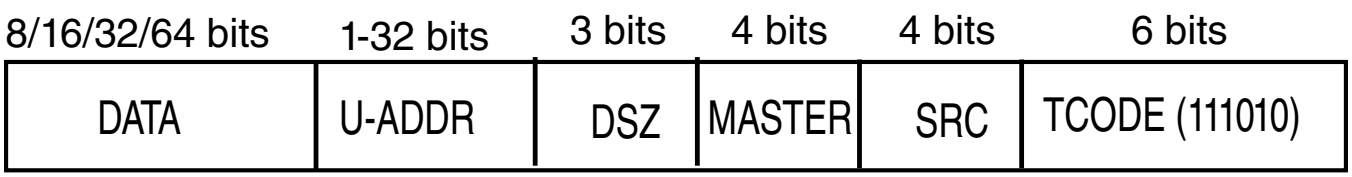

Figure 10-5. Non-sync M-Data trace write message format

The TSTAMP field not shown over here is an optional variable field upto 26 bits, is inserted optionally by the AHBMM clients based on controls received from NAR.

The second type is the MDWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent MDWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

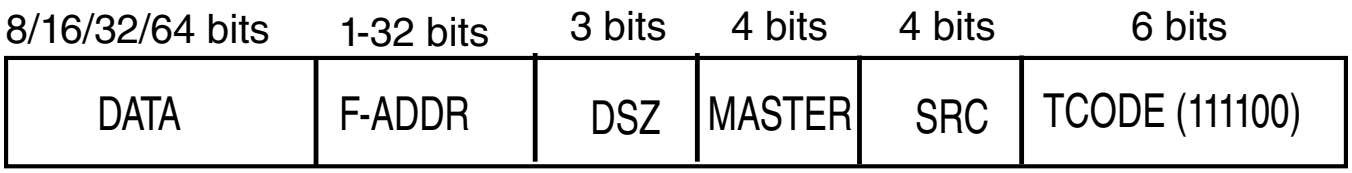

Figure 10-6. Sync M-Data trace write message foramt

The table below shows the data size (DSZ) encoding for NXMC data trace message.

Table 10-3. NXMC DSZ encoding

DSZ	Data Size
001	1-byte
010	2-byte
011	4-byte
100	8-byte
000,101-111	Reserved

10.3.4 Address Tag Check (ATC)

DWPU allows filtering operation on data writes to any address within system RAM and tightly coupled data memory. Each 64-bit word in the supported system RAM or data memory address space corresponds to a single bit in Tag RAM; therefore, the required Tag RAM size is 1/64th of the address space to be filtered. Data write messages within the supported address range are dropped by ATC if the corresponding bit in Tag RAM is not set. The data write messages with the corresponding Tag bit set are passed over to Message Formatter for further processing.

Writes to addresses outside of the supported address range can be configured to be either removed from the trace stream or retained. This option is controlled by a single user accessible control bit. Data reads and other Nexus message formats submitted in the DWPU trace stream are always dropped by DWPU.

Tag RAM is accessible through software (IPS) as well as JTAG interface via PD addressing. All the IPS access is possible in supervisor mode only. The access to Tag RAM is carried out indirectly through three registers: TRC_CTRL, TRC_ADR and TRC_DATA registers. Users should write the TRC_CTRL register followed by the TRC_ADR register before accessing the TRC_DATA register. Any write access to the TRC_ADR register results in a Tag RAM access request. Users should ensure that the Tag RAM request is completed by providing the required TRC_DATA access based on the length of the transfer. In case of block access, the TRC_DATA register is accessed subsequently and user should ensure that the block access length does not cross the region boundary. Deviation in the sequence of register access for TAG RAM access results in errornous and incomplete transfers.

In PD addressing, the configured PD address in the TRC_ADR register is translated to a TAG RAM address using mapping derived from the FAR_SA_CFGn and FAR_RS_CFGn register. The PD address configured in the FAR_SA_CFG0 register is always translated to the zeroth address of Tag RAM.

The equation to convert system/PD address to Tag RAM address where the System/PD address falls within region n is given below:

Tag RAM address = System/PD address[31:8] - Region n base address[31:8] + Total sum of previous region (n-1) size[31:8]

The Tag RAM address for System/PD address that falls on region 2 is given by:

System/PD address[31:8] - Region 2 base address[31:8] + (region 0 size[31:8] + region 1 size[31:8])

This figure shows an example of the Tag RAM organization for 8 Kbyte Tag RAM with PD base address configured.

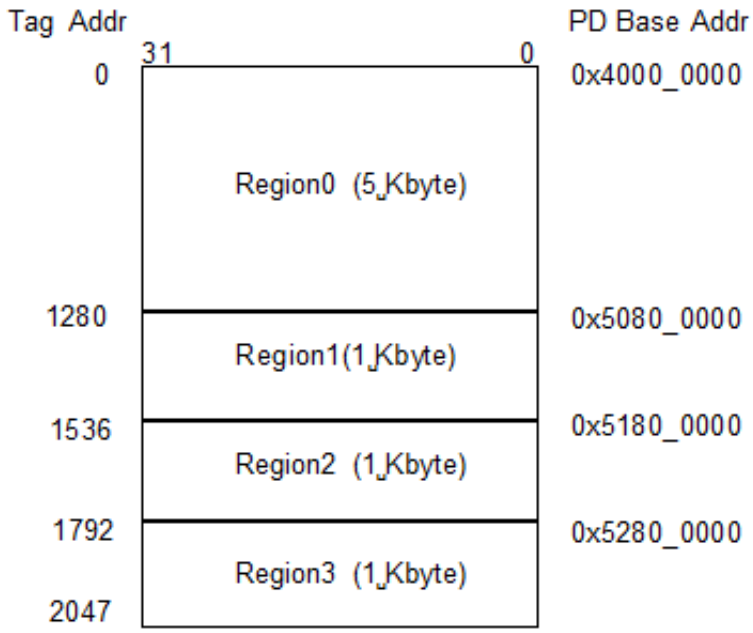

Figure 10-7. Tag RAM organization example

The table below shows an example of address translation from PD addresses to Tag RAM address.

Table 10-4. Address translation example

PD address		Tag RAM address
Start	End	
0x4000_0000	0x4000_00FF	0x0
0x4000_0100	0x4000_01FF	0x1
0x4004_FF00	0x4004_FFFF	0x4FF
0x5080_0000	0x5080_00FF	0x500
0x5180_0000	0x5180_00FF	0x600
0x5280_0000	0x5280_00FF	0x700
0x5280_FF00	0x5280_FFFF	0x7FF

During the data write filtering operation, the system RAM or data memory address is extracted from the input message. It is then compared to ascertain the address space (whether it is within system RAM space or data memory or outside the supported address range). Finally it is translated to Tag RAM address and initiate a read to Tag RAM. From the Tag RAM 32-bit read accessed, the system/PD address bit [7:3] determine the Tag bit position that is associated with the decoded absolute system/PD address. If the corresponding bit is set, then the input message is passed for message formatting else it is dropped by ATC.

This figure shows the data flow for address Tag filtering.

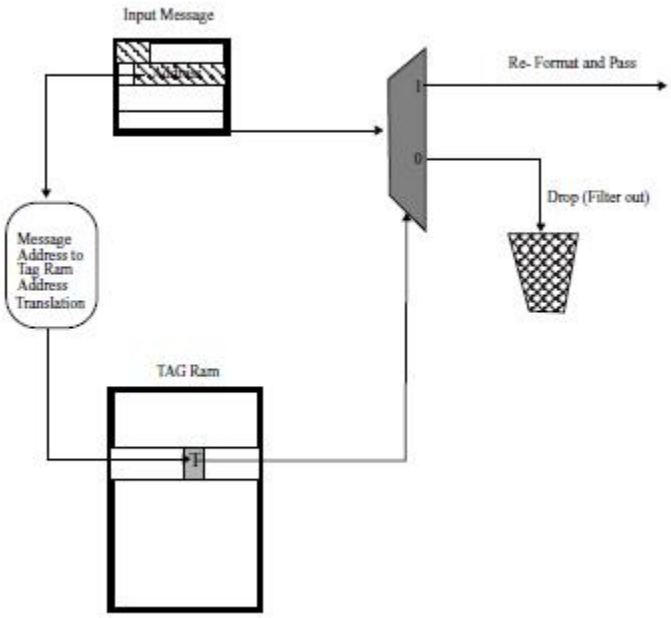

Figure 10-8. Address tag filtering

10.3.5 Out of Range Check (ORC)

In addition to the trace filtering function, the DWPU also supports detection of outside/ inside range writes to RAM locations. Both the data range values and address of RAM locations to be checked are user specified. It also has configurable support to detect target inside or outside data range values specified.

A total of four sets of address and data range comparators are supported, where each set of comparators include an address match comparator, a greater than or equal data value comparator and a less than or equal data value comparator. This figure shows the block diagram for range detect comparators.

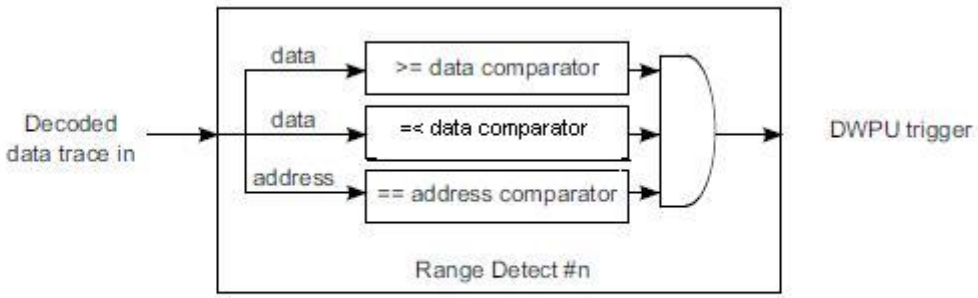

Figure 10-9. Range detect comparators

ORC supports unsigned, signed and floating point data ranges. Signed numbers are represented in 2's complement. 32-bit IEEE-754 single-precision floating-point format is used for floating point representation.

ORC has a configurable option to support for 8/16/32 bit unsigned/signed range detection and 32-bit floating point range comparison. Address comparison is carried out with full the device address. An output signal from DWPU is triggered in response to a detected out of range condition along with a status bit being set in a ORC status register indicating which range comparator has caused the trigger.

10.3.5.1 Comparator capabilities

The primary usage for out of range detect function is to detect out of range conditions on unsigned integer and pointer variables, although it also supports signed and floating point data types comparison. It also has a configurable option to support for 8/16/32 bit unsigned range detection. The unsigned data is directly compared with the stored data ranges.

To support use with signed variables, each data comparator supports 8/16/32 bit signed operation. All the signed numbers are represented in two’s complement. Data comparison happens only when the sign bit matches.

To detect range of floating point variables, each data comparator supports only 32-bit comparison mode. All the floating point numbers are represented in 32-bit IEEE-754 single precision with biased exponent. The floating point data is directly compared with the stored floating point ranges which are also represented in 32-bit IEEE-754 single precision with biased exponent.

10.3.6 Message Formatter (MF)

Message Formatter (MF) module receives message information from ATC and reformats the data write messages to comply with output Nexus message format. A user defined message format is used for sending out the filtered messages as shown below.

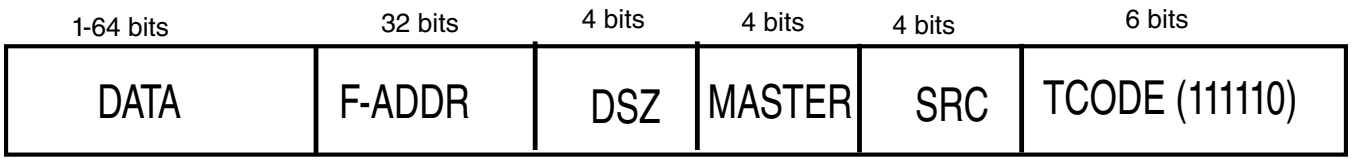

Figure 10-10. DWPU message format

Table 10-5. Message field description

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
DWPU message	6	6	TCODE	fixed	TCODE number = 62
	4	4	SRC	fixed	Source client identifier
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access. For core clients 1111 is inserted. For the NXMC clients, same value is inserted as received.
	4	4	DSZ	fixed	Data size
	32	32	F-ADDR	fixed	Full data write address
	1	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	26	26	TSTAMP	fixed	Timestamp (Optional and omitted if there is no valid timestamp)

10.3.7 Nexus Client Interface (NCI)

The Nexus Client Interface (NCI) sends out the formatted filtered data write messages to BD NAR. It also supports the buffer reallocation to increase the Q size.

10.4 Non-memory mapped registers

This section describes the DWPU Nexus register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. In addition, some register are accessible through the IPS interface which are described in the next section.

The table below shows the JTAG mapped DWPU registers.

Table 10-6. JTAG DWPU registers

Nexus register index	Register	Access	Read address	Write address	Reset value
0x02	Global Control (GLB_CTRL)	R/W	0x04	0x05	0x0000_0002

10.5 Memory mapped registers

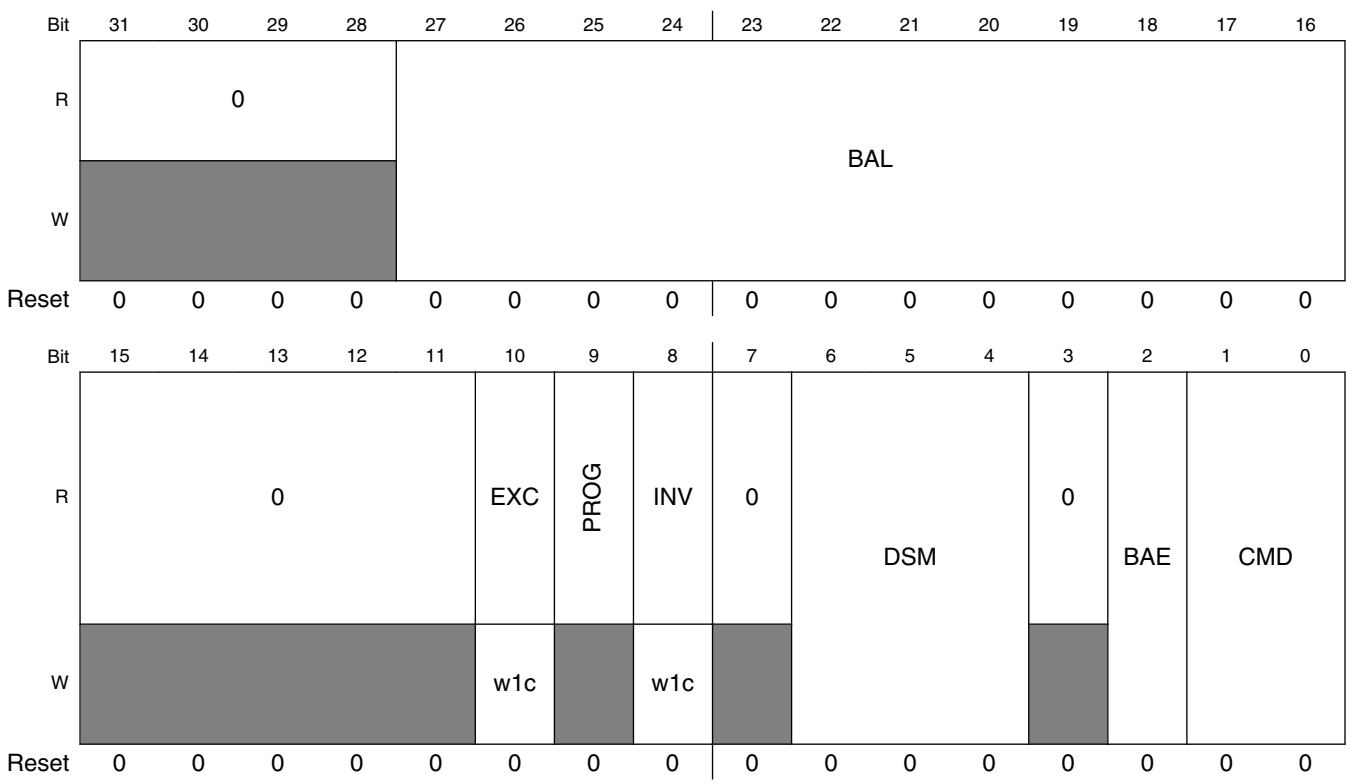
DWPU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Tag RAM Control (DWPU_TRC_CTRL)	32	R/W	0000_0000h	10.5.1/181
4	Tag RAM Configuration Address (DWPU_TRC_ADR)	32	R/W	0000_0000h	10.5.2/183
8	Tag RAM Configuration Data (DWPU_TRC_DATA)	32	R/W	0000_0000h	10.5.3/183

10.5.1 Tag RAM Control (DWPU_TRC_CTRL)

Tag RAM Control register provides the configuration for Tag RAM access. It supports byte write IPS access. It also has a status bit to indicate the status of the Tag RAM access.

Address: 0h base + 0h offset = 0h



DWPU_TRC_CTRL field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

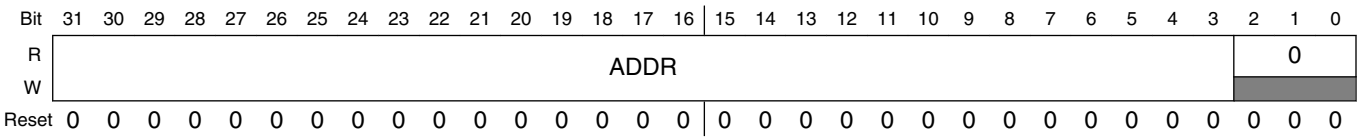
DWPU_TRC_CTRL field descriptions (continued)

Field	Description
27–16 BAL	Block Access Length. Should not cross region boundary. Valid only when BAE = 1
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 EXC	Excess Tag RAM access by IPS Generates when the IPS acsess to Tag RAM exceeds the configured length 0 No excess access to Tag RAM 1 Exceeds the configured access length
9 PROG	IPS access to Tag RAM in progress 0 No Tag RAM access by IPS 1 Tag RAM access by IPS is in progress
8 INV	Invalid IPS access Generated when the targetted PD/system address in TRC_ADR register falls outside the configured Tag RAM region 0 No error 1 Invalid address
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 DSM	Data Size Mode Valid only for writes, all reads are fixed 32 bits only. 000 Word (32 bit) access to the Tag RAM. 001 Half-Word (16 bit) access to the Tag RAM. 16 bit LSBs of the TRC_DATA is used. 010 Byte (8 bit) access to the Tag RAM. 8 bit LSBs of the TRC_DATA is used. 100 Bit access to the Tag RAM. LS bit of the TRC_DATA is used.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 BAE	Block Access Enable. Block access is carried out with 32-bit Data Size Mode only. 0 Block Access disable 1 Block Access enable
CMD	Read/Write access 00 No read or write access to Tag RAM 01 Read access to Tag RAM. Any write to TRC_ADR register results in read access to the Tag RAM. Read data is stored in the TRC_DATA register. 10 Write access to Tag RAM. Any write to TRC_ADR register results in write access request to Tag RAM and subsequent TRC_DATA register write results in actual data to be written into Tag RAM addressed by TRC_ADR register. 11 Reserved

10.5.2 Tag RAM Configuration Address (DWPU_TRC_ADR)

Tag RAM Configuration Address provides the system address for Tag RAM access. Any write to this register initiates a Tag RAM access request at the address which is being translated from system address configured. It is always accessed in 32-bit only.

Address: 0h base + 4h offset = 4h



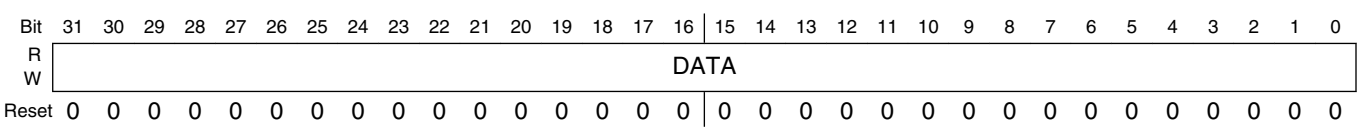
DWPU_TRC_ADR field descriptions

Field	Description
31–3 ADDR	PD Address. It should be aligned depending on Data Size mode field. DSM = 000, 256 byte aligned DSM = 001, 128 byte aligned DSM = 010, 64 byte aligned DSM = 100, 8 byte aligned (default) If the PD address is not aligned to the DSM, this results in a erroneous data read/write.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.5.3 Tag RAM Configuration Data (DWPU_TRC_DATA)

Tag RAM Configuration read/write data register. Generate ips_xfer_err on accessing this register before configuring TRC_ADDR register. Also on read access to this register while Tag RAM write is in progress and vice vera. Access is always 32-bit. During write, TRC_ADR.DSM determines which part of TRC_DATA should be written irrespective of byte enable

Address: 0h base + 8h offset = 8h



DWPU_TRC_DATA field descriptions

Field	Description
DATA	Reflets the content of Tag RAM on Tag RAM read access. Also provides data for Tag RAM write access

Chapter 11
Buddy Device—Nexus Read Write Access (RWA)

11.1 Introduction

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in Nexus register access via JTAG. The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

11.2 Register definition

This table details the register map for the RWA module.

Table 11-1. RWA register map

Register	Nexus access opcode	Read/ write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

11.2.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in this table.

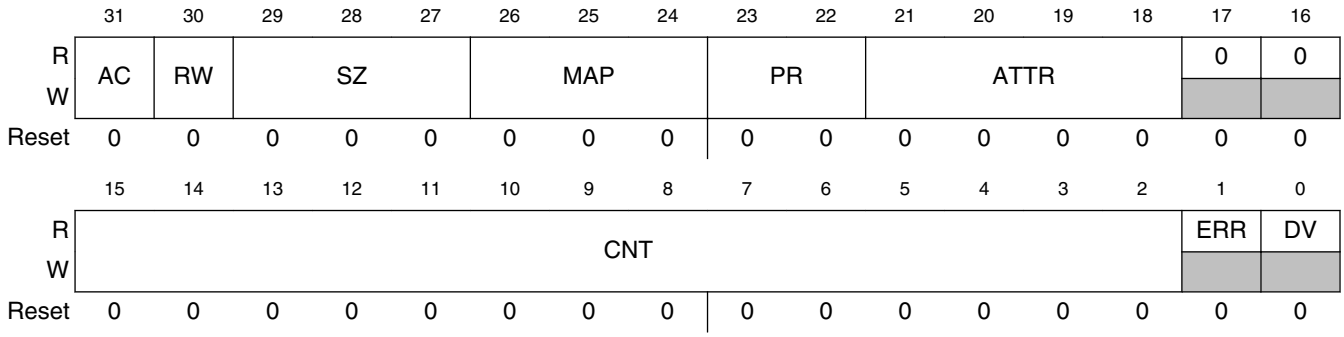


Table 11-2. RWCS fields

Field	Description	
31 AC	Access Control.	
	0	End access/ Access has completed
	1	Start access
30 RW	Read/Write Select.	
	0	Read access
	1	Write access
29:27 SZ	Word Size.	
	000	8-bit (byte)
	001	16-bit (half-word)
	010	32-bit (word)
	011	Reserved (default to word)
	100	Reserved (default to word)
	101	Reserved (default to word)
	110	Reserved (default to word)
	111	Reserved (default to word)
26:24 MAP	MAP Select.	
	000	Primary memory map
	001	Reserved
	010	Reserved
	011	Reserved
	100	Reserved
	101	Reserved
	110	Reserved
	111	Reserved

Table continues on the next page...

Table 11-2. RWCS fields (continued)

Field	Description
23:22 PR	Read/Write Access Priority. 00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority
21:18 ATTR	Access Attributes. RWA accesses are run as privileged data non-cacheable accesses by default, and drive the p_d_hprot[5:0] bus access attributes to 6'b000011 accordingly. This field is provided to allow a portion of these default values to be modified when performing read or write accesses using the RWA as shown in Table 11-4. hprot[1] must be set to one. 0xxx Reserved 1xxx Reserved x0xx p_d_hprot[4] driven to 0 for accesses x1xx p_d_hprot[4] driven to 1 for accesses xx0x p_d_hprot[3] driven to 0 for accesses xx1x p_d_hprot[3] driven to 1 for accesses xxx0 p_d_hprot[2] driven to 0 for accesses xxx1 p_d_hprot[2] driven to 1 for accesses
17:16	Reserved for future functionality.
15:2 CNT	Access Control Count. Number of accesses of word size SZ.
1 ERR	Read/Write Access Error (see Table 11-3).
0 DV	Read/Write Access Data Valid (see Table 11-3).

Table 11-3. Read/Write access status bit encoding

Read action	Write action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

Table 11-4. Protection encoding

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
0	0	0	Cache-inhibited
0	0	1	Guarded, not cache-inhibited
0	1	0	Reserved
0	1	1	Reserved

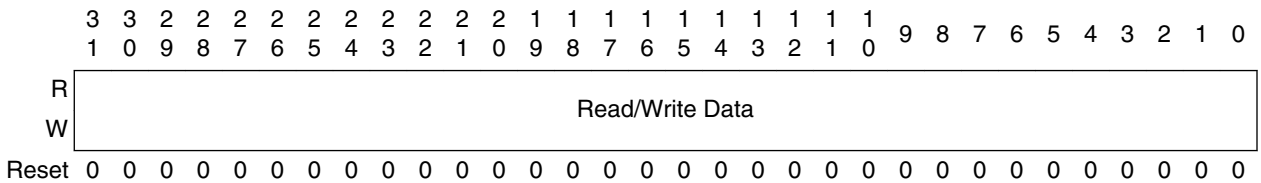
Table continues on the next page...

Table 11-4. Protection encoding (continued)

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

11.2.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.



Read/write accesses to the memory require that the debug firmware properly retrieve/ place the data in the RWD. This table shows the proper placement of data into the RWD.

Table 11-5. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD[1]			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

This table shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 11-6. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD[1]			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]

Table continues on the next page...

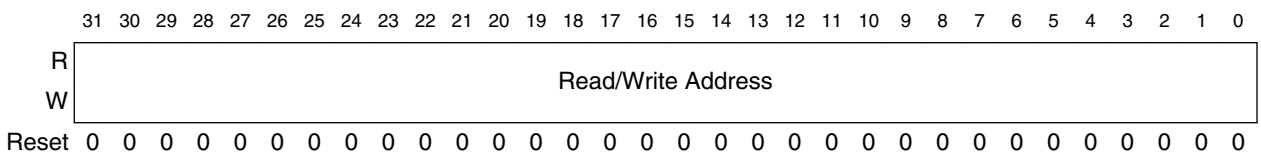
Table 11-6. RWD byte lane mapping (continued)

Transfer size and byte offset	RWA(2:0)	RWD[1]			
		31:24	23:16	15:8	7:0
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—-	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—-	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]
Word @000	0 0 0	XBAR[31:24]	XBAR[23:16]	XBAR[15:8]	XBAR[7:0]
Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

11.2.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.



11.3 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 11-1.

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in Table 11-1. This is achieved by loading an 8-bit value into the JTAG data register (DR).

This register has the following format:

(7bits)	(1 bit)
Nexus access opcode	R/W

Table 11-7. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 11-1
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

11.4 Memory access examples

The following subsections describe the steps which are required to access memory.

11.4.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
   - Write Address = 32h'xxxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   - Access Control (AC) = 1b'1 (to indicate start access)
   - Map Select (MAP) = 3b'000 (primary memory map)
   - Access Priority (PR) = 2b'00 (lowest priority)
   - Read/Write (RW) = 1b'1 (write access)

- Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
- Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
   - Write Data = 32h'xxxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1'b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

11.4.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

11.4.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
   - Read Address = 32h'xxxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   - Access Control (AC) = 1b'1 (to indicate start access)
   - Map Select (MAP) = 3b'000 (primary memory map)
   - Access Priority (PR) = 2b'00 (lowest priority)
   - Read/Write (RW) = 1b'0 (read access)
   - Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

11.4.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.

4. Repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note

The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

Chapter 12
Buddy Device – LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed debug

12.1 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode, enabling high speed debug communications through the JTAG port.

12.2 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

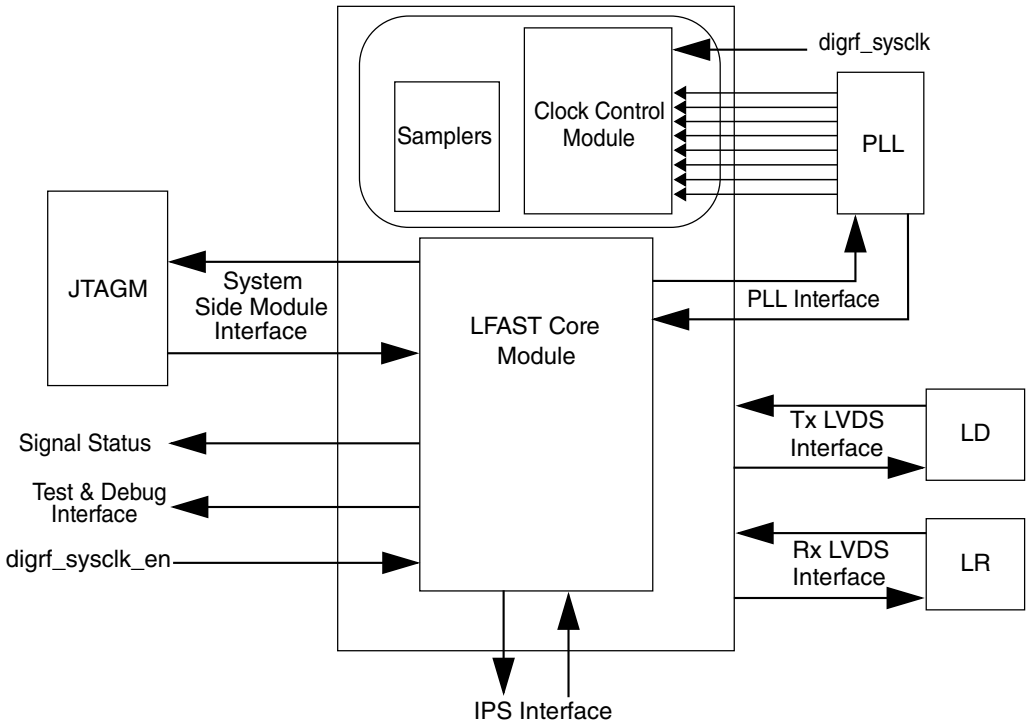


Figure 12-1. LFAST block diagram

12.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
    - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
    - Reference clock of the LFAST master and slave
- txdatap/txdatan
    - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
    - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface with maximum data rate of 320 Mbps.

12.3.1 LFAST operating data rates

Table 12-1. Operating modes for LFAST interface

Interface	Tx/Rx Data Rate
LFAST Transmit	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps
LFAST Receive	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low and data rates 312 Mbps and 320 Mbps is referred to as high data rates.

12.4 LFAST frame structure

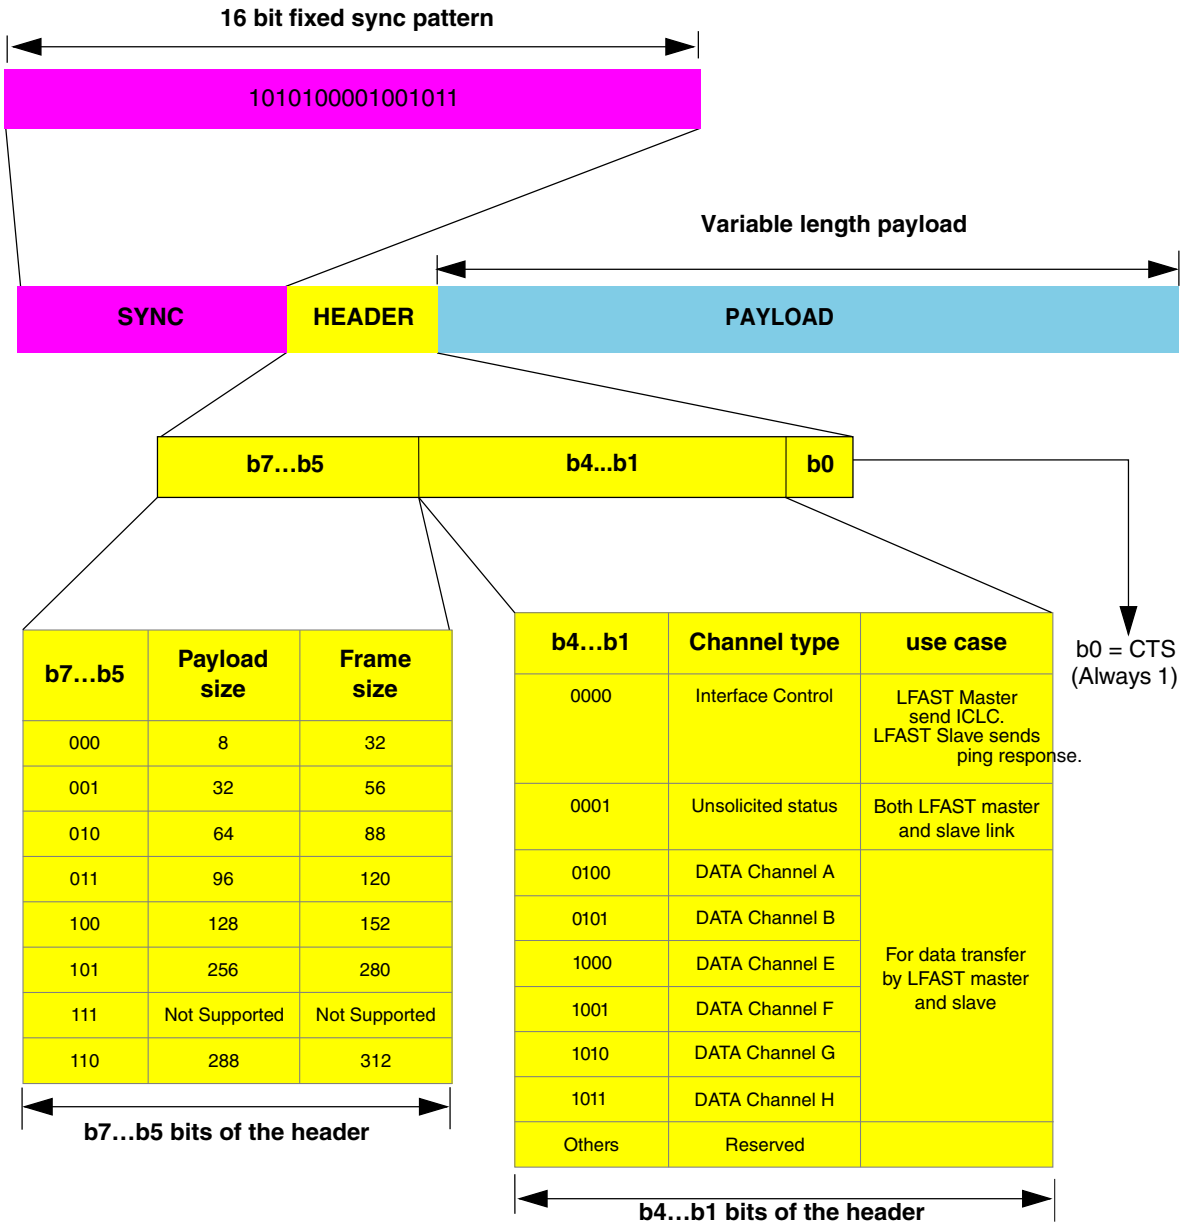
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See Figure 12-2 for details of the LFAST frame.



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported
110	288	312

b4…b1	Channel type	use case
0000	Interface Control	LFAST Master send ICLC. LFAST Slave sends ping response.
0001	Unsolicited status	Both LFAST master and slave link
0100	DATA Channel A	For data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 12-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

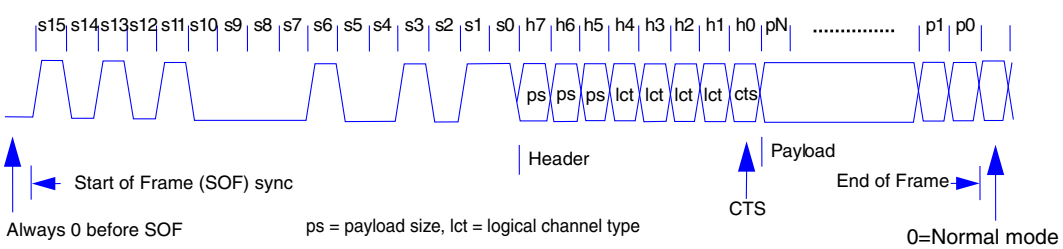


Figure 12-3. Serial frame structure

The frame structure is shown in Figure 12-3 and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in Table 12-2 :

Table 12-2. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

12.5 Features

- Supports slave only mode.
- Supports asynchronous data transfer at data rates up to a maximum of 320 Mbps.

- Transmits and receives data, ICLC and unsolicited frames.
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation .
- Supports for detection of unsupported channel number and unsupported payload size.

12.6 Memory map and register definition

All registers are 32 bits wide.

LFAST memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1	LFAST Mode Configuration Register (LFAST_MCR)	32	R/W	See section	12.6.1/203

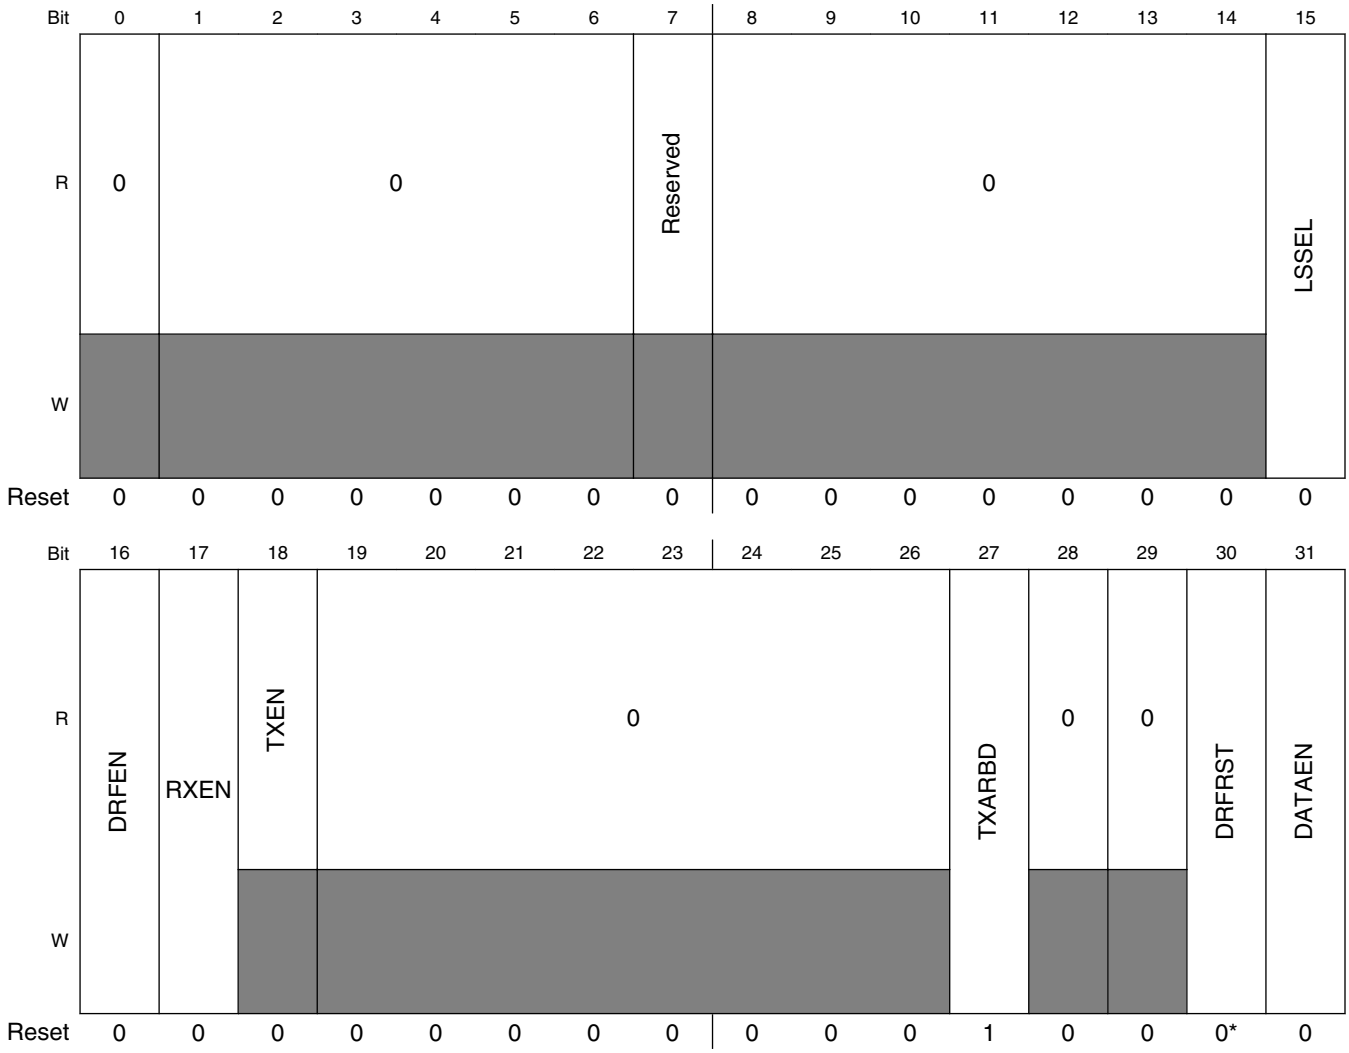
12.6.1 LFAST Mode Configuration Register (LFAST_MCR)

Address: 1h base + 0h offset = 1h



* Notes:
- DRFRST field: Set by user software and then cleared by system hardware.

LFAST_MCR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved.

Table continues on the next page...

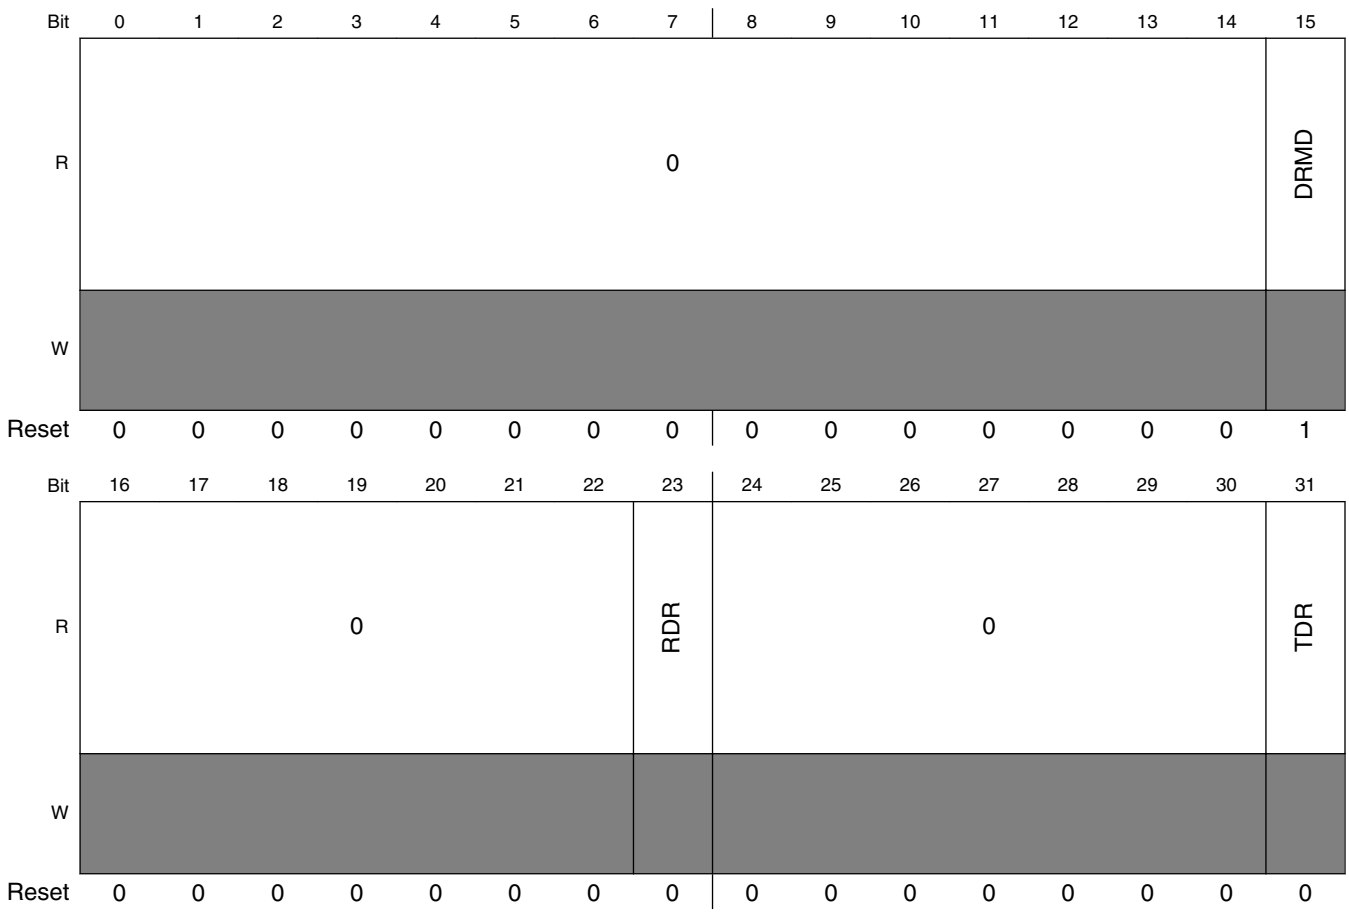
LFAST_MCR field descriptions (continued)

Field	Description
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit shows the whether the transmitter is enabled or disabled. This field is read only in slave only mode (LFAST_GSR[DUALMD] = 0) and must not be written. 0 LFAST transmitter Interface is disabled. 1 LFAST transmitter Interface is enabled.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset.. 0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

12.6.2 LFAST Speed Control Register (LFAST_SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 1h base + 4h offset = 5h



LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. This bit shouldn't be modified by S/W and left as SCR[DRMD] =1.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit shows the data rate of the receiver. This bit should not be modified by S/W in slave only mode (LFAST_GSR[DUALMD] = 0). 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is 312/320 Mbps.

Table continues on the next page...

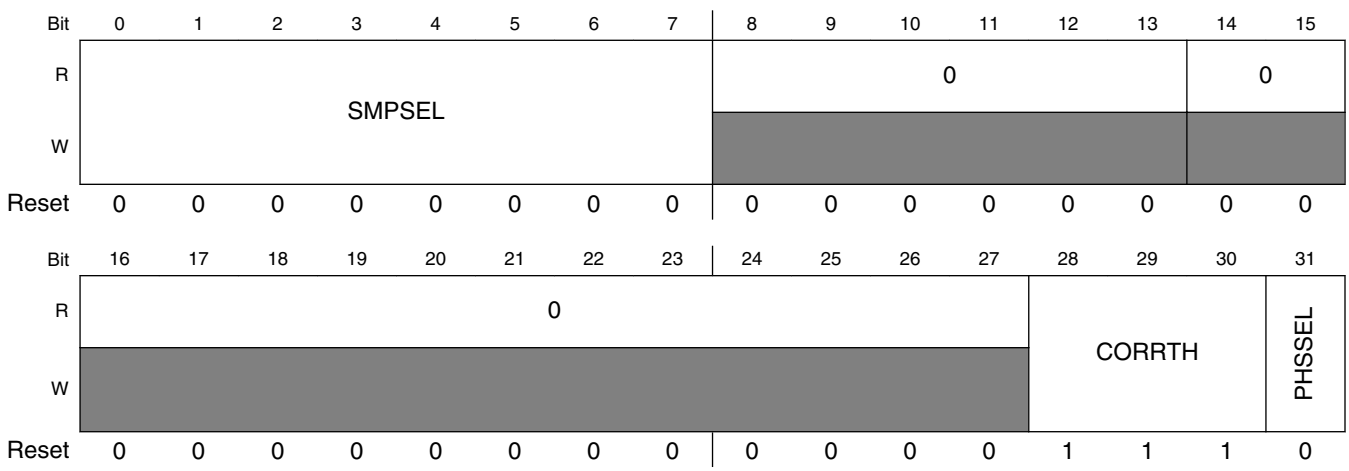
LFAST_SCR field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit shows the data rate of the transmitter. This bit should not be modified by S/W in slave only mode (LFAST_GSR[DUALMD] = 0). 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is 312 /320 Mbps.

12.6.3 LFAST Correlator Control Register (LFAST_COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 1h base + 8h offset = 9h



LFAST_COCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0. 00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected

Table continues on the next page...

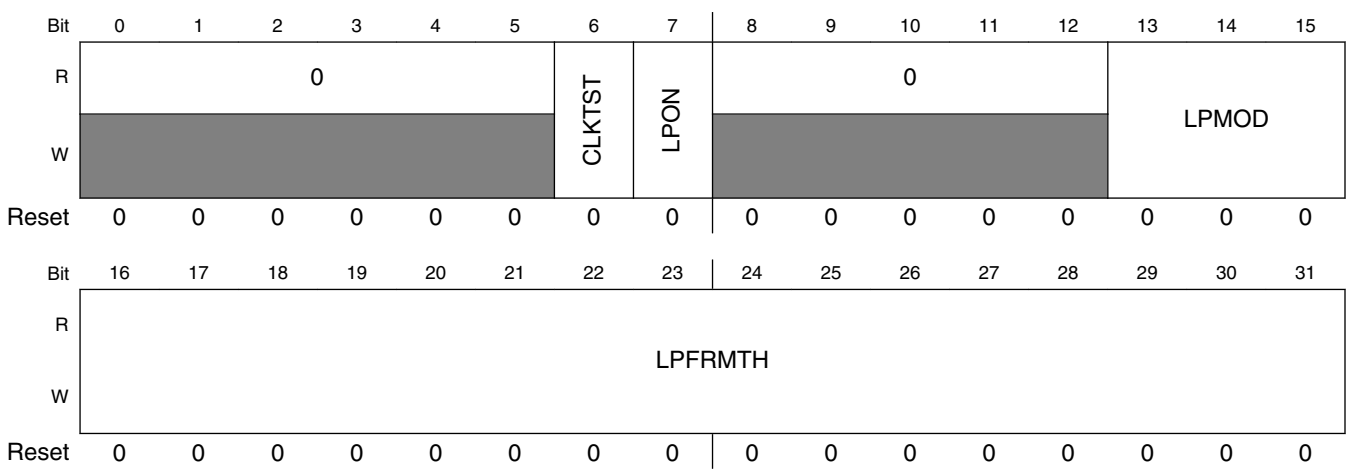
LFAST_COCR field descriptions (continued)

Field	Description
	40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

12.6.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 1h base + Ch offset = Dh

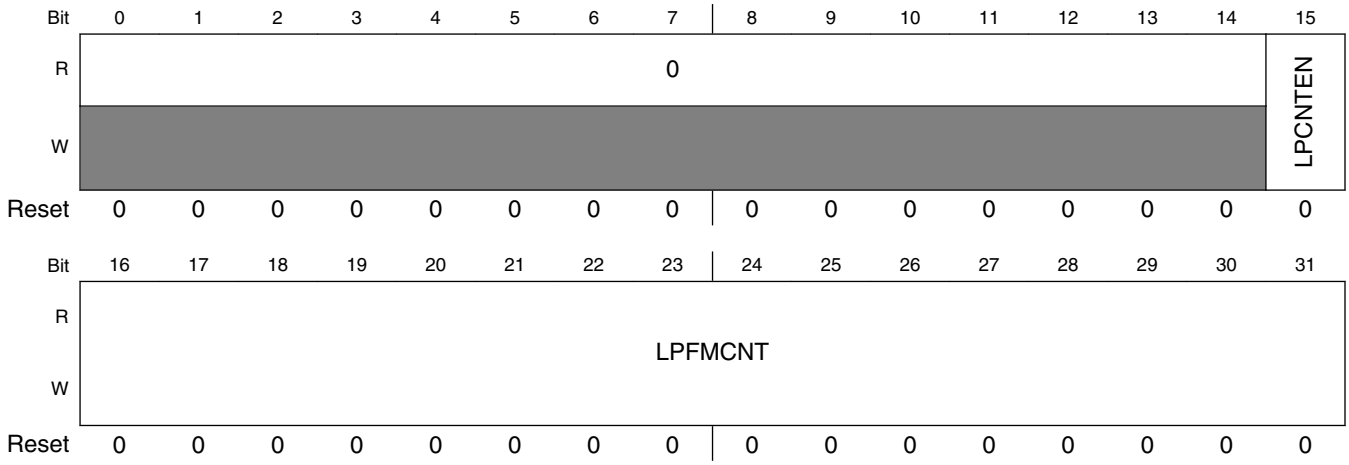


LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by H/W on reception of an ICLC command. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved 110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

12.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 1h base + 10h offset = 11h

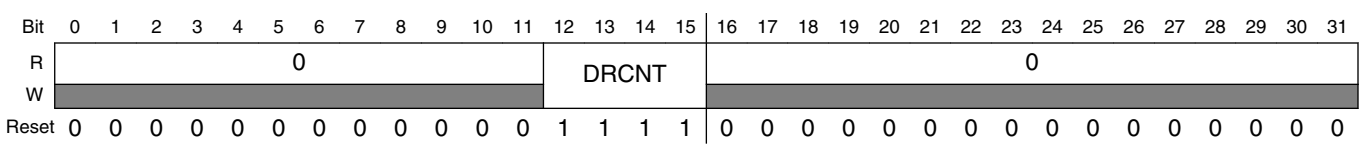


LFAST_ALCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LPCNTEN	Auto Loopback Frame Transmission Count Enable. Enables fixed number of auto pre-defined loopback frame transmission. This field can only be written when TMCR[LPON] = 0. 0 Infinite pre-defined loopback frame transmission enabled 1 Fixed count of pre-defined loopback frame transmission enabled
16–31 LPFMCNT	Auto Loopback Frame Transmission Count. Defines the number of pre-defined auto loopback frames to be sent. The pre-defined loopback frame has payload CBh, header 13h and valid sync. This mode is valid if TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Send 1 frame with correct sync, header and payload ... FFFEh Send 65534 frames with correct sync, header and payload FFFFh Send 65535 frames with correct sync, header and payload

12.6.6 LFAST Rate Change Delay Control Register (LFAST_RCDCR)

Address: 1h base + 14h offset = 15h



LFAST_RCDCR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 DRCNT	Data Rate Controller Counter Value. Defines the number of cycles of Phase 0 clock needed by the Tx interface Data rate change controller to switch from one speed mode to another. The arbitrator ignores all requests during this period. This field can only be written when MCR[DRFEN] = 1. Number of cycles = DRCNT value.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

12.6.7 LFAST Wakeup Delay Control Register (LFAST_SLCR)

Address: 1h base + 18h offset = 19h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ... 12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles

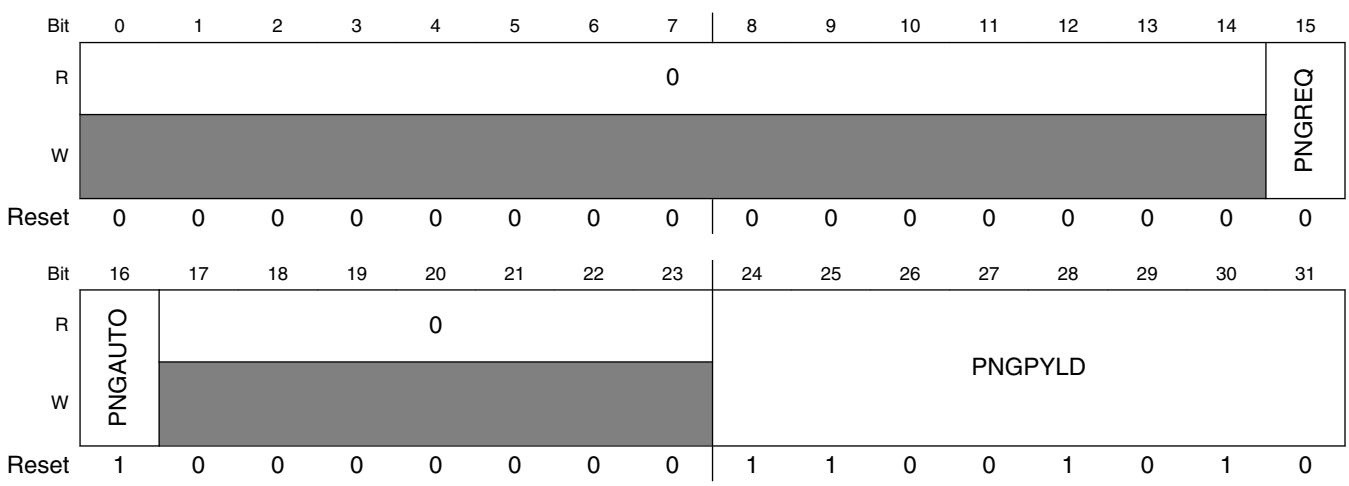
Table continues on the next page...

LFAST_SLCR field descriptions (continued)

Field	Description
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 µs) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 µs) ... Eh 14 cycles Fh 15 cycles

12.6.8 LFAST Ping Control Register (LFAST_PICR)

Address: 1h base + 20h offset = 21h



LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

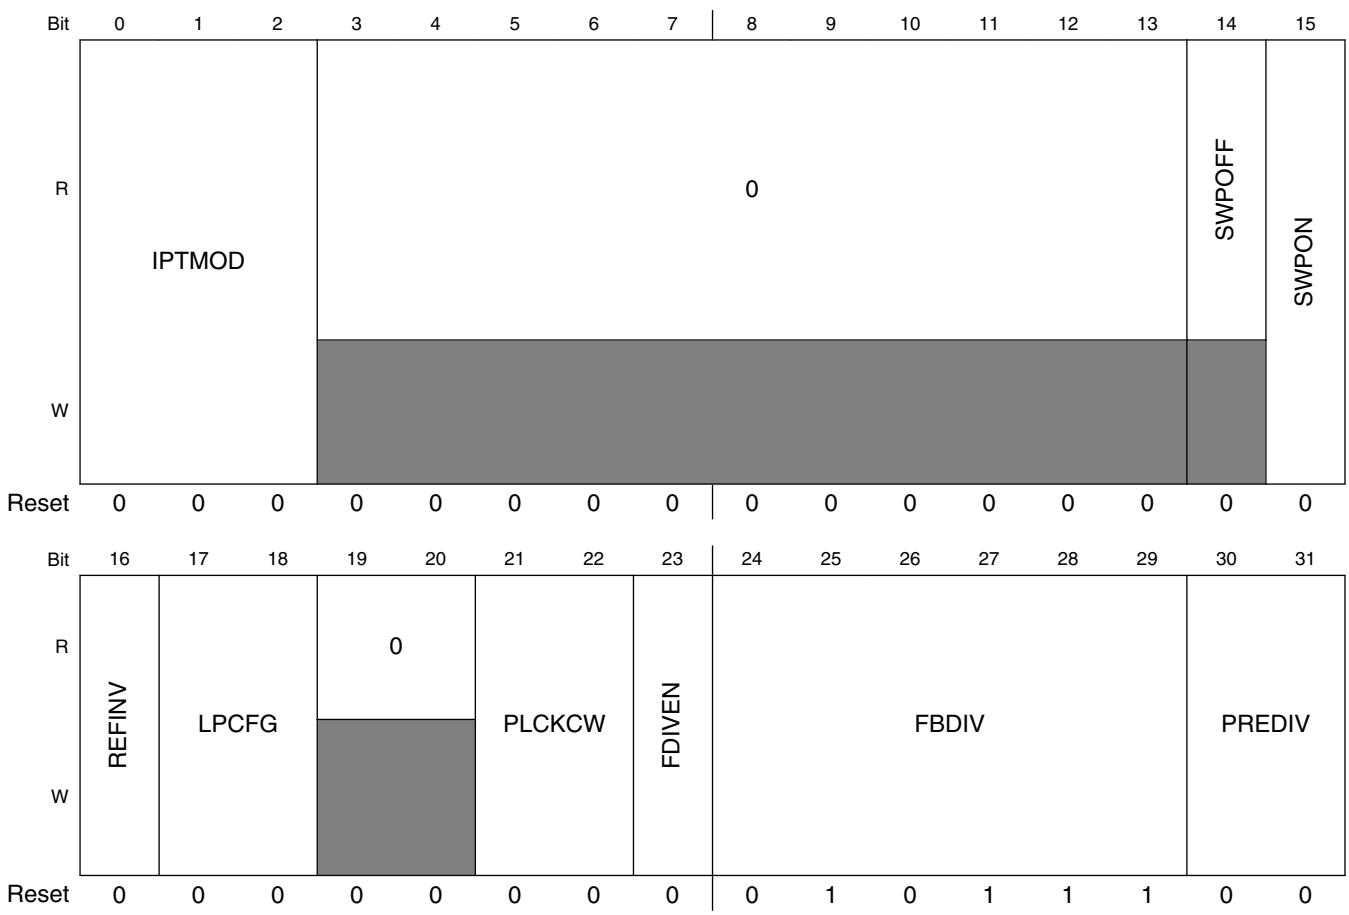
Table continues on the next page...

LFAST_PICR field descriptions (continued)

Field	Description
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. This bit should not be modified by S/W.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0.

12.6.9 LFAST PLL Control Register (LFAST_PLLCR)

Address: 1h base + 3Ch offset = 3Dh



LFAST_PLLCR field descriptions

Field	Description
0–2 IPTMOD	Test mode programmability 000 Functional mode 001 Closed Loop 1 010 Force Vctrl 011 Charge Pump Up 100 Charge Pump Up Internal Test 101 Charge Pump Idle 110 Charge Pump Down 111 Closed Loop 2
3–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SWPOFF	This bit shouldn't be modified by S/W.
15 SWPON	This bit shouldn't be modified by S/W.
16 REFINV	Inverts reference clock edge to PFD. If System PLL PFD using same reference clock, enabling this feature will minimize noise injection crosstalk via the substrate. 0 Do not inverted 1 Invert
17–18 LPCFG	PLL Loop Optimization for sysclk frequency 00 1 × IBASE current 01 0.5 × IBASE current 10 1.5 × IBASE current 11 2 × IBASE current
19–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 PLCKCW	PLL Lock Ready Count Width. Defines the number of cycles PLL waits for before asserting lock_ready flag High 00 1040 cycles 01 520 cycles 10 320 cycles 11 200 cycles
23 FDIVEN	Enable fraction division mode in feedback divider. Enables the division of vco clock output by a factor of (FBDIV + 0.5). 0 Fraction division mode not enabled 1 Fraction division mode enabled
24–29 FBDIV	Feedback Division factor for VCO output clock. This field can only be written when LFAST_MCR[DRFEN] = 0. 00h No clock output 01h – 0Ah Reserved

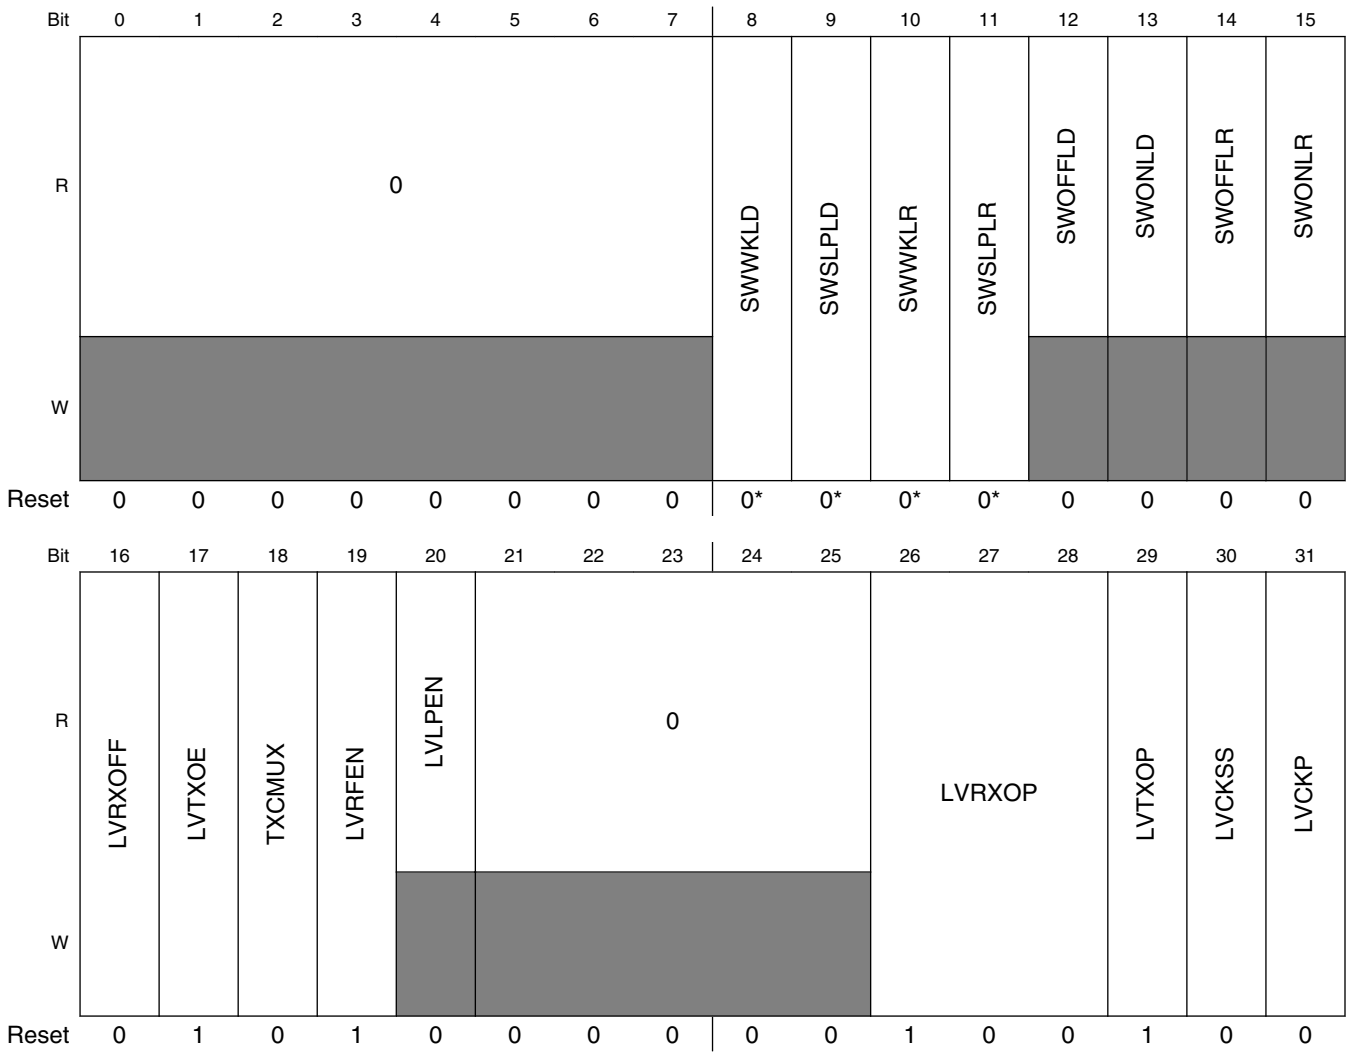
Table continues on the next page...

LFAST_PLLCR field descriptions (continued)

Field	Description
	0Bh Divide by 12 (11.5, if FDIVEN = 1) ... ... 1Fh Divide by 32 (31.5, if FDIVEN = 1) 20h – 3Fh Reserved
30–31 PREDIV	Division factor for PLL Reference Clock input. This field can only be written when LFAST_MCR[DRFEN] = 0. 00 Direct clock passed 01 Divide by 2 10 Divide by 3 11 Divide by 4

12.6.10 LFAST LVDS Control Register (LFAST_LCR)

Address: 1h base + 40h offset = 41h



* Notes:
- SWSLPLR field: Set by user software and cleared by system hardware.
- SWWKLR field: Set by user software and cleared by system hardware.
- SWSLPLD field: Set by user software and cleared by system hardware.
- SWWKLD field: Set by user software and cleared by system hardware.

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
13 SWONLD	SW signal to turn ON the LVDS LD. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
15 SWONLR	SW signal to turn ON the LVDS LR. This bit can be changed only when DRFEN is high. This bit shouldn't be modified by S/W.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled

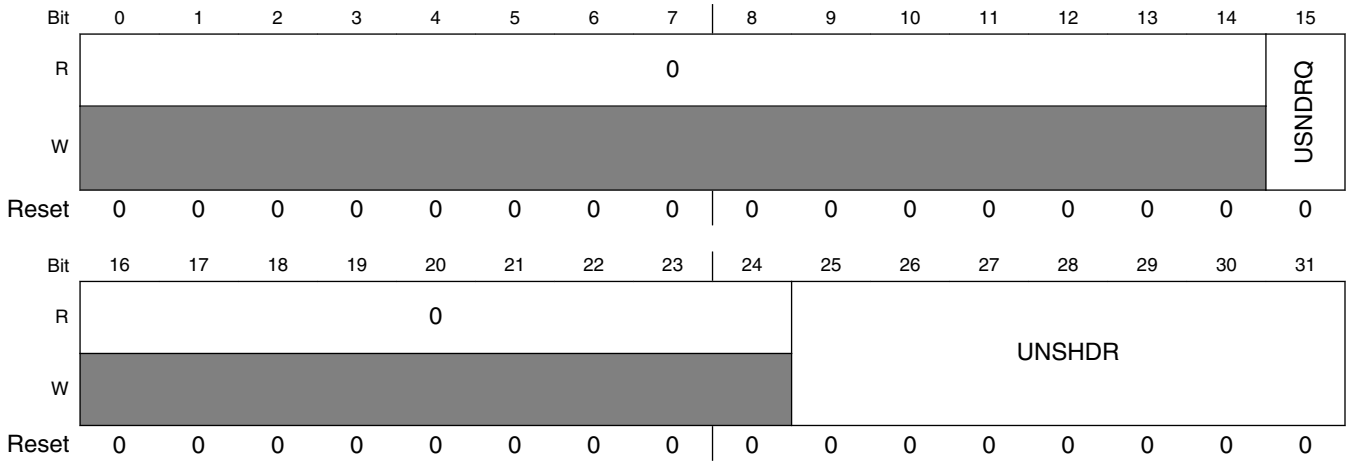
Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
	1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable The bit is reflected by output signal ipp_digrf_lvds_lpbk_en.The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–28 LVRXOP	LVRXOP[2] – Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 0 Disable on-chip LFAST receiver termination 1 Enable on-chip LFAST receiver termination LVRXOP[1] – Reserved LVRXOP[0] – Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than 320Mbps. 1 Required for LFAST receiver maximum baud rate (320Mbps).
29 LVTXOP	Control signal for LFASTand Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Data select. This bit is used for selecting use of clock sampled data or normal data in LVDS. 0 normal data to be used inside the LVDS 1 synchronized data to be used inside the LVDS
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

12.6.11 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 1h base + 44h offset = 45h

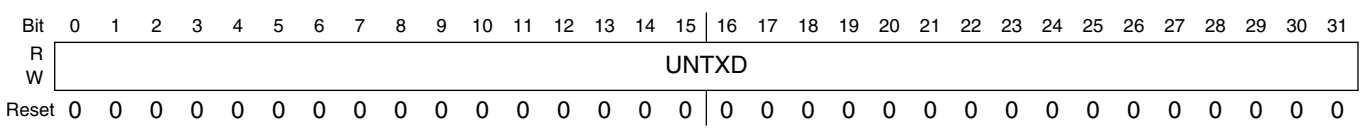


LFAST_UNSTCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 USNDRQ	Tx Unsolicited send request. Set by user software and cleared by system hardware. 0 No valid Unsolicited frame exists 1 Valid Unsolicited frame exists for transmission
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 UNSHDR	Tx Unsolicited message header. This field can only be written when LFAST_UNSTCR[USNDRQ] = 0

12.6.12 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)

Address: 1h base + 48h offset + (4d × i), where i=0d to 8d

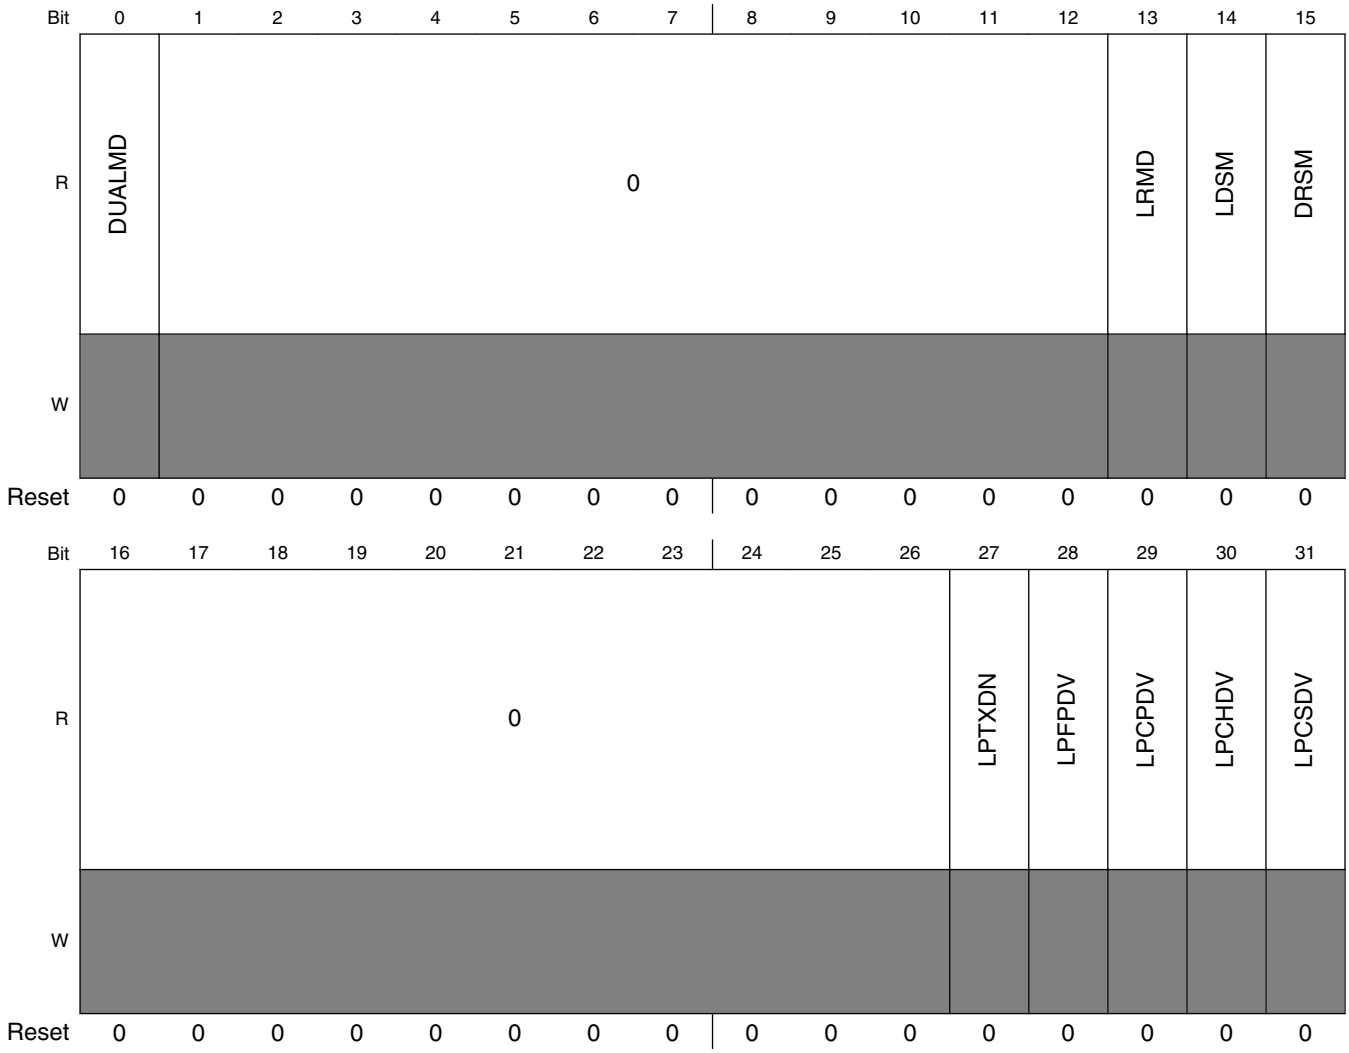


LFAST_UNSTDR*n* field descriptions

Field	Description
0–31 UNTXD	Unsolicited Transmit Data 8-0. This represents 9 registers for Unsolicited transmit data. The first bit to transmitted as part of the payload will be from UNTXD8[31], second bit from UNTXD8[30], and so on. So the last bit transmitted will be from UNTXD0[0] in case of 288 bit payload.

12.6.13 LFAST Global Status Register (LFAST_GSR)

Address: 1h base + 80h offset = 81h



LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode 0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active.

Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

12.6.14 LFAST Data Frame Status Register (LFAST_DFSR)

Address: 1h base + 94h offset = 95h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

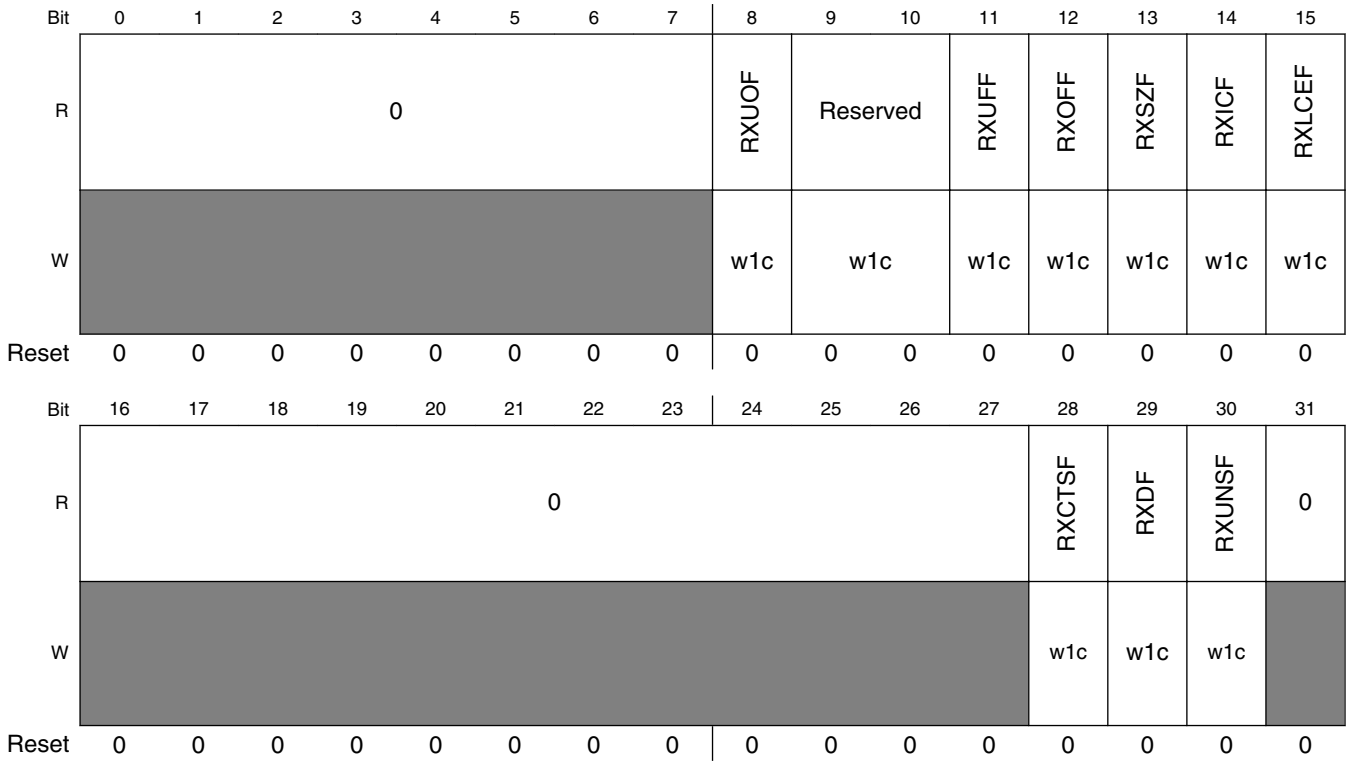
LFAST_TISR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIEF	TxData Interface not enabled. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 TXOVF	Transmit Data FIFO Overflow Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGF	Ping response frame transmitted interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TXUNSF	Unsolicited Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 TXICLCF	ICLC Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 TXDTF	Data Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred

12.6.16 LFAST Rx Interrupt Status Register (LFAST_RISR)

Address: 1h base + 9Ch offset = 9Dh



LFAST_RISR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RXUOF	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt event has not occurred 1 Interrupt event has occurred
9–10 Reserved	Reserved. The User should ignore the bit in this mode. This field is reserved.
11 RXUFF	Rx Data FIFO Underflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
12 RXOFF	Rx Data FIFO Overflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
13 RXSZF	Frame with unsupported frame size received. See "Frames Supported by LFAST interfaces" table for details. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame with payload size for a frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
14 RXICF	Invalid ICLC code Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 RXLCEF	Invalid Logical Channel Type. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSF	Frame with CTS bit Low Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 RXDF	Data frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 RXUNSF	Unsolicited Frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

12.6.17 LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)

Address: 1h base + A0h offset = A1h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_RIISR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ICPFF	Ping Frame Response failed 0 Interrupt event has not occurred 1 Interrupt event has occurred
19 ICPSF	Ping Frame Response successful 0 Interrupt event has not occurred 1 Interrupt event has occurred
20 ICPRF	ICLC Ping Frame Request received 0 Interrupt event has not occurred 1 Interrupt event has occurred
21 ICTOF	ICLC frame for Test mode off received 0 Interrupt event has not occurred 1 Interrupt event has occurred
22 ICLPF	ICLC frame for Loopback On received 0 Interrupt event has not occurred 1 Interrupt event has occurred
23 ICCTF	ICLC frame for Clk Test mode received 0 Interrupt event has not occurred 1 Interrupt event has occurred
24 ICTDF	ICLC frame for LFAST Slaves Tx Interface Disable received

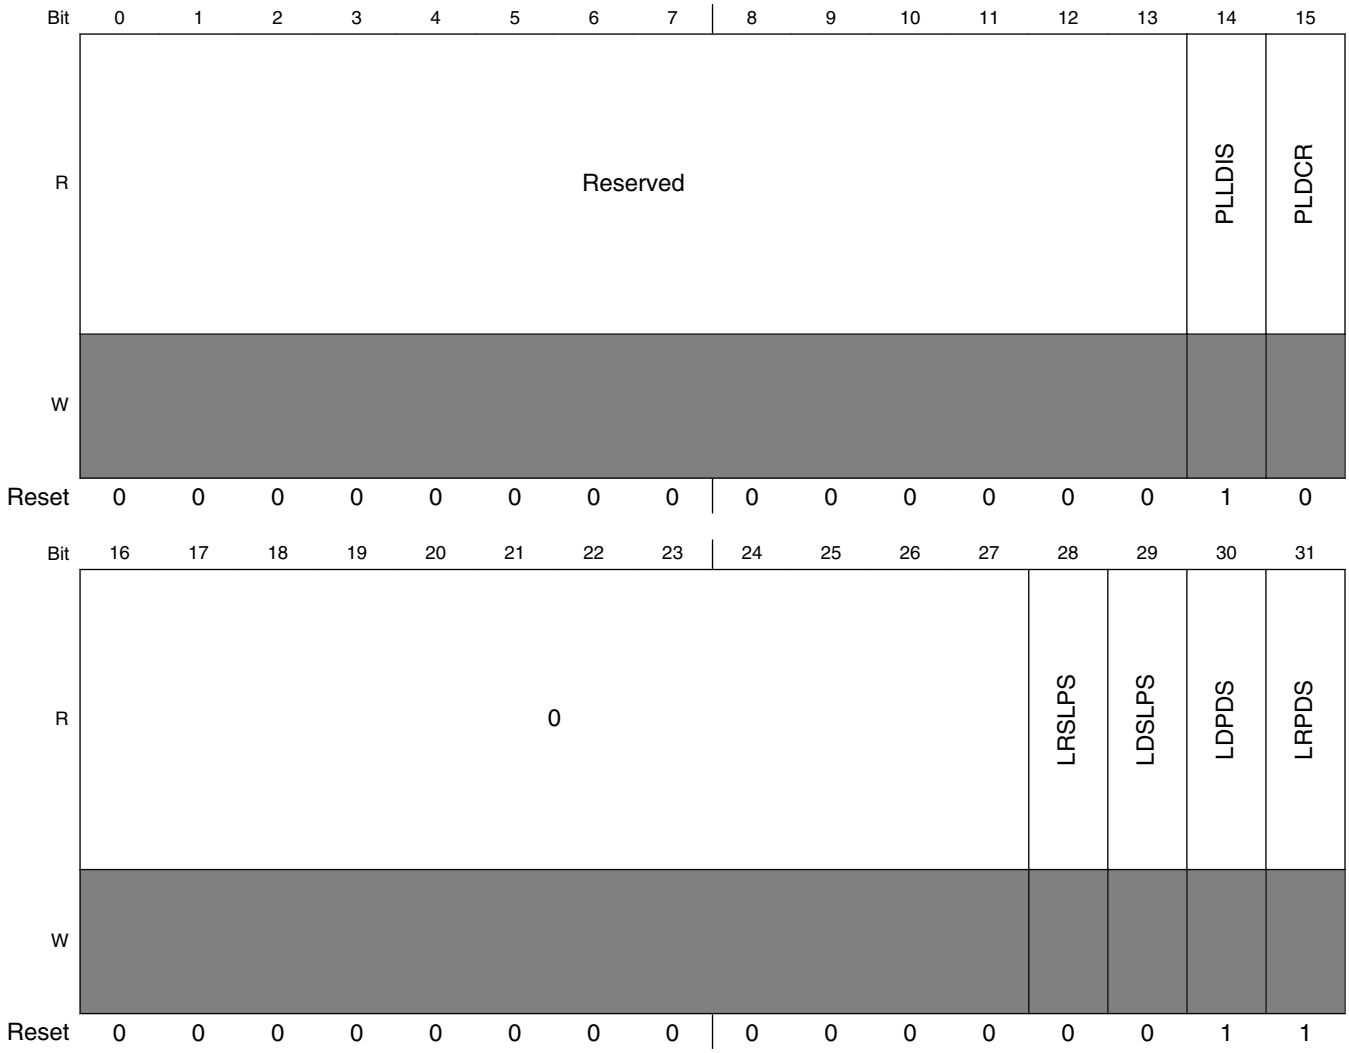
Table continues on the next page...

LFAST_RIISR field descriptions (continued)

Field	Description
	0 Interrupt event has not occurred 1 Interrupt event has occurred
25 ICTEF	ICLC frame for LFAST Slaves Tx Interface Enable received 0 Interrupt event has not occurred 1 Interrupt event has occurred
26 ICRFF	ICLC frame for LFAST Slaves Rx Interface fast mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
27 ICRSF	ICLC frame for LFAST Slaves Rx Interface slow mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 ICTFF	ICLC frame for LFAST Slaves Tx Interface fast mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 ICTSF	ICLC frame for LFAST Slaves Tx Interface slow mode switch received 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 ICPOFF	ICLC frame for PLL OFF received 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 ICPONF	ICLC frame for PLL ON received 0 Interrupt event has not occurred 1 Interrupt event has occurred

12.6.18 LFAST PLL and LVDS Status Register (LFAST_PLLLSR)

Address: 1h base + A4h offset = A5h



LFAST_PLLLSR field descriptions

Field	Description
0–13 Reserved	This field is reserved.
14 PLLDIS	PLL disable Status. When asserted, PLL is put in the power down state. 0 PLL disable signal is negated. 1 PLL disable signal is asserted.
15 PLDCR	PLL Lock Delay Counter Ready. When asserted this bit indicates that the PLL is locked after N number of reference/PLLCR[PREDIV] cycles 0 PLL Lock delay counter is not decremented to 0 1 PLL Lock delay counter is decremented to 0

Table continues on the next page...

LFAST_PLLLSR field descriptions (continued)

Field	Description
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 LRSLPS	This bit indicates the real time status of LR sleep signal 0 LR power sleep signal is negated. 1 LR power sleep signal is asserted.
29 LDSLPS	This bit indicates the real time status of LD sleep signal 0 LD sleep signal is negated. 1 LD sleep signal is asserted.
30 LDPDS	This bit indicates the real time status of LD power down signal When asserted, LD is put in the power down state. 0 LD power down signal is negated. 1 LD power down signal is asserted.
31 LRPDS	This bit indicates the real time status of LR power down signal When asserted, LR is put in the power down state. 0 LR power down signal is negated. 1 LR power down signal is asserted.

12.6.19 LFAST Unsolicited Rx Status Register (LFAST_UNSRSR)

Address: 1h base + A8h offset = A9h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_UNSRSR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 URXDV	Unsolicited data valid. Indicates a valid frame exists in the Unsolicited Data registers.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 URPCNT	Rx Unsolicited payload. Indicates the number of bytes of valid Rx unsolicited Data payload present in the LFAST_UNSRDR[8:0].

12.6.20 LFAST Unsolicited Rx Data Register (LFAST_UNSRDR*n*)

Address: 1h base + ACh offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	UNRXD																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_UNSRDR*n* field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

12.7 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements[6]. All registers of the LFAST module are classified as non-safety relevant.

12.8 Functional description

6. See the “Functional Safety” chapter for register classification details.

12.8.1 LFAST Interface enable signal (lfast_sysclk_en)

The LFAST interface enable signal (lfast_sysclk_en) signal is present only in the case LFAST Slave . It also functions as the LFAST Interface control Signal. The interface control functions are:

LFAST interface enable (lfast_sysclk_en) negation:

1. If LCR[SWONLD] = 0, the LD LVDS pad is shut down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is shut down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then S/W writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

1. The LD LVDS pad is power up, if all conditions are met:
   - LCR[SWOFFLD] = 0.
   - LCR[SWONLD] = 1.
   - MCR[TXEN] = 1.
   - When frame ICR[ICLCPLD] = 31h is received.
2. LR LVDS pad is powered up if all conditions are met:
   - LCR[SWOFFLR] = 0.
   - LCR[SWONLR] = 1.
   - MCR[RXEN] = 1.

12.8.2 Line Receiver

This section describes the Line Receiver.

12.8.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 12-4 shows the block diagram of Uplink Controller.

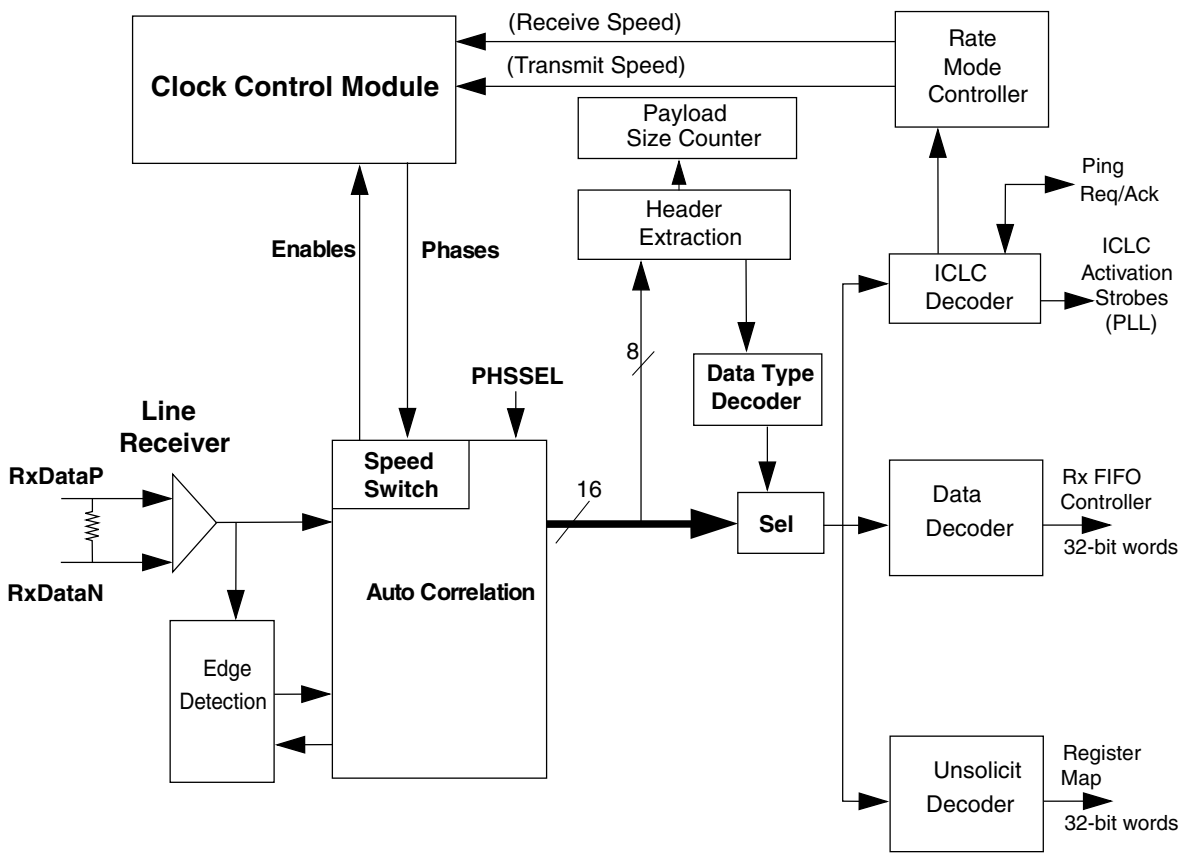

Figure 12-4. Top Level Receive Controller

12.8.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

12.8.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

12.8.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 12-5 shows the block diagram of Hunt Correlation mode.

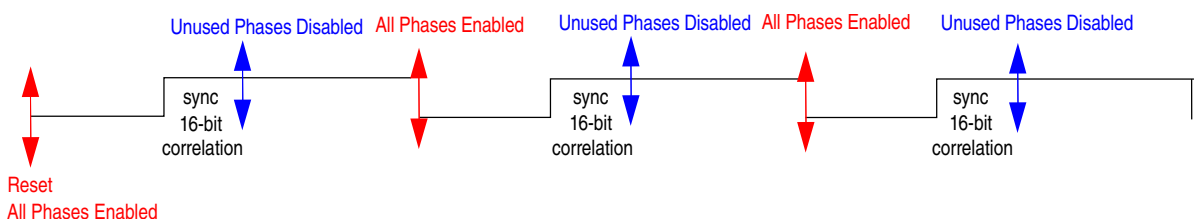

Figure 12-5. Hunt Correlation mode

12.8.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

12.8.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

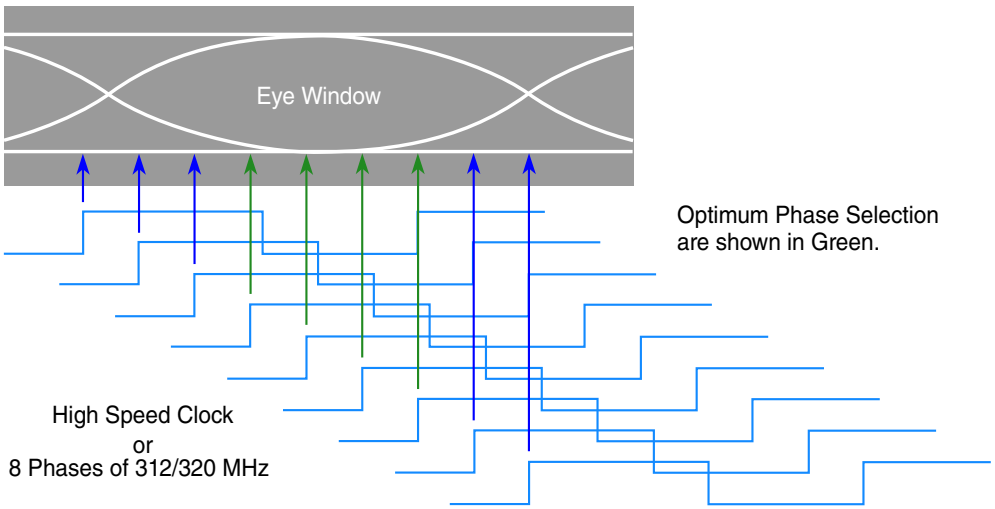

Figure 12-6. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

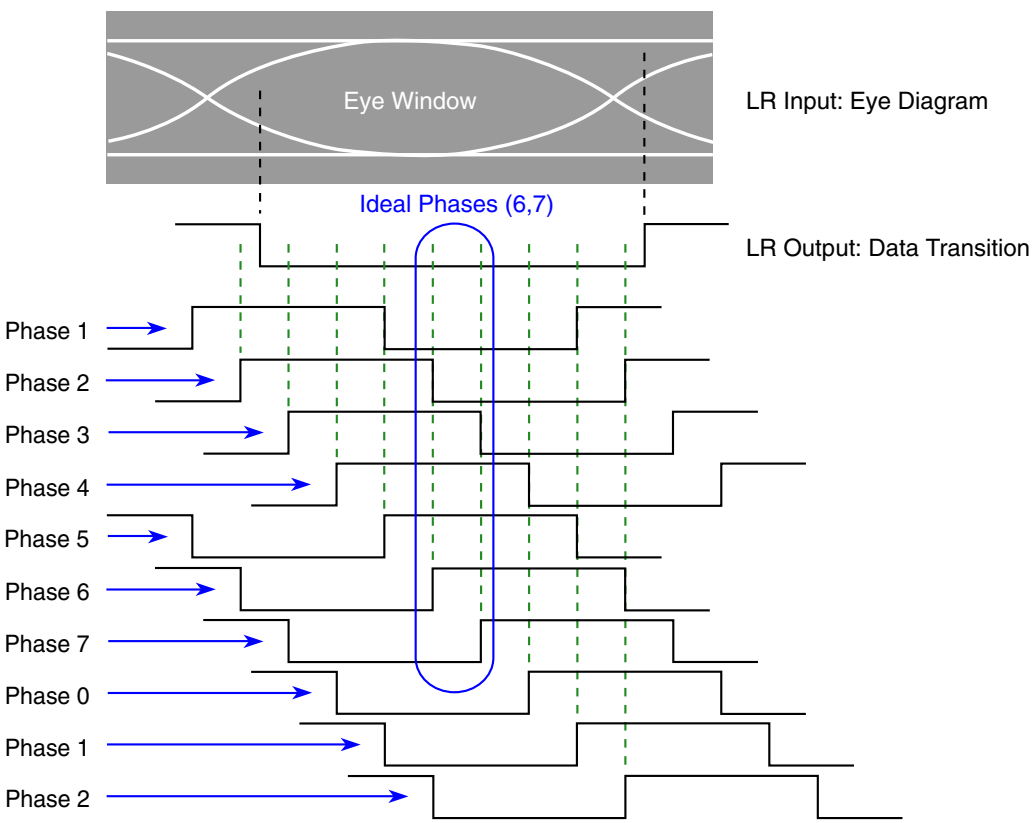

Figure 12-7. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in Figure 12-8 and Figure 12-9.

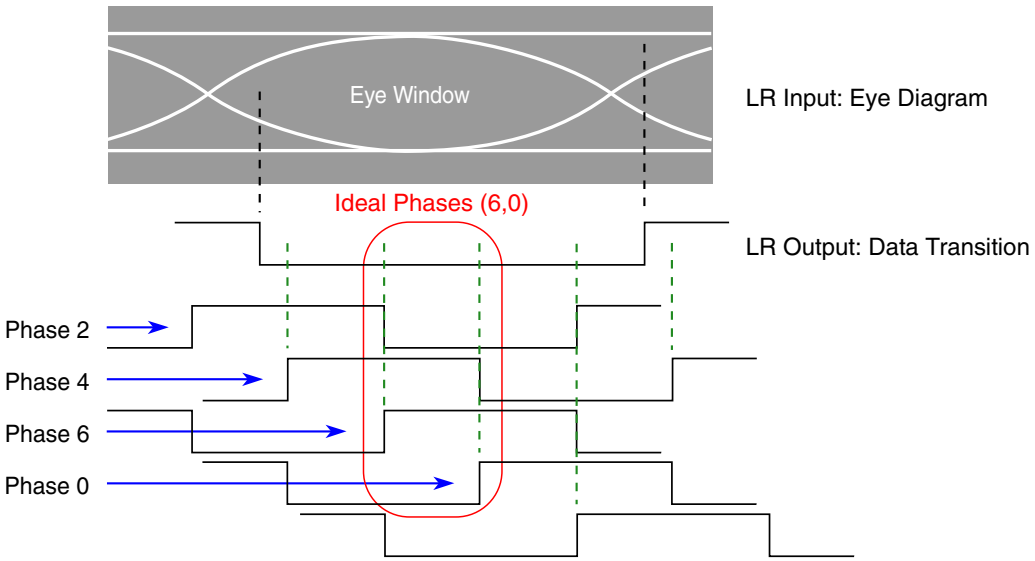

Figure 12-8. High Speed 4 Phase Clock Alignment Example

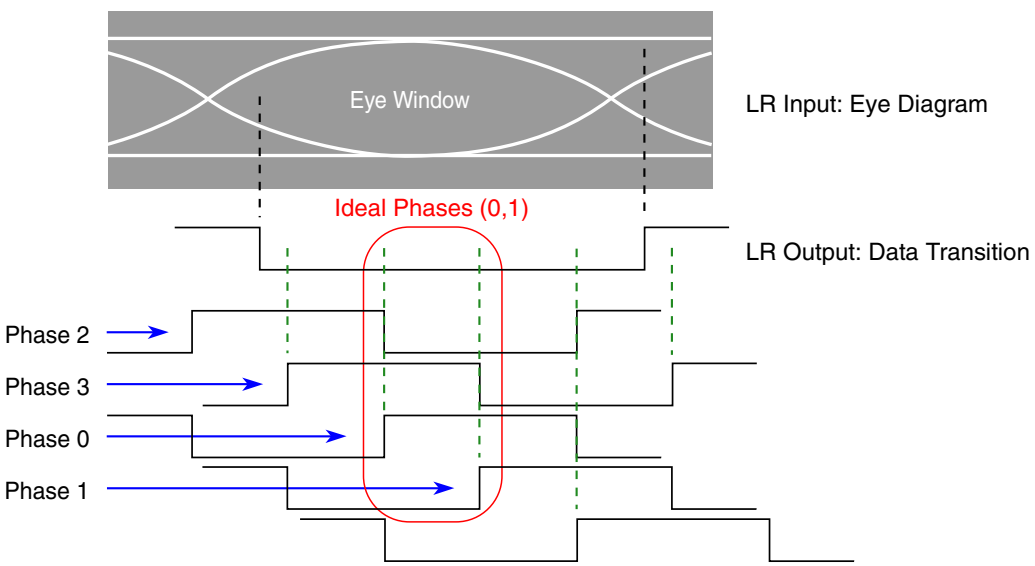

Figure 12-9. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed (312/320 MHz) 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in Table 12-3, Table 12-4, and Table 12-5 before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 12-3. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 12-4. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See Table 12-4, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 12-5. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 12-5. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See Table 12-5, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

12.8.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

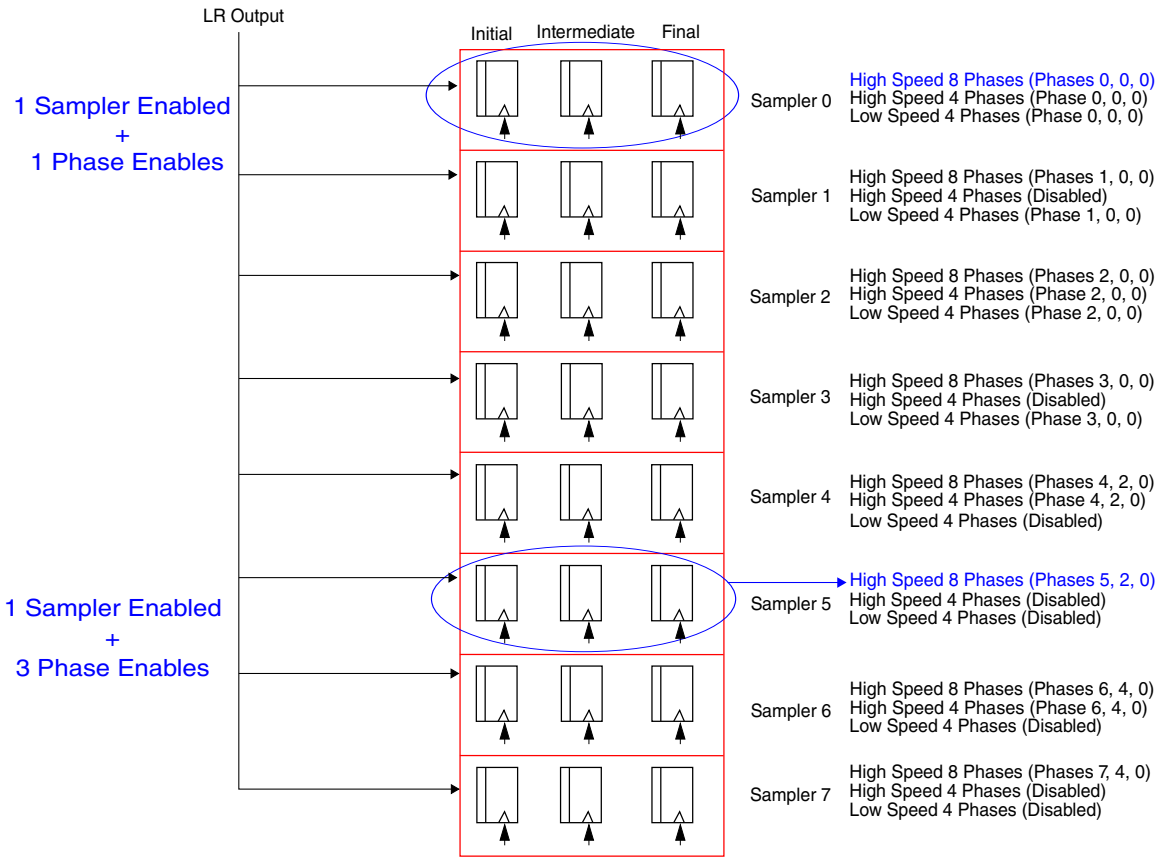

Figure 12-10. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

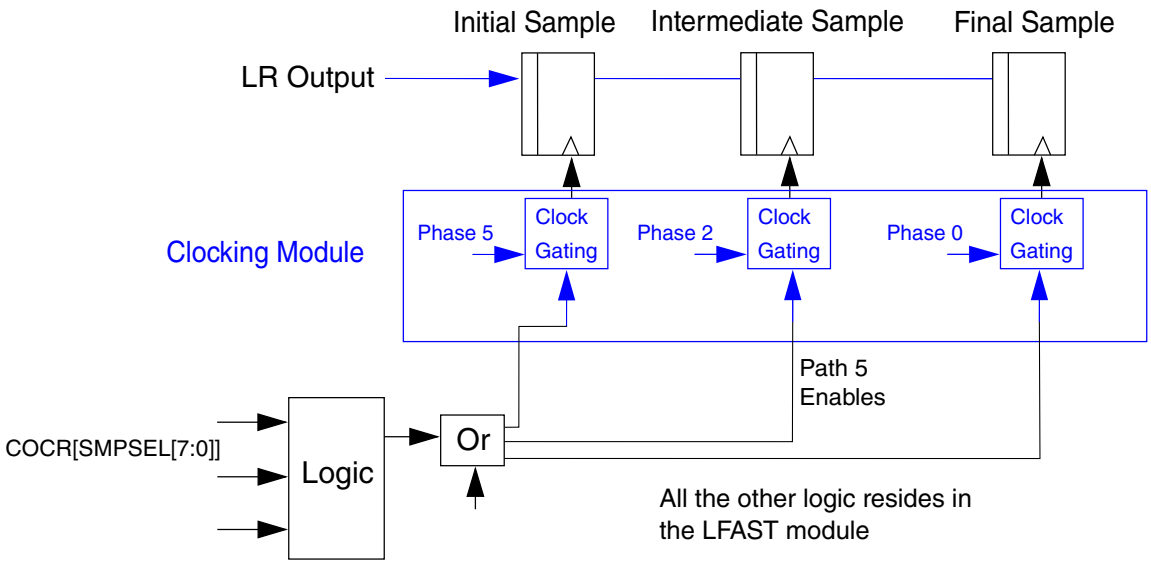

Figure 12-11. Sampler 5 Logic

12.8.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the Figure 12-12.

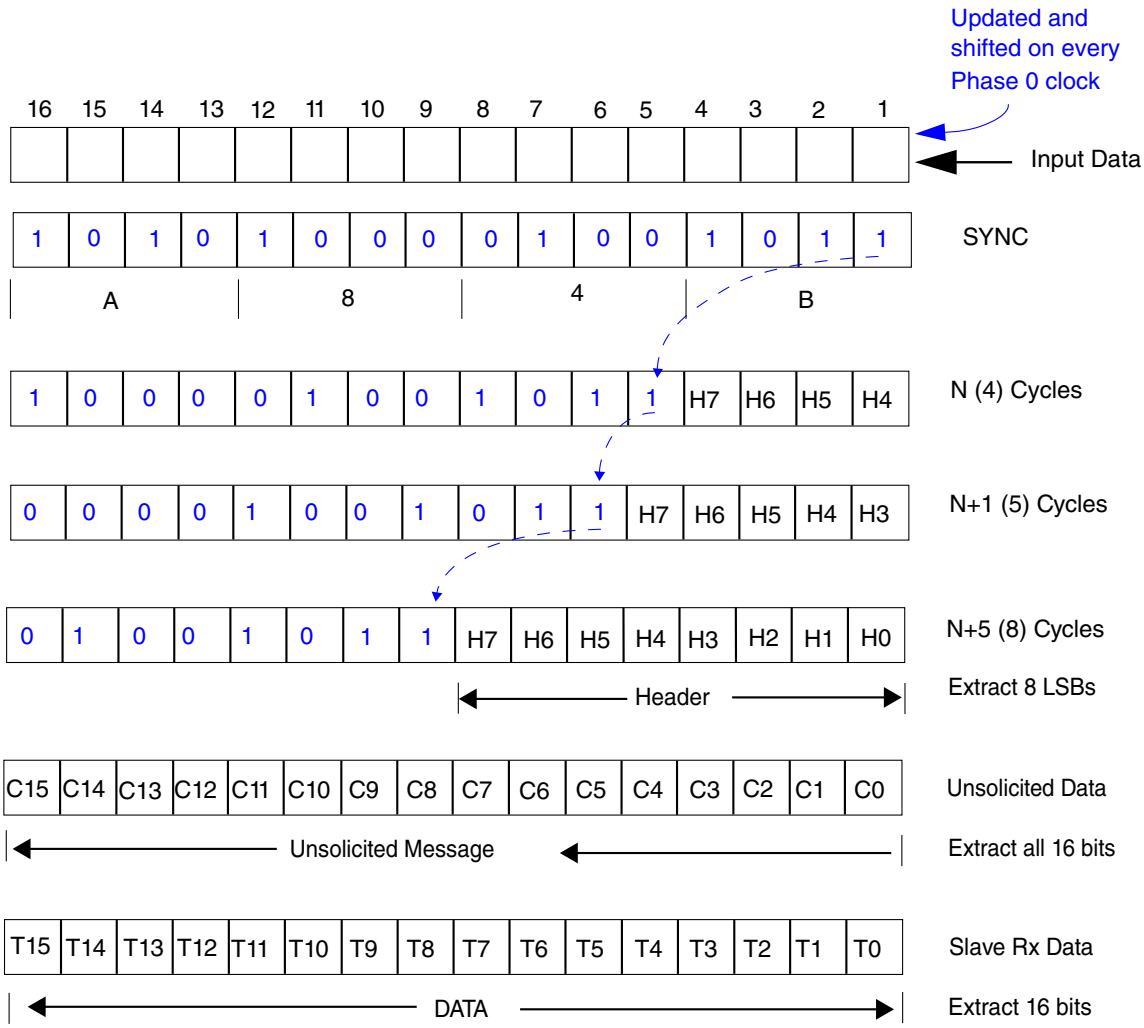

Figure 12-12. Extracting Header and Payload from the 16-bit output from Auto correlation.

12.8.3 Transmit Controller

This section describes the Transmit Controller.

12.8.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

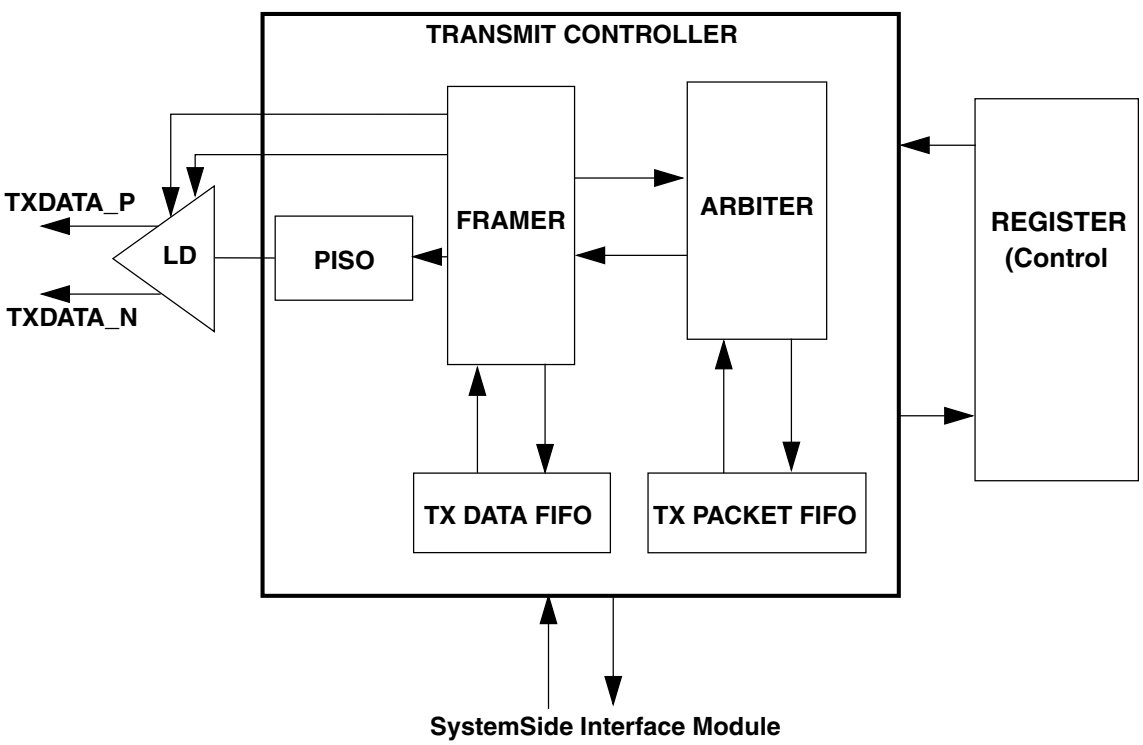

Figure 12-13. Transmit Controller Connections

12.8.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in Table 12-6

Table 12-6. Priority Levels for the Tranmsit Controller

Request	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
LFAST interface enable (lfast_sysclk_en)	1	• LFAST interface enable (lfast_sysclk_en) is asserted • LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	• TMCR[LPON] = 1 • LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	• Valid only if Last Frame with header b0 = 1 received from the peer LFAST • UNSTCR[USNDRQ] = 1

Table continues on the next page...

Table 12-6. Priority Levels for the Tranmsit Controller (continued)

Request	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
Data frame from Tx FIFO	7	• Tx FIFO contains one or more frames • Last Frame with header b0 = 1 received from the peer LFAST device • MCR[DATAEN] = 1
Clock mode test	8	• TMCR[CLKTST] = 0 • LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

12.8.3.3 Line Driver digital connections

12.8.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

  The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down

completely. In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

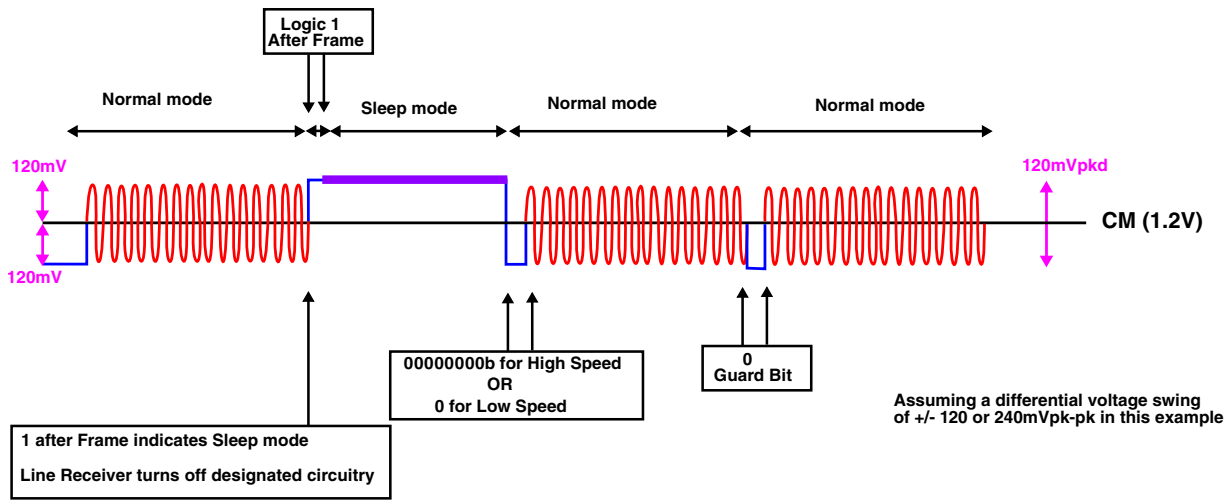

Figure 12-14. Example of Sleep mode

As shown in Figure 12-14 before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 12-7. Line Driver States

LD State	LFAST Slave Triggers
Shutdown	• LFAST interface enable (lfast_sysclk_en) negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

12.8.4 Frames supported

Table 12-8 provides the frames supported and their permissible payload sizes

Table 12-8. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO[1]	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

12.8.5 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

12.8.5.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

12.8.5.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

12.8.5.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer

12.8.5.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

12.8.5.2 Unsolicited flow

12.8.5.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

12.8.5.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
    - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
        - UNSTCR[USNDRQ] = 0
        - TISR[TXUNSF] = 1
    - If UNSTCR[USNDRQ] = 0 then:
        - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
        - Program the unsolicited frame header in UNSTCR[UNSHDR].
        - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

12.8.5.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

12.8.5.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

12.8.5.3.1 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

12.8.5.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

12.8.5.3.1.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

12.8.5.3.1.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

12.8.5.3.1.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

12.8.5.3.1.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

12.8.5.3.1.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

12.8.5.3.1.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

12.8.6 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

12.8.6.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 12-9. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

12.8.6.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

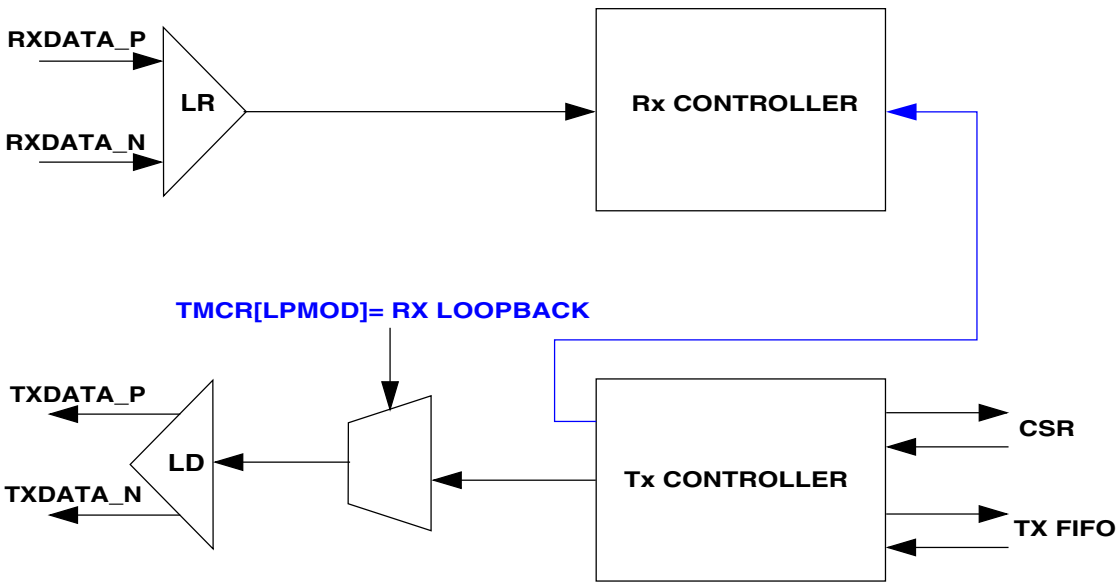

Figure 12-15. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

12.8.6.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

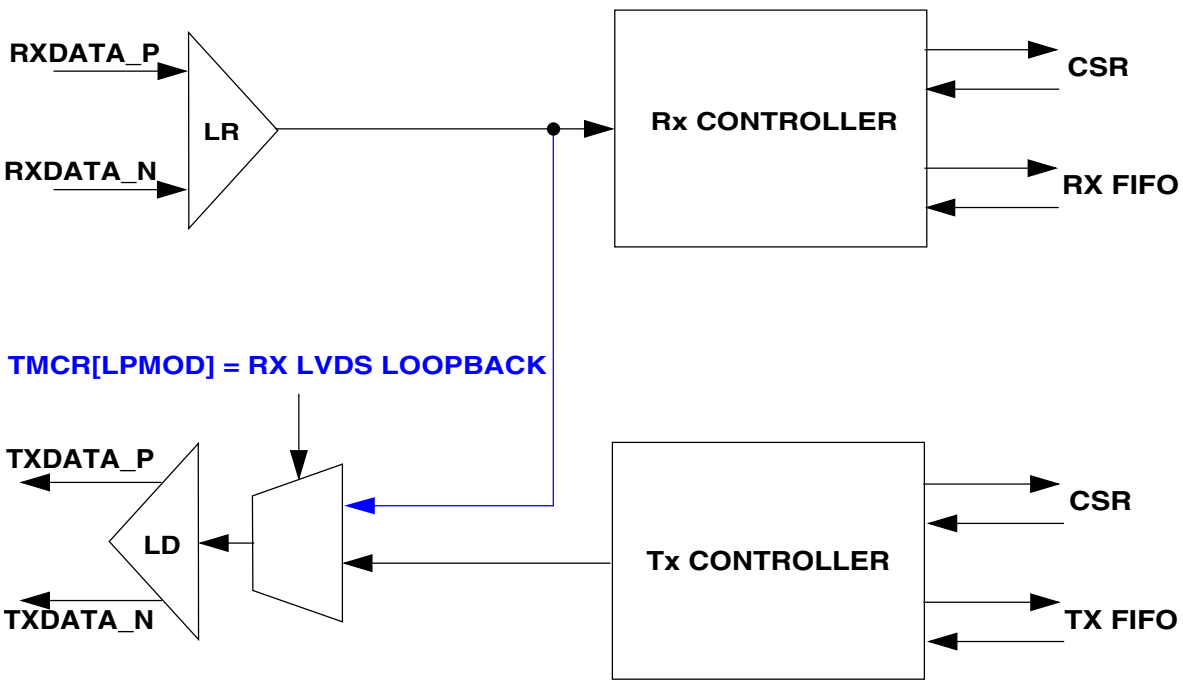

Figure 12-16. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   - S/W writes TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.
  - Deassertion of the LFAST interface enable (lfast_sysclk_en).

12.8.6.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

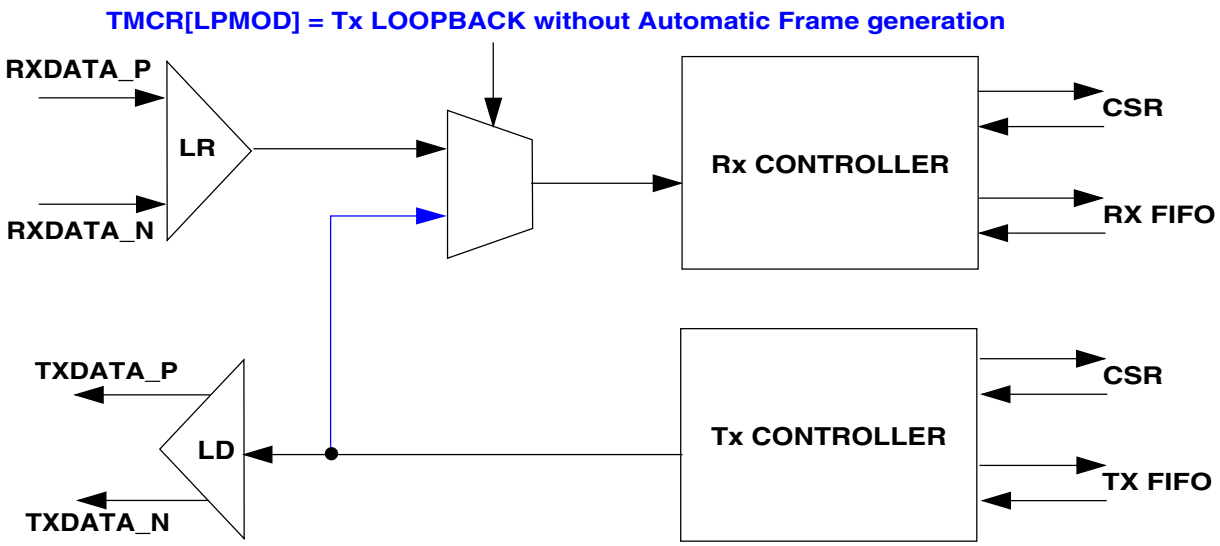

Figure 12-17. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

12.8.6.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

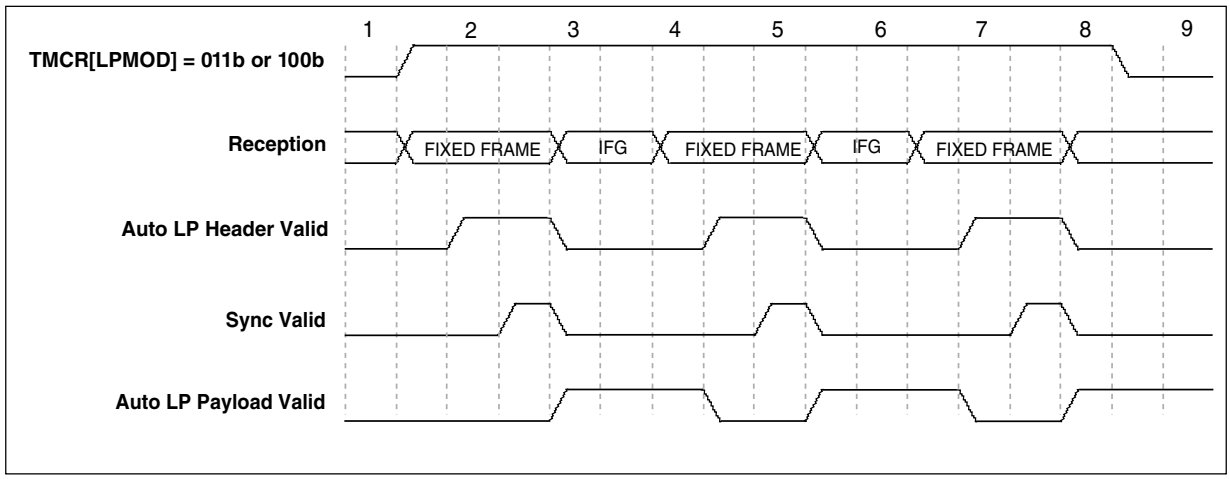

Figure 12-18. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

12.8.6.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

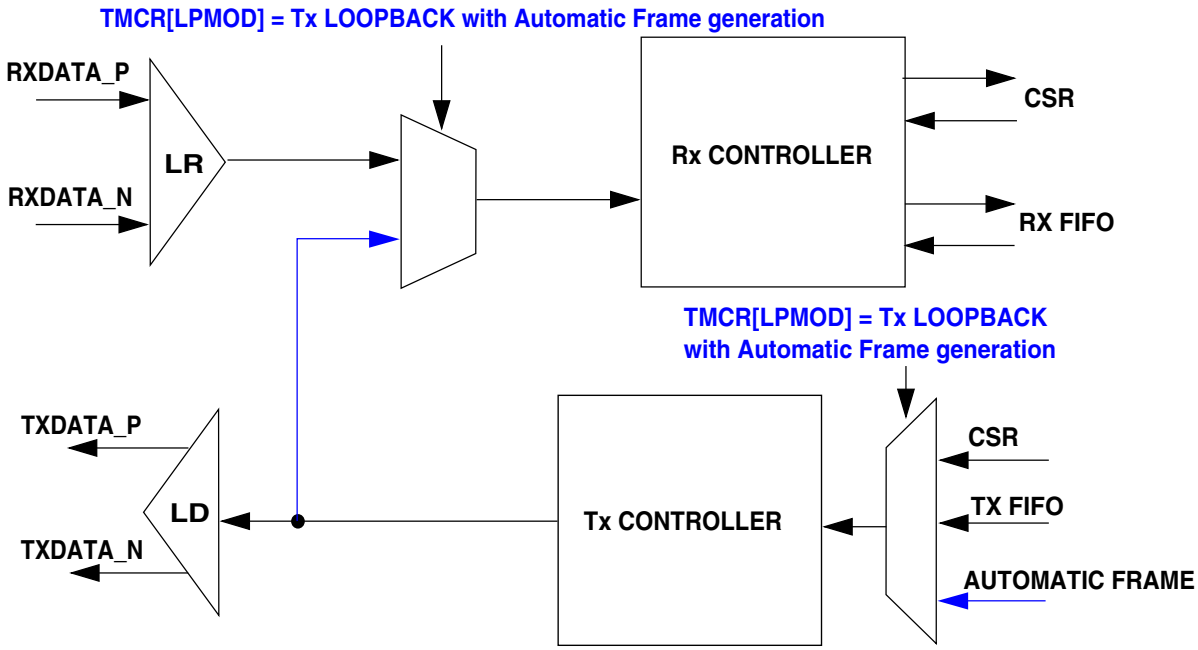

Figure 12-19. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

12.8.6.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

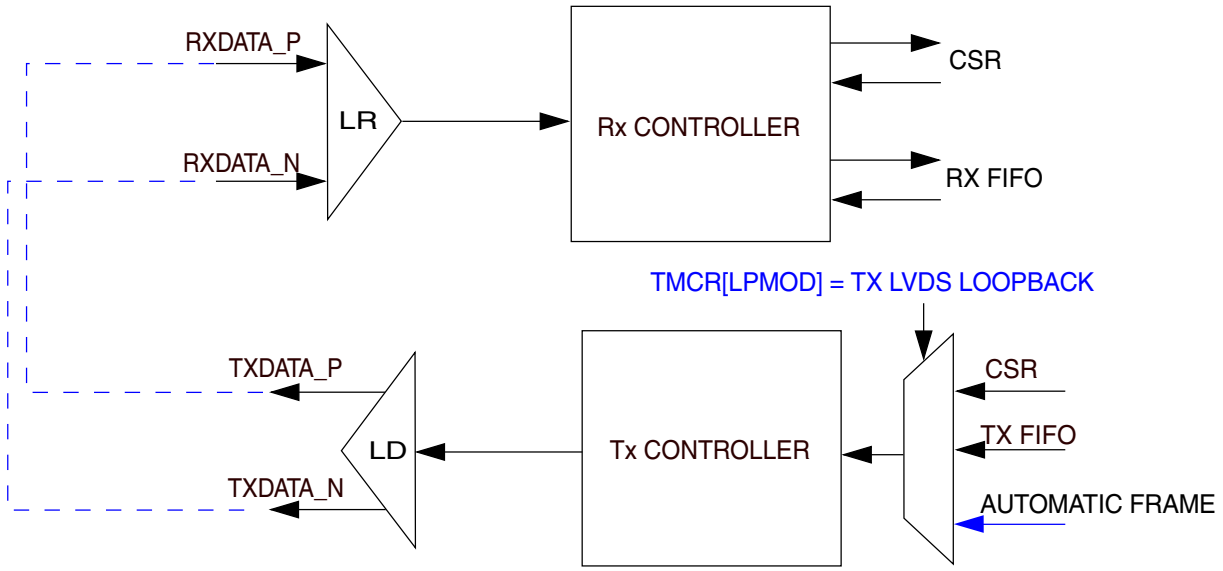

Figure 12-20. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

12.8.6.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

12.9 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 12-10. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet[3]	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

3. Ping response packet

12.10 Resets

The various blocks in LFAST are reset as described in the table below.

Table 12-11. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reseted while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON]

Table continues on the next page...

Table 12-11. Recommended receive exception handling mechanism (continued)

Reset	Blocks Reset
	• ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ] These bits doesn't remain reseted while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only • TISR, • RISR, • RIISR, • GSR[LPTXDN] and GSR[LPFPDV] • These bits doesn't remain reseted while the LFAST interface enable (lfast_sysclk_en) is High.

12.11 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

12.11.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

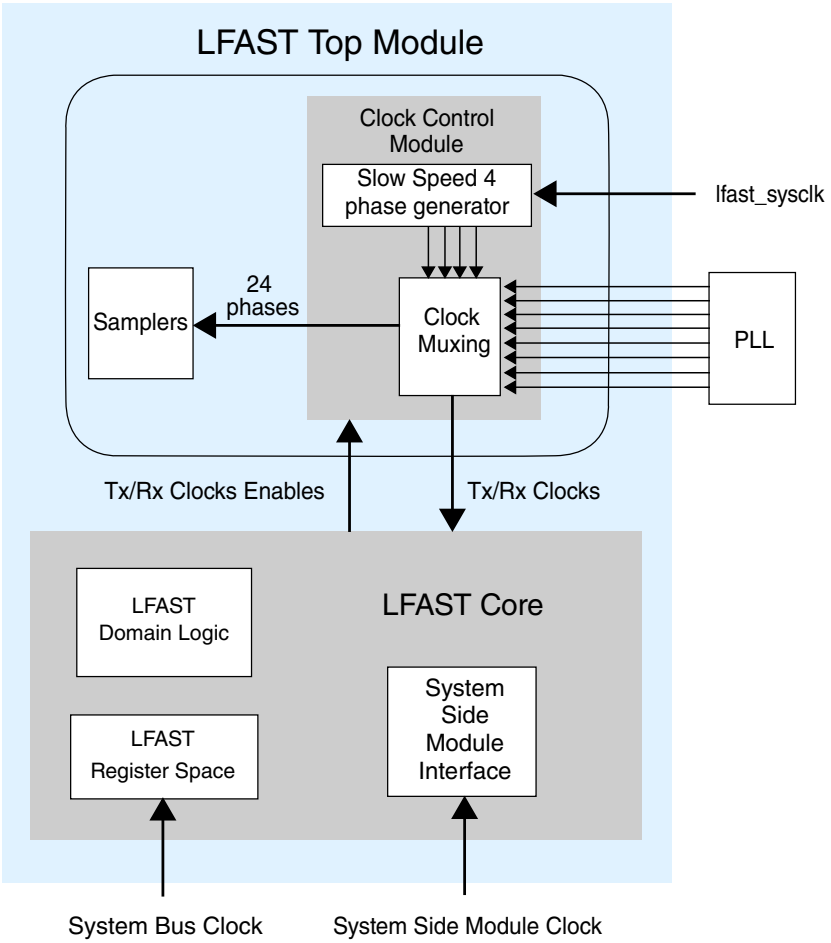

Figure 12-21. LFAST module clock domains

12.11.2 Slow speed clock

12.11.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in Figure 12-22, Figure 12-23 and Figure 12-24.

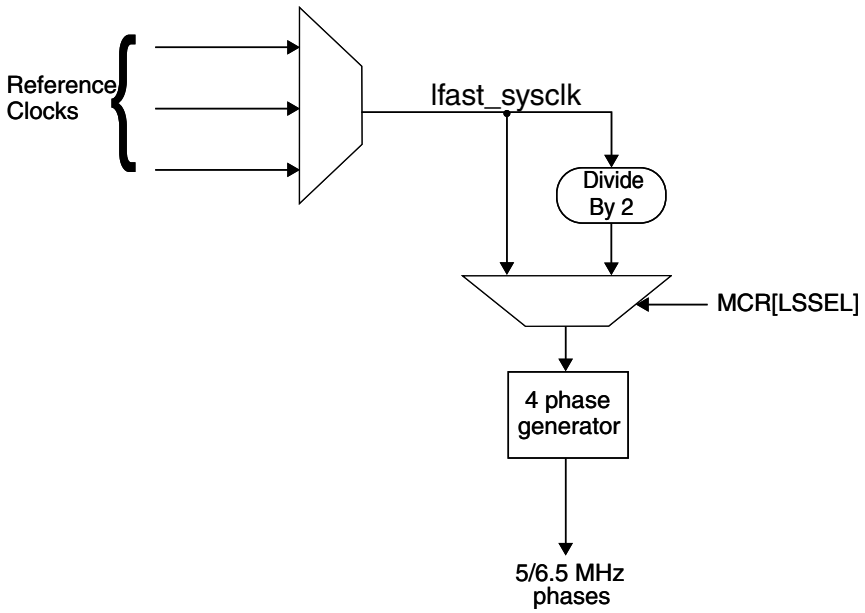

Figure 12-22. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in Figure 12-22.

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 12-23 (selected clock path shown in green).

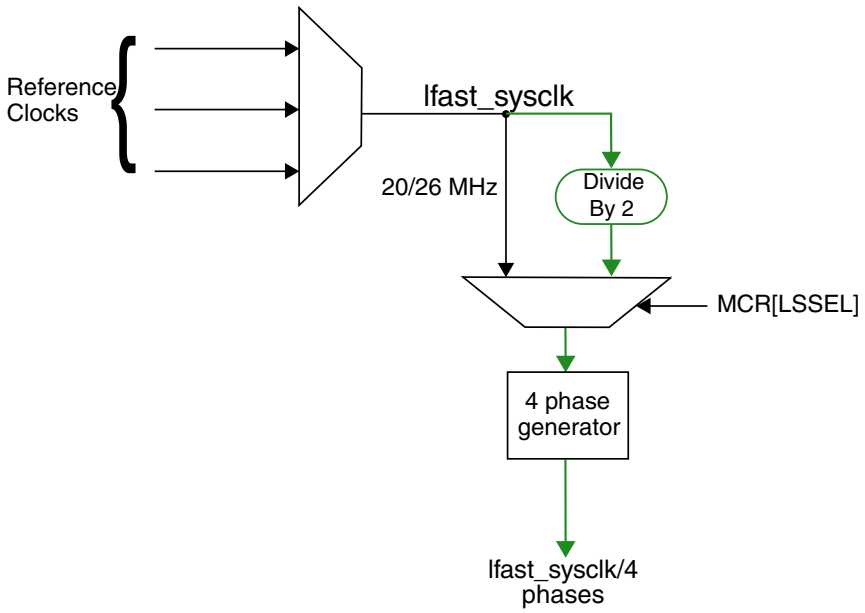

Figure 12-23. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 12-24 (selected clock path selected shown in magenta).

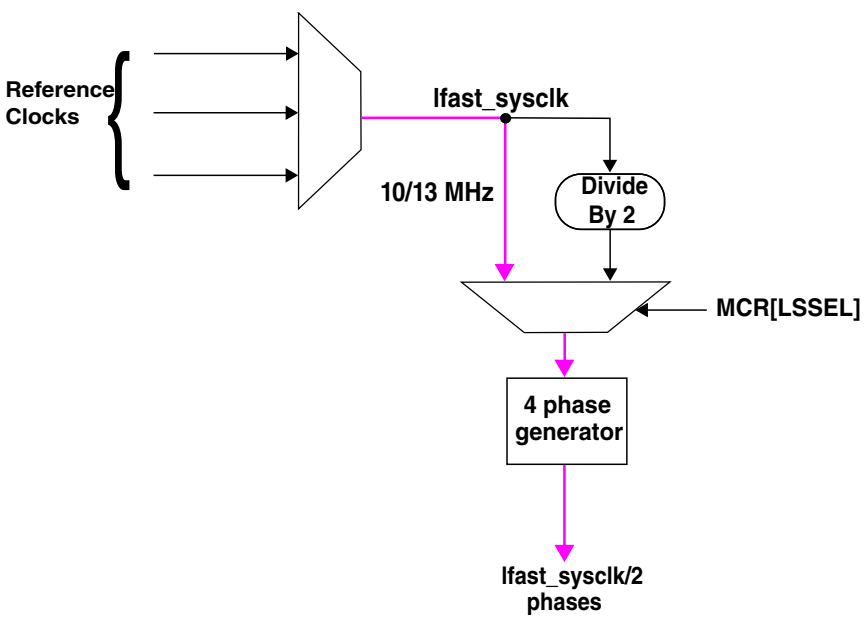

Figure 12-24. External clock muxing of lfast_sysclk of 10 MHz

12.11.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using lfast_sysclk.

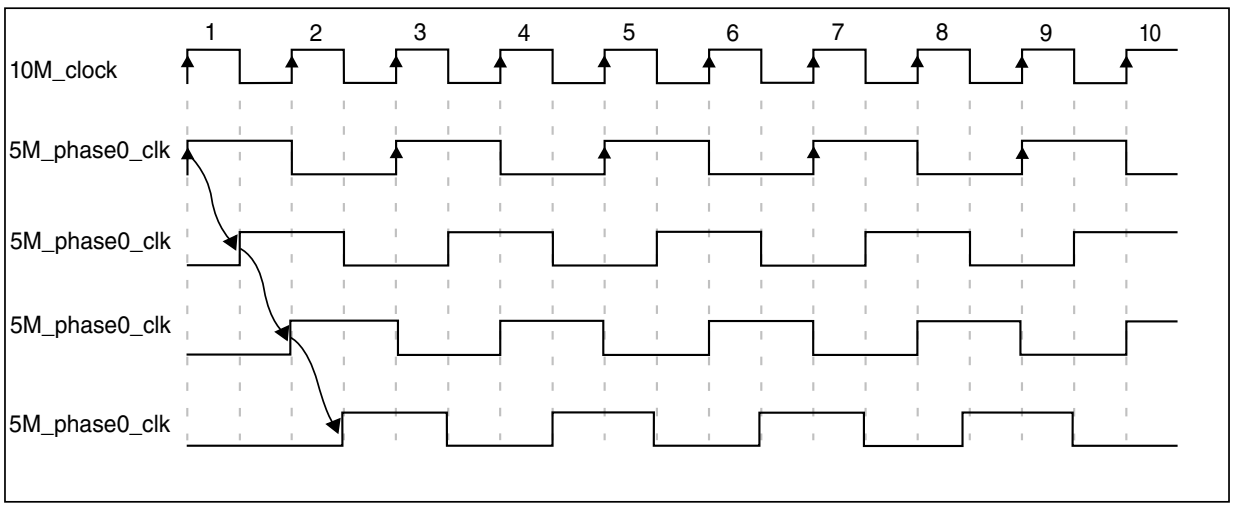

Figure 12-25. Slow speed 4 phases generation

12.11.3 Rx Controller Clocks

12.11.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

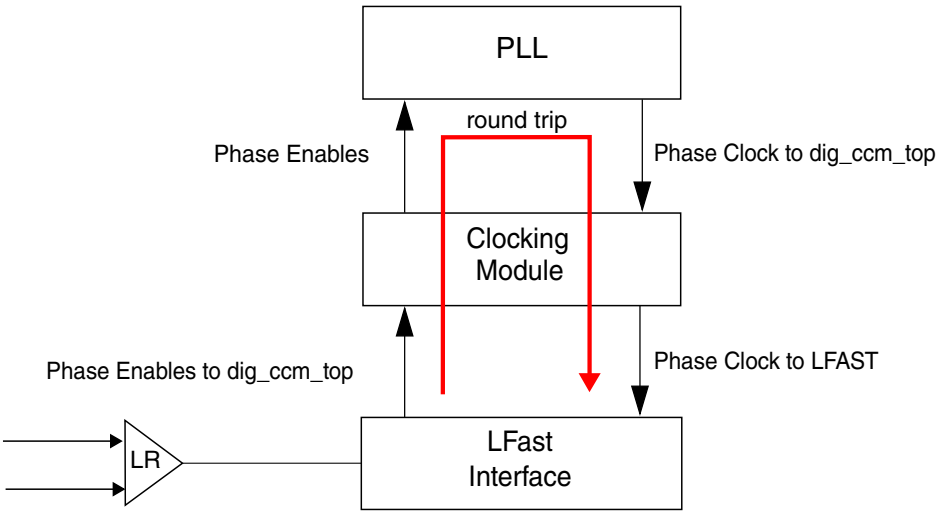

Figure 12-26. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

12.11.5 Clock module requirements for low speed phases

12.11.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 12-12. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

12.11.6 Tx Controller Clocks

12.11.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 12-13. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

12.11.6.2 Transmit Clock Muxing

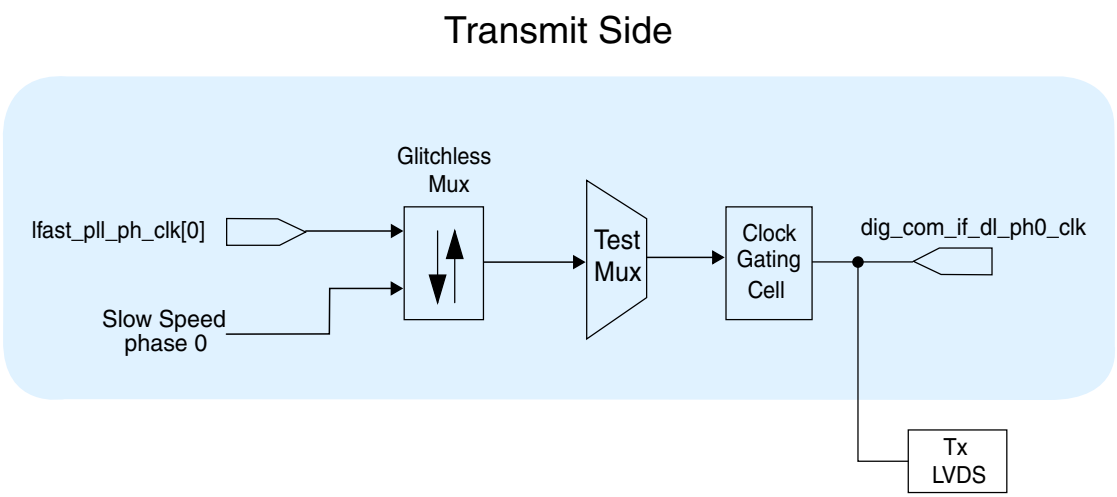

Figure 12-27. Transmit Clocks Muxing

12.11.6.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

Appendix A
Release Notes for Revision 3

A.1 BD Intro changes

- Minor updates.
- Updated references to IEEE 1149.1 or IEEE 1149.7.
- Updated references of IEEE-ISTO 5001-2011 to IEEE-ISTO 5001-2012.

A.2 Buddy Device SIUL changes

- No substantial content changes

A.3 DCI changes

- In "Software enabled debug and calibration mode" section, minor edit and removed second paragraph of NOTE.
- Removed the following sections: Break control, Cross-triggering control, Synchronous restart control, and EVTO management.
- Updated references to IEEE 1149.1 and IEEE 1149.1.

- In DCI control register (BD_DCI_CR) and Figure 4-2, updated Buddy Device DCI_CR register name to BD_DCI_CR.

- In System watchdog control , revised this section to say "The BD DCI does not include the Software Watchdog Timer (SWT) disable feature".

A.4 JTAGC module changes

- In the "JTAGC block instructions" section, separated General JTAGC instructions and ACCESS_AUX instructions into separate tables. Moved ACCESS_AUX instruction table to the chip configuration debug information.

- In the Features section, removed text "and the ability to share the TAP" form the JCOMP feature bullet.

- In the General JTAG instructions table, updated the Instruction summary cells to emphasize which instructions assert functional reset.

A.5 JTAGM changes

- Updated JTAGM_SR bit 10 reset value to 1.
- Reformatted JTAGM_SR[dci_status] field into separate fields.
- Reformatted JTAGM_SR[lfast_status] field into separate fields.

A.6 NAR changes

- In Error conditions, added Receive Queue Overrun row to NAR error types table.
- In Application information, added description of example flow of NAR configuration for different cases.
- In Trace Memory fill level and partition configuration register (NAR_AHFPAR) and Global (Development tool client) stall control, NAR_AHFPAR[GSE] field description, updated dci_evti[1] to dci_evti[0].

A.7 NAL changes

- Added GSR[TXONLY] bit field.

A.8 DWPU changes

- Removed introductory text at the beginning of register sections.

A.9 Nexus Aurora Phy changes

- Minor non-tecnical edits
- In Introduction, added io_control signal to High speed Nexus interface block diagram.

A.10 RWA changes

- No substantial content changes

A.11 LFAST module changes

• PLL and LVDS Status Register (PLLLSR)
  • Table, "PLLLSR field descriptions"
  • Swapped the field description and bit field value descriptions for LDPDS and LRPDS. Previously, incorrectly defined

• Section, PLL Control Register (PLLCR)
  • Table, "PLLCR field descriptions"
  • Updated IPTMOD field row with new defintions.
  • Updated REFINV field row with new defintions.
  • Updated LPCFG field row with new defintions.
  • Updated FBDIV field row with new defintions.

• Added Section, 'LFAST Tx Interrupt Status Register (LFAST_TISR)' • Added Section, 'LFAST Rx Interrupt Status Register (LFAST_RISR)' • Added Section, 'LFAST Rx ICLC Interrupt Status Register (LFAST_RIISR)'
• LVRXOP   • Replaced the description of the LVRXOP field.
• Data receive   • In the first paragraph, changed "MCR[TXEN]" to "MCR[RXEN]".

• LFAST LVDS Control Register (LFAST_LCR)
  • Added LVTXOP at bit 29 (MSB=0).
  • Updated LVTXOP bitfield reset to 1.
