MPC5777M Reference Manual

This is the MPC5777M Reference Manual set, consisting of the following files:

- MPC5777M Reference Manual, Rev. 4.3
- MPC5777M Reference Manual, Rev. 4.2
- MPC5777M Reference Manual, Rev.4. 1
- MPC5777M Reference Manual, Rev. 4

.

Addenda Overview

1.1 Addenda Overview

The table below displays the updates for MPC5777M RM Rev 4.3, RM Rev 4.2 and RM Rev 4.1.

Table 1-1. MPC5777M RM Addenda

Location	Description
MPC5777M RM 4.3 (01/2017)	
	• Updated Reference Manual footer to remove Preliminary.
MPC5777M RM 4.2 (08/2016)	
Chapter 2, Introduction	
Page 124	• Updated the Block Diagram. See Block Diagram
Chapter 5, Memory Map	
Page 153	• Updated the "Used size" of Flash to 512 KB in the table 'Overview memory map'. See Data Flash Blocks–no overlay
Page 167	• Updated the row "0x00400104" in the table 'UTest flash memory map'. See System RAM memory maps
Chapter 7, Device Configuration	
Page 212	• Added 'IPS Clock Gating Module Enable 1 (IPS_CGM_EN1) Register'. See Clock Gating Module Enable 1 (IPS_CGM_EN1)
Page 222	• Changed the address offset of IPS Clock Gating Module Enable 0. See IPS Clock Gating Module Enable 0 (IPS_CGM_EN0)
Page 224	• Added a note in the section 'INTC implemented registers'. See INTC implemented registers
Page 224	• Removed interrupts in 'Table 7-23 Interrupt sources', which are not supported by the device.

Table continues on the next page...

Table 1-1. MPC5777M RM Addenda (continued)

Location	Description
	See Interrupt sources
Page 268	• Corrected the Reset value of SWT_CR0, SWT_CR1, SWT_CR2, and SWT_CR3 registers in the section 'Default configuration'. See Default configuration
Page 273	• Updated the FEC interface selection section and table FEC interface selection. See FEC interface selection
Page 284	• Changed the Auto configuration for linflex_1 to linflex_16 from 'no' to 'n/a'. See LINFlexD configurations
Page 285	• Updated the MREV and JPIN value in the table 'SSCM_MEMCONFIG Reset Values'. See SSCM_MEMCONFIG reset values
Page 287	• Added a new section 'Reset values on BAF exit'. See Reset values on BAF exit
Page 294	• Updated some entries in table 'LVD /HVD self test decoding' column 'LVD / HVD under test'. See LVD /HVD self test decoding
Page 308	• Updated the table 'Availability and reset values of selected FCCU registers'. See FCCU chip-specific register reset values
Page 310	• Updated the figure 'Error signal flow'. See Error signal flow
Page 311	• Updated the footnotes of 'Table 7-86. FCCU failure inputs'. See FCCU failure inputs
Chapter 12, Calibration and Debug	
Page 443	• Added sections DCI signals and DCI EVTx Pin Multiplexing Control Register (DCI_PINCR). See, DCI signals and DCI $\overline{\text{EVTx}}$ Pin Multiplexing Control Register (DCI_PINCR)
Chapter 14, Core description	
Page 532	• Updated the Reset value of DMEM Control Register 0. See DMEM Control register 0
Page 539	• Updated the Reset value of IMEM Control Register 0. See IMEM Control register 0
Chapter 15, Core description	
Page 615	• Updated the Reset value for DMEM Control Register 0.

Table continues on the next page...

Table 1-1. MPC5777M RM Addenda (continued)

Location	Description
	See DMEM Control register 0
Page 623	• Updated the Reset value of IMEM Control Register 0. See IMEM Control register 0
Chapter 17, Crossbar Switch	
Page 771	• Updated the reset value of XBAR Control Register. See, XBAR Control register.
Chapter 23, Interrupt Controller (INTC)	
Page 926	• Updated the section 'Examining LIFO contents'. See, Examining LIFO contents.
Chapter 24, Enhanced Direct Memory Access (eDMA)	
Page 930	• Updated the description of Memory map/register definition section. See Memory map/register definition
Chapter 26, Clocking	
Page 1086	• Updated the table 'Maximum system level clock frequencies'. See System clock frequency limitations
Page 1088	• Updated the table 'JTAG frequencies'. See JTAG frequencies
Page 1088	• Added a new section 'System clock ratio restrictions'. See System Clock ratio restrictions
Page 1097	• Updated the Clock distribution figure. See Clock distribution
Page 1102	• Added a note in the M_TTCAN/M_CAN clocking section. See, M_TTCAN/M_CAN clocking
Page 1108	• Added guideline for PCS register configuration in the 'Progressive clock switching' section. See, Progressive clock switching
Chapter 27, Dual PLL Digital Interface (PLLDIG)	
Page 1118 and Page 1123	• Added a reference to the section 'Clock configuration' in register description of PLLDIG PLL0 Divider Register and PLLDIG PLL1 Divider Register.
Page 1129	• Added equation for f_{pll1_VCO} and f_{pll1_phi} when PLLDIG_PLL1FD[FDEN] = 1b. • Updated equations f_{PLL1_PHI} and f_{pll1_VCO}. • See Clock configuration
Chapter 29, Clocking Generation Module	
Page 1204	• Updated Equation 11.

Table continues on the next page...

Table 1-1. MPC5777M RM Addenda (continued)

Location	Description
	See Generic clock change properties
Chapter 31, IRCOSC Digital Interface	
Page 1230	• Updated the Reset value of 'IRCOSC Control Register (IRCOSC_CTL)'. See IRCOSC Control register
Chapter 34, Embedded Flash Memory (c55fmc)	
Page 1303	• Changed the reset value of the Alternate Module Configuration Register, the footnote in the register diagram replaced with footnotes for Over-Program Protection 0 register, and the Footnote in the register diagram replaced with footnote in Over-Program Protection 1 register, Over-Program Protection 2 register, and Over-Program Protection 3 register. See C55FMC Memory map and register definition
Page 1346	• Updated the existing Note in the section 'Program suspend/resume'. See Program suspend/resume
Page 1352	• Paragraph added to section 'Array integrity self check'. See Array integrity self check
Chapter 37, External Bus Interface	
Page 1418 and 1458	• Removed the column 'EBI_MCR [SIZE]' from the tables 'Table 37-3. Write/ Byte Enable Signals Function', ' Table 37-9. Data Bus Requirements for Read Cycles' and 'Table 37-10. Data Bus Contents for Write Cycles'. See, External Bus Interface
Chapter 38, Analog-to-Digital Converters (ADC) Configuration	
Page 1496	• Updated the figure SAR ADC integration diagram. See SAR ADC integration diagram
Page 1500	• SARADC_B sampling time unit changed. See Self Test features
Page 1547, 1550, and 1553	• Updated the field name 'SARADCx_ICWSELR7' in the tables 'Table 38-31 SARADC_8 register definitions, Table 38-32 SARADC_9 register definitions and Table 38-33 SARADC_10 register definitions'. See SARADC register description
Chapter 39 Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface,	
Page 1572	• Added FRST and FOWEN fields in FIFO Control Register. See FIFO Control register
Chapter 40, Successive Approximation Register Analog-to- Digital Converter (SARADC) Digital Interface	
Page 1651	• Added a Note in the Test Channel Data Register (SARADC_TCDRn) description. See Test Channel Data register
Chapter 48, CAN Subsytem	
Page 1837	• CAN FD support is removed throughout the document.

Table continues on the next page...

Table 1-1. MPC5777M RM Addenda (continued)

Location	Description
	See, CAN Subsystem
Page 1879	• The FOS field width updated to 7 bits for the Rx FIFO 0 Configuration Register . See M_CAN_RXF0C[F0S]
Page 1867	• Added bit field values for the DRXE field in Interrupt Enable Register. See DRXE
Chapter 52, LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications	
Page 2282	• Changed the instances of digrf to LFAST. See, Digrf changed to LFAST
Page 2312	• Fixed typo error, changed the fields name from CTSMN to RCTSMN, CTSMX to RCTSMX, and TISR[CTSMX] to RFCR[CTSMX] in the section CTS mode support. See CTS mode support
Chapter 59, LINFlexD	
Page 3199 and Page 3219	• Updated the field description of IOPE in the LIN Control Register2 and in the LINS field changed the bit field value description of 0001 Init mode in the LIN Status Register. See LINFlexD
Chapter 63 Power Management Controller digital interface	
Page 3407	• Added a sentence in the Reset Event Select Register description. See Reset Event Select register
Chapter 73, JTAG Master	
Page 3956	• For the field TCKSEL updated the TCK divide value. See Module Configuration register
Chapter 76, LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed debug	
Page 4004	• Changed the instances of digrf to LFAST. See, Digrf changed to LFAST
Page 4066	• Updated the description of the field LVLPEN. See LVLPEN
Chapter 86, Self-Test Control Unit	
Page 4463	• Updated the section 'Register write-access watchdog timer'. See, Register write-access watchdog timer
	• Added a chip specific topic. See STCU2 • Added a chip specific topic for AUTOLOCK_VALUE with info about DCF_COMPLETION.

Table continues on the next page...

Table 1-1. MPC5777M RM Addenda (continued)

Location	Description
	See AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion
Chapter 85, Fault Collection and Control Unit (FCCU)	
Page 4423 and 4447	• Removed a note from the RFS Configuration Register and NMI Enable Register. See FCCU
MPC5777M RM 4.1 (05/2015)	

Chapter 5, Memory Map, page167	• Table 5-6,In the UTest flash memory map, made the following changes for starting address 0x00400308:
	  • Changed the name in the Description column" to "Reserved".
	  • Changed the existing note.
	  • Added an additional note.
	See, UTest flash memory map

Chapter 2
RM Addendum Rev 4.3

2.1 Overview

The update for MPC5777M RM Rev 4.2 is as follows:

- Updated Reference Manual footer to remove Preliminary.

Chapter 3
RM Addendum Rev 4.2

3.1 Overview

The updates for MPC5777M RM Rev 4.1 are described in detail below.

3.1.1 Block Diagram

- The Block Diagram is updated. The 'Concentrator with E2E ECC 50 MHz' changed to 'Concentrator with E2E ECC' and the connection arrows from the FlexRay Ethernet and LFAST & SIPI now have the frequency listed on them.

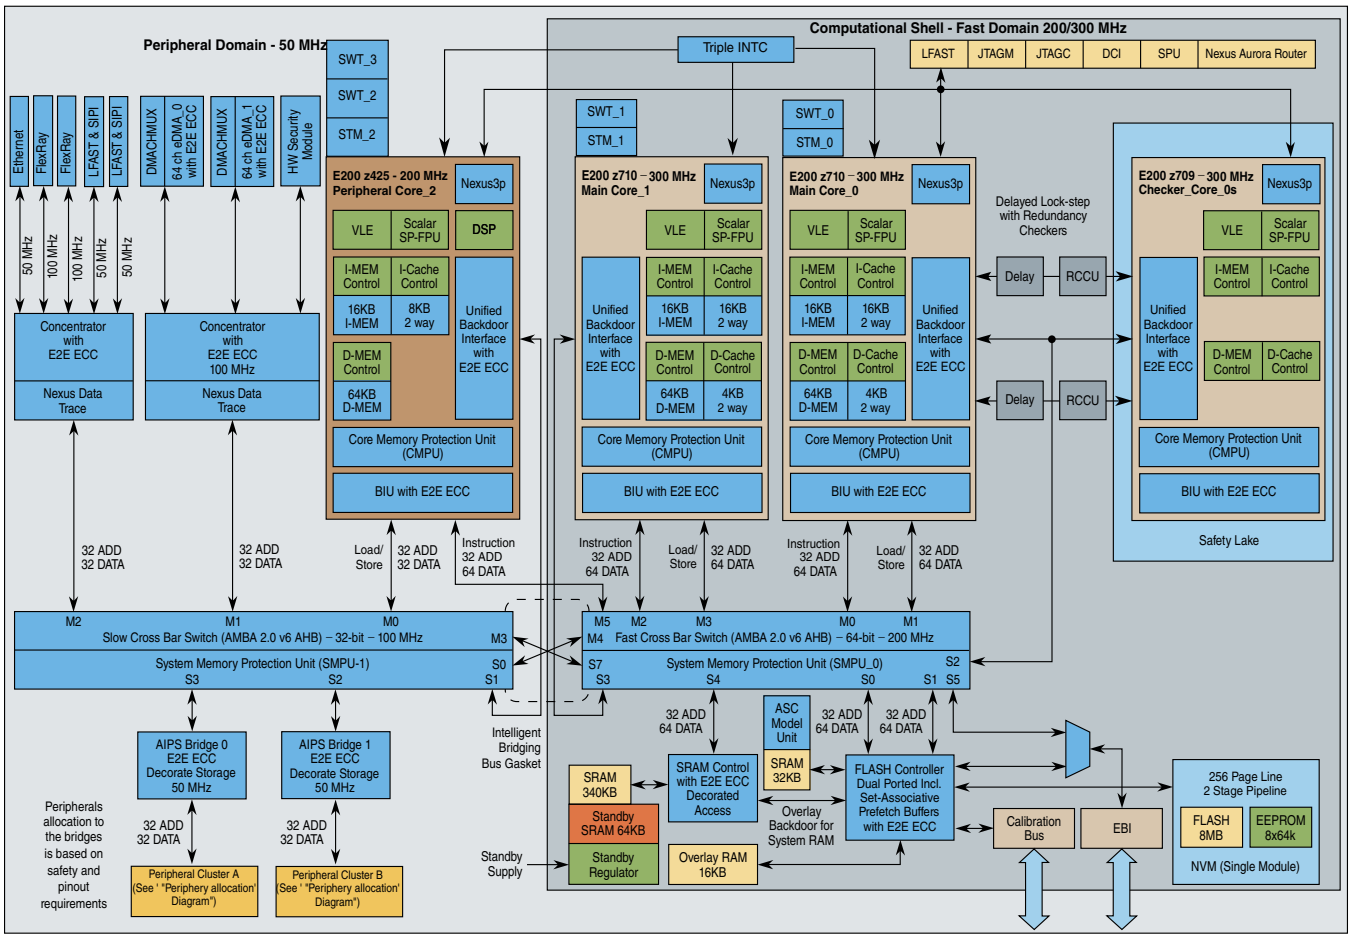

Figure 3-1. Block diagram

3.1.2 Memory Map

3.1.2.1 Data Flash Blocks–no overlay

- In Table 3-1, for the starting address 0x00800000, changed the "Used size" to 512 KB.

Table 3-1. Overview memory map

Start address	End address	Allocated size	Used size	Description
Flash (XBAR port 0—0)				
0x00800000	0x009FFFFF	2 MB	512 KB	Data Flash Blocks–no overlay

3.1.2.2 System RAM memory maps

- Updated the 0x00400104 row in table UTest flash memory map:

Table 3-2. UTest flash memory map

Start address	End address	Allocated size [bytes]	Description	Comments
0x00400104	0x0040011F	28	Fuse Bypass Password (FA flash test password)	The FA flash test password must be left erased unless the application requires an additional password for testing the flash during failure analysis. If a password is required, additional programming is necessary. See the Security Reference Manual entry for "Fuse Bypass Password" for more information.

3.1.3 Device configuration

3.1.3.1 Clock Gating Module Enable 1 (IPS_CGM_EN1)

- Clock Gating Module Enable 0 (IPS_CGM_EN0) register is added under the section Platform Configuration Module.

Offset 18h Access: Supervisor read/write

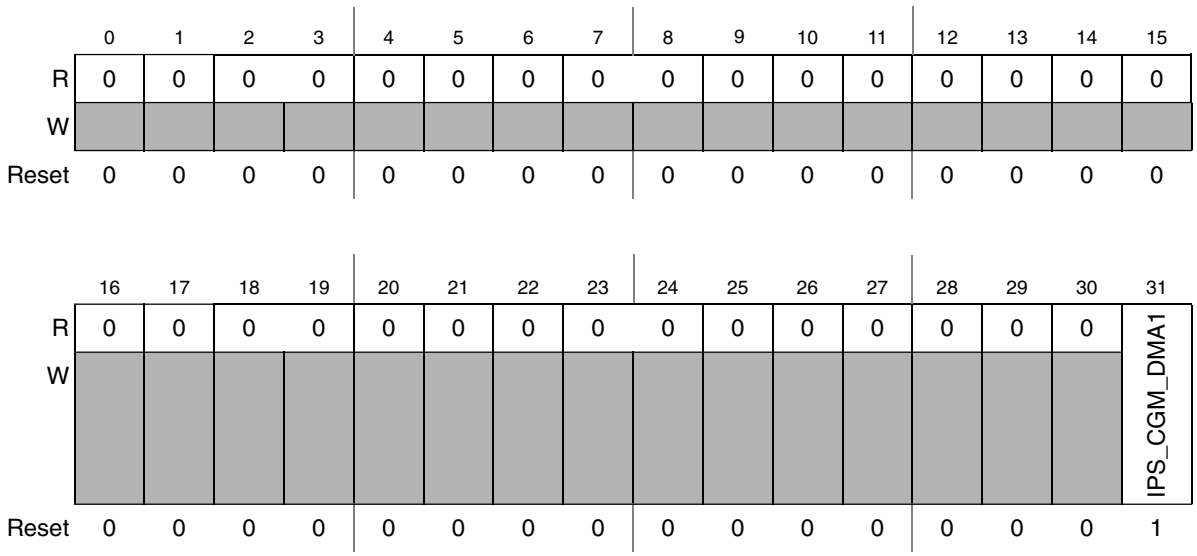

Figure 3-2. IPS Clock Gating Enable 1 (IPS_CGM_EN1) register

Table 3-3. IPS_CGM_EN1 field description

Field	Description
0–30	Reserved
31 IPS_CGM_DMA1	IPS clock gating enable for DMA1 1 Enable clock gating, one IPS clock delay is introduced between master and slave. 0 Disable clock gating.

3.1.3.2 IPS Clock Gating Module Enable 0 (IPS_CGM_EN0)

- Changed the address offset of IPS Clock Gating Module Enable 0 register to 0x14h.

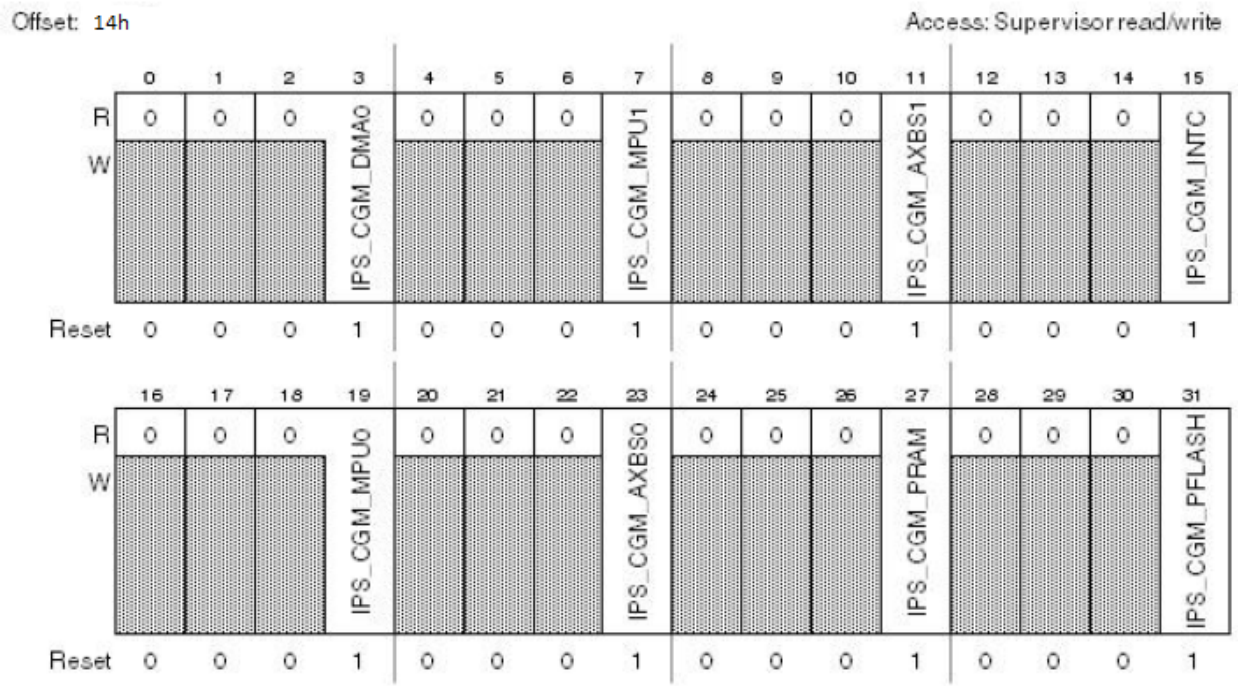

Figure 3-3. IPS Clock Gating Module Enable 0 register

3.1.3.3 INTC implemented registers

- The following note has been added to the section:

NOTE

There are four cores implemented on this chip, but core 3 is strictly a checker core. The INTC only supports the three functional cores 0, 1, and 2. Therefore, the registers INTC_IACKR3, INTC_CPR3, and INTC_EOIR3 are not supported, and any attempt to access these registers results in a bus error. Also, writing to the HVEN3 bit in the INTC_BCR register has no effect.

3.1.3.4 Interrupt sources

- Removed the following interrupts not supported by the device from 'Table 7-23 Interrupt sources':
  - DSPI_0_SR(TFIWF)
  - DSPI_1_SR(TFIWF)

- DSPI_2_SR(TFIWF)
- DSPI_3_SR(TFIWF)
- DSPI_4_SR(TFIWF)
- DSPI_5_SR(TFIWF)
- DSPI_6_SR(TFIWF)
- DSPI_12_SR(TFIWF)

3.1.3.5 Default configuration

- Changed the reset values of SWT_CR [0, 1, 2, 3] registers.
  For SWT[0, 1, 3], the SWT_CR register reset value of 0xFF00_010A selects:
  - All masters allowed access
  - Reset on invalid access
  - Oscillator clock selected
  - Counter stops in debug mode
  - Watchdog is disabled

  For SWT[2], the SWT_CR register reset value of 0xFF00_011B selects:
  - All masters allowed access
  - Reset on invalid access
  - Oscillator clock selected
  - Counter stops in debug mode
  - Soft locked
  - Watchdog is enabled

3.1.3.6 FEC interface selection

- On this chip, the FEC interface depends on the settings of FEC_RCR[MII_MODE] (in the FEC) and the SoC Configuration Register0 SIUL2_SCR0[FEC_MODE].

Table 3-4. FEC interface selection

FEC_RCR[MII_MODE]	SIUL2_SCR0[FEC_MODE]	Interface used by the FEC
0	0 or 1	7-wire
1	0	RMII
	1	MII

3.1.3.7 LINFlexD configurations

- The Auto synchronization for Linflex1-16 changed from 'no' to 'n/a' in LINFlexD configurations table.

Table 3-5. LINFlexD configurations

Description	linflex_0	linflex_1	linflex_2	linflex_14	linflex_15	linflex_16
Number of filters implemented	16	0	0	0	0	0
Number of Tx DMA channels	1	1	1	1	1	1
Number of Rx DMA channels	1l	1	1	1	1	1
LIN operation mode	master/ slave	master	master	master	master	master
Auto synchronization	yes	n/a	n/a	n/a	n/a	n/a

3.1.3.8 SSCM_MEMCONFIG reset values

- In the table SSCM_MEMCONFIG reset values' updated the MREV and JPIN values.

Table 3-6. SSCM_MEMCONFIG reset values

Field	Field Definition	Value
MREV	Minor Revision	0001b
JPIN	JTAG Part ID	30Fh

3.1.3.9 Reset values on BAF exit

Added the section reset values on BAF exit under the section Boot Assist Flash (BAF) configuration.

- BAF interacts with various modules during its course of execution. BAF enables and disables the reset of values of registers for these modules. The reset values of some status registers which are not restored by BAF on exit are listed in the table below.

Table 3-7. Reset Values at Serial Boot

Sl. No.	Module Name	Register	BAF Exit Reset Value
1	MC_ME	MC_ME_RUN_PC_0	0xFE
2	MC_ME	MC_ME_DRUN	0x130072
3	MC_ME	MC_ME_GS	0x130072
4	MC_CGM	MC_CGM_SC_DC2	0x80010000
5	MC_CGM	MC_CGM_AC3_SC	0x0

Table continues on the next page...

Table 3-7. Reset Values at Serial Boot (continued)

Sl. No.	Module Name	Register	BAF Exit Reset Value
6	MC_CGM	MC_CGM_AC0_SC	0x02000000
7	MC_CGM	MC_CGM_AC0_DC4	0x80000000
8	MC_CGM	MC_CGM_AC8_SC	0x01000000
9	MC_CGM	MC_CGM_AC8_DC0	0x80000000
10	PLLDIG	PLLDIG_PLL0DV	0x00061021
11	FCCU	FCCU_RF_CFG_0	0xFFFFEFFF

Table 3-8. Reset Values at Flash Boot

Sl. No.	Module Name	Register	BAF Exit Reset Value
1	MC_ME	ME_IS	0x00000001
2	MC_ME	ME_DMTS	0x30000000
3	FCCU	FCCU_RF_CFG_0	0xFFFFEFFF

3.1.3.10 LVD /HVD self test decoding

- Entries updated under column 'LVD / HVD under test' in the table LVD /HVD self test decoding:

Table 3-9. LVD /HVD self test decoding

Current Name	New Name
POR098_C	LVD096_C
LVD114_C	LVD112_C
POR098_F	LVD096_F
LVD114_F	LVD108_F
LVD114_P	LVD108_P
LVD114_H	LVD108_C
LVD280_IF2	LVD270_IF2
LVD280_IE	LVD270_IE
LVD280_C	LVD270_C
LVD280_IF	LVD270_IF
LVD280_IM	LVD270_IM
LVD280_IJ	LVD270_IJ
LVD280_O	LVD270_O
LVD300_F	LVD295_F
LVD300_A	LVD295_A

3.1.3.11 FCCU chip-specific register reset values

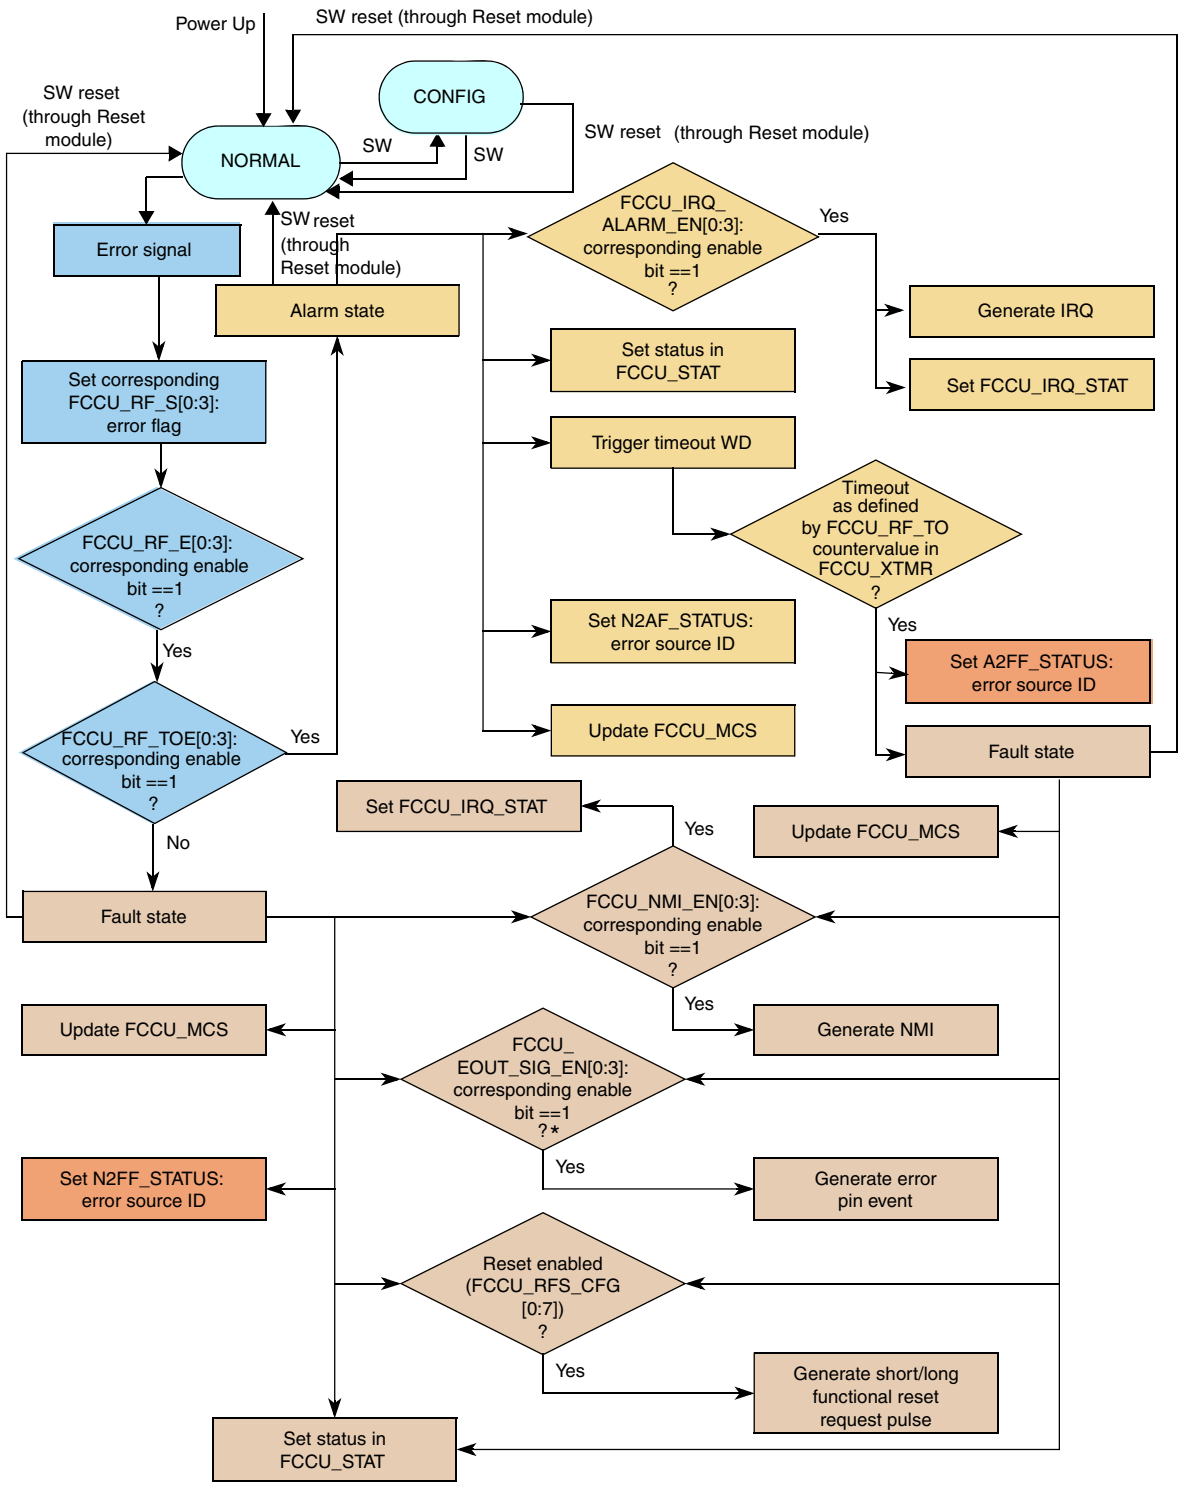
This table lists in alphabetical order by mnemonic the FCCU registers whose reset values are specific to this chip.

Table 3-10. Availability and reset values of selected FCCU registers

Register	Reset value
FCCU_CFG	0x0000_0000
FCCU_CFG_TO	0x0000_0006
FCCU_MCS	0x0000_0000
FCCU_RF_CFG0	0xFFFF_FFFF
FCCU_RF_CFG1	0xFFFF_FFFF
FCCU_RF_CFG2	0xFFFF_FFFF
FCCU_RF_CFG3	0xFFFF_FFFF
FCCU_RF_E0	0xFFFF_FFFF
FCCU_RF_E1	0xFFFF_FFFF
FCCU_RF_E2	0xFFFF_FFFF
FCCU_RF_E3	0xFFFF_FFFF
FCCU_RF_TO	0x0000_FFFF
FCCU_RF_TOE0	0xFFFF_FFFF
FCCU_RF_TOE1	0xFFFF_FFFF
FCCU_RF_TOE2	0xFFFF_FFFF
FCCU_RF_TOE3	0xFFFF_FFFF
FCCU_RFS_CFG0	0x0000_0000
FCCU_RFS_CFG1	0x0000_0000
FCCU_RFS_CFG2	0x0000_0000
FCCU_RFS_CFG3	0x0000_0000
FCCU_RFS_CFG4	0x0000_0000
FCCU_RFS_CFG5	0x0000_0000
FCCU_RFS_CFG6	0x0000_0000
FCCU_RFS_CFG7	0x0000_0000

3.1.3.12 Error signal flow

In the Figure 3-4, added a footnote 'This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM])'.



* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 3-4. Error signal flow

3.1.3.13 FCCU failure inputs

- Editorial updates in the footnotes of Table 7-86. FCCU failure inputs:
  - Added cross reference to Figure 26-1 and Figure 26-2 Clock generation in footnote number 12.
  - Removed the footnote number 14.
  - Changed 200z4 Core to z7 core in footnote number 18.
  - For Channel 31 updated the footnotes to Channel 31 [1,13].

3.1.4 DCI signals

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. The tables below summarize the source and destination of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the PD and the BD. For example, for the PD, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU and inputs to the cores, HSM, GTM, and NXMC.

Table 3-11. PD DCI signals

Signal	Cores	HSM	GTM	NXMC	NAR	JTAGM	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	I	I	—	O	I/O	—
$\overline{\text{EVTI}}$[1]	—	—	—	—	—	O	I/O	—
$\overline{\text{EVTO}}$[0]	O	O	O	O	—	I[1]	I/O	—
$\overline{\text{EVTO}}$[1]	—	—	—	—	—	I[1]	I/O	O
Core debug event	I	—	—	—	—	—	—	—
DCI cross triggering	O	—	O	—	—	—	—	—

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32MHz.

Table 3-12. BD DCI signals

Signal	RWA	NAR	NAL	JTAGM
$\overline{\text{EVTI}}$[0]	—	I	—	O
$\overline{\text{EVTI}}$[1]	—	—	—	O
$\overline{\text{EVTO}}$[0]	—	—	—	I[1]
$\overline{\text{EVTO}}$[1]	—	—	—	I[1]

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32MHz.

The DCI sends the system debug signal, ipg_debug, to the modules below. For details regarding module functionality during system debug, refer to the individual module chapter.

- AMU
- CAN
- LFAST (Interprocessor Communications instance only)
- DSPI
- eDMA
- FCCU
- GTMINT
- I2C
- NXMC
- PIT
- PSI5
- SARADC
- SDADC
- SRX
- SSCM
- STM
- SWT

3.1.4.1 DCI $\overline{\text{EVTx}}$ Pin Multiplexing Control Register (DCI_PINCR)

The DCI $\overline{\text{EVTx}}$ Pin Multiplexing Control Register (DCI_PINCR) is described below. The $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ functions share the same set of possible pins. If this register is written to enable both $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ on the same pin, the $\overline{\text{EVTI}}$ function is selected, although this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}$[0] or $\overline{\text{EVTI}}$[1] inputs to come from more than one pin is considered a programming error and no pin is enabled.

	31	30	29	28	27	26	25	24
R W	Reserved							EVTO0E

Table continues on the next page...

Reset	0	0	0	0	0	0	0	0
	23	22	21	20	19	18	17	16
R W	Reserved			EVTI1E	Reserved			EVTI0E

1 EVTI0B	Enables $\overline{\text{EVTI}}$[0] function on pin PF[15]
0 EVTI0A	Enables $\overline{\text{EVTI}}$[0] function on pin PF[14]

3.1.5 Core description

3.1.5.1 DMEM Control register 0

- The Reset value for DMEM Control Register 0 is updated to 0x0000_041C.

DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

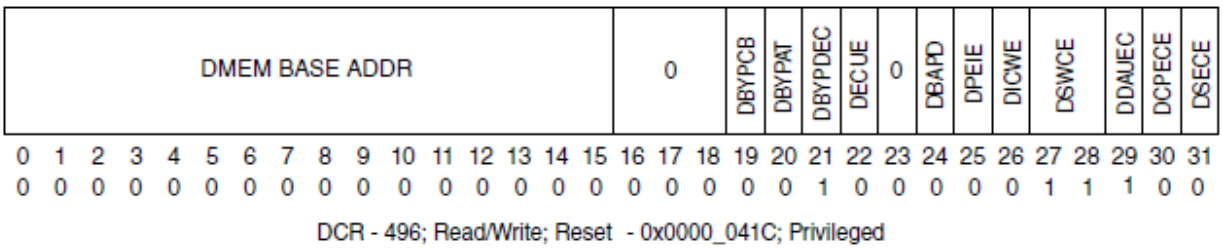

Figure 3-5. DMEM Control register 0 (DMEMCTL0)

- Updated the Note to 'This field is updated by an internal Power_On_Reset signal or an Internal Destructive Reset.' in the field description of DBYPCB, DBYPAT, DBYPDEC, DECUE, DSWCE, DDAUEC, DCPECE, and DSECE fields.

3.1.5.2 IMEM Control register 0

- The reset value of IMEM Control register 0 updated to 0x0000_0000.

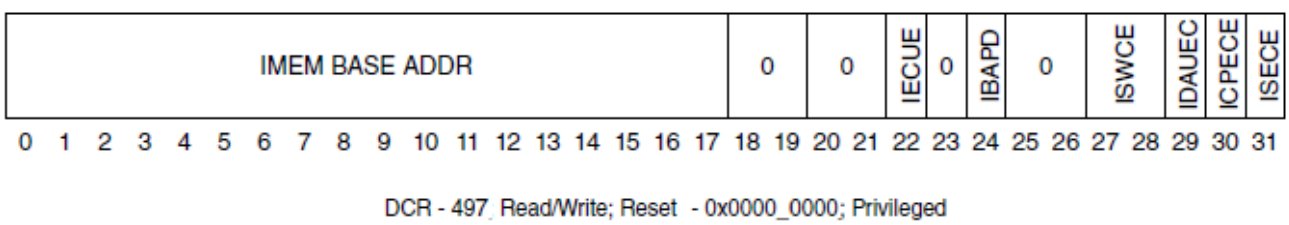

Figure 3-6. IMEM Control register 0

NOTE

This register is reset by an internal Power-On-Reset signal or by an internal destructive reset signal. It is unaffected by p_reset_b.

- Updated the field description of IECUE field.
  - This field is updated by an internal Power_On_Reset signal or an internal destructive reset.

- Updated the Note in the field description of ISWCE, IDAUEC, ICPECE, and ISECE fields.

- This field is updated by an internal Power_On_Reset signal or an internal destructive reset.

3.1.6 Core description

3.1.6.1 DMEM Control register 0

- The Reset value for DMEM Control Register 0 is updated to 0x0000_041C.

DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCPECE	DSECE
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0	0	0	1	0	0	0	0	1 1	1	0	0

DCR - 496; Read/Write; Reset - 0x0000_041C; Privileged

Figure 3-7. DMEM Control register 0 (DMEMCTL0)

- Updated the Note in the field description of fields DBYPCB, DBYPAT, DBYPDEC, DECUE, DSWCE, DDAUEC, DCPECE, and DSECE.
  - This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset.

3.1.6.2 IMEM Control register 0

- The reset value of IMEM Control register 0 updated to 0x0000_001B.

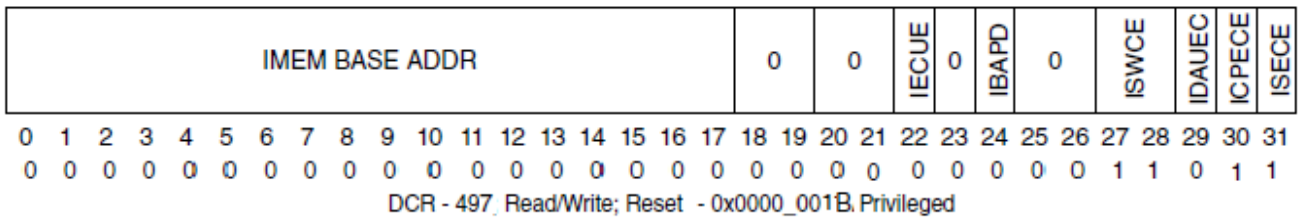

Figure 3-8. IMEM Control register 0

NOTE

This register is reset by an internal Power-On-Reset signal or by an internal destructive reset signal. It is unaffected by p_reset_b.

- Updated the field description of the IECUE field.
  - This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset.

- Updated the 'Note' in the field description of ISWCE, IDAUEC, ICPECE, and ISECE fields.
  - This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset.

3.1.7 XBAR Control register

- Changed the reset value of the XBAR Control register to 0x003F_0000 (previously it was 0x00FF_0000).

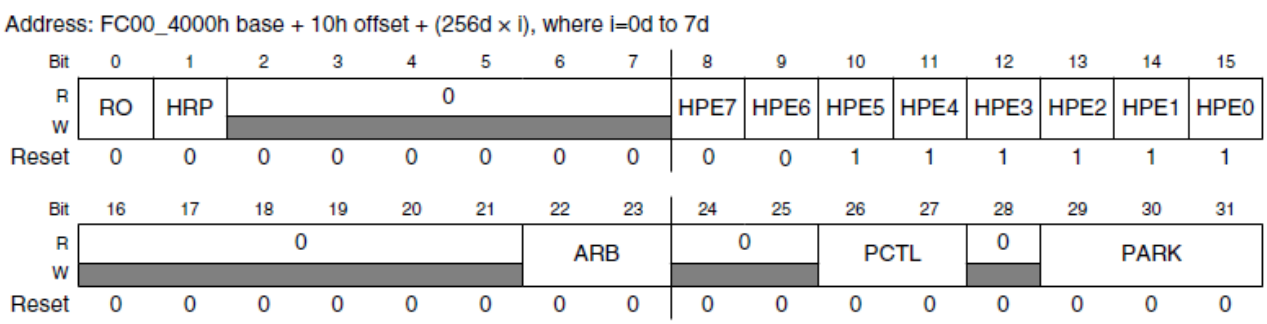

Figure 3-9. XBAR Control register

3.1.8 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRIN field in the INTC current priority register (INTC_CPRn). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPRn, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
     wrteei 0                # disable processor recognition of external
interrupts
     oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)
pop_lifo:
     store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI N, etc...
     examine INTC_CPRn[PRI N], and store onto stack
     if PRI N is not zero or value when interrupts were enabled, branch to pop_lifo
     branch to push_lifo
```

A side effect of examining LIFO contents is the clearing of a pending SWTN field without triggering the interrupt. To compensate for this issue, you must load the PSR again to restore the SWTN field.

The following describes the restoring of the LIFO and the SWTN field:

```
push_lifo:

load stacked INTC_PSRn[PRIN] value and store to INTC_CPRn

read INTC_IACKRn # Pushes INTC_CPRn to LIFO but also clears INTC_PSRn[SWTN]

load INTC_PSRn again to restore INTC_PSRn[SWTN]

if stacked INTC_PSRn[PRI] values are not depleted, branch to push_lifo
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

3.1.9 Memory map/register definition

In the memory map/register description added information about TCD.

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCDn definition is presented as 11 registers of 16 or 32 bits.

TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

DMA Basics: TCD Structure
- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

Word Offset	0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15	16 17 18 19	20 21 22 23	24 25 26 27	28 29 30 31
0x1000	SADDR

[1] The fields implemented in Word 2 depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

3.1.10 Clocking

3.1.10.1 System clock frequency limitations

- Updated the SAR_CLK to 14.6 MHz

Table 3-14. Maximum system level clock frequencies

Clock Selector	Nominal programmed Max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
Aux Clock 0 Selector	400	0	PER_CLK	80
		1	SD_CLK	16
		2	SAR_CLK	14.6

3.1.10.2 JTAG frequencies

- Updated the e200z7 max. internal JTAG frequency to 100 MHz for PD.

Table 3-15. JTAG frequencies

Device	Configuration	e200z7 max. internal JTAG frequency	Buddy device max. RWA internal frequency	Max. external JTAG frequency	Notes
PD	Unconfigured clock	—	N/A	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock on PD (IRC) with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 300 MHz	100 MHz			

3.1.10.3 System Clock ratio restrictions

The device supports the following clock ratios:

- COMP_CLK/CHKR_CLK : FXBAR_CLK - 1:1, 3:2
- FXBAR_CLK : SXBAR_CLK - 1:1, 2:1
- SXBAR_CLK : PBRIDGEA_CLK/PBRIDGEB_CLK - 1:1, 2:1
- SXBAR_CLK : HSM_CLK - 1:1, 2:1, 4:1
- FXBAR_CLK : CLKOUT - 1:1, 2:1, 3:1, 4:1, 5:1, 6:1, 7:1, 8:1

NOTE

When changing system clock ratios, the Divider Update Trigger (MC_CGM_DIV_UPD_TRIG) and System Clock Divider Ratio Change (SYS_DIV_RATIO_CHNG) must be used. This assures that the system is properly halted by hardware to allow the clocks to be correctly updated.

3.1.10.4 Clock distribution

- The figure Clock Distribution is updated. Changed the BIU Module Clock FlexRay (2) Protocol Clock connection from PBRIDGEx_CLK to SXBAR_CLK.

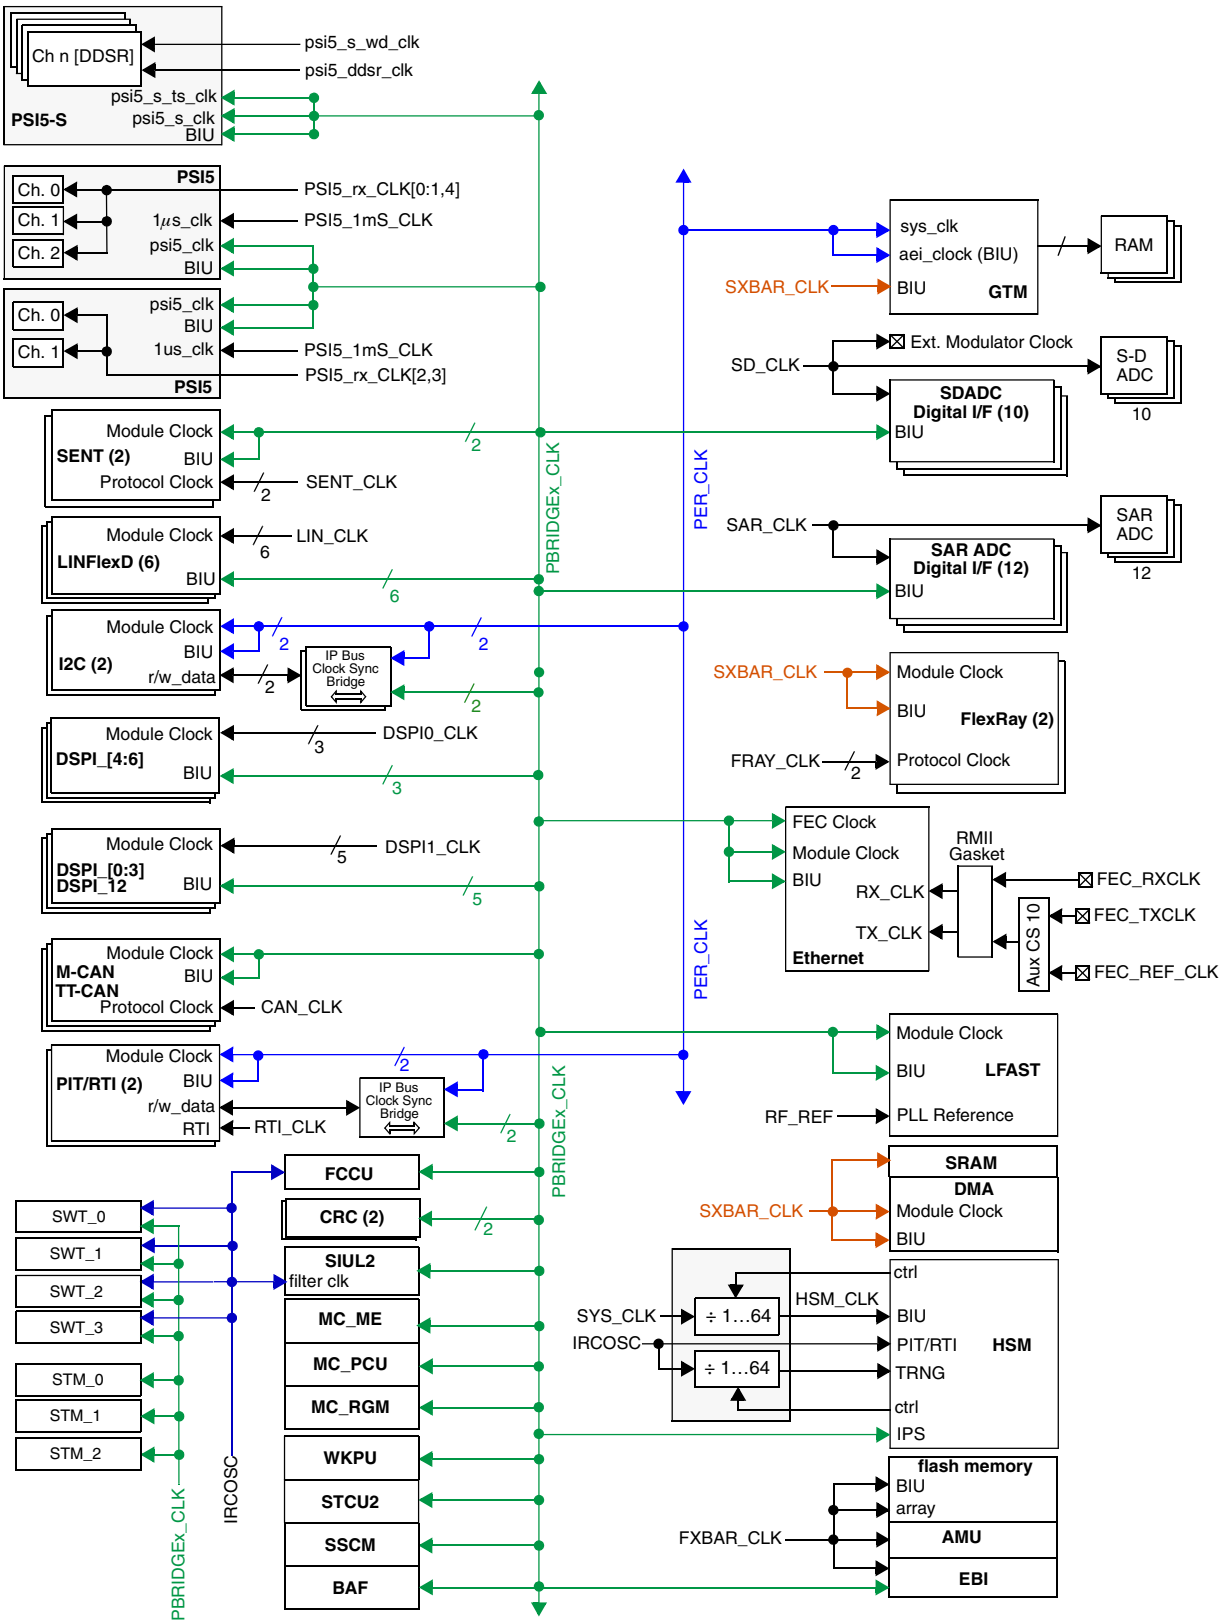

Figure 3-10. Clock distribution

3.1.10.5 M_TTCAN/M_CAN clocking

- Added a note in the section M_TTCAN/M_CAN clocking:
  - The CAN clock frequency needs to be 8 MHz minimum in order to wake up from STOP mode.

3.1.10.6 Progressive clock switching

- Added guideline for PCS register configuration:
  - It is recommended to program the PCS configuration registers (i.e. MC_CGM_PCS_SDUR, MC_CGM_PCS_DIVCn, MC_CGM_PCS_DIVEn and MC_CGM_DIVSn) with IRC selected as the system clock. This insures that during the PCS register programming if a SAFE mode or RESET event happens then there is reliable progressive clock operation.

3.1.11 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0\_phi} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

Equation 1. PLL0 PHI Output Frequency

$$f_{pll0\_phi1} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Equation 2. PLL0 PHI1 Output Frequency

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 3. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD]}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 4. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

The relationship between the VCO frequency (fVCO) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0\_VCO} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}\right)$$

Equation 5. PLL0 VCO Frequency

$$f_{pll1\_VCO} = f_{pll1\_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}\right)$$

Equation 6. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1\_VCO} = f_{pll1\_ref} \times PLL1DV[MFD]$$

Equation 7. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

NOTE

f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of the analog PLL blocks to go below the prescribed ranges.

The lock signal and PLLnSR[LOCK] flag are immediately negated if the fields of the PLLnDV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLLnSR[LOCK] flag is held negated. After the timer expires, the PLLnSR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLLnCR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

NOTE

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_mode_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

3.1.12 Generic clock change properties

Updated the equation in the Generic clock change properties section.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(f_{src}/(16MHz/1000)\right)}{d}} \right\rceil$$

Equation 1. Equation for k

3.1.13 IRCOSC Control register

- Updated the reset value of IRCOSC Control register from 0x0100_0000 to 0x0000_0000.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							Reserved	0			USER_TRIM				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0			Reserved					0		Reserved	0				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 3-11. IRCOSC Control register

3.1.14 Embedded Flash Memory (c55fmc)

3.1.14.1 Program suspend/resume

- Updated the existing note:

NOTE

Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 20 µs between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

3.1.14.2 Array integrity self check

- Added a new paragraph to the section - 'Array integrity processing requires the flash memory controller's PFLASH_PFCR1[RWSC] and PFLASH_PFCR1[APC] register fields to be set to values that are valid for the system frequency being used. Only the valid/recommended RWSC and APC values for a given frequency, as stated in the device data sheet, are supported.'

3.1.14.3 C55FMC Memory map and register definition

- Reset value of the Alternate Module Configuration Register was changed to 0000_0600h, and the footnote was removed from the register description and diagram.

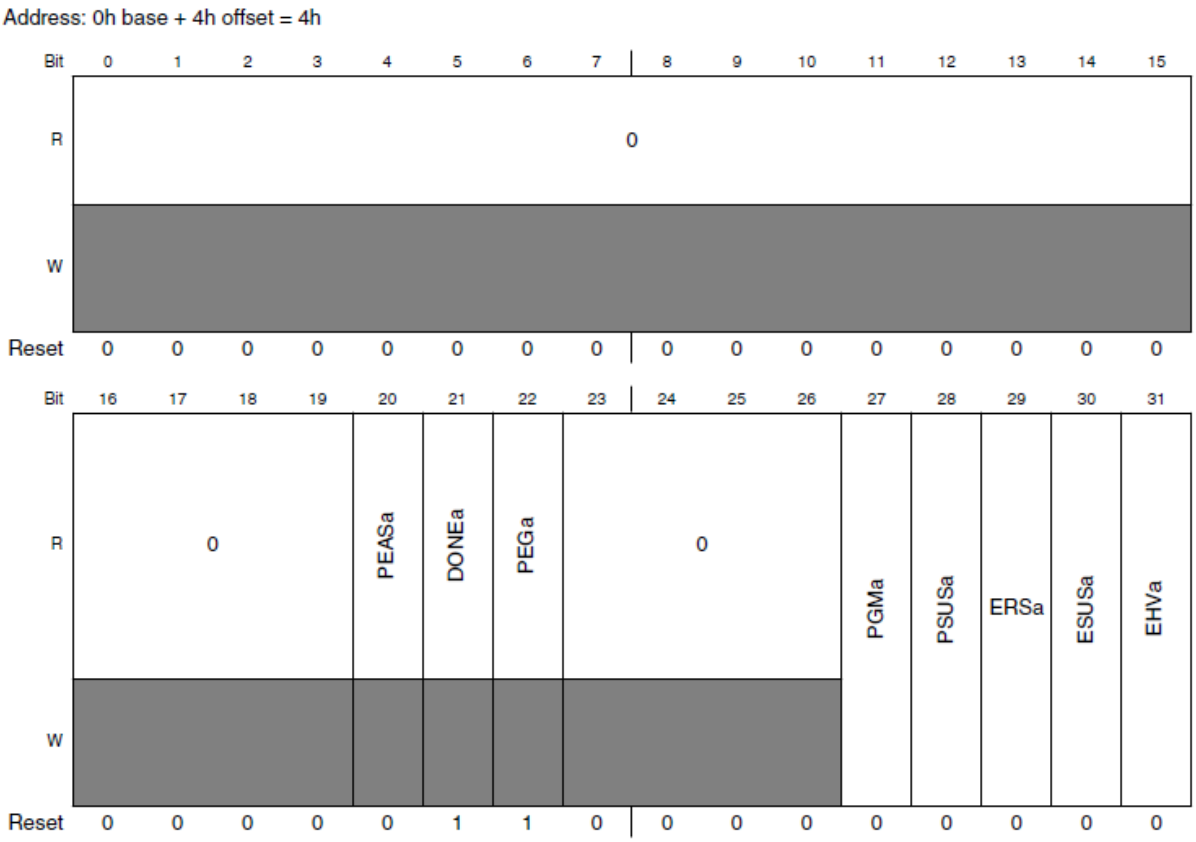

Figure 3-12. Alternate Module Configuration register

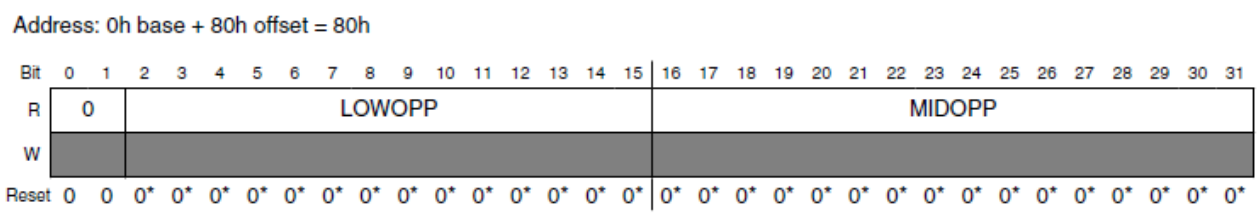
- In the Over-Program-Protection 0 register, replaced the footnote in the register diagram with footnotes stating that the reset value of each field (LOWOPP and MIDOPP) varies among devices..



* Notes:

- MIDOPP field: The reset value of the MIDOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.
- LOWOPP field: The reset value of the LOWOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Figure 3-13. Over-Program Protection 0 register

- In the Over-Program-Protection 1 register, replaced the footnote in the register diagram with a footnote stating that the reset value of the HIGHOPP field varies among devices.

Address: 0h base + 84h offset = 84h

Bit	0–15	16–31
R	0	HIGHOPP
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0*

* Notes:
- HIGHOPP field: The reset value of the HIGHOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Figure 3-14. Over-Program Protection 1 register

- In the Over-Program-Protection 2 register, replaced the footnote in the register diagram with a footnote stating that the reset value of the A256OPP field varies among devices.

Address: 0h base + 88h offset = 88h

Bit	0–15	16–31
R	A256KOPP	
W		
Reset	0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0*	0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0*

* Notes:
- A256KOPP field: The reset value of the A256KOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Figure 3-15. Over-Program Protection 2 register

- In the Over-Program-Protection 3 register, replaced the footnote in the register diagram with a footnote stating that the reset value of the A256KOPP field varies among devices.

Address: 0h base + 8Ch offset = 8Ch

Bit	0–15	16–31
R	0	A256KOPP
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0* 0*

* Notes:
- A256KOPP field: The reset value of the A256KOPP field is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Figure 3-16. Over-Program Protection 3 register

3.1.15 External Bus Interface

- Removed the references to EBI_MCR[SIZE] from the following tables:

Table 3-16. Write/Byte Enable Signals Function

Transfer Size	Address		32-Bit Port Size				16-Bit Port Size[1]			
	A30	A31	WE0/BE0	WE1/BE1	WE2 /BE2	WE3 /BE3	WE0 /BE0	WE1/BE 1	WE2 /BE2	WE3 /BE3
Byte	0	0	X				X			
	0	1		X				X		
	1	0			X		X			
	1	1				X		X		
16-bit	0	0	X	X			X	X		
	1	0			X	X	X	X		
32-bit	0	0	X	X	X	X	X[-1]	X[-1]		
Burst	0	0	X	X	X	X	X	X		

1. Also applies when DBM=1 for 16-bit data bus mode.

Table 3-17. Data Bus Requirements for Read Cycles

Transfer Size	Address		32-Bit Port Size				16-Bit Port Size[1]	
	A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7[2]	D8:D15[3]
Byte	0	0	OP0	-	-	-	OP0	-
	0	1	-	OP1	-	-	-	OP1
	1	0	-	-	OP2	-	OP2	-
	1	1	-	-	-	OP3	-	OP3
16-bit	0	0	OP0	OP1	-	-	OP0	OP1
	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	0	0	OP0	OP1	OP2	OP3	OP0/OP2[4]	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].
4. This case consists of two 16-bit external transactions, the first writing OP0 and OP1, and the second writing OP2 and OP3.

Table 3-18. Data Bus Contents for Write Cycles

Transfer Size	Address		32-Bit Port Size				16-Bit Port Size[1]	
	A30	A31	D0:D7	D8:D15	D16:D23	D24:D31	D0:D7[2]	D8:D15[3]
Byte	0	0	OP0	-	-	-	OP0	-
	0	1	-	OP1	-	-	-	OP1
	1	0	-	-	OP2	-	OP2	-
	1	1	-	-	-	OP3	-	OP3
16-bit	0	0	OP0	OP1	-	-	OP0	OP1
	1	0	-	-	OP2	OP3	OP2	OP3
32-bit	0	0	OP0	OP1	OP2	OP3	OP0/OP2[4]	OP1/OP3

1. Also applies when DBM=1 for 16-bit data bus mode.
2. For address/data muxed transfers, DATA[16:23] are used externally, not DATA[0:7].
3. For address/data muxed transfers, DATA[24:31] are used externally, not DATA[8:15].

4. This case consists of two 16-bit external transactions, the first writing OP0 and OP1, and the second writing OP2 and OP3.

3.1.16 Analog-to-Digital Converters (ADC) configuration

3.1.16.1 SAR ADC integration diagram

- Updated the figure SAR ADC integration diagram.

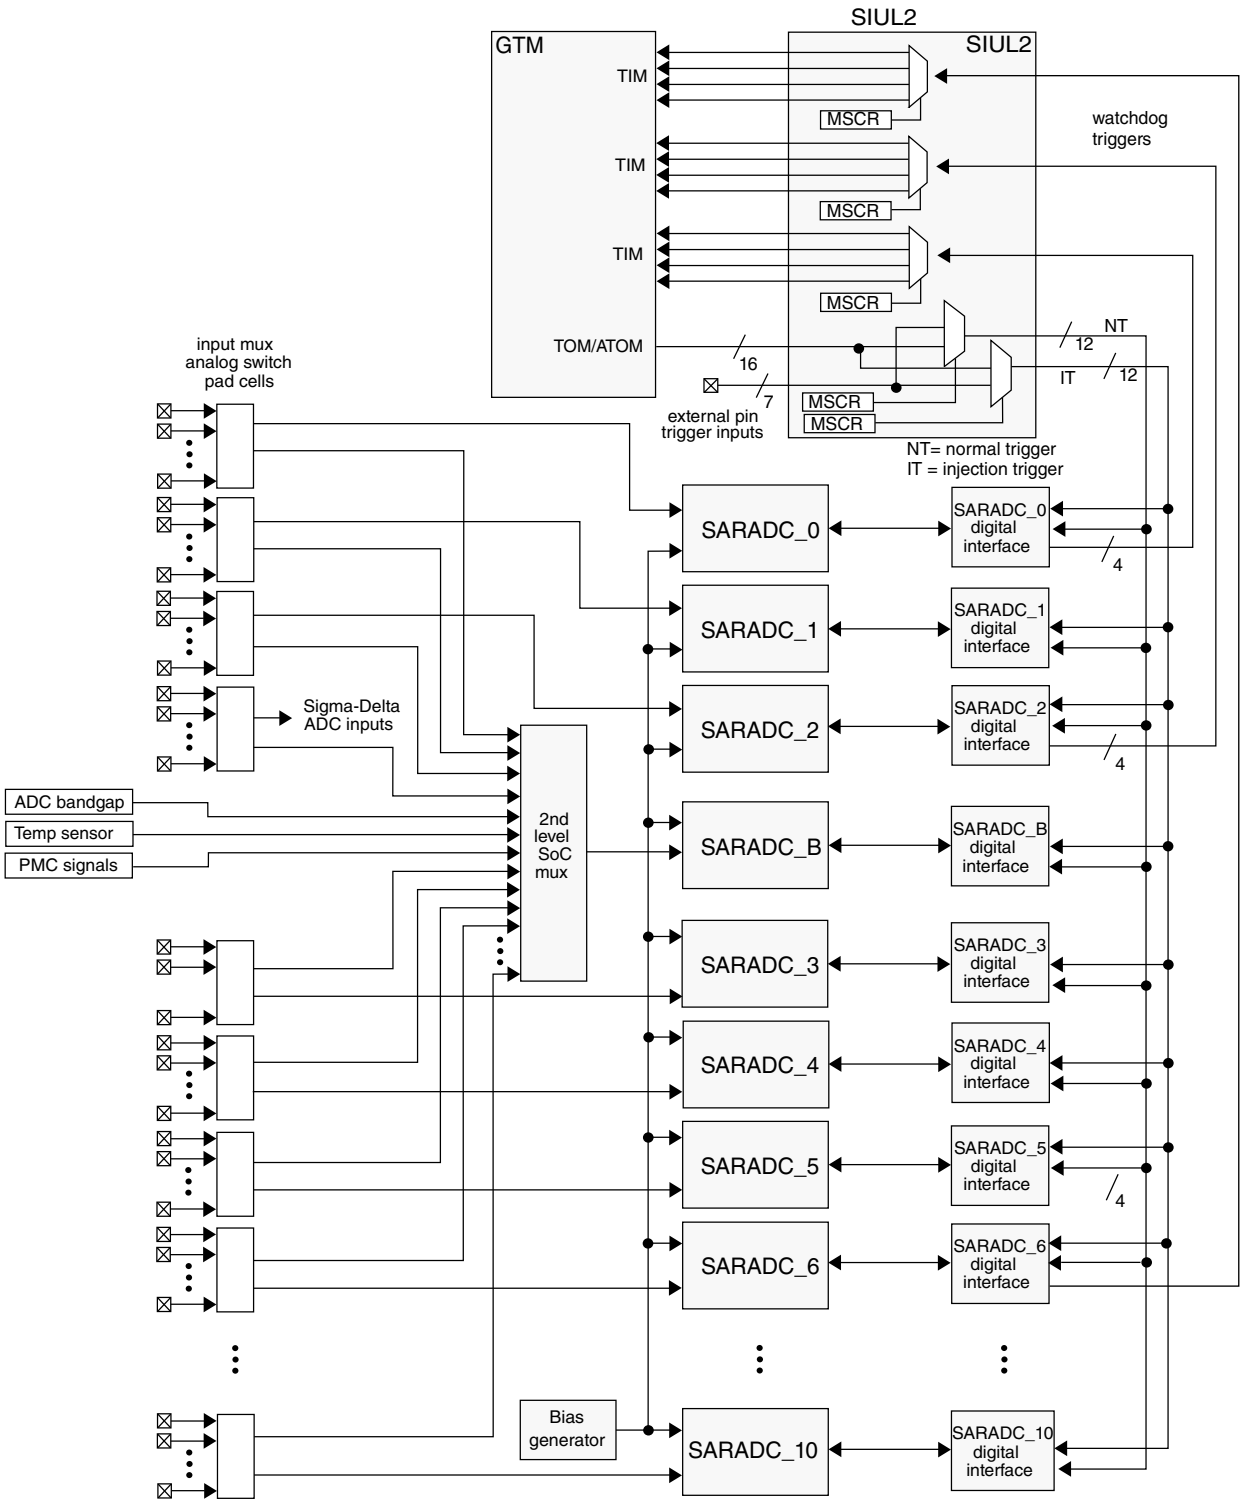


Figure 3-17. SAR ADC integration diagram

3.1.16.2 Self Test features

- The sampling time of SARADC_B was changed from 2.2 ms to 2.5 µs.
  - Extended the sampling time of SARADC_B to 2.5 µs due to long settling time induced by the high impedance of the source (20 kΩ).

3.1.16.3 SARADC register description

- Changed the field name from SARADCx_ICWSELR7 to the following:
  - SARADC8_ICWSELR8
  - SARADC9_ICWSELR9
  - SARADC10_ICWSELR10

3.1.17 FIFO Control register

- Added FRST and FOWEN fields at 15 and 28 bit field in FIFO Control Register.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															0
W																FRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				FTHLD				0				FOWEN	FSIZE		FE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Field	Description
FRST	FIFO Flush Reset This is functional soft reset to flush the current FIFO content and initialize the internal FIFO pointers. This is W1S(write one shot) bit which can be written as '1' but always read as '0'. Use this option only after disabling the ADC i.e. MCR[EN]='0'.

Table continues on the next page...

Field	Description
	0 No effect. 1 Generate a single cycle reset event to flush the FIFO.
FOWEN	FIFO Over Write Enable When set the built-in FIFO structure allows the overwritting of new converted data over older converted data after the FIFO has number of entries equal to the FSIZE. In this case overrun will not be seen. 0 Data FIFO OW option disabled. 1 Data FIFO OW option enabled.

3.1.18 Test Channel Data register

- Added a note 'This register should be accessed 32-bit R/W', in the description of the Test Channel Data register (SARADC_TCDRn).

3.1.19 CAN subsytem

3.1.19.1 CAN Subsystem

- CAN FD support is removed throughout the document. See attached *CAN Subsystem* pdf for details.

3.1.19.2 M_CAN_RXF0C[F0S]

- The width of field M_CAN_RXF0C[F0S] is increased to 7. This field now ranges from bit 9 to bit 15.

3.1.19.3 DRXE

- Added bit field values in the DRXE field.

DRXE	Message stored to Dedicated Rx Buffer Interrupt Enable

	0 Interrupt disabled 1 Interrupt enabled

3.1.20 CTS mode support

The LFAST module supports flow control methods. CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by the proper programming of Rx FIFO Lower threshold (RFCR[RCTSMN]) and Higher threshold (RFCR[RCTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by writing MCR[CTSEN] = 1, then:

- Send the CTS bit as 0 in the LFAST frame (bit[0] of the Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield RFCR[RCTSMX]. This indicates that the LFAST device does not want the peer device to send data. The CTS bit of all frames are sent 0 until the Rx FIFO pointer reaches the lower threshold, as described below.
- Send the CTS bit as 1 in the LFAST frame (bit[0] of the Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield RFCR[RCTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frames are sent 1 until the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in the LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of the Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frames sent will have the CTS bit as 1 in the LFAST frame (bit[0] of the Header field)RCTSMN.

3.1.21 LINFlexD

- In the LIN Status Register, the bit field value description of the LIN field for 0001 Init mode changed to 'LINFlexD is in Initialization mode'.
- In the LIN Control Register2 IOPE field description, changed the 'If generic slave...' sentence to 'If generic slave = 0, then this bit will always read a 0, and cannot be programmed'.

3.1.22 Reset Event Select register

- Updated the register description by adding the sentence, 'When the Temperature Sensor is set to cause Functional Resets, the device will not exit from reset until the temperature has returned to a level that is not detected as an event. Destructive resets from the Temperature Sensor are not affected in the end.

3.1.23 Module Configuration register

- The TCK divide values for TCKSEL field were updated to:
  - 000 TCK is system clock /2
  - 001 TCK is system clock /4
  - 010 TCK is system clock /6
  - 011 TCK is system clock /8
  - 100 TCK is system clock /10
  - 101 TCK is system clock /12
  - 110 TCK is system clock /14
  - 111 TCK is system clock /16

3.1.24 LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed debug

3.1.24.1 LVLPEN

- Updated the field description of the LVLPEN field in the LFAST LVDS Control register by adding the following sentence:
  - The internal loopback feature is not intended for board level functionality, so this feature should not be implemented.

3.1.24.2 Digrf changed to LFAST

- All the instances of digrf in the Reference Manual and Emulation and Debug Device Reference Manual have been changed to LFAST.
  - pp_digrf_lvds_lpbk_en changed to pp_lfast_lvds_lpbk_en.
  - digrf_sysclk_en and digrf_sysclk changed to lfast_sysclk_en and lfast_sysclk in Figure 76-1 LFAST block diagram and Figure 76-2 LFAST block diagram.

3.1.25 Self-Test Control Unit (STCU2)

3.1.25.1 STCU2

NXP has validated and therefore supports only particular STCU2 built-in self-test (BIST) sequences for this chip. For descriptions of the supported BIST sequences for this chip, see the application note titled *Using the Built-in Self-Test (BIST) on the MPC5777M* (document AN5131).

3.1.25.2 Register write-access watchdog timer

As explained in the STCU2_SKC register description:

- A key mechanism protects STCU2 registers during the self-test configuration phase (both online/offline) by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2_SKC.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

Note: For write completion, each DCF record requires a number of STCU2 clock cycles equal to DCF_COMPLETION. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK_VALUE divided by DCF_COMPLETION. See the chip-specific STCU2 information for the value of DCF_COMPLETION.

The hardware watchdog timer is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

3.1.25.3 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion

Register write-access watchdog timer refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

Clock-cycle value	Number of STCU2 clock cycles
AUTOLOCK_VALUE	1024
DCF_COMPLETION	16

3.1.26 FCCU

- Removed the following note from the FCCU_RFS_CFGn and FCCU_NMI_ENn registers:
  - Do not configure the same channel for both a RESET reaction in the FCCU_NCFS_CFGn register and an NMI reaction in the FCCU_NMI_ENn register at the same time.

Chapter 4
RM Addendum Rev 4.1

4.1 Overview

The updates for MPC5777M RM Rev 4 is described in detail below.

4.2 UTest flash memory map

In the UTest flash memory map starting at address 0x00400308, the updated “Reserved” row at starting address 0x00400308 now looks like this:

Start address	End address	Allocated size [bytes]	Description	Comments
0x00400308	0x00400347	64	Reserved	Space for 8 DCF records used to load the HSM 'ROM' keys. **Note:** When device is in CUST_DEL (or later) life cycle and prefetching is enabled in the platform flash controller (PFLASH_C55FM), it reads the Reserved locations (0x0400308-0x0400347) and returns dummy DCF records. However, accesses to these locations may result in anomalous operation. Reading the Reserved locations can result in a false ECC event, specifically either a false single-bit correction or a false multi-bit error detection. Reading the Reserved locations can also interfere with an unrelated, but coincident, loading of the PFLASH_C55FM prefetch buffers. As a result, a subsequent request to flash may result in a false ECC event, specifically either a false single-bit correction or a false multi-bit error detection. **Note:** Program MPU to prevent accesses to 0x0400308 - 0x0400347. Avoid accessing the Reserved locations in the flash UTEST region (0x0400308 - 0x0400347). Prior to making access to this region, disable flash buffer prefetches.

Preface

1.1 Overview

The primary objective of this document is to define the functionality of the MPC5777M microcontroller for use by software and hardware developers. The MPC5777M is built on Power Architecture ® technology and integrates technologies that are important for today's and tomorrow's automotive applications. MPC5777M applications include automotive powertrain controller and chassis control for eight cylinder gasoline and diesel engines, transmission control, steering and braking, as well as high end hybrid, electric power steering, chassis, and safety applications that require a high safety integrity level.

The information in this book is subject to change without notice, as described in the disclaimers on the title page. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the Freescale/ Web site at "http://www.freescale.com".

1.2 Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the MPC5777M device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

1.3 Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or device-specific information
- Part II includes chapters that describe the functionality of the individual modules on the device
- Part III includes chapters that describe the functionality of the emulation device.

1.4 Register conventions

The following figure and table provide the register conventions used throughout this manual.

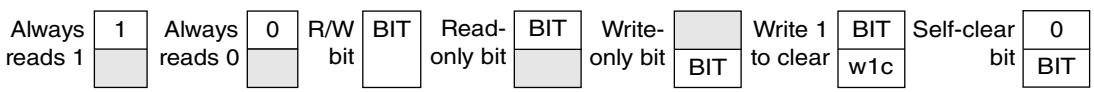

Figure 1-1. Key to register fields

Table 1-1. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset values	
0	Resets to zero
1	Resets to one
—	Undefined at reset
u	Unaffected by reset
[signal_name]	Reset value is determined by polarity of indicated signal.

1.5 Acronyms and abbreviations

The following table lists some acronyms and abbreviations used in this document.

Table 1-2. Acronyms and abbreviations

Term	Meaning
ATX	Analog Test Module
AUTOSAR®	Automotive Open System Architecture
BAF	Boot Assist Flash
CAN	Controller Area Network
CGM	Clock Generation Module
CMU	Clock Monitoring Unit
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAMUX	Direct Memory Access Controller Multiplexer
DSPI	Deserial Serial Peripheral interface
DTS	Development Tool Semaphore
FCCU	Fault Collection and Control Unit
FEC	Fast Ethernet controller
FLEXRAY	Automotive network communications protocol
GPIO	General-purpose I/O
GTM	Generic Timer module
IEEE	Institute for Electrical and Electronics Engineers
IIC	Inter-Integrated Circuit (I^2C)
IMA	Indirect Memory Access
INTC	Interrupt Controller
JDC	JTAG Data Communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
LFAST	LVDS Fast Asynchronous Serial Transmission
LINFlexD	Local Interconnect Network controller
ME	Mode Entry Module (MC_ME)
MEMU	Memory Error Management Unit
Mux	Multiplex
OSC	Oscillator
PASS	Password and Device Security Module
PCM	Platform Configuration Module
PCU	Power Control Unit
PFLASH	Flash controller
PIT	Periodic Interrupt Timer
PMC	Power Management Controller
PRAM	RAM controller
PSI5	Peripheral Sensor Interface
RCOSC	RC Oscillator
RGM	Reset Generation Module

Table continues on the next page...

Table 1-2. Acronyms and abbreviations (continued)

Term	Meaning
RTL	Register transfer language
Rx	Receive
SD ADC	Sigma Delta Analog to Digital Converter
SAG	Safety Application Guide
SAR ADC	Successive Approximation Register Analog to Digital Converter
SEMA4	Semaphore
SENT	Single Edge Nibble Transmission
SIPI	System Interprocessor Interface
SIUL	System Integration Unit Lite
SMPU	System Memory Protection Unit
SoC	System on Chip
SSCM	System Status and Configuration Module
STCU	Self Test Control Unit
STM	System Timer module
SWT	Software Watchdog Timer
TBD	To be defined
TSENS	Temperature Sensor
TTCAN	Time Triggered CAN
Tx	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable Fault
WKPU	Wakeup Unit
XBAR	Crossbar

1.6 Reference documents

In addition to this reference manual, the following documents provide additional information on the operation of the MPC5777M:

- IEEE-ISTO 5001-2003 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture
- Power Architecture Book E V1.0 (http://www.freescale.com/files/32bit/doc/user_guide/BOOK_EUM.pdf)

Chapter 2
Introduction

2.1 MPC5777M microcontroller

The MPC5777M microcontroller is a member of a family of devices superseding the MPC5600 family. The MPC5777M builds on the legacy of the MPC5600 family, while introducing new features coupled with higher throughput to provide a substantial reduction in cost per feature as well as significant improvements in power and performance (MIPS per mW). There are five processor cores on the MPC5777M device.

Table 2-1. Processor cores

Computational Shell		
Core0	Main Core_0	e200z710
Core1	Main Core_1	e200z710
Checker Core0	Checker Core_0s	e200z709
I/O Processor		
Core2	Peripheral Core_2	e200z425
Hardware Security Module		
e200z0h Core		

2.1.1 Target applications

This device is targeted at automotive powertrain controller and chassis control applications for gasoline and diesel engines, transmission control, steering and braking applications, as well as high-end hybrid and advanced combustion systems.

Many of these applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-D compliance. For this reason safety measures have been added that are further described in Functional Safety chapter as well as the *Safety Manual*.

2.1.2 Overall architecture

The architecture is split into two distinct regions, as shown in Figure 2-1 : the computational shell and the I/O subsystem. The computational shell consists of three CPUs (two in lock-step for safety), fast local memories inside the CPUs, and fast system memory. All components of the computational shell are connected through a fast crossbar switch (XBAR_0).

The I/O subsystems consists of an I/O processor (IOP), DMA, Hardware Security Module (HSM), and all the other peripherals connected through a slow crossbar switch (XBAR_1).

The computational shell is optimized for performance and the I/O subsystem is optimized for low power.

The two crossbars (XBAR_0 and XBAR_1) are connected by a pair of cross-connected master - slave ports. The result of this is that all crossbar masters on both crossbars, can directly access all crossbar slaves on both crossbars. From a software perspective, every bus masters (all CPUs, DMA, SIPI, Ethernet, FlexRay, HSM) sees every memory and peripheral (all RAMs, flash, and peripherals) in a consistent flat memory map.

2.1.3 Core features

The MPC5777M includes four user programmable CPU cores and one safety core. The main computational shell consists of dual e200z7 CPUs operating at up to 300 MHz with a third, identical CPU running as a safety checker core in delayed lockstep mode with one of the dual z7 cores. The I/O subsystem includes a CPU targeted at managing the peripherals. The I/O subsystem core is an e200z4 CPU running at up to 200 MHz and including enhancements to implement Digital Signal Processing (DSP) algorithms. The fifth programmable CPU is an e200z0 running at up to 100 MHz and embedded in the HSM. All CPUs are compatible with the Power Architecture® VLE instruction set, which supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.1.4 I/O Processor

The I/O Processor (IOP), also referred to as Peripheral Core_2, is one of five processor cores on the MPC5777M device as shown in Figure 2-1. In general, the intended use of the IOP is to initially configure the machine and then control various peripheral elements of the device. However, the IOP is not limited to any particular duty.

The data bus structure of the IOP, that consists of a 32-bit address bus and a 32-bit data bus, is connected to the slow crossbar switch, which operates at 100 MHz. The instruction bus structure of the IOP, which consists of a 32-bit address bus and a 32-bit data bus, is connected to the fast crossbar switch, which operates at 200 MHz. The address bus structure and the data bus structure of Main Core_0 and Main Core_1 are also connected to the fast crossbar switch. The data bus structure of the IOP is connected to the slow crossbar switch, which operates at 100 MHz. Thus, data fetches run at only one-half the speed of instruction fetches.

It is possible to fetch data from memory elements connected to the fast crossbar switch and it is also possible to fetch instructions from memory elements connected to the slow crossbar switch. In both cases, the instruction and data paths would have to go through both the slow and fast crossbar switches and would be relatively slow. When the IOP first starts, it will start executing from memory elements on the fast crossbar switch. However, good programming techniques will cause the IOP to fill its internal instruction cache so that accesses through the fast crossbar switch occur less often.

The I/O Processor is automatically started during the boot-up sequence after the release of reset. This process is fully described in Reset and Boot chapter. During the boot sequence the System Status and Configuration Module (SSCM) reads and interprets a set of device configuration records located in the TEST flash area. One of these records is the start address of the code where the IOP will begin program execution. This vector will always point to a location in the Boot Assist Flash (BAF). Once the SSCM finds and interprets this particular device configuration record, it will write the start address for the IOP to the appropriate location in the Mode Entry Module (MC_ME). When the internal reset signal is released, the MC_ME transfers the IOP start address to the IOP and code execution begins at that address.

The code for the Boot Assist Flash, the TEST Device Configuration records and some of the UTEST Device Configuration records are written by the device manufacturer and are programmed into the device during production testing. All MPC5777M devices are shipped with startup code programmed into the BAF. Also, the MPC5777M is configured such that code execution by the IOP must begin with a start address located in the BAF.

If there is no user application code for the IOP to execute, the IOP, executing pre-programmed code in the BAF, will attempt to download user application code through the LINFlexD port using a specific data transfer protocol. Serial download can also be initiated from the CAN. This downloaded code is installed into program memory and code execution will begin at the start address embedded in the downloaded code.

As previously stated, the IOP's data bus structure is connected to the slow crossbar switch, which provides access to many of the peripheral devices on the device. The instruction bus of the IOP is connected to the fast crossbar switch, which gives the IOP access to the BAF, as well as all of the other memory elements. When the IOP begins

code execution, a considerable amount of traffic through the fast crossbar switch will be required. The IOP has both internal instruction cache and internal data cache. Once the IOP gets started and the internal instruction cache begins to fill, significantly less traffic will be required by the IOP through the fast crossbar switch. Accesses to the peripheral elements on the slow crossbar switch is transparent to activity occurring on the fast crossbar switch.

The IOP is placed in the MPC5777M architecture in such a way that enables it to access many of the peripheral elements without affecting the processing speed of Main Core_0 and Main Core_1. On the MPC5777M device, there are several analog-to-digital channels taking data that must be analyzed for various spectral components.

The IOP has an integrated DSP processor that has special hardware to execute multiply and accumulate operations. Because the DSP unit functions as a coprocessor integrated into the e200z425 core, data fetched by the z425 core can be evaluated with much greater speed than if the data had to reside in a memory element outside the z425 core.

One intended purpose for the IOP is to manage a system of analog-to-digital converters and fetch the digital data that is generated. The integrated DSP unit uses a signal processing algorithm to digest the incoming data. The results of this signal processing algorithm are used in other engine control algorithms. Using the IOP to manage the analog-to-digital converters and do the initial signal processing of the data allows Main Core_0 and Main Core_1 to focus on other compute intensive applications instead of managing relatively slow peripheral elements.

Once the IOP has performed its initialization duties (as determined by pre-loaded instruction code in the BAF) and downloaded any needed applications code, the IOP can essentially be programmed to perform any duty or access any memory element. When executing instructions from its internal instruction cache and fetching data from peripherals connected to the slow crossbar switch, the IOP operates autonomously from Main Core_0 and Main Core_1.

2.1.5 Memory hierarchy

The MPC5777M computational shell has three levels of memory hierarchy. At the top level is a 16 KB instruction cache and a 4 KB data cache; 16 KB local instruction RAM; 64 KB local data RAM. The local RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time. The second level of memory is system RAM and flash memory. These are connected by a 200 MHz, 64-bit wide crossbar. The third level of memory system is the I/O subsystem. All of the I/O peripherals are connected together

by a 100 MHz, 64-bit wide crossbar switch, while peripherals are connected at either 100 or 50 MHz, depending on their need. The reduced speed for the peripherals helps to reduce power.

2.2 Features summary

On-chip modules within MPC5777M include the following features:

- Three main CPUs, dual issue, 32-bit CPU core complexes (e200z7), one of which is a dedicated lockstep core.
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - 16 KB Local instruction RAM and 64 KB local data RAM
  - 16 KB I-Cache and 4 KB D-Cache
- I/O Processor, dual issue, 32-bit CPU core complexes (e200z4), with
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - Lightweight Signal Processing Auxiliary Processing Unit (LSP APU) instruction support for digital signal processing (DSP)
  - 16 KB Local instruction RAM and 64 KB local data RAM
  - 8 KB I-Cache
- 8640 KB on-chip flash
  - Supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
- 404 KB on-chip general-purpose SRAM including 64 KB standby RAM (+ 192 KB data RAM included in the CPUs). Of this 404 KB, 64 KB can be powered by a separate supply so the contents of this portion can be preserved when the main MCU is powered down.

- Multichannel direct memory access controllers (eDMA): 2 x 64 channels per eDMA (128 channels total)
- Triple Interrupt controller (INTC)
- Dual phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual crossbar switch architecture for concurrent access to peripherals, flash, or RAM from multiple bus masters with end-to-end ECC
- Hardware Security Module (HSM) to provide robust integrity checking of flash memory
- System Integration Unit Lite (SIUL)
- Boot Assist Module (BAM) supports factory programming using serial bootload through 'UART Serial Boot Mode Protocol'. Physical interface (PHY) can be:
  - UART/LIN
  - CAN
  - FlexRay
- GTM104 — generic timer module
- Enhanced analog-to-digital converter system with
  - Twelve separate 12-bit SAR analog converters
  - Ten separate 16-bit Sigma-Delta analog converters
- Eight deserial serial peripheral interface (DSPI) modules
- Two Peripheral Sensor Interface (PSI5) controllers
- Three LIN and three UART communication interface (LINFlexD) modules (6 total)
  - LINFlexD_0 is a Master/Slave
  - LINFlexD_1, LINFlexD_2, LINFlexD_14, LINFlexD_15, and LINFlexD_16 are Masters
- Four modular controller area network (MCAN) modules and one time-triggered controller area network (M-TTCAN)
- External Bus Interface (EBI)
  - Dual routing of accesses to EBI

- Access path determined by access address
- Access path downstream of PFLASH controller
  - Allows EBI accesses to share buffer and prefetch capabilities of internal flash
  - Allows internal flash accesses to be remapped to memories connected to EBI
- Access path via dedicated AXBS slave port
  - Avoids contention with other memory accesses

- Two Dual-channel FlexRay controllers
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Self-test capability

2.3 Feature list

The following table lists a summary of major features for the MPC5777M device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on-chip module is given later in this document.

Table 2-2. Features List

Feature	Description
MPC5700 family	55 nm process
Main Cores	
Main Core	e200z7
Number of Main Cores	2
Number of checker cores	1
Local RAM (per main core)	16 KB Instruction 64 KB Data
Single Precision Floating Point	Yes
VLE	Yes
Cache	16 KB Instruction 4 KB Data
Peripheral Core	

Table continues on the next page...

Table 2-2. Features List (continued)

Feature	Description
Peripheral Core	e200z4
Local RAM	16 KB Instruction 64 KB Data
Single Precision Floating Point	Yes
SIMD	Yes
VLE	Yes
Cache	8 KB Instruction
Other	
MMU Entries	0
MPU	Yes
Semaphores	Yes
CRC Channels	2
Software Watchdog Timer (SWaT)	4
Core Nexus Class	3+
Sequence Processing Unit (SPU)	16
Debug and Calibration Interface (DCI) / Run control Module	Yes
System SRAM	404 KB (Including 64 KB standby)
Flash	8640 KB
Flash fetch accelerator	Two 64-bit AHB ports, 256-bit read data interface. Each AHB port contains 4-entry, 2-way set-associative mini-cache
Data flash (EEPROM)	8 × 64 KB
Flash Overlay RAM	16 KB
External bus	Yes
Calibration Interface	64-bit IPS Slave
DMA channels	2 × 64
DMA Nexus Class	3
LINFlexD	6
M_CAN	4
M_TTCAN	1
DSPI	8
Microsecond channel downlink	Yes
SENT bus	15
I^2C	2
PSI5 bus	5
FlexRay	2 × Dual channel
Ethernet	Yes

Table continues on the next page...

Table 2-2. Features List (continued)

Feature	Description
SIPI / LFAST Interprocessor bus	High Speed
System Timers	8 PIT chan 4 AUTOSAR® (STM)
GTM Timer	48 Input Channels, 152 Output Channels
GTM RAM	54 KB
Interrupt controller	722 sources
ADC (SAR)	12
ADC (SD)	10
Temp. sensor	Yes
PLL	Dual PLL with FM
External Power Supplies	5 V 3.3 V 1.2 V
Low Power Modes	Stop Mode Slow Mode

2.4 Packaging

The MPC5777M is available in the following production packages: 416 BGA and 512 BGA. All BGA packages support development and production applications with the same package.

2.5 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development and calibration of constant data. These features include:

- Nexus code execution trace on all CPUs
- Nexus data trace on bus masters; DMA, Interprocessor bus, CPUs, and so on. Note that the Buddy Device—LFAST does not include Nexus data trace.
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering
- 16 KB of overlay RAM

For more complex software development and calibration of constant data, a Buddy Device (BD) is packaged together with the MPC5777M production device as a multi-die emulation and is referred to as an Emulation Device (ED).

The ED provides exactly the same features as the PD. The ED is available in the same package as the PD but has an additional overlay RAM (up to 1M byte in MPC5777M) and a high-speed Nexus trace output port consisting of four lanes of Aurora (LVDS) operating up to 1.25 Gbit/s.

2.6 Block diagrams

The figures below show the top-level block diagrams.

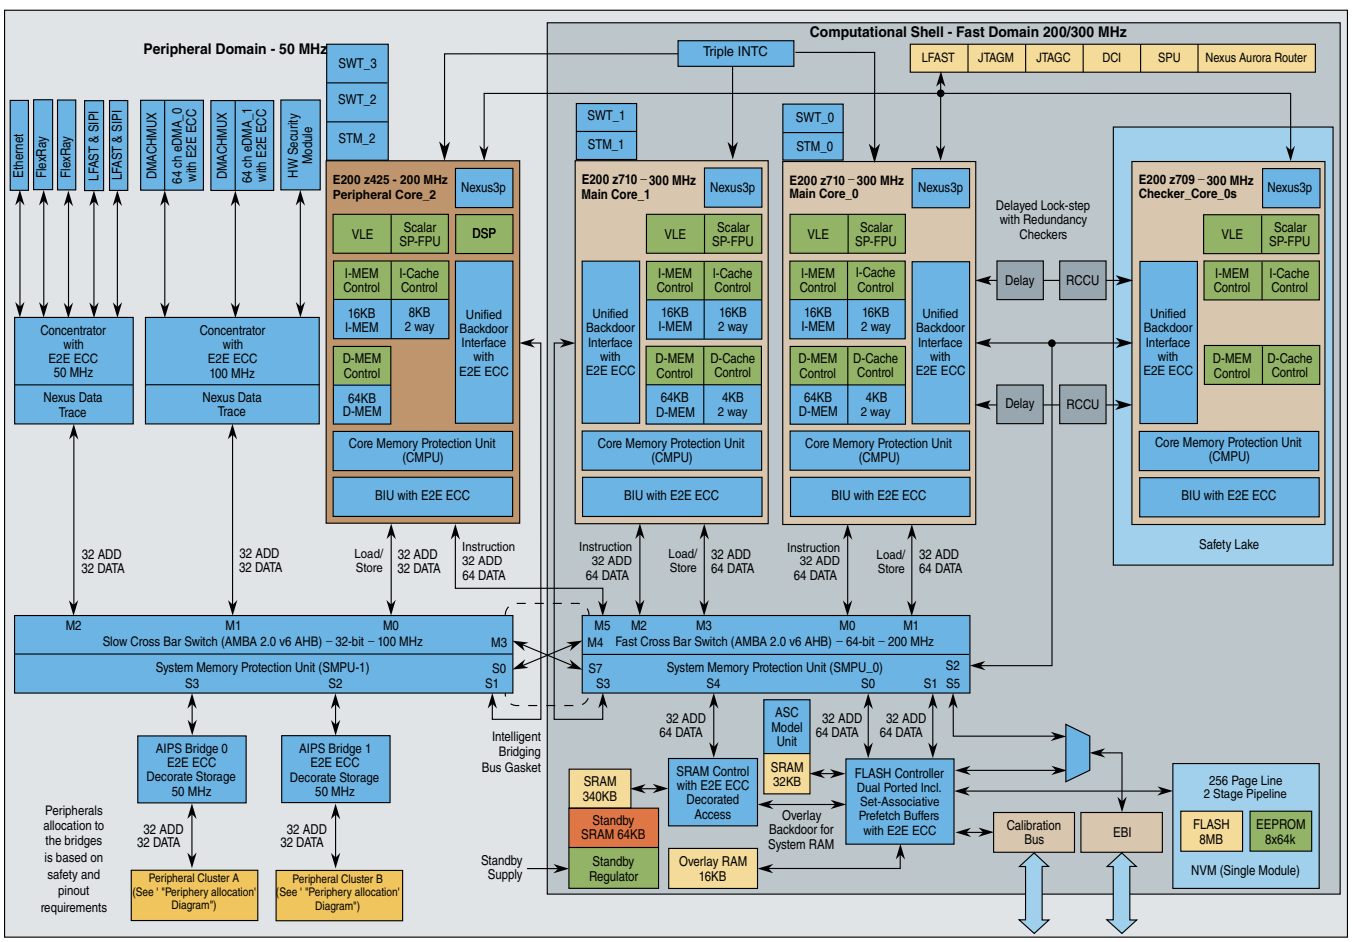

Figure 2-1. Block diagram

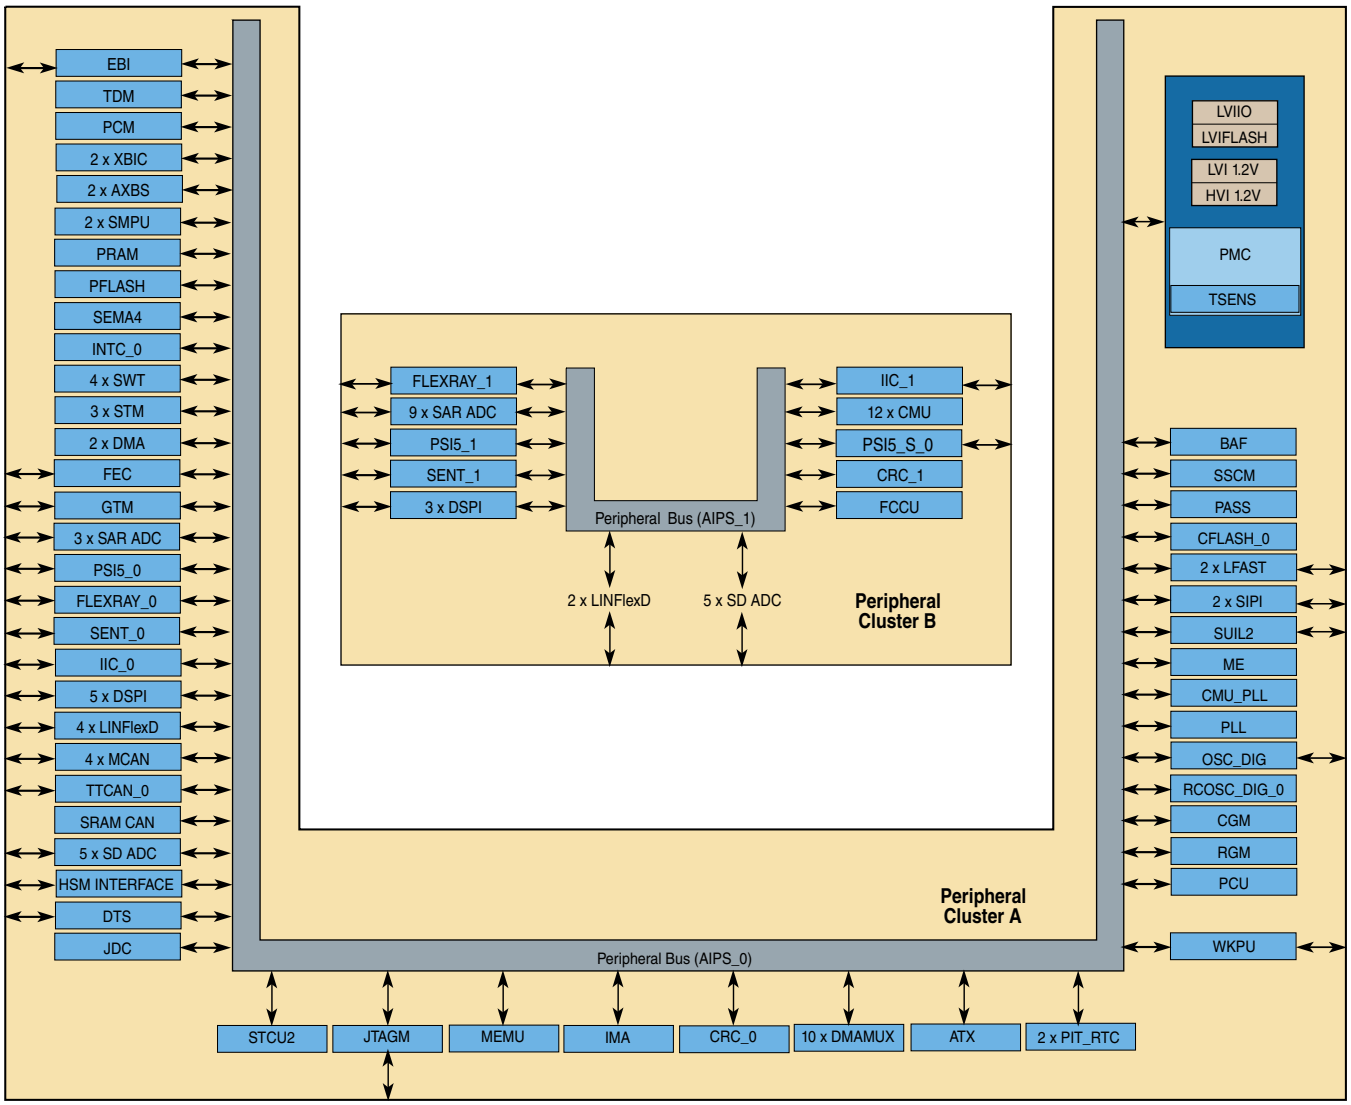

Figure 2-2. Periphery allocation

Chapter 3
Embedded memories

3.1 Overview

The embedded memory architecture for MPC5777M devices is a significant departure from previous-generation devices. Features include:

- Onboard SRAM, including system SRAM, local instruction and data memory for each processor core, and overlay SRAM
- Onboard system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Built-in flash memory security features including censorship and a programmable Hardware Security Module (HSM)
- Embedded memories in the peripherals[1] :
  - CAN
  - eDMA
  - FEC
  - FlexRay
  - GTM

3.2 SRAM

This section describes SRAM.

1. Refer to the respective module chapter for details.

3.2.1 System SRAM

MPC5777M devices include 404 KB of general-purpose on-chip ECC SRAM, including 64 KB standby RAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PFCR1 register in the SRAM controller.

- See RAM controller (PRAM) chapter for details on configuring the SRAM controller.
- See System RAM memory maps for the MPC5777M SRAM map.

3.2.2 Standby SRAM Regulator

A total of 64 KB of the system SRAM on the device can remain powered when the rest of the device is powered down. This is achieved with the dedicated VDDSTBY pin in the packages. When the standby RAM is powered by VDDSTBY, the RAM is not operational, but the contents are retained.

The Standby RAM regulator has the following key features:

- Automatic, safe, switch between operational (VDD_LV) and standby (VDDSTBY) supplies
- Internal regulation of the high voltage VDDSTBY supply to the low voltage standby RAM supply
- Brownout detection (minimum RAM data retention voltage violation) and reporting via a S/W clearable register bit

The Standby RAM regulator block diagram is given in the following figure.

There are two primary modes of operation with the standby RAM feature:

- Standby RAM feature is not required in the application - in this case, the VDDSTBY pin is connected to ground, and the standby RAM on the device is supplied by VDD_LV and will behave as normal RAM for all conditions.
- Standby RAM feature is required in the application - in this case, the VDDSTBY pin is connected to a voltage within the range given in the device data sheet. The VDDSTBY pin is assumed to be connected to a constant supply, and present before and after the power up/down of the device LV and HV supplies. When the VDD_LV supply to the RAM is above the LV operational voltage threshold, the standby RAM is fully operational and behaves exactly the same as the non-standby system RAM.

When the VDD_LV supply falls below the LV Detect threshold, the RAM low voltage supply is switched to the standby supply. For voltages above 1.2V, the standby regulator is enabled. For voltages below 1.2V, the VDDSTBY pin voltage is passed through directly to the RAM. See the device data sheet for min/max VDDSTBY values, LV supply thresholds, and the operational and brownout detection voltages.

The brownout detection feature of the standby RAM regulator informs the user if any voltage dip caused a RAM retention failure in standby mode. The brownout detector monitors the supply to the RAM array, and sets a latch in the PMC digital interface, when the voltage falls below the minimum RAM retention voltage given in the device data sheet. The latch is set on power up of the device. S/W then clears the latch by writing a '1' to the SBRAM_BRDET bit in the VD_UTST register of the PMC digital interface. If the minimum RAM retention voltage is violated, the latch will be set again. The latch is set on every power-up of VDD_LV unless VDDSTBY is present and within the specified ranges in the data sheet. See Standby RAM Regulator Interface Logic, for more information on the VDDSTBY pin.

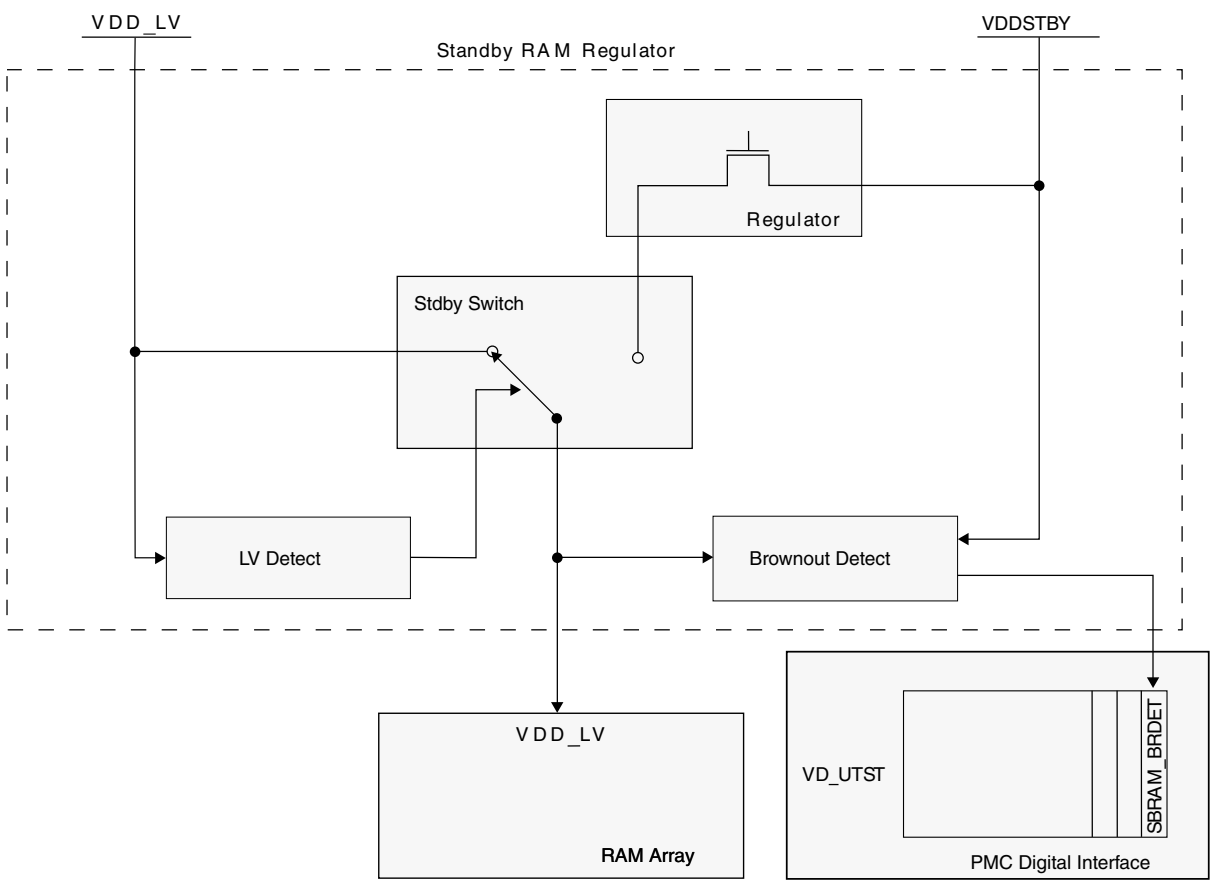

Figure 3-1. Standby RAM Regulator Block Diagram

3.2.3 Overlay SRAM

Overlay SRAM is included in the MPC5777M family of devices as part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces.The MPC5777M has two 8 KB banks of ECC-protected RAM, for a total of 16 KB.

Note

Overlay SRAM is normally used for system development purposes only. Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) regardless of the PFCRCR[IRMEM] setting.

Overlay memory can also be used to hold the device debug trace stream without requiring complex debug tool hardware and access to a high-speed trace port. Timing for calibration accesses to a particular overlay SRAM is the same as access to the underlying flash memory if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The calibration remap function supports three different types of overlay SRAM:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is available only on special emulation and debug devices.
- A portion of the system RAM can be used as the overlay RAM.

The overlay function is implemented using registers in the flash memory controller.

1. Using PFlash Calibration Region Descriptors (PFCRDn) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFDCRDE).

3. Enable overlay using the PFCRCR[GRMEN] field.

See PFlash calibration remap support section, for details on memory overlay (remapping).

3.2.4 Processor core local SRAM

MPC5777M devices include local instruction and data SRAM (I-MEM and D-MEM) for each processor core to provide enhanced performance.

- Each main processor core has 16 KB of instruction SRAM and 64 KB of data SRAM.
- The peripheral processor core has 16 KB of instruction SRAM and 64 KB data SRAM.

The core SRAM supports zero wait-state, single-cycle latency on processor local accesses.

Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices. See System RAM memory maps for details.

3.3 Embedded flash memory

Flash memory on MPC5777M devices consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. The following figure shows the memory architecture.

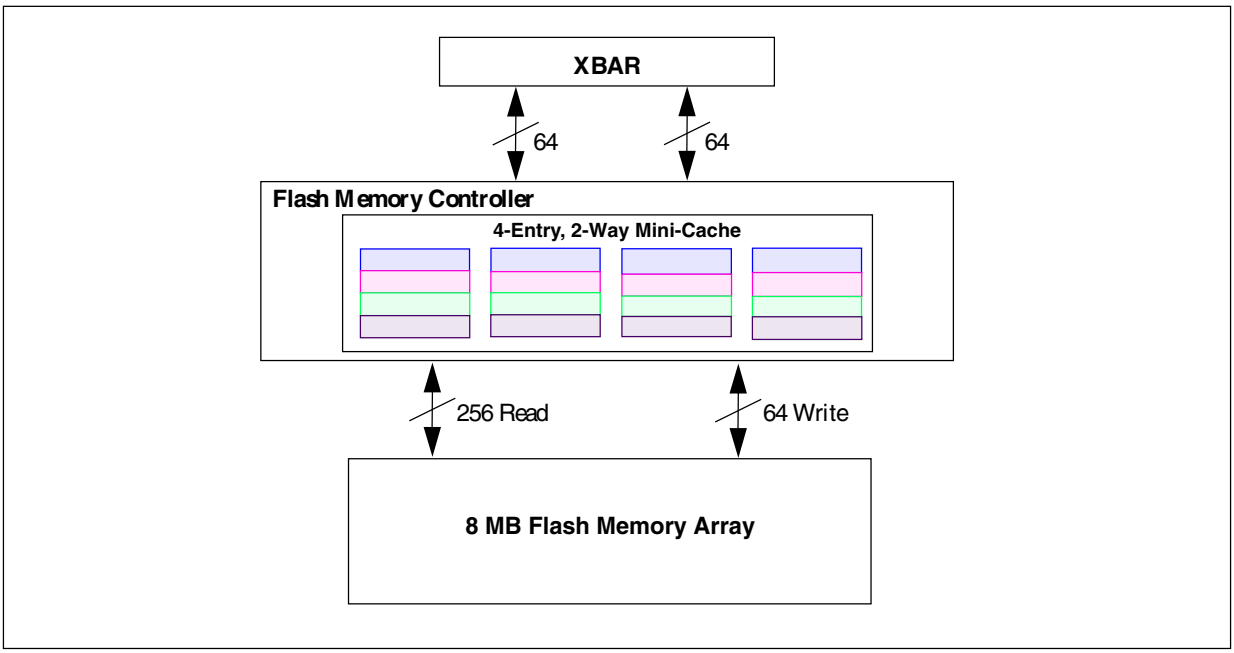

Figure 3-2. MPC5777M flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

3.3.1 Flash memory controller

The MPC5777M flash memory controller acts as an interface between the system bus and the flash memory array and serves as the interface to the on-chip overlay RAM and off-chip Buddy Device.[2]

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash memory.

See Flash memory controller chapter for details.

2. The Buddy Device is an optional companion chip with additional memory and debug features. A Buddy Device is combined with a Production Device to form an Emulation and Debug Device (ED) for use during system development. It is not used in production systems.

3.3.2 Flash memory array

MPC5777M devices include a single 8640 KB flash memory array, referred to as "main space," plus an independent 16 KB block of one-time-programmable (OTP) flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as "UTEST space."

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

3.3.2.1 Features

- Flash segmentation
  - 16 KB, 32 KB, 64 KB, and 256 KB blocks provided for code or data
  - Eight 64 KB blocks provided for EEPROM emulation
  - One 16 KB block and two 64 KB block provided for secure code
  - Two 16 KB blocks provided for secure data
  - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with double bit detection, single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.3.2.2 Flash organization

The embedded flash memory consists of six address spaces in four groupings:

- 16 KB low address space, 32 KB low address space, and 64 KB low address space
- 16 KB mid address space
- 64 KB high address space
- 256 KB address space

Address space group (low-, mid-, or high-address space) determines which registers/ fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The flash module is further divided into ten partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a "write" (program or erase) to a given partition, it can simultaneously read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The following figure shows the flash block segmentation and read-while-write partitioning for MPC5777M devices.

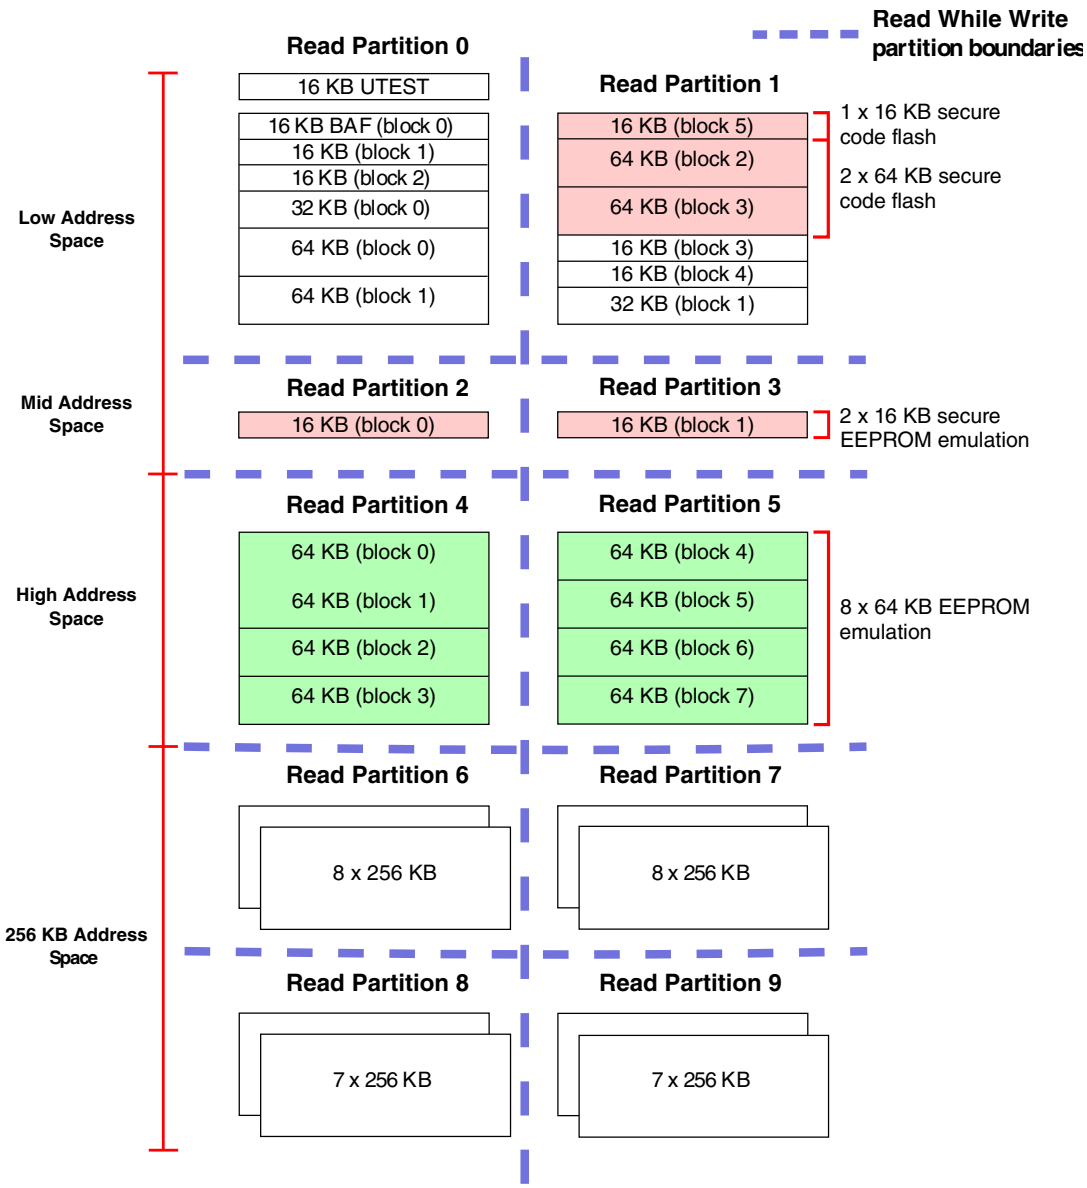

Figure 3-3. Flash memory segmentation and read-while-write partitioning

Note

See Table 5-3 in Memory Map" for the MPC5777M flash memory map.

3.3.2.3 UTEST memory space

Devices in the MPC5777M family contain a 16 KB area of One-Time Programmable (OTP) flash memory for storing test information and device configuration data. See Memory map tables in Memory Map" for the MPC5777M UTEST flash memory map.

3.3.2.4 Chip-specific C55FMC flash register information

The following sections contain chip-specific layouts of the on-chip flash memory control registers that contain bits used to lock individual flash blocks from accidental erase or select individual flash blocks for operations.

3.3.2.4.1 C55FMC_LOCK0 register bit mapping

The flash memory blocks mapped to the C55FMC_LOCK0 register bits are as follows.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table continues on the next page...

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional "ECC at memory" functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request

has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in the following table.

Table 3-1. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell or 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations "covered" by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.5 Security features

The MPC5777M architecture uses a combination of device life cycle monitoring and password protection to limit the conditions under which debugging interfaces can access certain areas of flash memory.

Note

Detailed information on the MPC5777M security architecture is published in a separate document and is available on a limited basis to customers who have a non-disclosure agreement (NDA) with Freescale Semiconductor Inc.

Chapter 4
Signal Description

4.1 Production packages

The following production packages are available for the MPC5777M device:

- 416 BGA
- 512 BGA

The 512 BGA is a superset of the 416 BGA. Compared to the 416 BGA, the 512 BGA contains additional GPIO and analog inputs.

The EBI (External Bus Interface) is the only new external interface on MPC5777M that is not currently on other family devices. The EBI is supported on the 512 BGA package but not on the 416 BGA package.

Case number and outline drawings for each package are provided in the MPC5777M data sheet.

4.2 Emulation packages

The following emulation packages are available for the MPC5777M device

- 416 BGA: The emulation and production devices are maintained in the same 416 BGA footprint. The emulation signals are bonded out in the emulation BGA, and not in the production BGA The JTAG interface on the buddy device is bonded out to the JTAG pins in the emulation package. The JTAG interface on the production device is bonded out to the JTAG pins in the production package.
- 512 BGA: The emulation and production devices are maintained in the same 512 BGA footprint.

The case outline drawings for the emulation packages are provided in the MPC5777M data sheet.

4.3 Package pinouts and ballouts

For pin package pinouts and ballouts refer to the MPC5777M Microcontroller Data Sheet.

4.4 Pin/ball descriptions

The complete Signal Description of the MPC5777M device is provided the following sections:

- Pin/ball startup and reset states
- Power supply and reference voltage pins/balls
- System pins/balls
- LVDS pins/balls
- Generic pins/balls

In addition, the signal multiplexing options are provided in two registers:

I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO_*n*), "I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO_n)."

Multiplexed Signal Configuration Register for Multiplexed Input Selection (SIUL2_MSCR_MUX_*n*), "Multiplexed Signal Configuration Register for Multiplexed Input Selection (SIUL2_MSCR_MUX_n)."

4.4.1 Pin/ball startup and reset states

This table provides startup state and reset state information for device pins/balls.

Table 4-1. Pin/ball startup and reset states

Pin	Startup state[1]	State during reset	State after reset
I/O pins[2]	Weak pullup	Input, weak pullup	Input, weak pullup
Analog Inputs[3]	High-impedance	High-impedance	High-impedance

Table continues on the next page...

Table 4-1. Pin/ball startup and reset states (continued)

Pin	Startup state[1]	State during reset	State after reset
F0 (ERROR0, FI0)[4]	High-impedance	Input, high-impedance	Input, high-impedance
ESR0	Output	Output, open-drain	Input, weak pullup
ESR1	Weak pullup	Input, weak pullup	Input, weak pullup
PORST	Weak pulldown	Input, weak pulldown	Input, weak pulldown
TESTMODE[5]	Weak pulldown	Input, weak pulldown	Input, weak pulldown
JCOMP (TRST)	High-impedance	Input, weak pulldown	Input, weak pulldown
TDI	Weak pullup	Input, weak pullup	Input, weak pullup
TDO	Weak pullup	Weak pullup	High-impedance
TMS	High-impedance	Input, weak pullup	Input, weak pullup
TCK	High-impedance	Input, weak pulldown	Input, weak pulldown
XTAL/EXTAL[6]	High-impedance	High-impedance	High-impedance

1. Startup state is exited when the core and high-voltage supplies reach minimum levels as defined in the Power Management chapter.
2. Pins on the device that are not supply or reference are not explicitly defined in this table.
3. Pure analog inputs, on digital output function.
4. F0 is also referred to as ERROR0 and FI0.
5. The MPC5777M MCU does not implement a system configuration pin—TESTMODE is the only pin that affects device configuration. It is latched on the PORST rising edge and internally pulled-down.
6. Function of XTAL/EXTAL pins defined by the enable bit in the flash user test row. If enabled, the pins are analog inputs to the oscillator. If disabled, the XTAL/EXTAL pins default to TBD.

4.4.2 Power supply and reference voltage pins/balls

Power supply and reference pins/balls for the MPC5777M are listed in this section.

The following table contains information on power supply and reference pin functions for the devices.

NOTE

All ground supplies must be tied to ground. They can NOT float.

Table 4-2. Power supply and reference pins

Table 4-2. Power supply and reference pins (continued)

Supply			BGA ball			
Symbol	**Type**	**Description**	**416PD**	**416ED**	**512PD**	**512ED**
V_{SS_LV}	Ground	Low voltage ground	K10, K11, K12, K15, K16, K17, L10, L11, L12, L13, L14, L15, L16, L17, M10, M11, M12, M13, M14, M15, M16, M17, N10, N11, N12, N13, N14, N15,N 16, N17, P11, P12, P13, P14, P15, P16, R 11, R12, R13, R14, R15, R16, T10, T11, T12, T13, T14, T15, T16, T17		M14, M17, N14, N15, N16, N17, P12, P13, P15, P16, P18, P19, R13, R14, R15, R16, R17, R18, T13,T14, T15, T16, T17, T18, U12, U13, U 15, U16, U18, U19, V14, V15 V16, V17, W14, W17	
$V_{SS\_HV\_ADV}$	Ground	Ground supply for ADC	—		—	
V_{DD_LV}	Power	Low voltage power supply for production device (PLL is also powered by this pin.)	B26, C25, D9, D24, E23, H4, P23, V23, AB23, AC20		M18, N19, V12, V19, W13, W18	
$V_{DD\_LV\_BD}$	Power	Low voltage power supply for buddy die	R1, R4		M13, N12	
$V_{DD\_HV\_PMC}$	Power	High voltage power supply for internal power management unit	D14		—	
$V_{DD\_HV\_IO\_MAIN}$	Power	High voltage power supply for I/O	A25, B24, C23, D22, K4, AC16, AD16, AE16, AF16		A2, A29, B3, B28, F7, F24, G8, G23, AC24, AD25, AH29, AJ30	
$V_{DD\_HV\_IO\_BD}$	Power	High voltage power supply for buddy die I/O	—	P17	—	R19
$V_{DD\_HV\_OSC}$	Power	Oscillator pin supply	E26		V25	
$V_{SS\_HV\_OSC}$	Ground	Oscillator ground supply	F25		T25	
$V_{DD\_HV\_JTAG}$	Power	JTAG pin supply	E26		V25	
$V_{DD\_HV\_IO\_FLEX}$	Power	FlexRay/Ethernet 3.3 V I/O supply	D7		J10	
$V_{DD\_HV\_IO\_FLEXE}$	Power	FLexRay/Ethernet/EBI I/O Segment Voltage Supply	AC18, AC22		AJ11, AK11, AK20, AK29	
$V_{DD\_HV\_IO\_EBI}$	Power	EBI Address/Control I/O Segment Voltage Supply	M23,T23,Y23		J29, J30, V30, AH30	
$V_{DD\_HV\_FLA}$	Power	Decoupling supply pin for flash	A18, B18		J21, K20	
$V_{DD\_HV\_ADV}$	Power	High voltage supply for ADC	—		—	
$V_{SS\_HV\_ADV\_S}$	Reference	Ground reference of ADC SAR	AF9		AF9, AJ8	
$V_{DD\_HV\_ADV\_S}$	Reference	Voltage reference of ADC SAR	AE9		AE10, AJ9	
$V_{SS\_HV\_ADV\_D}$	Reference	Ground reference of ADC σ/δ	AF5		AK8	
$V_{DD\_HV\_ADV\_D}$	Reference	Voltage reference of ADC σ/δ	AE5		AK9	
V_{DDSTBY}	Power	Standby RAM Supply Input	AD9		AA16	

4.4.3 System pins/balls

The following table contains information on system pin functions for the devices.

Table 4-3. System pins

Symbol	Description	Direction	BGA ball			
			416PD	416ED	512PD	512ED
PORST	Power on reset with Schmitt trigger characteristics and noise filter. PORST is active low	Bidirectional	B22		M22	
ESR0	External functional reset with Schmitt trigger characteristics and noise filter. ESR0 is active low	Bidirectional	A23		L21	
TESTMODE	Pin for testing purpose only TESTMODE pull-down is implemented to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to VSS_HV_IO on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. **Note:** The device will not exit reset with the TESTMODE pin asserted during power-up.	Input only	B23		N24	
XTAL	Analog output of the oscillator amplifier circuit needs to be grounded if oscillator is used in bypass mode.	Output	G25		U24	
EXTAL	Analog input of the oscillator amplifier circuit when oscillator is not in bypass mode. Analog input for the clock generator when oscillator is in bypass mode.	Input	G26		U25	

4.4.4 LVDS pins/balls

The following table contains information on LVDS pin functions for the devices.

Table 4-4. LVDSM pin descriptions

Functional block	Port pin	Signal	Signal description	Direction	BGA ball (416 PD, 416 ED)	BGA ball (512 PD, 512 ED)
SIPI / LFAST[1]	PD[7]	SIPI_RXP	Interprocessor Bus LFAST, LVDS Receive Positive Terminal	I	G23	P24
	PF[13]	SIPI_RXN	Interprocessor Bus LFAST, LVDS Receive Negative Terminal	I	H23	R24
	PA[14]	SIPI_TXP	Interprocessor Bus LFAST, LVDS Transmit Positive Terminal	O	C26	T25

Table continues on the next page...

Table 4-4. LVDSM pin descriptions (continued)

Functional block	Port pin	Signal	Signal description	Direction	BGA ball (416 PD, 416 ED)	BGA ball (512 PD, 512 ED)
	PD[6]	SIPI_TXN	Interprocessor Bus LFAST, LVDS Transmit Negative Terminal	O	D26	R25
High-Speed Debug (HSD) / LFAST[1] [2]	PA[7]	DEBUG_TXP	Debug LFAST, LVDS Transmit Positive Terminal	O	F24	R21
	PA[8]	DEBUG_TXN	Debug LFAST, LVDS Transmit Negative Terminal	O	E25	N22
	PA[9]	DEBUG_RXP	Debug LFAST, LVDS Receive Positive Terminal	I	D25	N21
	PA[5]	DEBUG_RXN	Debug LFAST, LVDS Receive Negative Terminal	I	F23	T24
DSPI 4 Microsecond Bus	PD[2]	SCK_P	DSPI 4 Microsecond Bus Serial Clock, LVDS Positive Terminal	O	C18	F17
	PD[3]	SCK_N	DSPI 4 Microsecond Bus Serial Clock, LVDS Negative Terminal	O	C17	G18
	PD[0]	SOUT_P	DSPI 4 Microsecond Bus Serial Data, LVDS Positive Terminal	O	C16	F16
	PD[1]	SOUT_N	DSPI 4 Microsecond Bus Serial Data, LVDS Negative Terminal	O	D17	G16
DSPI 5 Microsecond Bus	PF[10]	SCK_P	DSPI 5 Microsecond Bus Serial Clock, LVDS Positive Terminal	O	J24	W24
	PF[9]	SCK_N	DSPI 5 Microsecond Bus Serial Clock, LVDS Negative Terminal	O	K23	W25
	PF[12]	SOUT_P	DSPI 5 Microsecond Bus Serial Data, LVDS Positive Terminal	O	J26	Y24
	PF[11]	SOUT_N	DSPI 5 Microsecond Bus Serial Data, LVDS Negative Terminal	O	J25	Y25
DSPI 6 Microsecond Bus	PQ[9]	SCK_P	DSPI 6Microsecond Bus Serial Clock, LVDS Positive Terminal	O	A17	A16
	PQ[8]	SCK_N	DSPI 6 Microsecond Bus Serial Clock, LVDS Negative Terminal	O	B17	B16

Table continues on the next page...

Table 4-4. LVDSM pin descriptions (continued)

Functional block	Port pin	Signal	Signal description	Direction	BGA ball (416 PD, 416 ED)	BGA ball (512 PD, 512 ED)
	PQ[11]	SOUT_P	DSPI 6 Microsecond Bus Serial Data, LVDS Positive Terminal	O	B16	A15
	PQ[10]	SOUT_N	DSPI 6 Microsecond Bus Serial Data, LVDS Negative Terminal	O	A16	B15
Differential DSPI 2	PD[2]	SCK_P	Differential DSPI 2 Clock, LVDS Positive Terminal	O	C18	F17
	PD[3]	SCK_N	Differential DSPI 2 Clock, LVDS Negative Terminal	O	C17	G17
	PD[0]	SOUT_P	Differential DSPI 2 Serial Output, LVDS Positive Terminal	O	C16	F16
	PD[1]	SOUT_N	Differential DSPI 2 Serial Output, LVDS Negative Terminal	O	D17	G16
	PD[7]	SIN_P	Differential DSPI 2 Serial Input, LVDS Positive Terminal	I	D17	P24
	PF[13]	SIN_N	Differential DSPI 2 Serial Input, LVDS Negative Terminal	I	H23	R24
Differential DSPI 5	PI[15]	SCK_P	Differential DSPI 5 Clock, LVDS Positive Terminal	O	G26	P22
	PI[14]	SCK_N	Differential DSPI 5 Clock, LVDS Negative Terminal	O	J23	R22
	PF[12]	SOUT_P	Differential DSPI 5 Serial Output, LVDS Positive Terminal	O	J26	Y24
	PF[11]	SOUT_N	Differential DSPI 5 Serial Output, LVDS Negative Terminal	O	J25	Y25
	PD[7]	SIN_P	Differential DSPI 5 Serial Input, LVDS Positive Terminal	I	G23	P24
	PF[13]	SIN_N	Differential DSPI 5 Serial Input, LVDS Negative Terminal	I	H23	R24

1. DRCLK and TCK/DRCLK usage for SIPI LFAST and Debug LFAST are described in the MPC5777M Microcontroller Reference Manual SIPI LFAST and Debug LFAST chapters.
2. Pads use special enable signal form DCI block: DCI driven enable for Debug LFAST pads is transparent to user.

Table 4-5. Aurora pin descriptions

Functional Block	PAD	Signal	Signal Description	Direction	BGA			
					416PD	416ED	512PD	512ED
Nexus Aurora High Speed Trace	—	TX0P	Nexus Aurora High Speed Trace Lane 0, LVDS Positive Terminal	O	—	U15	—	AB19
	—	TX0N	Nexus Aurora High Speed Trace Lane 0, LVDS Negative Terminal	O	—	U14	—	AB18
	—	TX1P	Nexus Aurora High Speed Trace Lane 1, LVDS Positive Terminal	O	—	U13	—	AB17
	—	TX1N	Nexus Aurora High Speed Trace Lane 1, LVDS Negative Terminal	O	—	U12	—	AB16

	—	TX2N	Nexus Aurora High Speed Trace Lane 2, LVDS Negative Terminal	O	—	U10	—	W15
	—	TX3P	Nexus Aurora High Speed Trace Lane 3, LVDS Positive Terminal	O	—	P10	—	R12
	—	TX3N	Nexus Aurora High Speed Trace Lane 3, LVDS Negative Terminal	O	—	R10	—	T12
	—	CLKP (BD-AGBTCLKP)	Nexus Aurora High Speed Trace Clock, LVDS Positive Terminal	I	—	U17	—	AB21
	—	CLKN (BD-AGBTCLKN)	Nexus Aurora High Speed Trace Clock, LVDS Negative Terminal	I	—	U16	—	AB20

4.4.5 Generic pins/balls

The I/O Signal Description Table contains information on generic pins/balls. See the MPC5777M I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination. For additional information, refer to SIUL2 chapter.

The I/O Signal Description Table provides the port pin, SIUL MSCR number, MSCR SSS, function, module, signal description, direction, pad type, and package pin/ball numbers for each I/O pin on the device.

Chapter 5
Memory Map

5.1 Overview memory maps

Table 5-1 shows the device memory map for the MPC5777M.

All addresses on the MPC5777M, including those that are reserved, are identified in the table. The addresses represent the physical addresses assigned to each region or module name. All memory not listed in this table is reserved, and access to those locations may produce undesirable results.

Table 5-1. Overview memory map

Start address	End address	Allocated size	Used size	Description
Flash (XBAR port 0—0)				
0x00000000	0x003FFFFF	—	—	Reserved
0x00400000	0x005FFFFF	2 MB		UTest NVM Block–no overlay
0x00600000	0x0067FFFF	512 KB	134 KB	HSM Code–no overlay
0x00680000	0x007FFFFF	1.5 MB	32 KB	HSM Data–no overlay
0x00800000	0x009FFFFF	2 MB	256 KB	Data Flash Blocks–no overlay
0x00A00000	0x00FFFFFF	6 MB	256 KB	Small and Medium Flash Blocks–no overlay
0x01000000	0x01FFFFFF	16 MB	3584 KB	Large Flash Blocks–no overlay
0x02000000	0x089FFFFF	8 MB	—	Reserved
0x02800000	0x02FFFFFF	8 MB	—	Reserved
0x03000000	0x037FFFFF	8 MB	—	Reserved
0x03800000	0x03FFFFFF	8 MB	—	Reserved
0x04000000	0x047FFFFF	8 MB	—	Reserved
0x04800000	0x04FFFFFF	8 MB	—	Reserved
0x05000000	0x057FFFFF	8 MB	—	Reserved
0x05800000	0x07FFFFFF	40 MB	—	Reserved
0x08000000	0x083FFFFF	4 MB	—	Reserved
0x08400000	0x089FFFFF	6 MB	—	Reserved
0x08A00000	0x08FFFFFF	6 MB	256 KB	Mirror Small and Medium Flash Blocks

Table continues on the next page...

Table 5-1. Overview memory map (continued)

Start address	End address	Allocated size	Used size	Description
0x09000000	0x09FFFFFF	16 MB	3.5 MB	Mirror Large Flash Blocks
0x0A000000	0x07FFFFFF	8 MB	—	Reserved
0x0A800000	0x0AFFFFFF	8 MB	—	Reserved
0x0B000000	0x0B7FFFFF	8 MB	—	Reserved

Chapter 6
Functional Safety

6.1 Introduction

The MPC5777M offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL D of ISO 26262. This chapter gives an overview of the safety implementation for the MPC5777M, and discusses the operation of the safety mechanisms.

6.2 Safety overview

The MPC5777M has been designed for automotive applications executing safety-relevant tasks that require a fail-silent or fail-indicate MCU. The MPC5777M supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms as documented in the Safety Manual (SM), but the MPC5777M generally supports an FTTI of 10 ms.

6.3 Module categorization

The definition of the MPC5777M safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in Table 6-1.

Table 6-1. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules that belong in one of the above categories but that do not require hardware-level safety measures. Examples include the DMA, the performance core, and the I/O core. Only their non-interference with modules from the other categories is ensured by hardware. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation.
Other support modules	SuMo	These are modules that, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

Table 6-2 shows module classifications for the MPC5777M.

Table 6-2. Module classification

Classification	Modules
ViMos	Master Safety Core (Z7), Master Safety Core D-Cache controller, Master Safety Core I-Cache controller, Master Safety Core D-MEM controller, Master Safety Core I-MEM controller, Safety Core D-Cache array, Safety Core I-Cache array, Safety Core Local D-Mem array, Safety Core Local I-Mem array, INTC, XBAR_0 (Computational - Fast), SMPU, SRAM controller, system RAM array, flash memory controller, flash memory array, Overlay RAM, STM_0 (System Timer), MC_RGM, MC_RSL,

Table continues on the next page...

Table 6-2. Module classification (continued)

Classification	Modules
	Dual PLL (Digital and Analog), XOSC, MC_CGM (ViMos portion), MC_ME (ViMos portion), DSMC (ViMos portion), PMC (Digital and Analog - Voltage Regulator), STCU, SSCM, IAHB Gaskets, PIT
PeMos	SARADC (Digital, Analog, AMUX5 and BIAS), SDADC (Digital, Analog and Bandgap), PSI5, PSI5_S, SENT, LINFlexD, DSPI, FlexRay, FlexRay DRAM array, FlexRay LRAM array, FEC, FEC FIFO array, FEC MIB array, SIUL2, XBAR_1 (Peripheral - Slow), BUSC (Concentrator - FEC, FlexRay and LFAST), AIPS MC_CGM (PeMos portion), MC_ME (PeMos portion),
SuMos	RCCU, Checker Safety Core (Z7), Checker Safety Core D-Cache controller, Checker Safety Core I-Cache controller, Checker Safety Core D-MEM controller, Checker Safety Core I-MEM controller, CRC units, Temperature Sensors,

Table continues on the next page...

Table 6-2. Module classification (continued)

Classification	Modules
	IRCOSC, CMU, PMC-HVD12, PMC-HVD33, PMC-LVD12, PMC-LVD33, LBIST, MBIST, IMA, REG_PROT, SWT_0, FCCU, MEMU CGL (Clock Gating Logic), MC_CGM (SuMos portion), MC_ME (SuMos portion), PTM, PMC (Standby RAM)
NoSaMos	Performance Core (Z7), Peripheral Core (Z4), Performance Core D-Cache controller, Performance Core I-Cache controller, Performance Core D-MEM controller, Performance Core I-MEM controller, Performance Core D-Cache array, Performance Core I-Cache array, Performance Core Local D-Mem array, Performance Core Local I-Mem array, Peripheral Core I-Cache controller, Peripheral Core D-MEM controller, Peripheral Core I-MEM controller, Peripheral Core I-Cache array, Peripheral Core Local D-Mem array, Peripheral Core Local I-Mem array, EBI (LFAST, SIPI), eDMA, GTM, HSM

Table 6-2. Module classification

Classification	Modules
	DMAMUX, Nexus, JTAG (JTAGC, JTAGM), BUSC (Concentrator - DMA and HSM), I2C, SEMA4, WKPU SPU PASS, DCI DTS, JDC, NAR, NAR RAM Array, STM_1 and STM_2, SWT_1, SWT_2, and SWT_3, DSMC (NoSaMos portion),

The MPC5777M implements no specific protection of NoSaMos against Common Cause Failures between them.

6.4 System implementation

6.4.1 General concept

In general, safety integrity is achieved in the following ways:

- For the Safety Core and its closely related periphery, safety is ensured by a delayed lockstep approach (see Dual-core lockstep).
- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for individual modules. For the periphery, end-to-end ends at the I/O bridges (see End-to-End protection on data path).
- Clock-and-power generation and distribution are supervised by dedicated monitors (see Clock and power monitoring).

- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (see I/O peripherals, and Communication controllers).
- MBIST and LBIST are provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms (see Built-In Self-Tests (BIST)). Dedicated mechanisms are provided to check the availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection). Table 6-3 and Table 6-4 detail the available LBIST partitions.
- The Fault Collection and Control Unit (see "Fault Collection and Control Unit (FCCU)" chapter for FCCU details) is responsible for collecting and reacting to failure notifications (see FCCU and failure monitoring). MEMU (see Memory Error Management Unit (MEMU)) is responsible for the collection and reporting (to the FCCU) of error events in system memories, and flash memory, as well as E2E ECC errors caused by the XBAR, or RAM or flash memory controllers. Error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (see Common Cause Failure measures).

6.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected with at least 99% coverage via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a single-error correction, double-error detection (SECDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. The following figure shows a general view of ECC schema.

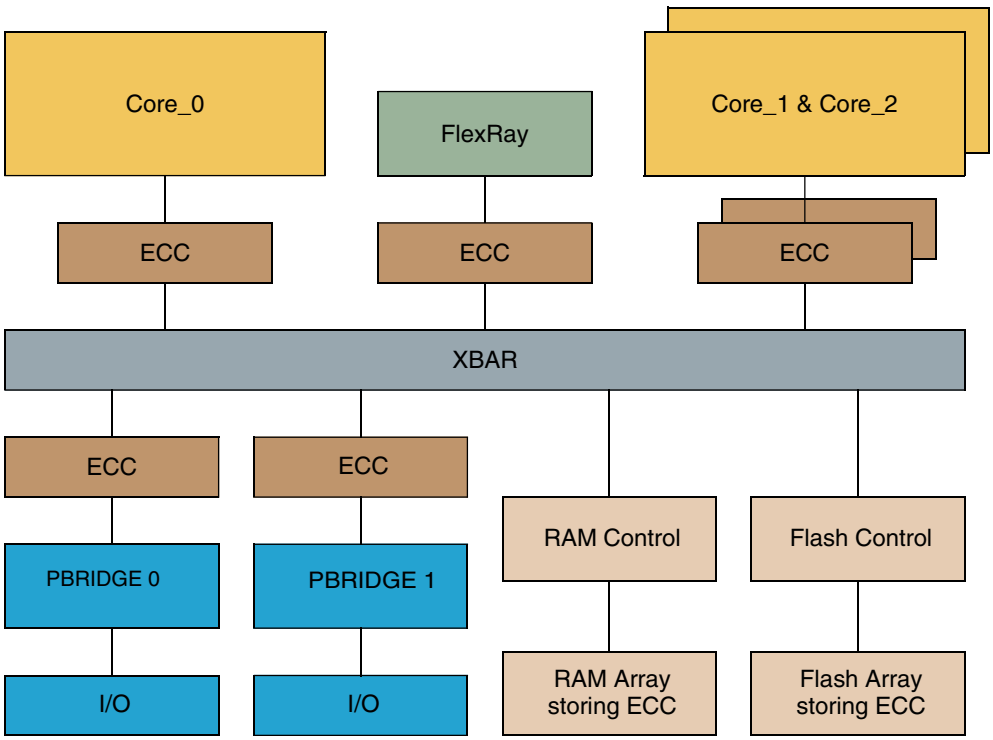

Figure 6-1. General view of E2E ECC

Note

Specific implementation for the MPC5777M vary depending on the special requirements of RAM and flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters (including, but not limited to the Safety Core) and checked on reads. The ECC correction bits are stored alongside the data in flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, apart from memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGEs and peripherals can be used redundantly (see I/O peripherals), or other mechanisms may be used to validate peripheral operation.

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) does allow the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address;
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash controllers; the target is respectively an XBAR slave port, the RAM array, or the Flash module (see "Crossbar Switch (XBAR)", "Flash memory controller", and "RAM controller (PRAMC)" chapters).

6.4.1.2 Clock and power monitoring

6.4.1.2.1 Clock

Clocks in the MPC5777M are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of clock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

The clock tree for Core_0 and Core_0 – Checker (the two lockstep cores comprising the Safety Core) consists of separate clock branches that are not shared with any other module. One CMU (CMU_1) is connected to the Main Core clock path, downstream from the common part of the clock tree for the Main and Checker Cores. In this way any frequency failure affecting the Main Core clock or the common clock (SYS_CLK) is detected by the CMU, and any frequency failure affecting the Checker Core clock is detected by the Redundancy Control and Checker Units (RCCUs) (see MCU clocking details).

6.4.1.2.2 Power

There are two types of voltage supervisors on the MPC5777M, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads, and so on) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion) (see "Power management" and "Power Control Unit (MC_PCU)" chapters for details on power monitoring).

6.4.1.3 I/O peripherals

To allow a safety application to make redundant use of all I/O peripherals, each peripheral has at least two instances (except for the GTM), and each instance is connected to a different PBRIDGE. This means, for example, that if DSPI is provided by the MCU, two DSPI modules (DSPI*n*, DSPI*m*) are included and connected externally through different pins. Internally, DSPI*n* would then be connected to PBRIDGE_A and DSPI*m* to PBRIDGE_B and be accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGEs, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism. The allocation of peripherals along the two PBRIDGEs are depicted in block diagrams found in the “Introduction” chapter of this reference manual.

6.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and are therefore subject to the same safety criteria as I/O peripherals. Yet we assume that for high bandwidth communication controllers, additional software measures are employed that do not require redundant communication peripherals.

The following communication controllers do not contain special safety mechanisms beyond their protocol specifications nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, see I/O peripherals):

- FlexRay

- FEC
- M_CAN
- M_TTCAN

Software measures for the communication controllers (also called fault-tolerant communication layer) may contain E2E CRC data protection, sender identification, sequence numbering, and an acknowledgement mechanism.

PSI5 represents an exception to the replication of low bandwidth communications controllers. The module itself is replicated, but the two PSI5 modules share a single synchronization bit needed for staggered sync mode. This single bit is a single source of failures for both PSI5 modules if it triggers spurious synchronizations. The failure mode must be addressed by application level measures, which are in any case needed to cover the single transceiver used in such a configuration.

6.4.1.4.1 Disabling of communication controllers

In the event of a dangerous failure, the MCU offers the capability of disabling transmission of individual channels of communication controllers (such as CAN modules and FlexRay). This prevents the transmission of erroneous messages while preserving the capability of communicating over the diagnostic bus. Disabling outputs is controlled by resetting the SIUL2_MSCR*n*[SMC] for the pins that are associated with communication controllers where this feature is needed. See the "System Integration Unit Lite2 (SIUL2)" chapter for details on disabling communication signals.

The FCCU can drive a fault state on FI[0] via:

- Error pin reaction to a fault
- Software writing FCCU_CFG[FCCU_SET_CLEAR] = 01b

When the FCCU drives FI[0] to a fault state, the SIUL2 disables the output drivers of all pins whose SIUL2_MSCR*n*[SMC] = 0. This disables the possible transmission of erroneous messages. As long as the FCCU drives FI[0] to faulty state, the communication controllers' Tx pins are disabled and internal pull-up are enabled. As soon as FI[0] is driven to non-faulty state, the communication controllers' Tx pins are automatically enabled and state of internal pull-up/down restored.

The application should configure SIUL2_MSCR*n*[SMC] for pins that have active mapping of CAN modules (M_CAN, M_TTCAN) or FlexRay functionality and ensure that pin does not stay in undriven state.

Note

The FCCU uses an internal signal to disable the communication controller transmission, so transmission is disabled even when the FCCU cannot drive the FI[0] pin because the pin is configured as GPIO. If FI[0] is used as error input, externally pulling it down will disable the communication controller transmission if this event drives FCCU to a fault state.

Note

Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, M_TTCAN, M_CAN, FlexRay) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events.

6.4.1.5 Built-In Self-Tests (BIST)

The term BIST refers to the set of built-in hardware mechanisms that permits a device to test itself (typically at startup) in order to avoid the accumulation of latent faults, a requirement defined by the ISO 26262 standard.

Different types of BIST are implemented in the MPC5777M:

- LBIST for digital logic—managed by the Self-Test Control Unit.
- MBIST for memories—managed by the Self-Test Control Unit.
- MCU built-in mechanisms for testing analog peripherals—requires software intervention.

See the “Self-Test Control Unit (STCU2)” chapter for further details.

6.4.1.5.1 BIST during boot (off-line)

A device BIST is performed every time the device boots and is application transparent while the device is still under reset. BIST failure holds the device in reset, but the BIST continues running where possible and informs the system of the failure. Since LBIST and MBIST are destructive, a reset is performed for the tested module (memory or partition) before going into operation again. Application software starts when the BIST finishes without detecting a fault.

The boot time BIST comprises:

- Memory BIST for all RAMs and ROM
- Scan-based Logic BIST for digital logic, which is divided into multiple partitions that can be configured to be tested in parallel or sequentially to find the best time versus power consumption trade off.

6.4.1.5.2 Online Logical BIST (LBIST)

Though LBIST and MBIST are primarily intended to be run at startup under STCU2 control, the MCU allows software to trigger a memory self-test or LBIST of one partition during runtime. Since LBIST and MBIST are destructive, a reset is performed for the tested module (memory or partition) before going into operation again. This leads to a reset of the MCU or of those LBIST partitions. If a runtime LBIST requires a reset of the whole device, the LBIST result is accessible to software after the reset. If a reset occurs during LBIST, the LBIST is aborted. Output signals from each LBIST partition are set to a defined state when starting LBIST of that partition until the entire LBIST sequence completes. This has influence on the state of I/O signals. Table 6-3 and Table 6-4 below show the module groupings for each LBIST partition.

Note

When Scan mode is entered through LBIST, the flash memory must be in IDLE state, therefore Program or Erase operations must not be either active or suspended.

Table 6-3. LBIST partitions

LBIST partition	Instance name

6.4.1.6 Redundancy Control and Checker Units (RCCUs)

The RCCU compares a set of equivalent input signals provided by different sources and issues an alarm in case of a mismatch. For example, an RCCU compares the output of the checker core against the output of the main core and issues an alarm if they do not match. In case of a compare mismatch the fault stays stable until clearing the FCCU channel status.

6.4.1.7 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

6.4.1.7.1 External error indication

Failure of the MCU is signaled to one or two pins, FI[0] (ERROR0) and FI[1] (ERROR1). FI[0] can also serve as an error input mechanism (see "Fault Collection and Control Unit (FCCU)" chapter, and "FCCU configuration" section of the "Device configuration" chapter, for details on the fault output signals). Both pins can be multiplexed with other functions with different defaults.

The error indication on pins FI[0] and FI[1] is controlled by SIUL2 and FCCU. The mapping of the FCCU output signals on the relevant pins and the associated electrical characteristics are enabled by the SIUL2_MSCR[*n*] register (see table "SIUL2_MSCR0 - SIUL2_MSCR511 field description" in the "System Integration Unit Lite2 (SIUL2)" chapter for signal mapping details). Once the FCCU is mapped onto the pin, the logic level is driven by the FCCU.

FI[0] is controlled by the FCCU at startup by default, but the state of FI[1] is like other I/O signals (see table "Pin/ball startup and reset states" in chapter "Signal Description" for default states of FI[0] and FI[1]).

Since it is possible to reset FCCU and SIUL2 independently, the behavior of FI[0] and FI[1] is the result of the combined state of SIUL2_MSCR[*n*] and the FCCU. (see section "Reset interface" in chapter "Fault Collection and Control Unit (FCCU)" for FCCU reset details, and chapter "Reset and Boot" for the state of the FCCU relative to the system during different reset phases).

FCCU_STAT[ESTAT] flags whether the FCCU is in an error state. This flag can be set by software to a '1' (fault) or '0' (operational) when the FCCU is in operational state. FCCU_STAT[PSTAT] mirrors the physical state of the *Fn* external pin's value, though this may differ from the logical state if a toggling protocol is used.

6.4.1.7.2 Failure handling

The FCCU is an autonomous module that manages the different reactions configured for each failure source. Overall failure reaction time includes error detection, processing, and indication. In this interval, the MPC5777M may provide wrong results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU
- Control logic and signals monitored by the FCCU itself (see chapter "Fault Collection and Control Unit (FCCU)").
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Note that software can also directly influence the state of the F*n* pins.
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERROR*n*
- Disabling the transmission capabilities of communication controllers (FlexRay, CAN, FEC) (Note: only possible in conjunction with changing the state of the failure indication pins)
- No reaction

Software can read the failure source that caused a fault, either before or after a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication remains for a configurable minimum time. If necessary, software can also reset the MCU

6.4.1.8 Operational interference protection

Being a multi-master system, MPC5777M provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom mechanisms are arranged in a hierarchical memory protection schema including:

- MPUs
- PBRIDGEs
- Register protection.

There are two Memory Protection Unit levels included in the MPC5777M. The Core Memory Protection Unit (CMPU) is a mechanism included in each core (except HSM core) to protect address ranges against access by software developed according to lower ASIL. The CMPU is typically used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. The MPUs prevent access of different bus masters to address ranges and are typically used by the safety application to prevent NoSaMos (such as the DMA or the Performance Core) to access the application's safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual registers to be locked against any manipulation without unlocking.

These safety mechanisms are further described in the "System Memory Protection Unit (SMPU)" chapter.

6.4.1.9 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU observes the outputs of the FCCU (IRQ, RESET, F*n*). If the FCCU does not react within a predefined interval as specified in the "FCCU configuration" section of the "Device configuration" chapter, the FOSU assumes the FCCU has failed and causes a destructive reset.

The FOSU does not require any configuration by software.

6.4.2 Dual-core lockstep

The MPC5777M duplicates its safety-relevant processing elements and compares their operation in Lockstep mode (LSM). This Safety core consists of two cores, Checker Core_0 and Main Core_0, and as far as software is concerned they behave as one core. Main Core_0 is the main execution core of the pair, where Checker Core_0 follows the execution of the Main Core in lockstep.

The replicated processing elements contain:

- Core
- Cache control
- Local memory control
- Core MPU
- Core System Bus Interface, including e2eECC logic

Together each set of replicated elements forms a channel (for example, the Main channel and the Checker channel).

Elements that are not replicated are:

- Performance or I/O cores
- Cache and local memory arrays
- INTC
- Interconnect (XBAR)
- RAM controller
- Flash memory controller
- eDMA controller

Note

This is not a complete list of all non-replicated elements. The elements listed are sometimes replicated in similar lockstep architectures.

Equivalent operation of replicated resources is supervised by comparators on all functional signals leaving the channels for the rest of the MCU. Any operational deviations between the supervised signals causes the FCCU to be notified of the discrepancy.

The Checker Core does not have a direct connection to the XBAR. All of the outputs of Checker Core_0 that target the XBAR (as well as any other non-duplicated resource, like local memories) end in an RCCU for verification, and all the inputs to Checker Core_0 from the XBAR are split off from the Main Core_0 XBAR inputs.

An abstract view of the implementation including delays and RCCUs is shown in Figure 6-2, but does not show local memory.

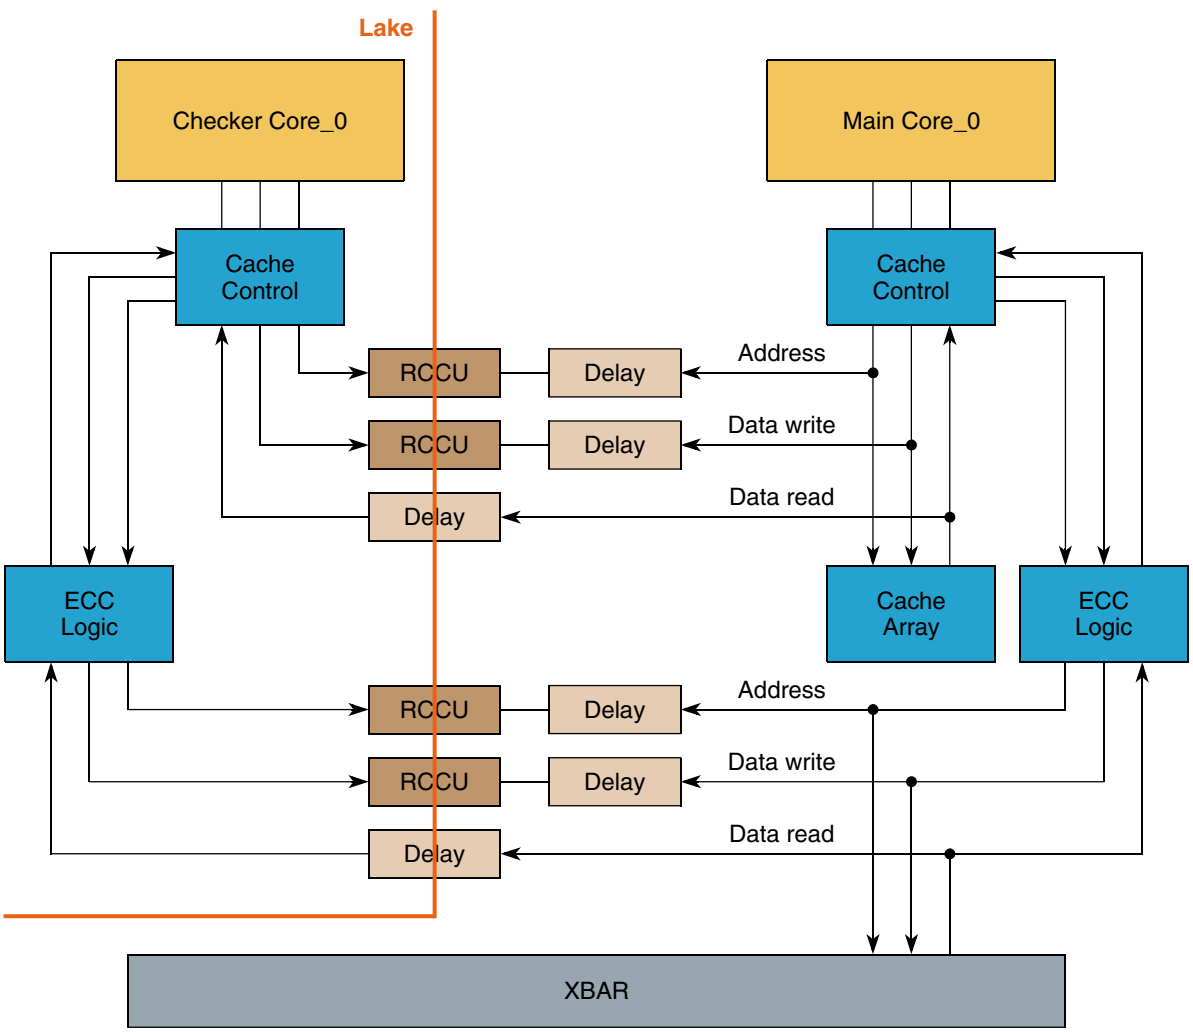

Figure 6-2. Dual core concept

A delay of two clock cycles exists between the Main and Checker channel to reduce their susceptibility to CCFs caused by power and clock disturbances. Outputs of the Main Core (such as XBAR addresses) are registered and delayed before being forwarded to the RCCUs, while inputs signals (such as XBAR read data) are registered and delayed before being fed to the Checker channel.

LSM can be disabled during boot by reprogramming the Flash memory (UTEST Miscellaneous DCF Client) or on-line by disabling the checker but not the main Core_0[1]. LSM is also automatically disabled when Core_0 enters debug mode and automatically reenabled when it leaves it. If LSM is disabled, the RCCUs are disabled and a signal is sent to the FCCU. If SW enables the checker core by writing in MC_ME - MC_ME_CCTL register while LSM is disabled (not recommended), this does not enable LSM and the RCCUs do not generate any errors in case of mismatch. Thus no user-initiated dynamic enabling of LSM is possible. Furthermore, it is not a valid operation to stop main core_0 only or to reset one of the cores only. If the cores are out of lock, a destructive or functional reset is needed to reestablish LSM.When safety core enters debug mode, the signaling of potential mismatches by RCCUs (FCCU channels #10 and #11) is disabled. RCCU signaling is automatically re-enabled when safety core leaves debug mode. If LSM or the RCCU signaling is disabled a signal is sent to the FCCU (FCCU channels #51). A reset is needed to reestablish LSM. Also, in contrast to the MPC564xL , no Decoupled Parallel Mode (DPM) is available (Main Core_0 and Checker Core_0 cannot operate as two independent cores running different software). Main Core_0 is able to operate as an independent core if Checker Core_0 is disabled. The status of LSM for the Safety core can be verified by checking the appropriate FCCU register.

6.4.3 Common Cause Failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the replication of the Safety Core or of the peripherals. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

There are also configuration registers that can affect the execution of the MCU's safety function when changed and simultaneously disable the respective safety mechanism. These are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing the register protection described above.

1. Disabling both cores in a single mode transition will not disable LSM.

6.4.4 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

6.4.4.1 ECC for storage

All storage (system RAM, local memory, Flash memory, peripheral RAM) used in normal operation is protected by ECC with SECDED (Single Error Correct and Double Error Detect) with the following exceptions:

- The caches in the cores are protected by EDC (Error Detection Code), which only detects errors.
- FlexRay's schedule information RAM is protected by EDC only.

A list showing the implementation of RAMs with ECC (including address protection) and for the MPC5777M is shown in Table 6-5.

Table 6-5. ECC RAM implementations

Location	Memory	Memory classification	ECC	Address in ECC	Muxing factor	Reacts to uncorrectable error

Platform	FEC/MIB	Peripheral	SEC/DED	Y	4	N

Table 6-5 shows that some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback).This is different for storage related to PeMos. PeMos generally use an ECC without address error protections and do not include additional measures to detect them. All ECC calculations for RAMs in PeMos are accomplished by logic outside of the RAM, not in the RAM block.

An exception to this is the GTM's RAMs. They include addressing failure detection measures in the ECC. In addition, the individual RAM ports of the GTM do not share common parts and connect to individual (non-interfering) RAM arrays.

6.4.4.2 All-x words and ECC

There is a special case for legal ECC values in the MPC5777M. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not legal for memory that is checked by ECC. The flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses, All-0 or All-1 may be legal.

All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be uncorrectable errors.For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, an All-x content may result in a correctable error.

Note

For flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (see "Embedded Flash Memory" chapter, for more details on flash memory safety mechanisms).

6.4.4.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU . The MEMU (see Memory Error Management Unit (MEMU)) may filter ECC error notification for known ECC error addresses (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU, which filters and then forwards unfiltered notifications in an aggregated manner to the FCCU.

6.4.4.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events associated with ECC logic used on SRAM (system RAMs in this context are those RAMs with "System RAM" memory classification as in Table 6-5), peripheral RAM, and flash memory. When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU .

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses in the table is ensured. For example, if an address is already stored in the MEMU's table, correctable errors at that address will no longer be reported to the FCCU.
- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory.
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU.

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (see Memory Error Management Unit (MEMU) chapter for more information).

6.4.4.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- the (optional) ECC-syndrome or MBIST bad-bit information
- A configuration specifying whether the ECC unit is attached to a vital memory (SRAM, local memory, and system RAM of Safety Core), to flash memory, or to a peripheral RAM

Not all ECC units provide a syndrome. If an ECC unit does not provide the syndrome, FFh is stored in the MEMU error table instead of the syndrome. If an error is signaled, it is compared against all errors known for that storage:

Note

If a previously known error has been marked invalid by software, no comparison against the address will occur.

- If no entry of that address is already in the buffer, it is to be added into the appropriate table depending on the SBE versus UCE indicator
- If there is no free entry left in that buffer, the overflow flag is set.

If a valid entry of that address is in the buffer and If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. In case the same error is reported by ECC which reports the syndrome and additionally by ECC which does not, the reporting order becomes important.

- If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer.If ECC which provides the syndrome reports first, the second reporting without syndrome is discarded.
- If ECC which does not provide the syndrome reports first, a second entry with the syndrome is stored in the table.

Chapter 7
Device Configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters
- Links for more information

7.2 Core modules

The MPC5777M has cores in three distinct modules:

- HSM (described in the HSM chapter of the *Security Reference Manual*)
- GTM (described in the *GTM Reference Manual*)
- Main platform has four separate cores that perform various computational and control functions as described below.

Table 7-1. MPC5777M core modules

Instance	Description
Main Core_0	The main computational shell consists of Main Core_0 and Main Core_1, both of which use an e200z710n3 core. These two cores are used for general computational functions.
Main Core_1	
Checker Core_0s	A third core, referred to as Checker Core_0s, uses an e200z709 core, which is a true subset of the e200z710n3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly. There is no lock step function associated with Main Core_1.
Peripheral Core_2	The fourth processor, Peripheral Core_2, employs an e200z425Bn3 core and is generally used to control various I/O modules.

For more information, please see Core Complex Overview.

7.2.1 Core Reset Settings

Table 7-2 shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately following a system reset.

7.2.2 Special Purpose Register Summary

PowerISA 2.06 and implementation-specific SPRs for the e200z710n3, e200z709, and e200z425Bn3 cores are listed in the following table. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in the following table.

Table 7-3. Special Purpose Registers

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No
CTR	Count Register	9	R/W	No	No
SRR0	Save/Restore Register 0	26	R/W	Yes	No

1. The Debug Status Register can be read using *mfspr RT,DBSR*. The Debug Status Register cannot be directly written to. Instead, bits in the Debug Status Register corresponding to '1' bits in GPR(RS) can be cleared using *mtspr DBSR,RS*.
2. Undefined on **POR** assertion, unchanged on **external PORESET** assertion.
3. The Machine Check Syndrome Register can be read using *mfspr RT,MCSR*. The Machine Check Syndrome Register cannot be directly written to. Instead, bits in the Machine Check Syndrome Register corresponding to '1' bits in GPR(RS) can be cleared using *mtspr MCSR,RS*.
4. The 64-bit DVC registers are accessed by using the DVC1,2 spr #s for the lower 32 bits, and the DVC1,2U spr #s for the upper 32 bits.

7.3 System modules

7.3.1 SIUL2 configuration

The System Integration Unit Lite 2 (SIUL2) controls:

- MCU pad configuration
- Ports
- General-purpose input and output (GPIO) signals
- External interrupts with trigger event configuration

For details please refer System Integration Unit Lite2.

7.3.2 Semaphores2 (SEMA42)

The peripheral platform shell includes a memory-mapped module (SEMA42) that provides

- Robust hardware support needed in multi-core systems for implementing semaphores
- Asimple mechanism to achieve "lock/unlock" operations via a single write access

The hardware semaphore module is an architecture-neutral solution that provides sixteen hardware-enforced gates for MPC5777M as well as other useful system functions related to the gating mechanisms. The capabilities provided by the hardware semaphore module are currently utilized in FSL's dual-core AUTOSAR® implementations and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

For details refer to Semaphores2 (SEMA42).

7.3.3 Crossbar switch configuration

This device contains two crossbar switch modules. Figure 7-1 illustrates that they are connected via a Cross-lake, which is composed of intelligent bridging bus gaskets. These bus gaskets handle the traffic that crosses between the shells and do not require any interaction with the user. This dual-crossbar architecture allows all masters to access all slaves across the computational shell and peripheral shell.

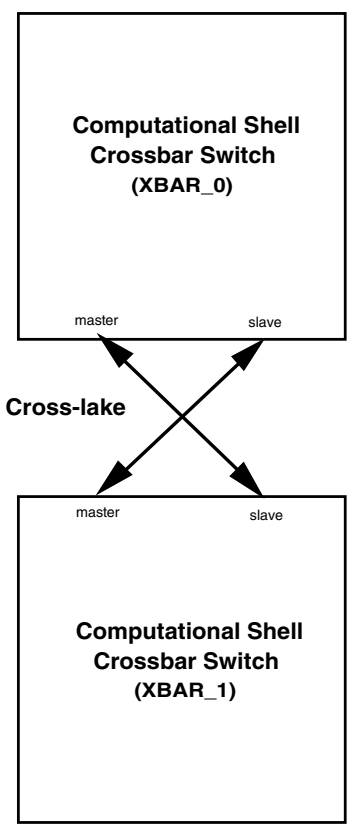

Figure 7-1. Crossbar switches diagram

The following sections explain how each crossbar switch is configured on this device.

7.3.3.1 Computational shell crossbar switch (XBAR_0) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

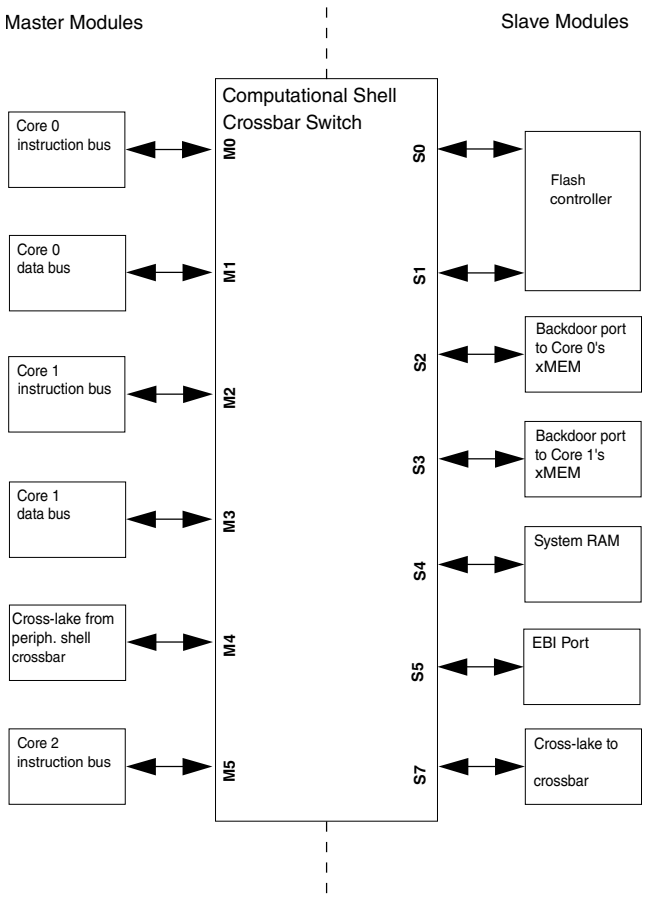

Figure 7-2. Computational shell's crossbar switch integration

Table 7-4. Reference links to related information

Topic	Related module	Reference

System memory map	—	Memory Map
Clocking	—	Clocking
Crossbar switch master	Cores	Core modules
Crossbar switch slave	Flash memory controller	Flash memory controller
Crossbar switch slave	Processor core local memory	Processor core local SRAM
Crossbar switch slave	System RAM	System SRAM

7.3.3.1.1 Computational shell crossbar switch master assignments

This device contains six masters connected to the computational shell's crossbar switch.

The master assignment is shown in Table 7-5.

Table 7-5. Computational shell crossbar switch master assignments_a

Master module	Physical master port number
Core 0 instruction bus	0
Core 0 data bus	1
Core 1 instruction bus	2
Core 1 data bus	3
Peripheral shell crossbar switch	4
Core 2 instruction bus	5

7.3.3.1.2 Computational shell crossbar switch slave assignments

This device contains seven slaves connected to the computational shell's crossbar switch.

The slave assignment is shown in Table 7-6.

Table 7-6. Computational shell crossbar switch slave assignments

Slave module	Physical slave port number
Flash memory controller port 0	0
Flash memory controller port 1	1
Backdoor port to Core 0's xMEM	2
Backdoor port to Core 1's xMEM	3
System RAM	4
EBI port	5
Peripheral shell crossbar switch	7

Access to the flash memory via slave ports 0 and 1 is routed based on the master. The master-to-flash memory port routing has been assigned in a way to balance data traffic, with attention paid to facilitate core instruction fetches. The following table shows the flash memory port assignments.

Table 7-7. Flash memory port assignments

Flash memory slave port 0	Flash memory slave port 1
Core 0 instruction bus (M0)	Core 0 data bus (M1)
Core 1 data bus (M3)	Core 1 instruction bus (M2)

Table continues on the next page...

Table 7-7. Flash memory port assignments (continued)

Flash memory slave port 0	Flash memory slave port 1
Peripheral shell crossbar switch (M4)	Core 2 instruction bus (M5)

7.3.3.1.3 PRS register reset values

The computational shell's XBAR_0 PRSn registers reset to 0x0030_1425. Note that these registers are read-only.

7.3.3.1.4 CRS register reset values

The computational shell's XBAR_0 CRSn registers reset to 0x003F_0100.

7.3.3.2 Peripheral shell crossbar switch (XBAR_1) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

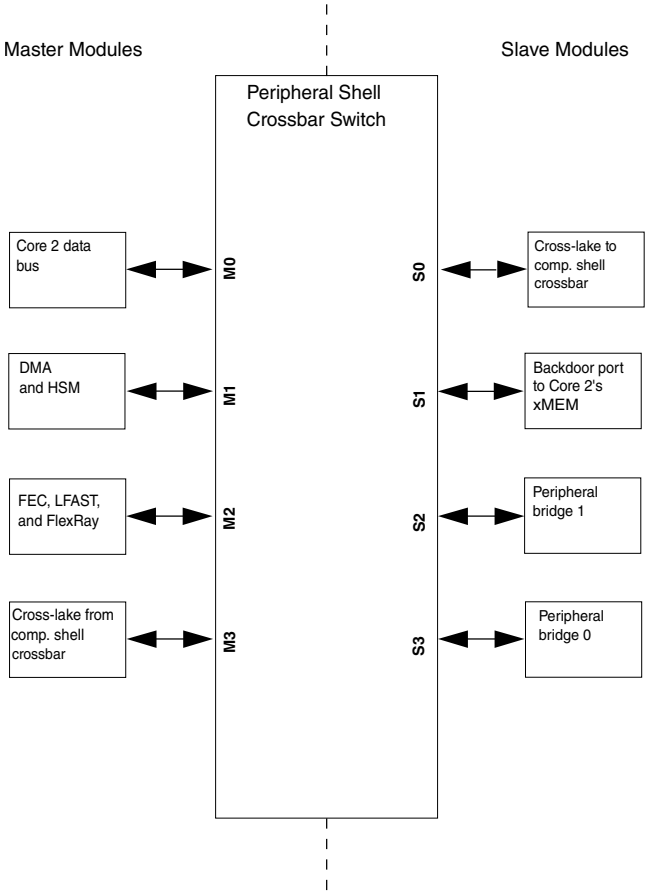

Figure 7-3. Crossbar switch integration

7.3.3.2.1 Peripheral shell crossbar switch master assignments

This device contains four masters connected to the peripheral shell's crossbar switch.

The master assignment is shown in Table 7-9.

Table 7-9. Peripheral shell crossbar switch master assignments_a

Master module	Physical master port number
Core 2 data bus	0
DMA and Hardware Security Module (HSM)	1
FEC, LFAST, and FlexRay	2
Cross-lake master	3

7.3.3.2.2 Peripheral shell crossbar switch slave assignments

This device contains four slaves connected to the peripheral shell's crossbar switch.

The slave assignment is shown in Table 7-10.

Table 7-10. Peripheral shell crossbar switch slave assignments_a

Slave module	Physical slave port number
Computational shell crossbar switch	0
Backdoor port to Core 2's xMEM	1
Peripheral bridge 1	2
Peripheral bridge 0	3

7.3.3.2.3 PRS register reset values_a

The peripheral shell's XBAR_1 PRS*n* registers reset to 0x0000_3102.

7.3.3.2.4 CRS register reset values_a

The peripheral shell's XBAR_1 CRS*n* registers reset to 0x000F_0100.

7.3.4 System Memory Protection Unit (SMPU) configuration

This chip contains three instances of the System Memory Protection Unit (SMPU):

- SMPU_HSM for the Hardware Security Module
- SMPU_0 for the Computational Shell
- SMPU_1 for the Peripheral Shell

The following sections explain how each SMPU is configured on this chip. See the *Microcontroller Security Reference Manual* for configuration details of SMPU_HSM.

7.3.4.1 SMPU0 configuration

The following sections explain how SMPU_0 and SMPU_1 are configured on this chip. For a comprehensive description of the module itself, see the chapter for that module.

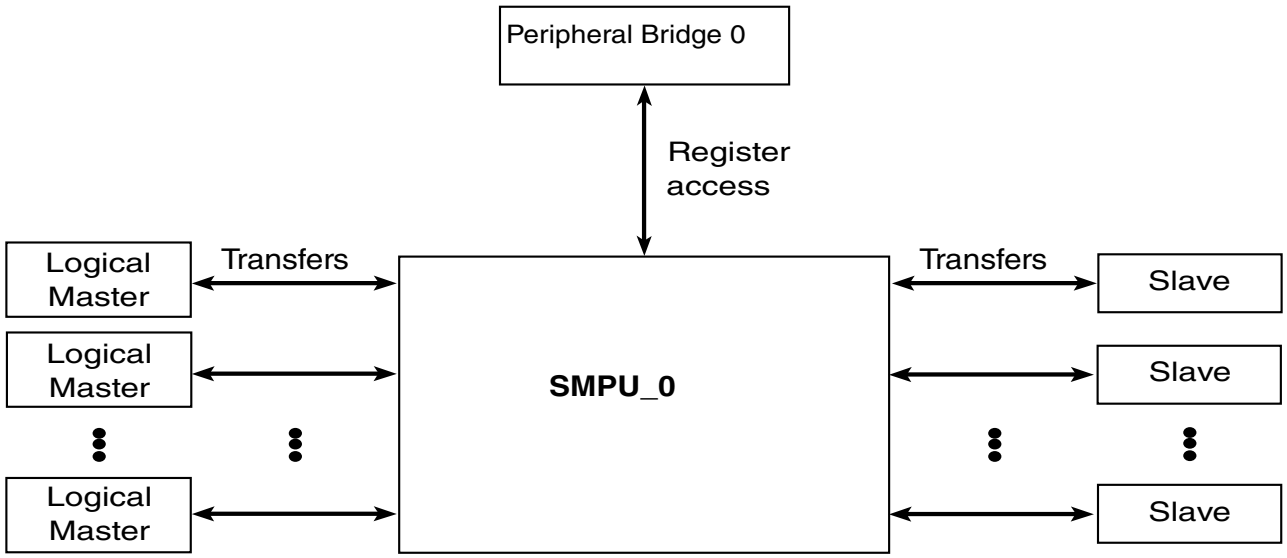

Figure 7-4. SMPU0 configuration

Table 7-11. Reference links to related information

Topic	Related module	Reference

RGD_WORD2 formats	—	RGD_WORD2 formats supported by SMPU0
Master Access Permissions	—	Master Access permissions for SMPU0

7.3.4.1.1 SMPU0 logical bus master assignments

The logical bus master assignments for the SMPU0 are:

Table 7-12. SMPU0 logical bus master assignments_a

SMPU logical bus master number	Bus master
0	Core_0
1	Core_1
2	Core_2
3	DMA_0
4	Ethernet
5	FlexRay_0
6	SIPI_1
7	SIPI_0/LFAST
8	Core_0 Debug
9	Core_1 Debug
10	Core_2 Debug
11	DMA_1
12	Reserved
13	FlexRay_1
14	HSM
15	NAR

7.3.4.1.2 Number of region descriptors supported by SMPU0

This instance of the SMPU module supports a maximum of twelve region descriptors.

7.3.4.1.3 RGD_WORD2 formats supported by SMPU0

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.1.4 Master Access permissions for SMPU0

The only masters allowed to access the SMPU0 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supervisor mode.

7.3.4.2 SMPU1 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

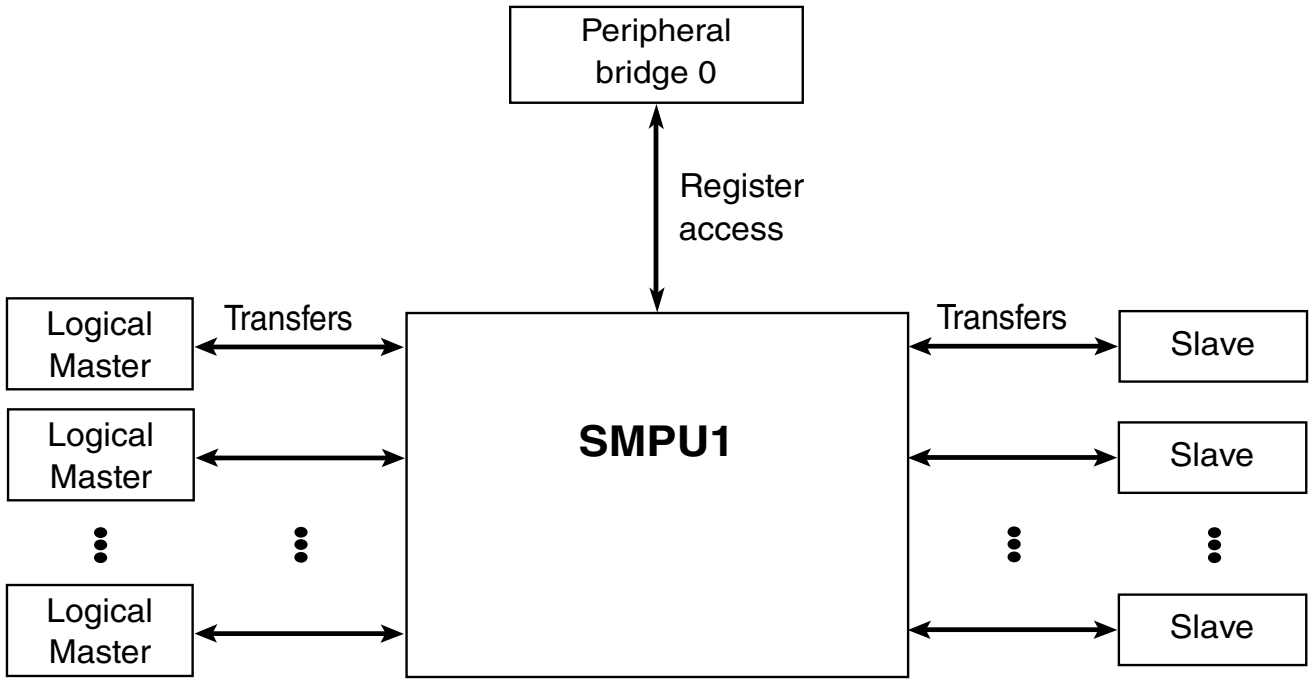

Figure 7-5. SMPU1 configuration

Table 7-13. Reference links to related information

7	SIPI_1/LFAST
8	Core_0 Debug
9	Core_1 Debug
10	Core_2 Debug
11	DMA_1
12	Reserved
13	FlexRay_1
14	HSM
15	NAR

7.3.4.2.2 Number of region descriptors supported by SMPU1

This instance of the SMPU module supports a maximum of eight region descriptors.

7.3.4.2.3 RGD_WORD2 formats supported by SMPU1

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.2.4 Master Access permissions for SMPU1

The only masters allowed to access the SMPU1 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supebe in supervisor mode.

7.3.5 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

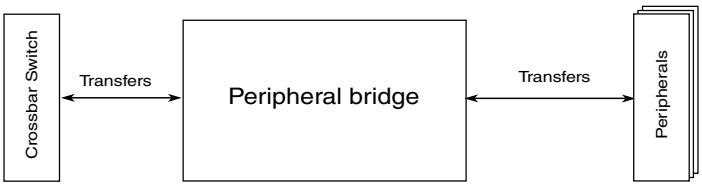

Figure 7-6. Peripheral bridge configuration

Table 7-15. Reference links to related information

Topic	Related module	Reference
Full description	Peripheral bridge	Peripheral Bridge
System memory map	—	Memory Map
Clocking	—	Clocking
Crossbar switch	Crossbar switch	Crossbar switch configuration

7.3.5.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

7.3.5.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See Memory Map" for the memory slot assignment for each module.

7.3.5.3 MPR registers

Each of the two peripheral bridges supports up to 16 crossbar switch masters, each assigned to a MPROT*n* field in the MPRA-B registers. However, fewer are supported on this device. See Crossbar switch configuration for details of the master port assignments for this device.

7.3.5.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each are assigned to a PACR*n* or OPACR*n* field within the PACRA-H/OPACRA-AF registers. See Memory Map chapter for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

7.3.6 Platform Configuration Module (PCM)

The Platform Configuration Module contains three miscellaneous configuration registers for the device. Currently, the configuration registers are related to the operation of the FEC and intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

7.3.6.1 FEC Burst Optimization Master Control Register (FBOMCR)

Offset: 00h Access: Supervisor read/write

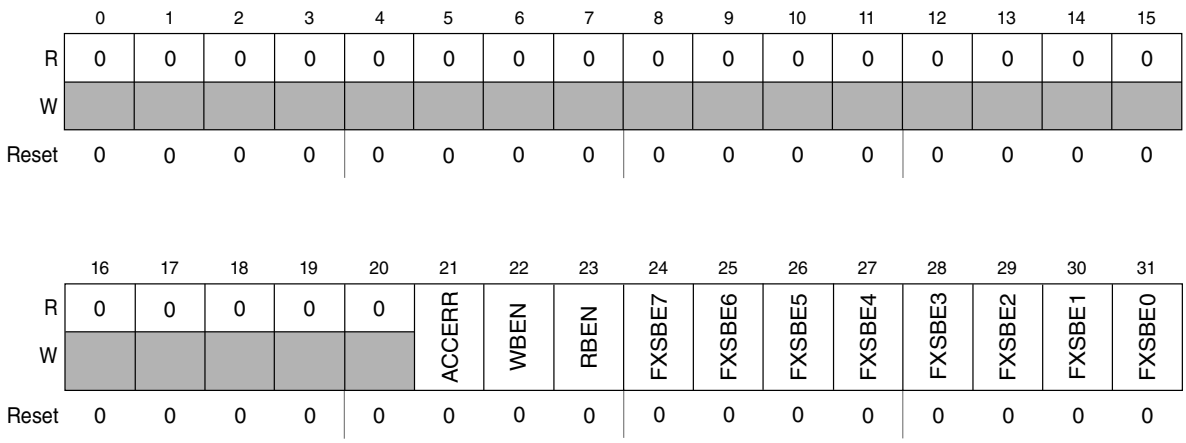

Figure 7-7. FEC Burst Optimization Master Control Register (FBOMCR)

Table 7-16. FBOMCR field description

Field	Description
0–20	Reserved
21 ACCERR	Accumulate error This bit determines whether an error response for the first half of the write burst is accumulated to the second half of the write burst or discarded. In order to complete the burst, the FEC interface to the system bus responds by indicating that the first half of the burst completed without error before it actually writes the data so that it can fetch the second half of the write data from the FIFO. When actually written onto the system bus, the first half of the write burst can have an error. Because this half initially responded without an error to the FIFO, the error is discarded or accumulated with the error response for the second half of the burst. 0 Any error to the first half of the write burst is discarded. 1 Any actual error response to the first half of the write burst is accumulated in the second half's response. In other words, an error response to the first half will be seen in the response to the second half, even if the second half does not contain an error.
22 WBEN	Global write burst enable to XBAR slave port designated by FXSBE*n*

Table continues on the next page...

Table 7-16. FBOMCR field description (continued)

Field	Description
	0 Write bursting to all XBAR slave ports is disabled. 1 Write bursting is enabled to any XBAR slave port whose FXSBE*n* bit is asserted.
23 RBEN	Global read burst enable from XBAR slave port designated by FXSBE*n* 0 Read bursting from all XBAR slave ports is disabled. 1 Read bursting is enabled from any XBAR slave port whose FXSBE*n* bit is asserted.
24-31 FXSBE[7:0]	The FEC burst optimization master control register (FBOMCR) controls FEC burst optimization behavior on the system bus. FXSBE — FEC XBAR slave burst enable. FXSBE*n* enables bursting by the FEC interface to the XBAR slave port controlled by that respective FXSBE*n* bit. If FXSBEn is asserted, then that XBAR slave port enabled by the bit can accept the bursts allowed by RBEN and WBEN. Otherwise, the FEC interface will not burst to the XBAR slave port controlled by that respective FXSBE*n* bit. Read bursts from that XBAR slave port are enabled by RBEN. Write bursts to that XBAR slave port are enabled by WBEN. FXSBE*n* assignments to XBAR slave ports: FXSBE0 = Flash FXSBE1 = reserved FXSBE2 = RAM, TCMA, TCMB, TCMC FXSBE3 = reserved FXSBE4 = reserved FXSBE5 = reserved FXSBE6 = reserved FXSBE7 = PBRIDGE0 and PBRIDGE1

7.3.6.2 IAHB Burst Enable 0 (IAHB_BE0) Register

Offset: 04h Access: Supervisor read/write

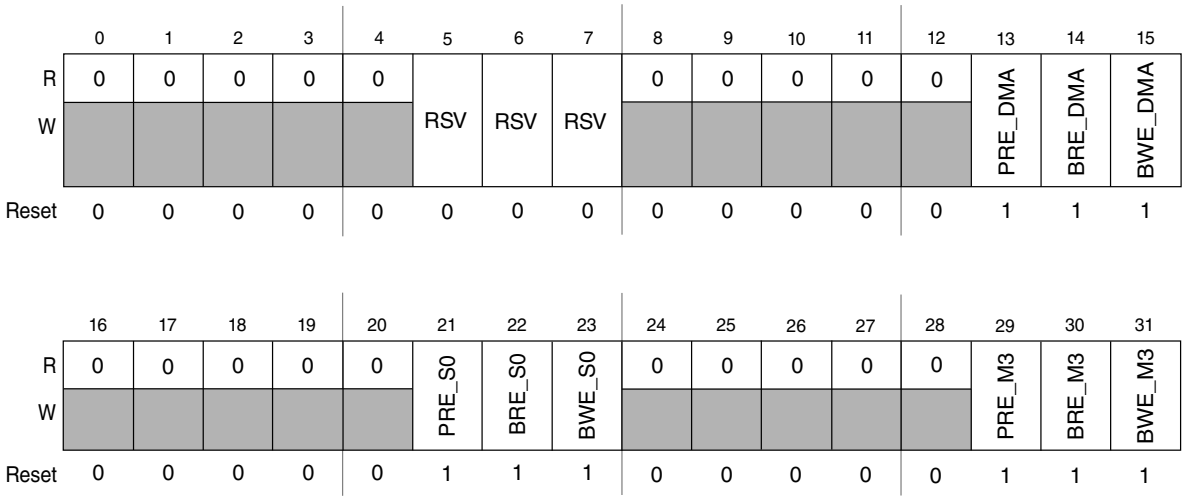

Figure 7-8. IAHB Burst Enable 0 (IAHB_BE0) Register

Table 7-17. IAHB_BE0 Register field description

Field	Description
0–4	Reserved
5–7 RSV	Reserved bits define the PRE, BRE and BWE of the bus gasket for the HSM.
8–12	Reserved
13 PRE_DMA	Pending read enable (PRE) DMA This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_DMA	Burst read enable (BRE) DMA This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_DMA	Burst write enable (BWE) DMA This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20	Reserved
21 PRE_S0	Pending read enable (PRE) S0 This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
22 BRE_S0	Burst read enable (BRE) S0 This bit controls the bus gasket's handling of burst read transactions.

Table continues on the next page...

15 BWE_COREB_INST_BUS	Burst write enable (BWE) Core B instruction bus This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16-20	Reserved
21 PRE_COREA_DATA_BUS	Pending read enable (PRE) Core A data bus This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
22 BRE_COREA_DATA_BUS	Burst read enable (BRE) COREA_DATA_BUS This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_COREA_DATA_BUS	Burst write enable (BWE) COREA_DATA_BUS This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket.

Table continues on the next page...

Table 7-19. IAHB_BE2 field description (continued)

Field	Description
	1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24-28	Reserved
29 PRE_COREA_INST_BUS	Pending read enable (PRE) Core A instruction Bus This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_COREA_INST_BUS	Burst read enable (BRE) Core A instruction Bus This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_COREA_INST_BUS	Burst write enable (BWE) Core A instruction bus This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

7.3.6.5 IAHB Burst Enable 3 (IAHB_BE3) Register

Offset: 0Ch Access: Supervisor read/write

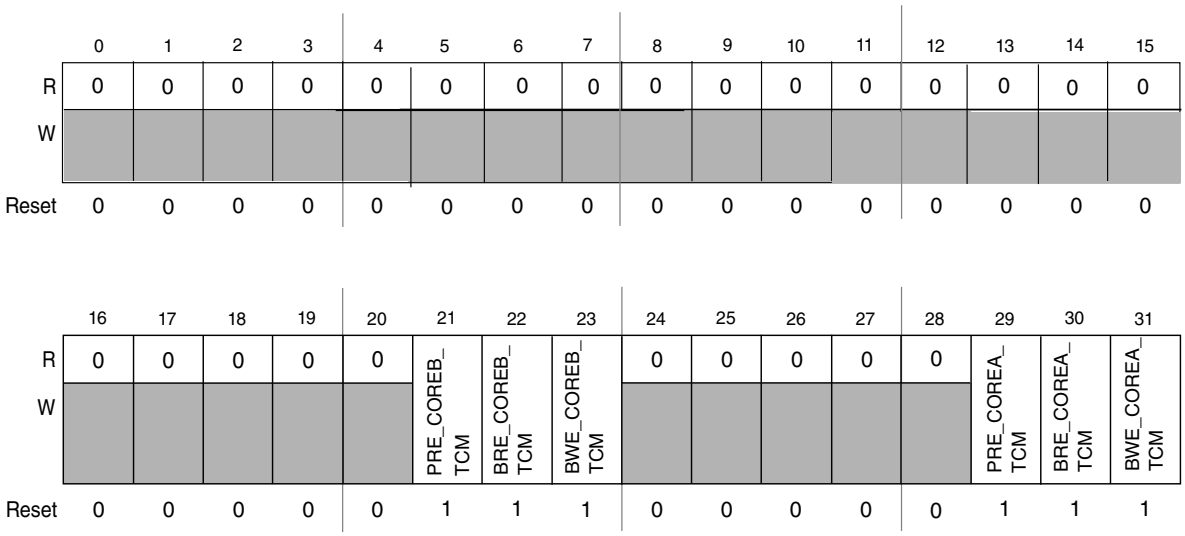

Figure 7-11. IAHB Burst Enable 3 (IAHB_BE3) Register

Table 7-20. IAHB_BE3 field description

Field	Description
0–15	Reserved
16-20	Reserved
21 PRE_COREB_TCM	Pending read enable (PRE) Core B TCM This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
22 BRE_COREB_TCM	Burst read enable (BRE) CORE B TCM This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_COREB_TCM	Burst write enable (BWE) CORE B TCM This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24-28	Reserved
29 PRE_COREA_TCM	Pending read enable (PRE) Core A TCM This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.

Table 7-21. IPS_CGM_EN0 field description

Field	Description
0–2	Reserved

Table continues on the next page...

Table 7-21. IPS_CGM_EN0 field description (continued)

Field	Description
3 IPS_CGM_DMA0	IPS clock gating enable for DMA0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
4-6	Reserved
7 IPS_CGM_MPU1	IPS clock gating enable for MPU1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
8-10	Reserved
11 IPS_CGM_AXBS1	IPS clock gating enable for AXBS1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
12-14	Reserved
15 IPS_CGM_INTC	IPS clock gating enable for INTC 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
16-18	Reserved
19 IPS_CGM_MPU0	IPS clock gating enable for MPU0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
20-22	Reserved
23 IPS_CGM_AXBS0	IPS clock gating enable for AXBS0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
24-26	Reserved
27 IPS_CGM_PRAM	IPS clock gating enable for PRAM Controller 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
28-30	Reserved
31 IPS_CGM_PFLASH	IPS clock gating enable for PFlash Controller 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.

7.3.7 Interrupt Controller (INTC) configuration

7.3.7.1 INTC configurable parameters

The INTC on this chip supports 4 processors.

7.3.7.2 INTC implemented registers

Table 7-22 shows the registers implemented on the INTC on this chip.

Table 7-22. INTC implemented registers

Address offset	Register
000h	INTC Block Configuration Register (INTC_BCR)
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)
014h	INTC Current Priority Register for Processor 1(INTC_CPR1)
018h	INTC Current Priority Register for Processor 2 (INTC_CPR2)
01Ch	INTC Current Priority Register for Processor 3 (INTC_CPR3)
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)
024h	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)
028h	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)
02Ch	INTC Interrupt Acknowledge Register for Processor 3 (INTC_IACKR3)
030h	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)
034h	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)
038h	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)
03Ch	INTC End Of Interrupt Register for Processor 3 (INTC_EOIR3)
040h-05Ch	INTC Software Set/Clear Interrupt Register 0-3 (INTC_SSCIR0_3) - INTC Software Set/Clear Interrupt Register 28-31 (INTC_SSCIR28_31)
05Ch-85Ch	INTC Priority Select Register 0-1 (INTC_PSR0_1) - INTC Priority Select Register 1022-1023 (INTC_PSR1022_1023)

7.3.7.3 Interrupt sources

The following table defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 7-23. Interrupt sources

IRQ #	Offset	Source description	Source name
0		Software settable flag 0	INTC_SSCIR0[CLR0]
1		Software settable flag 1	INTC_SSCIR0[CLR1]
2		Software settable flag 2	INTC_SSCIR0[CLR2]
3		Software settable flag 3	INTC_SSCIR0[CLR3]
4		Software settable flag 4	INTC_SSCIR0[CLR4]
5		Software settable flag 5	INTC_SSCIR0[CLR5]
6		Software settable flag 6	INTC_SSCIR0[CLR6]
7		Software settable flag 7	INTC_SSCIR0[CLR7]
8		Software settable flag 8	INTC_SSCIR0[CLR8]
9		Software settable flag 9	INTC_SSCIR0[CLR9]
10		Software settable flag 10	INTC_SSCIR0[CLR10]
11		Software settable flag 11	INTC_SSCIR0[CLR11]
12		Software settable flag 12	INTC_SSCIR0[CLR12]
13		Software settable flag 13	INTC_SSCIR0[CLR13]
14		Software settable flag 14	INTC_SSCIR0[CLR14]
15		Software settable flag 15	INTC_SSCIR0[CLR15]
16		Software settable flag 16	INTC_SSCIR0[CLR16]
17		Software settable flag 17	INTC_SSCIR0[CLR17]
18		Software settable flag 18	INTC_SSCIR0[CLR18]
19		Software settable flag 19	INTC_SSCIR0[CLR19]
20		Software settable flag 20	INTC_SSCIR0[CLR20]
21		Software settable flag 21	INTC_SSCIR0[CLR21]
22		Software settable flag 22	INTC_SSCIR0[CLR22]
23		Software settable flag 23	INTC_SSCIR0[CLR23]

7.3.7.4 Interrupt Latency

The Interrupt systems is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

The latency time is difficult to define exactly because it depends what interrupts the INTC is processing and what the CPU is doing.

But in general, the latency time is divided into 3 sub-sections:

- INTC Latency
  - 3 clock cycles (INTC clock domain) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency

- 4 clock cycles (CPU clock domain) from the assertion of the interrupt request from the INTC to the execution of the first instruction

- Software Latency
  - 7 clock cycles (CPU clock domain) to execute the 3 instructions needed to save essential registers and enable interrupts

For the MPC5777M, the INTC operates at 50 MHz and the CPUs operate at 300 MHz. So interrupt latency is:-

INTC Latency = 60 ns

CPU Latency = 13.33 ns

Software Latency = 23.33 ns

Interrupt Latency Total = 96.66 ns

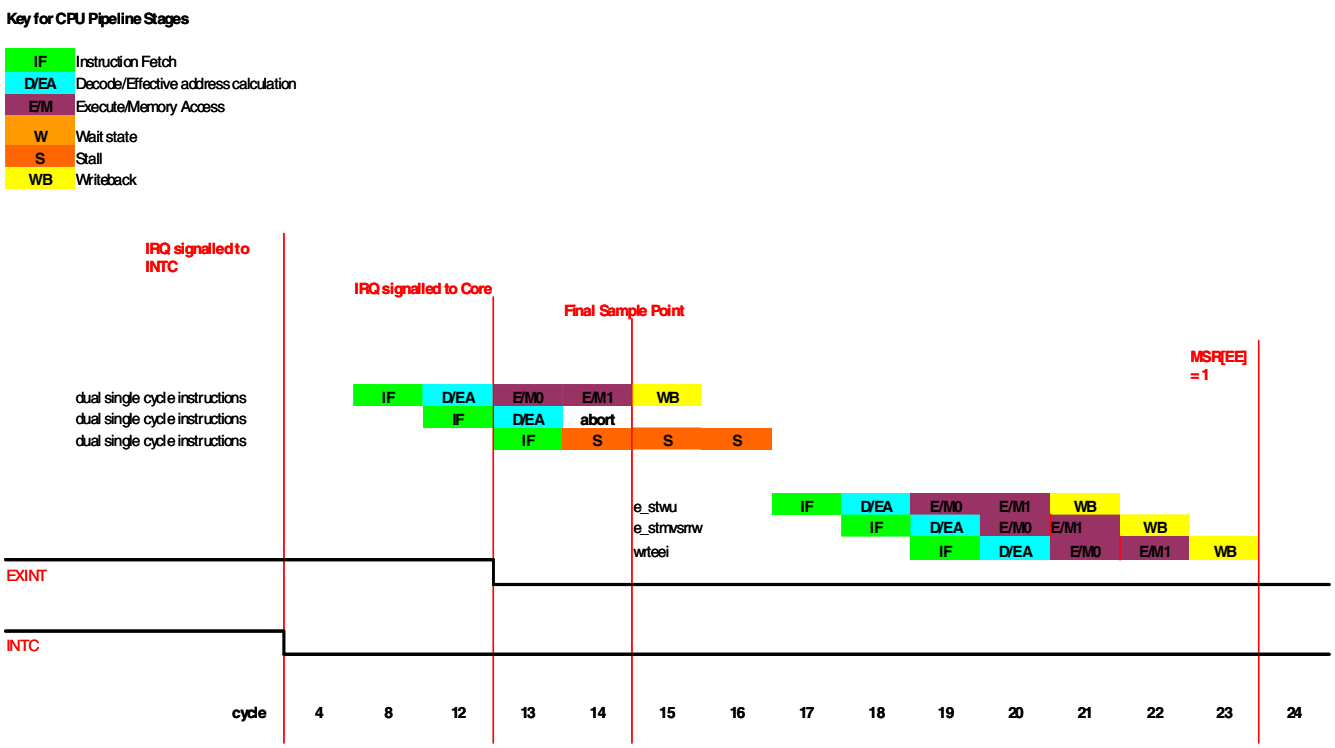

Figure 7-13. Interrupt timing

7.3.7.5 INTC (hsm_z0_platform) configuration

For interrupts specific to the Hardware Security Module (HSM) please refer to the *MPC5777M Security Reference Manual*.

7.4 DMA Controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

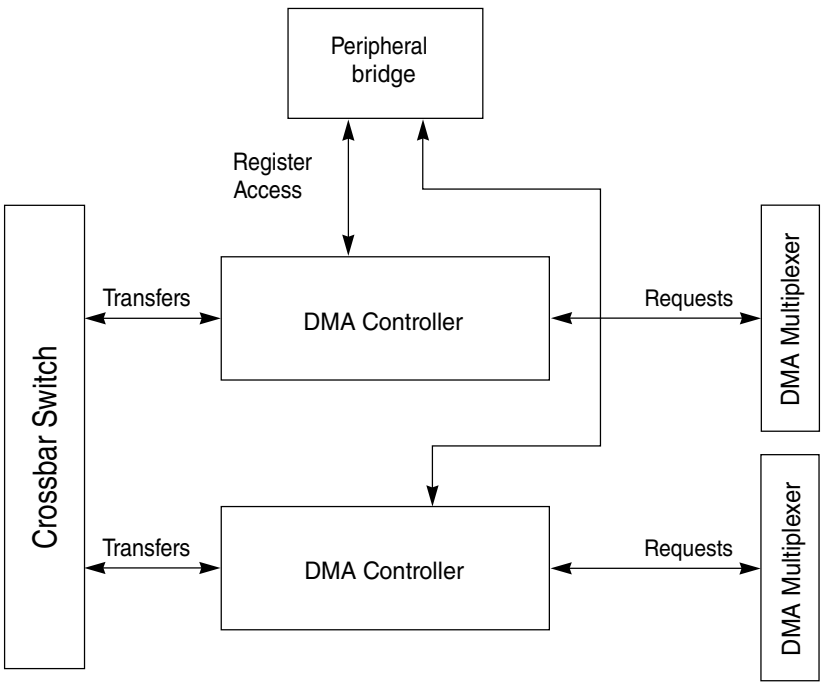

Figure 7-14. DMA controller configuration

Table 7-24. Reference links to related information

Topic	Related module	Reference
Full description	DMA Controller	Enhanced Direct Memory Access (eDMA)
System memory map		Memory Map
Register access	Peripheral bridge	Peripheral Bridge
Clocking		Clocking
Transfers	Crossbar switch	Crossbar Switch (XBAR)

7.5 DMACHMUX configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.5.1 DMA channel assignment

MPC5777M has ten multiplexers and a total of 128 DMA channels. Since more than 64 DMA channels are used, two eDMA modules (eDMA_0 and eDMA_1) are required. Table 7-25 lists which multiplexers and channels are available on MPC5777M.

Table 7-25. MPC5777M multiplexer and channel list

DMAMUX instance	Number of DMA channels	DMAMUX channel	eDMA_0 channel	eDMA_1 channel
0	8	0–7	0–7	
1	8	8–15	8–15	
2	8	16–23	16–23	
3	8	24–31	24–31	
4	16	32–47	32–47	
5	16	48–63	48–63	
6	16	64–79		0-15
7	16	80–95		16-31
8	16	96–111		32-47
9	16	112–127		48-63

7.5.2 DMA system level block diagram

The connections of the DMA channel multiplexers to the eDMA are shown in Figure 7-15.

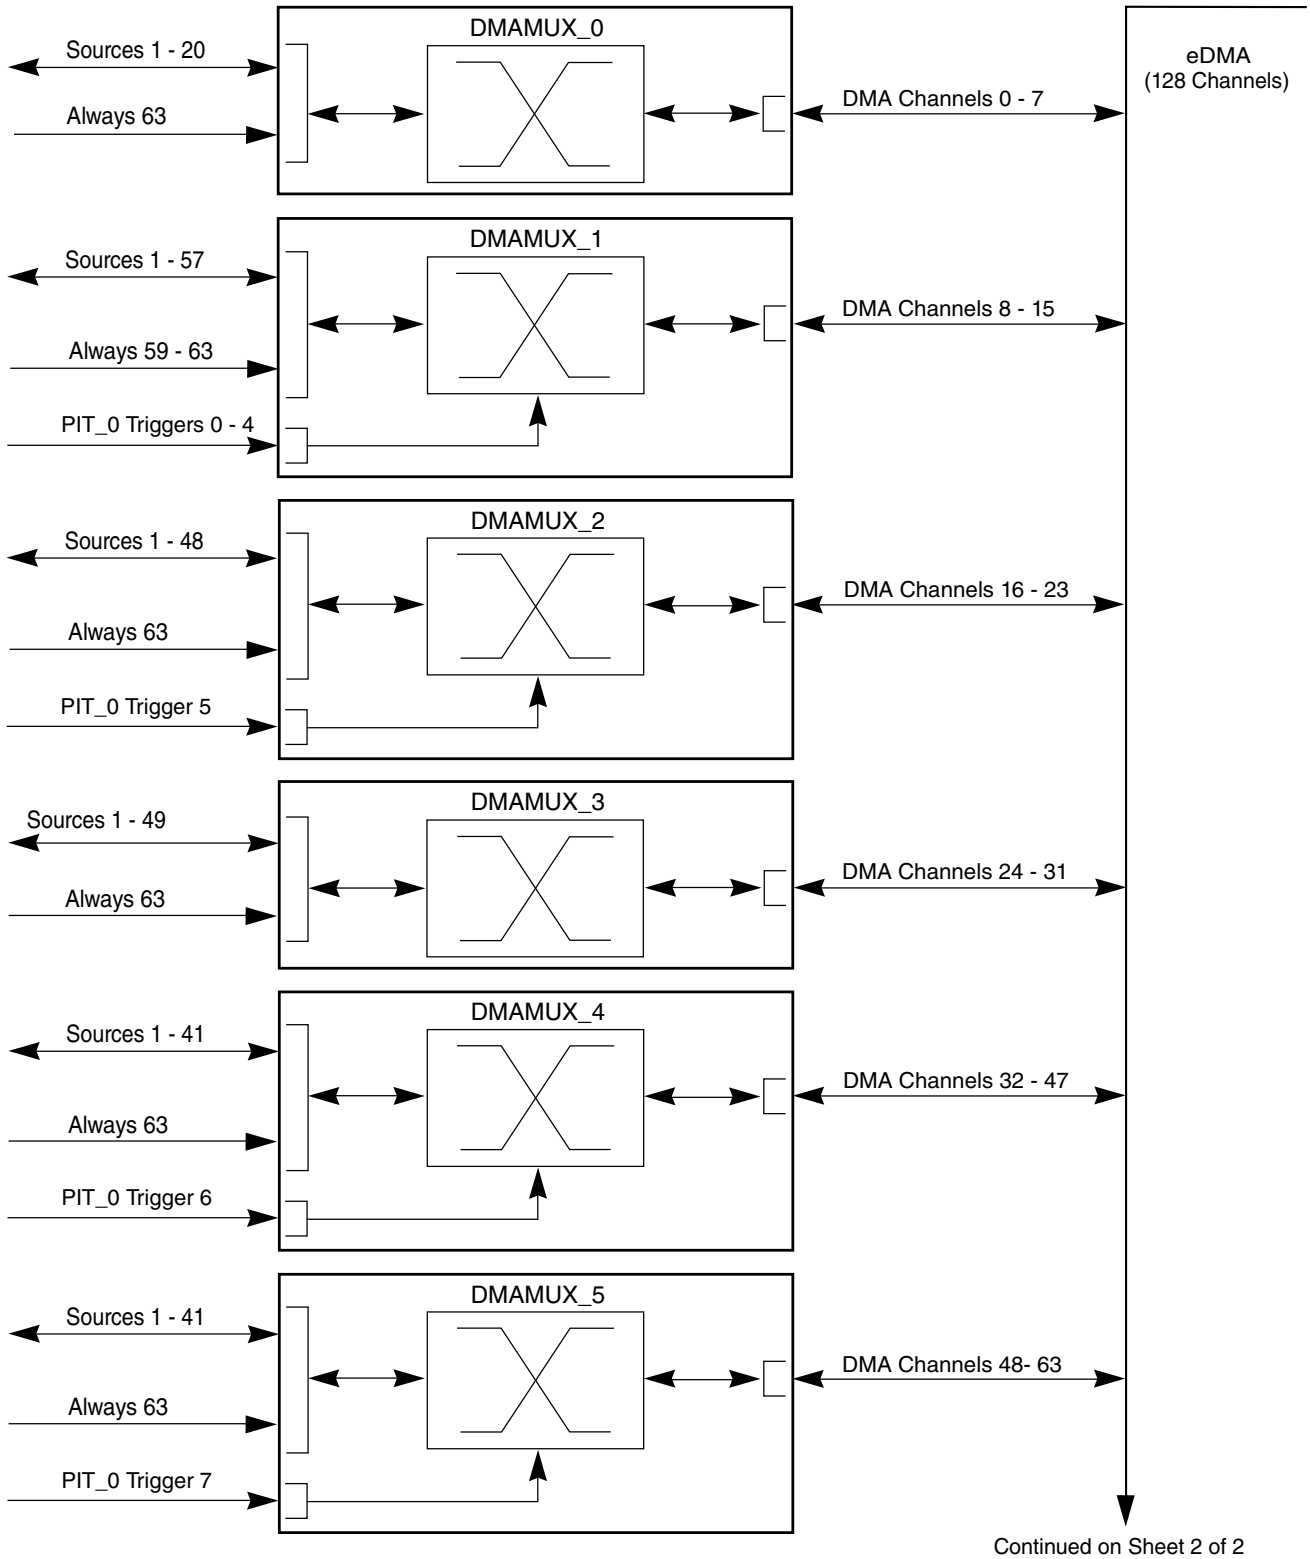

Figure 7-15. DMA channel multiplexing (Sheet 1 of 2)

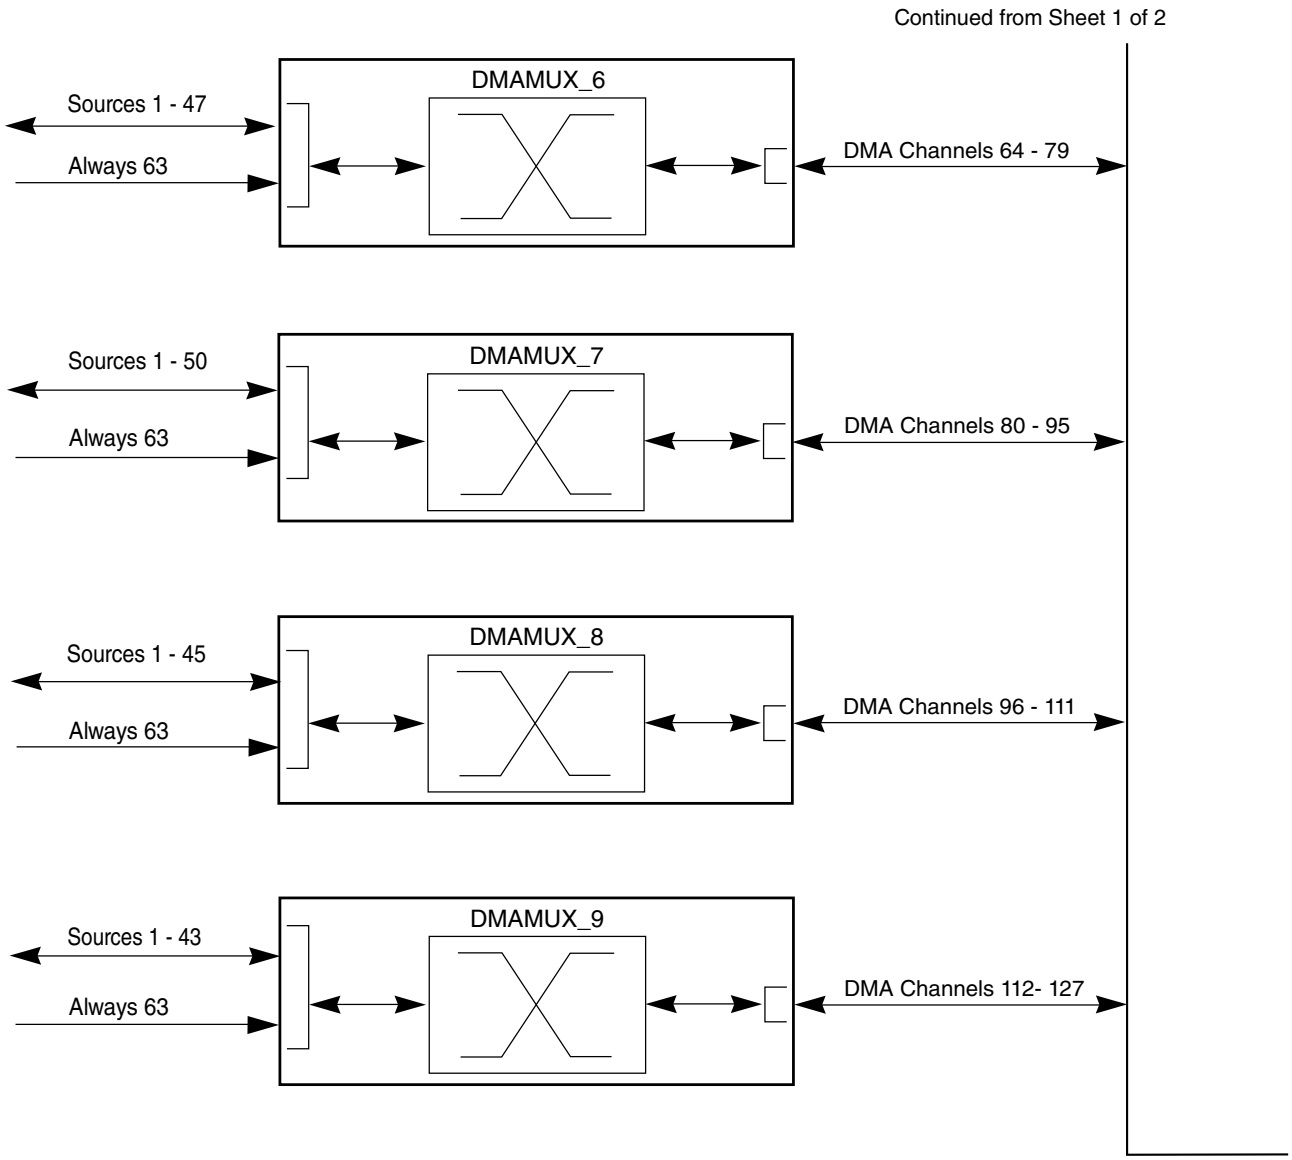

Figure 7-16. DMA channel multiplexing (Sheet 2 of 2)

7.5.3 DMA request mapping

The mapping of the peripheral DMA requests to the DMA_CH_MUX input sources is shown in Table 7-26.

The DMA requests from the Sigma-Delta Analog-to-Digital Converter (SDADC) must go through a two input AND gate before the DMAMUX. The other source of the AND gate is an IMUX output of GTM channels. The exact IMUX output is detailed in the SIUL2 chapter.

62	Reserved	Always on	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
63	Always on	Always on	Always on	Always on	Always on	Always on	Always on	Always on	Always on	Always on

Note

Just as multiple CHCONFIG registers within the same instance must not select the same source value, CHCONFIG registers among multiple instances must not select the same source value.

7.5.4 DMAMUX Memory map

The 10 instances of DMAMUX (0–9) on MPC5777M. Each instance is assigned to its own peripheral bridge slot and is allocated 512 bytes of memory space. The DMAMUX address offsets are shown in Table 7-27.

Table 7-27. DMAMUX memory map

Offset[1]	Register[3]	Access
0x0000	DMAMUX_0 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0200	DMAMUX_1 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0400	DMAMUX_2 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0600	DMAMUX_3 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0800	DMAMUX_4 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W

Table continues on the next page...

Table 7-27. DMAMUX memory map (continued)

Offset[1]	Register[3]	Access
0x0A00	DMAMUX_5 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W
0x0C00	DMAMUX_6 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W
0x0E00	DMAMUX_7 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W
0x1000	DMAMUX_8 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W
0x1200	DMAMUX_9 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W

1. Offsets are from DMAMUX base address (0xFFF6_C000), shown in .
2. Offsets are from DMAMUX base address (0xFFF6_C000), shown in .
3. Each channel must be configured separately via settings in a dedicated configuration channel. There is one configuration register per channel for each DMAMUX. See the DMACHMUX chapter for details.

7.7.1 Flash memory controller (PFLASH) configuration

The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, PFCR2, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See Table 7-7 in the crossbar switch configuration section for details. See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

7.7.1.1 Calibration remapping support

The PFLASH_C55FM flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM or on-chip system RAM that can be used as overlay RAM. The relationship between flash access latency and remapped overlay RAM latency is contingent upon operating frequency and intrinsic memory access times. describes the intrinsic cycle latency on a random, initial access for each supported overlay RAM target.

(See PFlash calibration remap support for more details on the relationship between flash access latency and overlay RAM access latency.

Note

Cycle times measured based on the PFLASH_C55FM clock.
See Clocking for more details on clocking.

Table 7-32. Calibration memory access times

Calibration memory	Burst access time (cycles)
On-chip overlay RAM	5
Buddy device overlay RAM	8
System RAM	9

7.7.1.2 Wait state settings for overlay flash latency matching

A remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time for a flash access as well as the required access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. The table below describes the minimum supported flash wait state setting to guarantee a remapped access matches the response latency of a flash access.

Table 7-33. Minimum wait state settings for overlay flash latency match

Overlay Target	PFCR1[RWSC] Minimum Value
BD RAM	6
On-Chip Overlay RAM	3
System RAM	6

If PFCR1[RWSC] is set sufficiently high such that the remapped burst access completes before flash read data is expected to be returned, the flash controller stalls the return of overlay data the appropriate number of additional cycles to ensure the access time matches the response latency of a flash access. Once the overlay access is stored in the flash controller mini-cache, subsequent requests that hit in the mini-cache are returned with zero wait state latency.

7.7.2 Decorated Storage Memory Controller (DSMC)

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR, and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The module includes error checking logic that validates the decoration field, making sure that it is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated storage memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

The DSMC is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

For the MPC5777M device, the DSMC is instantiated six times, three times in the computational platform shell and three times in the peripheral platform shell. The access size is forced to 64-bit for system RAM, 32-bit for the core xMEMs and PBRIDGE.

Table 7-34. MPC5777M DSMC instantiations

	DSMC and memory controller association
Computational shell	System RAM
	Main Core 0 xMEM (Backdoor Port to the core local Instruction and Data Memories)[1]
	Main Core 1 xMEM (Backdoor Port to the core local Instruction and Data Memories)[1]
Peripheral shell	IOP xMEM (Backdoor Port to the core local Instruction and Data Memories)[1]
	PBRIDGE 0 (Bridge to peripheral subsystem)
	PBRIDGE 1 (Bridge to peripheral subsystem)

1. Instances of the DSMC associated with processor core tightly-coupled memory do not protect both ports—only the backdoor port used by other cores or peripherals is protected. Any IMEM or DMEM location expected to be referenced with atomic access should only be accessed by the local processor core via a decorated storage instruction.

CAUTION

Do NOT perform decorated accesses to any address spaces other than those explicitly listed above. The EBI, for example, has no knowledge of or support for decorated accesses, and a decorated access to it could result in the data at that address being overwritten with zeros.

7.7.3 External Bus Interface (EBI) Support

An EBI is accessible from the device platform with internal connection architecture that allows versatile operation supporting multiple use cases.

- EBI accesses can optionally be routed via the platform flash controller, allowing them to benefit from read buffering and line prefetch support.
  - EBI access routing is determined by dual address mapping of EBI.
  - Optimizes performance of systems that use EBI-connected external flash memories to store program code.
- EBI accesses can be optionally routed via a dedicated AXBS slave port, allowing EBI accesses to be processed simultaneously with accesses to on chip memory resources.
- Internal overlay RAMs can be remapped over the EBI for calibration purposes.
  - Enables calibration of systems that use EBI-connected external flash memories to store constant data tables.
- External EBI connected overlay RAM can be remapped over internal flash memory.
  - Enables increase in overlay RAM resource, particularly for non ED devices

7.7.3.1 e2eECC and EBI Accesses

Since the EBI does not support transfer of any checkbit data outside of the device, all data transfers involving the EBI perform a different (effectively "reversed" compared to the operations of the initiating bus master) set of ECC calculations.

Specifically, EBI write data transfers perform an ECC decode and syndrome calculation, performing any needed data corrections before the data is driven onto the EBI for the actual memory device write. On EBI read data transfers, the data from the external memory device is passed through ECC encode logic to generate the appropriate read checkbits (including the address ECC) for the transmission through the system interconnect back to the requesting bus master. For additional details refer to End-to-end Error Correction Code (e2eECC) section.

For specific details on EBI including a block diagram, signal descriptions, supported timings, memory devices, and register definitions, see the External Bus Interface (EBI).

7.8 Analog modules

This section highlights the following analog modules that are implemented on MPC5777M:

Table 7-36. Analog modules

Module or Subsystem	Device-specific information	Block details
Temperature sensor	Temperature sensor configuration	Temperature Sensor Power Management Controller digital interface (PMC_dig) and Temperature Sensor interface logic
ADC subsystem	ADC overview	See individual modules.
Sigma-Delta Analog-to-Digital Converters (SDADCs)	Sigma-Delta Analog-to-Digital Converter (SDADC)	Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	Successive Approximation Register Analog-to-Digital Converter (SARADC)	Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface

7.8.1 Temperature sensor configuration

The temperature sensor is used to measure the temperature of the MPC5777M device. In general, the temperature sensor generates an analog voltage that is linearly proportional to temperature. The temperature sensor also generates three digital outputs (flags) that signal over/under-temperature thresholds.

During production testing of the device, the output of the temperature sensor is sampled by SARB input channel 120 of the onboard ADC module at a predefined high temperature and also at a predefined low temperature. These two temperature sensor readings are used to calculate two constants, TSCA and TSCB, according to the formulas in Temperature Sensor.

Once calculated, the values for TSCA and TSCB are programmed during production test into the UTEST flash memory at locations 0x0040_0000 and 0x0040_0002, respectively.

The ADC bandgap voltage, used in the temperature calculation, is sampled by SARB input channel 121 of the onboard ADC module.

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap voltage, $V_{BG}(T)$, using SARB input channel 121 of the onboard ADC module.
2. Calculate $V_{BG\_CODE}(T)$ according to the formula in Temperature Sensor.
3. Measure the temperature sensor output voltage, $V_{TSENS}(T)$, using SARB input channel 120 of the onboard ADC module.
4. Calculate $T_{TSENS\_CODE}(T)$ according to the formula in Temperature Sensor.
5. Retrieve parameters TSCA and TSCB from flash memory.
6. Calculate T according to the formula in Temperature Sensor.

Additional details are found in Power Management Controller digital interface (PMC_dig) (see Temperature Sensor interface logic).

7.8.2 Analog to Digital Converters (ADC) configuration

See Analog-to-Digital Converters (ADC) Configuration, for an overview of the ADC subsystem, including a block diagram and a summary of analog input pin multiplexing. The chapter also provides configuration details for the SARADCs and SDADCs.

7.8.2.1 SDADC configuration

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides the accurate conversion data for a wide range of applications.

MPC5777M includes 10 independent 16-bit SDADCs.

For details, see Analog-to-Digital Converters (ADC) Configuration.

7.8.2.2 SARADC configuration

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for an application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

The SARADCs are referred to SARADC_B, with a maximum 84:1 input mux, and different instances of Fast SARADCs, with a maximum 8:1 input mux for each. MPC5777M includes 12 independent 12-bit SARADCs (SARADC_0–SARADC_10 and SARADC_B). SARADC_B has access to all external analog input pins, access to the external multiplexed inputs, and has special safety features.

For details, see Analog-to-Digital Converters (ADC) Configuration.

7.9 Timers

Three types of timers and a complex timer subsystem are implemented on MPC5777M:

Table 7-37. Timers

Timer	Device-specific information	Block details
System Timer Module (STM)	System Timer Module (STM) configuration	System Timer Module (STM)
Software Watchdog Timer (SWT)	Software Watchdog Timer (SWT) configuration	Software Watchdog Timer (SWT)
Periodic Interrupt Timer (PIT)	PIT configuration	Periodic Interrupt Timer (PIT)
GTM104 Wrapper Module Configuration	Generic Timer Module 104 (GTM104) configuration	GTM Integration (GTMINT) Module

Each core will have a dedicated System Timer Module (STM) and a dedicated Software Watchdog Timer (SWT). The Checker core does not have a dedicated STM nor SWT.

An extra SWT (SWT_3) is available on the Peripheral core to enable a secure watchdog function.

Two Periodic Interrupt Timer (PIT) module instances are implemented. One PIT module is for 64-bit timer implementation by way of two 32-bit timer channels (0 and 1) with chaining mode; the timer value is unchanged by a non-destructive reset. The other PIT module is for general use and has eight 32-bit timer channels with no chaining mode.

The GTM104 is an implementation of the Robert Bosch GmbH GTM timer subsystem. It is not a single module; it is a complex timer subsystem that consists of many modules. It can be used to implement highly complex timer functions.

7.9.1 System Timer Module (STM) configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the appropriate system clock divided by an 8-bit prescale value (1 to 256).

MPC5777M includes three STMs, one for each core, with four 32-bit compare channels in each STM.

Table 7-38. System Timer Module (STM) instances

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM0	Intended for Main Core_0 in the high-speed computational clock domain.	4	14
STM1	Intended for Main Core_1 in the high-speed computational clock domain.	4	14
STM2	Intended for Peripheral Core_2 in the peripheral clock domain.	4	14

7.9.2 Software Watchdog Timer (SWT) configuration

MPC5777M includes four SWTs.

Table 7-39. Software Watchdog Timer (SWT) instances

Instance	Description
SWT0	Intended for Main Core_0 in the high-speed computational clock domain.
SWT1	Intended for Main Core_1 in the high-speed computational clock domain.
SWT2	Intended for Peripheral Core_2 in the peripheral clock domain. Elapsed times recorded in timeout register are different from SWT0 and SWT1.
SWT3[1]	Intended as security watchdog timer in the peripheral clock domain. Elapsed times recorded in timeout registers are different from SWT0 and SWT1

1. SWT3 can be stopped only when:
    1. all cores are either stopped or disabled, AND
    2. at least 1 core is enabled (note that this core is also stopped, to meet 1).

The SWT has the following features:

- 32-bit time-out register to set the time-out period

- Internal 16 MHz RC oscillator clock that is used for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.9.2.1 Security watchdog

SWT (SWT3 Security) is identical to the other SWT modules except the Instruction Address Compare feature is NOT instantiated.It is anticipated that each CPU would use an SWT to ensure software tasks continue to execute correctly.

If a CPU malfunctions (either software or hardware) the SWT is no longer serviced and a reset occurs. This is referred to as a Task Watchdog. The Security Watchdog is slightly different from the Task Watchdog.

The Security watchdog is intended to be serviced when the CPU executes an instruction at a specific address location. This address location would be an address within some fundamental section of security code. If this address location is not executed regularly, it implies that a malicious security attach has occurred and the device should be reset.

Additionally, the Security watchdog is deactivated by a device Power-On-Reset.

This security code could be executed on any of the CPUs. The SWT for that CPU would perform the Security Watchdog (SWT0, SWT1 or SWT2) because it includes the IAC feature. The Task Watchdog for that CPU would need to use SWT3 (Security), which does NOT include the IAC feature.

As a result the SWT3 (Security) is never used to perform the Security Watchdog; but is used for Task Watchdog to replace the SWT that IS being used for Security Watchdog

7.9.2.2 Reset assertion

The SWT can assert a reset when the watchdog timer expires. This reset causes a system reset equivalent to assertion of the RESET pin.

7.9.2.3 Default configuration

On MPC5777M, the SWTs come out of reset with the following default values. Table 7-40 summarizes the reset values. Minimum timeout value is 256 cycles for SWT0, SWT1, and SWT2.

Table 7-40. Register reset values

SWT instance	Register	Reset value
SWT0	SWT Control Register (SWT_CR)	0xFF00_010A
SWT0	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT1	SWT Control Register (SWT_CR)	0xFF00_010A
SWT1	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT2	SWT Control Register (SWT_CR)[1]	0xFF00_011B
SWT2	SWT Time-out (SWT_TO)	0x0003_FDE0
SWT3	SWT Control Register (SWT_CR)	0xFF00_010A
SWT3	SWT Time-out (SWT_TO)	0x0005_FCD0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is '1', but the DCI can override that default value by setting it to '0'. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT, it cannot enable it.) See the DCI chapter for details on the system watchdog control.

The Security Watchdog (SWT3) is enabled using DCF Records in conjunction with the BAF. Please see Security watchdog configuration for details.

For SWT[0,1,3], the SWT_CR register reset value of 0xFF00_011B selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Watchdog is disabled

For SWT[2], the SWT_CR register reset value of 0xFF00_010A selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Soft locked
- Watchdog is enabled

7.9.2.4 Service mode watchpoint input

Each SWT comes out of reset in 'Fixed Service Sequence' mode (SWT_CR[SMD] = 2’b00), but the Instruction Address Compare 8 (IAC8) register (SPR 568) can be used for servicing by using the SWT jd_watchpt input.

To use SWT address execution modes for this purpose, the e200z4 core IAC8 register signal jd_watchpt[15] is connected to the SWT jd_watchpt input. (See the "Watchpoint support" section for details.) The jd_watchpt[15] signal tells the SWT that an IAC8 compare occurred.

Set SWT_CR[SMD] to one of the following so the SWT is serviced by executing code at the address loaded into the IAC8 register:

- 2’b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this ‘freezes’ changes to the IAC8 register when the SWT is enabled.
- 2’b11 for Incremental Address Execution; the IAC8 register can be updated.

7.9.3 PIT configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

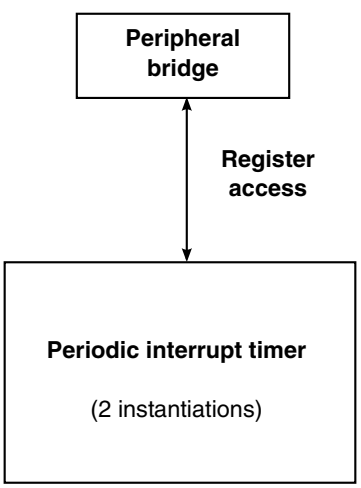

Figure 7-17. PIT configuration

7.9.3.1 PIT Instantiation

Table 7-42. PIT Information

PIT Module	No of Channels	Description
PIT0	8 + RTI	PIT0 has 8 standard channels and 1 RTI channel. In PIT0, all registers are cleared by any reset.
PIT1	2	PIT1 has chaining mode to implement a 64-bit timer and the timer value is unchanged by a functional reset.

7.9.3.2 PIT/DMA Periodic Trigger Assignments

In PIT1, DMA is not supported. The PIT0 generates periodic trigger events to the DMA Mux as shown in the table below.

Table 7-43. PIT0 channel assignments for periodic DMA triggering

DMA Channel	PIT0 Channel
DMA Channel 8	PIT0 Channel 0
DMA Channel 9	PIT0 Channel 1
DMA Channel 10	PIT0 Channel 2
DMA Channel 11	PIT0 Channel 3
DMA Channel 12	PIT0 Channel 4
DMA Channel 16	PIT0 Channel 5
DMA Channel 32	PIT0 Channel 6
DMA Channel 48	PIT0 Channel 7

7.9.3.3 PIT Registers

The following tables show the implementation of PIT registers in this MCU.

Table 7-44. PIT0 memory map

Absolute address (hex)	Register name
FFF8_4000	PIT Module Control Register (PIT0_MCR)[1]
FFF8_40E0 - FFF8_40E4	Reserved
FFF8_40F0 - FFF8_40FC	RTI Timer Channel Registers (PIT0_RTI_LDVAL, PIT0_RTI_CVAL, PIT0_RTI_TCTRL, PIT0_RTI_TFLG)
FFF8_4100 - FFF8_417C	Timer Channel [0:7] Registers (PIT0_LDVALn, PIT0_CVALn, PIT0_TCTRLn, PIT0_TFLGn)
FFF8_4180 - FFF8_7FFF	Reserved

1. The reset value of MCR is 0x06.

Table 7-45. PIT1 memory map

Absolute address (hex)	Register name
FFF8_0000	PIT Module Control Register (PIT1_MCR)[1]
FFF8_00E0	PIT Upper Lifetime Timer Register (PIT1_LTMR64H)
FFF8_00E4	PIT Lower Lifetime Timer Register (PIT1_LTMR64L)
FFF8_00F0 - FFF8_00F8	Reserved
FFF8_0100 - FFF8_011C	Timer Channel [0:1] Registers (PIT1_LDVALn, PIT1_CVALn, PIT1_TCTRLn, PIT1_TFLGn)
FFF8_0120 - FFF8_3FFF	Reserved

1. The reset value of MCR is 0x02.

7.9.3.4 PIT clocking

The PIT0 standard channels are clocked with the peripheral clock (PER_CLK).

The PIT0 RTI channel clock source is selectable between XOSC and RCOSC via the auxiliary clock selector 9.

The PIT 1 channels are clocked with the peripheral clock (PER_CLK).

7.9.4 GTM subsystem configuration

7.9.4.1 GTM subsystem

This diagram illustrates the parts of the GTM subsystem.

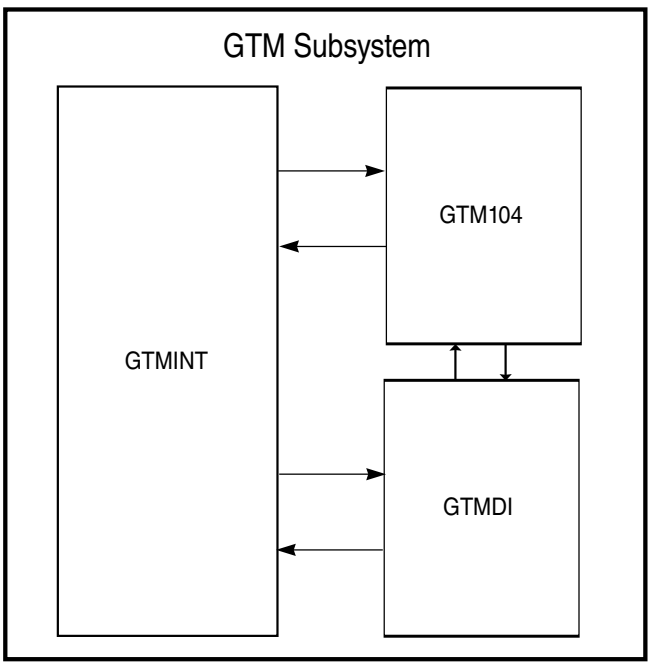

Figure 7-18. GTM subsystem

7.9.4.2 Parts of the GTM subsystem

This table describes the parts of the GTM subsystem.

Part	Function
GTMINT	Provides reset control, clock control, error-correcting code (ECC) functionality, interrupt and DMA control, and access to GTM104's memory-mapped registers. For debug accesses from GTMDI to GTM104 registers, prevents destructive read accesses into the GTM104 registers. For more information, see GTM Integration (GTMINT) Module.
GTM104	Provides programmable timer functionality. For more information, see the see Generic Timer Module (GTM104) chapter.
GTMDI	Provides real-time development capabilities for the GTM subsystem. For more information, see Development Interface (GTMDI) Module.

7.9.4.3 GTM subsystem clock sources

The system clock and the peripheral clocks to the GTM subsystem are provided by the Clock Generation Module (MC_CGM).

GTM subsystem clock	MC_CGM source	Maximum frequency
SYS_CLK	SXBAR_CLK	100 MHz
GTMIP_CLK	PER_CLK	80 MHz
GTMDI_CLK	PER_CLK	80 MHz
GTMINT_CLK	PER_CLK	80 MHz

7.9.4.4 Reset value of GTM Module Configuration Register (GTMMCR)

GTMMCR contains the control bits to configure the general operation of GTMINT and GTM-IP. The reset value of the register is 4000_4000h, which means that after reset the GTM subsystem is in Stop mode.

7.10 Communication interfaces

7.10.1 FEC interface selection

On this chip, the FEC interface depends on the settings of the RCR (in the FEC) and the UTEST Miscellaneous DCF Client, as shown in Table 7-46.

Table 7-46. FEC interface selection_a

RCR[MII_MODE]	"RMII MODE" field of the UTEST Miscellaneous DCF Client	Interface used by the FEC
0	0 or 1	7-wire
1	0	MII
	1	RMII

Refer to Fast Ethernet Controller (FEC) for detailed description.

7.10.2 CAN subsystem configuration

7.10.2.1 CAN nodes

Table 7-47 lists the number of CAN nodes and features available for the specific CAN nodes.

Table 7-47. CAN bus controllers

Types	Instances	CAN FD support	Debug on CAN Support
M_CAN	M_CAN_1	Yes	Yes
	M_CAN_2	Yes	Yes
	M_CAN_3	Yes	No
	M_CAN_4	Yes	No
M_CAN w ith TTCAN	M_TTCAN_0	Yes	No

7.10.3 DSPI configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

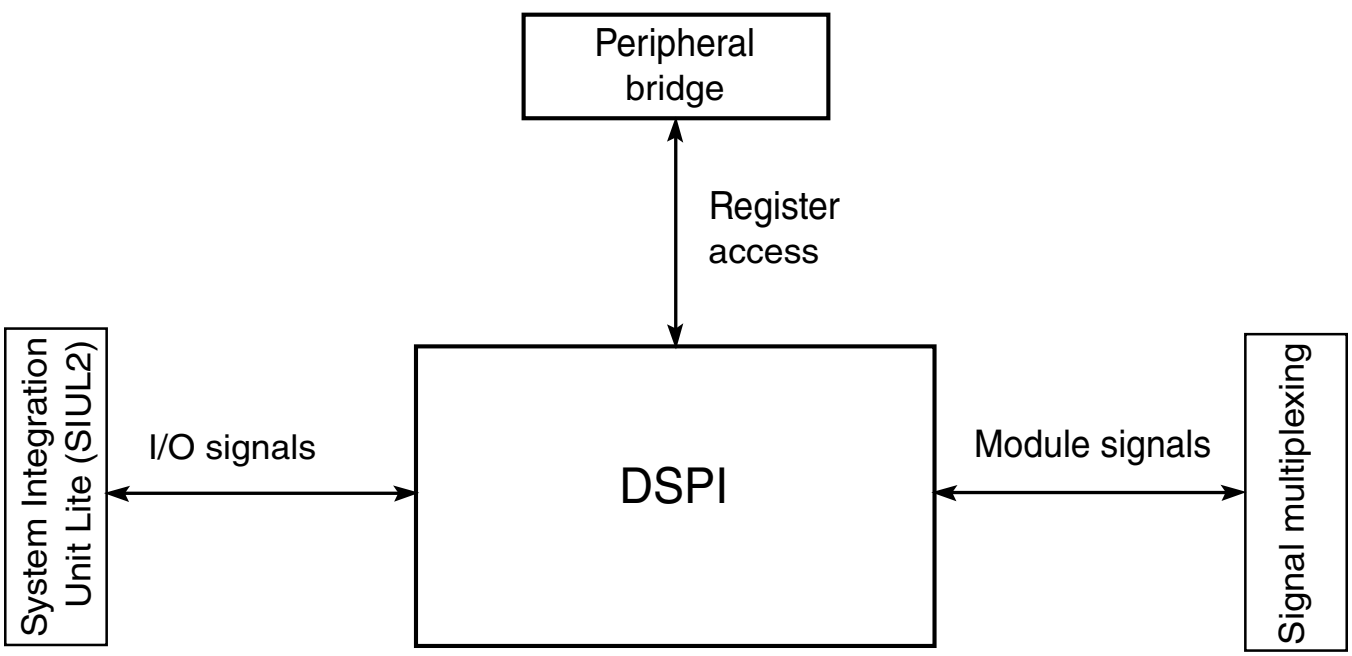

Figure 7-19. DSPI configuration

7.10.3.1 DSPI instantiation

This device contains eight DSPI modules. Table 7-49 shows the instantiation information for each module.

Table 7-49. DSPI instantiation

DSPI Module	CTARs	TX FIFO Depth	RX FIFO Depth	CMD FIFO Depth	PCS Signals	LVDS Support	DataSerialization Support
DSPI0	8	4	4	4	PCS[7:0]	Not Available	—
DSPI1	8	4	4	4	PCS[7:0]	Not Available	—
DSPI2	8	4	4	4	PCS[7], PCS[4:0]	Available[1]	—
DSPI3	8	4	4	PCS[7:0]	Not Available	—	

Table continues on the next page...

Table 7-49. DSPI instantiation (continued)

DSPI Module	CTARs	TX FIFO Depth	RX FIFO Depth	CMD FIFO Depth	PCS Signals	LVDS Support	Data Serialization Support
DSPI4[2]	8	4	4	4	PCS[7:4], PCS[2:0]	Available[3]	32
DSPI5	8	4	4	4	PCS[7:0]	Available[4]	32
DSPI6	8	4	4	4	PCS[5:4], PCS[2:0]	Available	32
DSPI12	8	4	4	4	PCS[2:0]	Not Available	—

1. Does not support Microsecond Bus.
2. Available in half duplex mode.
3. Supports Microsecond Bus SCK and SOUT LVDS signal pairs.
4. Supports Microsecond Bus SCK and SOUT LVDS signal pairs; supports Differential DSPI with SCK, SIN and SOUT LVDS signal pairs.

7.10.3.2 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all '1's.

7.10.3.3 Serialized timed I/O

The timer sources and injection pin inputs to be DSPI serialized downstream outputs are selected though the SIUL2 and selected through the MSCR registers. Inversion of these signals is also handled in the SIUL2. Refer to System Integration Unit Lite2 (SIUL2), for details.

7.10.3.4 High Speed and MicroSecond Channel (MSC) Support

The baud rate generator in the DSPI is clocked from the peripheral clock. The DSPI module can operate at a baud rate of up to half the peripheral clock. The peripheral clock frequency specification is 16 MHz to a maximum of 100 MHz. As long as the peripheral clock is 100 MHz, 50 MHz baud rate is achievable.

To support microsecond channel functionality, pairs of LVDS signals are implemented for the appropriate DSPI signals. Therefore, SOUT4, SOUT_5, SOUT_6, SCK_4, SCK_5, SCK_6, have LDVS capability. In addition, SIUL2 MSCR muxing is implemented to mux the SOUT and CLK onto these LVDS signals well as standard CMOS signals. Finally, in the SIUL2 MSCR pin muxing, 4 input pins can be routed to 32 possible serialization inputs, each selectable for a specific DSPI.

The following four external pins can be inserted into the MSC data stream:

- 0000_0010 IO_PAD PC[2]
- 0000_0011 IO_PAD PD[8]
- 0000_0100 IO_PAD PF[3]
- 0000_0101 IO_PAD PJ[4]

Details of these pin assignments can be found in the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input Multiplexing Table tab.

7.10.3.5 DSPI HT external trigger

External hardware triggers are not supported.

7.10.3.6 DSPI ITSB mode

For the ITSB trigger, the internal DSPI trigger (TRGPRD in DSICR1) is used. Use of external trigger is not supported.

7.10.3.7 DSPI registers

The following table shows the absolute addresses of DSPI module registers in this MCU.

Table 7-50. DSPI registers memory map

Absolute address (hex)	Module
FBE7_0000	DSPI2 registers
FBE7_4000	DSPI3 registers
FBE7_8000	DSPI5 registers
FFE7_0000	DSPI0 registers
FFE7_4000	DSPI1 registers
FFE7_8000	DSPI4 registers
FFE7_C000	DSPI6 registers
FFE8_8000	DSPI12 registers

7.10.3.7.1 DSPIx_MCR implementation

The following figure shows the implementation of DSPIx_MCR register in this MCU.

Address Base + 0x0000 Access: User read/write

:

Figure 7-20. DSPI Module Configuration Register (DSPIx_MCR)

7.10.4 FlexRay Configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of safety system.

For details, see the FlexRay Communication Controller (FlexRay).

7.10.4.1 Number of FlexRay modules

This device has two FlexRay modules.

7.10.4.2 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 7-51. Flexray_0 pin names

Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXD0_A
FR_A_TX (Transmit Data Channel A)	TXD0_A
FR_A_TX_EN (Transmit Enable Channel A)	TXEN0_A
FR_B_RX (Receive Data Channel B)	RXD0_B
FR_B_TX (Transmit Data Channel B)	TXD0_B
FR_B_TX_EN (Transmit Enable Channel B)	TXEN0_B
FR_DBG[0] (Debug Strobe Signal 0)	FR0_DBG0
FR_DBG[1] (Debug Strobe Signal 1)	FR0_DBG1
FR_DBG[2] (Debug Strobe Signal 2)	FR0_DBG2
FR_DBG[3] (Debug Strobe Signal 3)	FR0_DBG3

Table 7-52. Flexray_1 pin names

Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXD1_A
FR_A_TX (Transmit Data Channel A)	TXD1_A
FR_A_TX_EN (Transmit Enable Channel A)	TXEN1_A
FR_B_RX (Receive Data Channel B)	RXD1_B
FR_B_TX (Transmit Data Channel B)	TXD1_B

Table continues on the next page...

Table 7-52. Flexray_1 pin names (continued)

Signal description	Pin name
FR_B_TX_EN (Transmit Enable Channel B)	TXEN1_B
FR_DBG[0] (Debug Strobe Signal 0)	FR1_DBG0
FR_DBG[1] (Debug Strobe Signal 1)	FR1_DBG1
FR_DBG[2] (Debug Strobe Signal 2)	FR1_DBG2
FR_DBG[3] (Debug Strobe Signal 3)	FR1_DBG3

7.10.4.3 Stopwatch timer input

Stopwatch timer input is routed to FlexRay module (selected by SIUL MSCR register) via:

- STM0_CMP0
- STM1_CMP0
- STM2_CMP0
- PIT0_CH2

Details of these pin assignments can be found in the MPC5777M I/O Signal Description and Input Multiplexing Tables (excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it and select the Input Multiplexing Table tab.

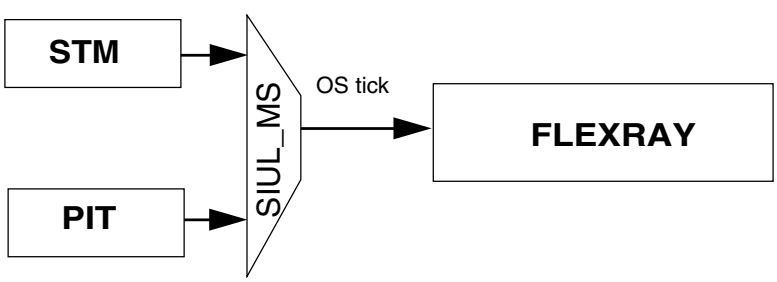

Figure 7-21. Stopwatch timer source muxing

7.10.5 Inter-Integrated Circuit (I2C) Configuration

MPC5777M has two I^2C modules: IIC_0 and IIC_1. See Inter-Integrated Circuit (I^2C) for detailed information.

7.10.6 PSI5 Controller Configuration

The PSI5 chapter has 2 instances. Parameters for the 2 instances are listed below:

Table 7-53. PSI5 controller generics.

Signal name	Description	PSI5_0	PSI5_1
PSI5_NUM_CH	Number of channels	3	2
PSI5_PDIS_RST	Default State of the IP after reset	1	1

PSI5_0 has three channels (Channel0, Channel1 and Channel2). PSI5_1 has two channels (Channel0 and Channel1). PSI5_0 is a master instance here hence the PSI5_GCR register for this instance controls all the 5channels; PSI5_0 (Channel 0, Channel 1 and Channel2) and PSI5_1 (Channel0 and Channel1). PSI5_1 instance does not contain the PSI5_GCR register and hence the corresponding PSI5_GCR address location for PSI5_1 is reserved. Further, with respect to the PSI5 base address, the unimplemented reserved locations for PSI5_0 extend from 0x0544 to 0xFFFF and unimplemented reserved locations for PSI5_1 extend from 0x0388 to 0xFFFF.

7.10.7 SENT receiver (SRX) configuration

The MPC5777M has two SENT modules. See SENT Receiver (SRX) for detailed information.

7.10.7.1 SRX channels

The following table shows the SENT receiver channels for each instance configured on this chip.

Table 7-54. SENT channel configuration

Instance	Channels (CH)
SENT 0	8 Channels: SENT_0_CH0 SENT_0_CH1 SENT_0_CH2 SENT_0_CH3 SENT_0_CH4 SENT_0_CH5

Table continues on the next page...

Table 7-54. SENT channel configuration (continued)

Instance	Channels (CH)
	SENT_0_CH6
	SENT_0_CH7
SENT 1	7 Channels:
	SENT_1_CH0
	SENT_1_CH1
	SENT_1_CH2
	SENT_1_CH3
	SENT_1_CH4
	SENT_1_CH5
	SENT_1_CH6

7.10.7.2 SRX registers

The following table lists the address offset and memory map for both SENT receiver (SRX) instances for this chip.

Table 7-55. SENT Receiver memory map

Offset	Register Name
0x0000	GBL_CTRL— Global Control Register
0x0004	CHNL_EN—Channel Enable Register
0x0008	GBL_STATUS—Global Status Register
0x000C	FMSG_RDY—Fast Message Ready Register

0x0220 - 0x02E0	Reserved

The LINFlexD has 6 instances on this chip. Configuration for the 6 instances are listed below:

Table 7-56. LINFlexD configurations

Description	linflex_0	linflex_1	linflex_2	linflex_14	linflex_15	linflex_16
Number of filters implemented	**16**	**0**	**0**	**0**	**0**	**0**
Number of Tx DMA channels	**1**	**1**	**1**	**1**	**1**	**1**
Number of Rx DMA channels	1l	1	1	1	1	1
LIN operation mode	master/slave	master	master	master	master	master
Auto synchronization	yes	no	no	no	no	no

7.11 Reset and boot modules

7.11.1 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the MPC5777M. For a comprehensive description of the SSCM, please reference the SSCM's dedicated chapter.

7.11.1.1 SSCM instantiation

There is one SSCM instance in the MPC5777M device. The SSCM is part of the reset and boot sub-system.

7.11.1.2 Device specific features

The SSCM allows Boot Assist from Flash (BAF), LINFlexD search at boot and utilizes PASS security concept. It also allows for external booting from the LINFlex port, but with no autobaud feature. The device specific resets value for the SSCM_MEMCONFIG register are shown in Table 7-57.

Table 7-57. SSCM_MEMCONFIG Reset Values

Field	Field Definition	Value
MREV	Minor Revision	0000b
JPIN	JTAG Part ID	30Eh

Table 7-58 shows the address locations that the SSCM uses to search for startup information.

Table 7-58. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET).	0040_0000h
Location of the Boot Assist code in Flash (BAF)	0040_4000h
Specify the locations which are searched for a valid HSM boot header. (starting from the lowest address)	60_C000h 61_0000h 62_0000h

7.11.1.3 Protected registers

The SSCM module has a built-in register protection mechanism that affects the behavior of write operations to one or more registers. After software has activated the protection for a register, writes can only be performed in supervisor mode until the protection is either deactivated by software or the device undergoes reset.

See the Register protection section of this chapter for a list of affected registers.

See the Register protection chapter for a detailed description of the register protection mechanism.

7.11.1.4 Memory map and register description

Table 7-59. Reference text to related information

Topic	Related Module	Reference
Reset	Reset Generation Module (MC_RGM)	Reset Generation Module (MC_RGM)
Reset/Boot	Reset and Boot	Reset and Boot
Boot	Boot Assist from Flash (BAF)	Boot Assist Flash (BAF)
Register Protection	Register Protection (REG_PROT)	Register Protection (REG_PROT)
Register Protection	Register Protection Configuration	System Status and Control Module (SSCM) protected registers
Serial Boot	LINFlexD	LINFlexD
Security	PASS	Password and Device Security Module (PASS)
Security	HSM	See the *Microcontroller Security Manual*

7.11.2 Boot Assist Flash (BAF) configuration

7.11.2.1 BAF memory map

The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in Table 7-60.

Table 7-60. BAF memory map

BAF component	Address
BAF address range	0040_4000h – 0040_7FFFh
BAF version number	0040_4000h
BAF code entry point	0040_4100h
BAF code exit point	5280_0080h
BAF data area and stack	5280_0000h – 5280_01FFh

Table 7-61 shows UTEST memory addresses used by the BAF.

Table 7-61. UTEST addresses

UTEST component	Address
Soft DCF Record Start Address	0040_00C0h
DCF Start Record	0040_0200h

7.11.2.2 LINFlexD_0 and MCAN_1 pin configuration

Table 7-62 shows the device pin configurations for LINFlexD_0 and MCAN_1 modules.

Table 7-62. MCAN_1 and LINFlexD_1 pin configuration

Pads	Reset Function	Initial Serial Boot mode		Serial Boot mode after valid CAN message received	Serial Boot mode after valid LINFlexD message received
		Function	Pad configuration	Function	Function
PA[10]	GPIO Input buffer off Output buffer off	MCAN_1 Tx	Output: Push/Pull medium drive no pullup/pulldown	MCAN_1 Tx	LINFlexD_0 Tx
PA[11]	GPIO Input buffer off Output buffer off	LINFlexD_0 Rx and MCAN_1 Rx	Input: pullup hystersis TTL voltage level	MCAN_1 Rx	LINFlexD_0 Rx

7.11.2.3 Search boot header and boot options

The BAF searches the flash memory for the boot header, checking the first word location of the 4 × 16 KB blocks, then the first of the 4 × 256 KB blocks. The blocks are searched in the order shown in Table 7-63. Once a Boot Header is found, no further blocks are searched.

Table 7-63. Locations of boot headers

Search order	Block	Address
1	16KB Code Flash block 0	00FC_0000h
2	16KB Code Flash block 1	00FC_4000h
3	16KB Code Flash block 2	00FC_8000h
4	16KB Code Flash block 3	00FC_C000h
5	256KB Code Flash block 0	0100_0000h
6	256KB Code Flash block 1	0104_0000h
7	256KB Code Flash block 2	0108_0000h
8	256KB Code Flash block 3	010C_0000h

The first header found that contains the value 005Ah in the first halfword is valid for booting. The whole header structure is shown in Table 7-64.

Table 7-64. Boot header structure

Address Offset	Contents
00h	Boot Header Configuration (see Table 7-65)
04h	CPU2 Reset Vector
08h	Configuration Bits
0Ch	Configuration Bits
10h	CPU0 Reset Vector
14h	CPU1 Reset Vector
18h	CPUC Reset Vector

Table 7-65. Boot header configuration

Offset 00h															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				5				A			
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				CPU1	CPUC	CPU0	CPU2

Table 7-66. Boot header configuration field description

Field	Description
CPU1	CPU1 is enabled (will start execution at CPU1 Reset Vector)
CPUC	CPU_SC is enabled (will start execution at CPU_SC Reset Vector, must be the same as CPU0 Reset Vector)
CPU0	CPU0 is enabled (will start execution at CPU0 Reset Vector)
CPU2 (IOP)	CPU2 (IOP) is enabled (starts execution at CPU2 Reset Vector)

The cores that are enabled in the boot header configuration field are enabled by programming MC_ME_CCTL*n*[DRUN] register to run in all DRUN modes and their reset vector is set in register MC_ME_CADDR*n*. Then, the memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally, a mode change (from DRUN to DRUN again) is requested from the MC_ME module to activate the new core configuration and make the cores jump to their respective reset vectors. At this point the BAF has finished its operation.

7.12 Power Management modules

7.12.1 PMC ADC test mode

All of the internal Power Management Controller (PMC) system analogue signals can be monitored by one of the Analog-to-Digital Converters (ADCs). SARADC_B channel 110 is dedicated for these monitoring purposes. The PMC ADC test mode is used for calibration, diagnostics during test, or for the user to actively monitor the signal levels. PMC signals are buffered to ensure correct ADC sampling. Supply for PMC to ADC buffer and transmission gates is the main PMC supply.

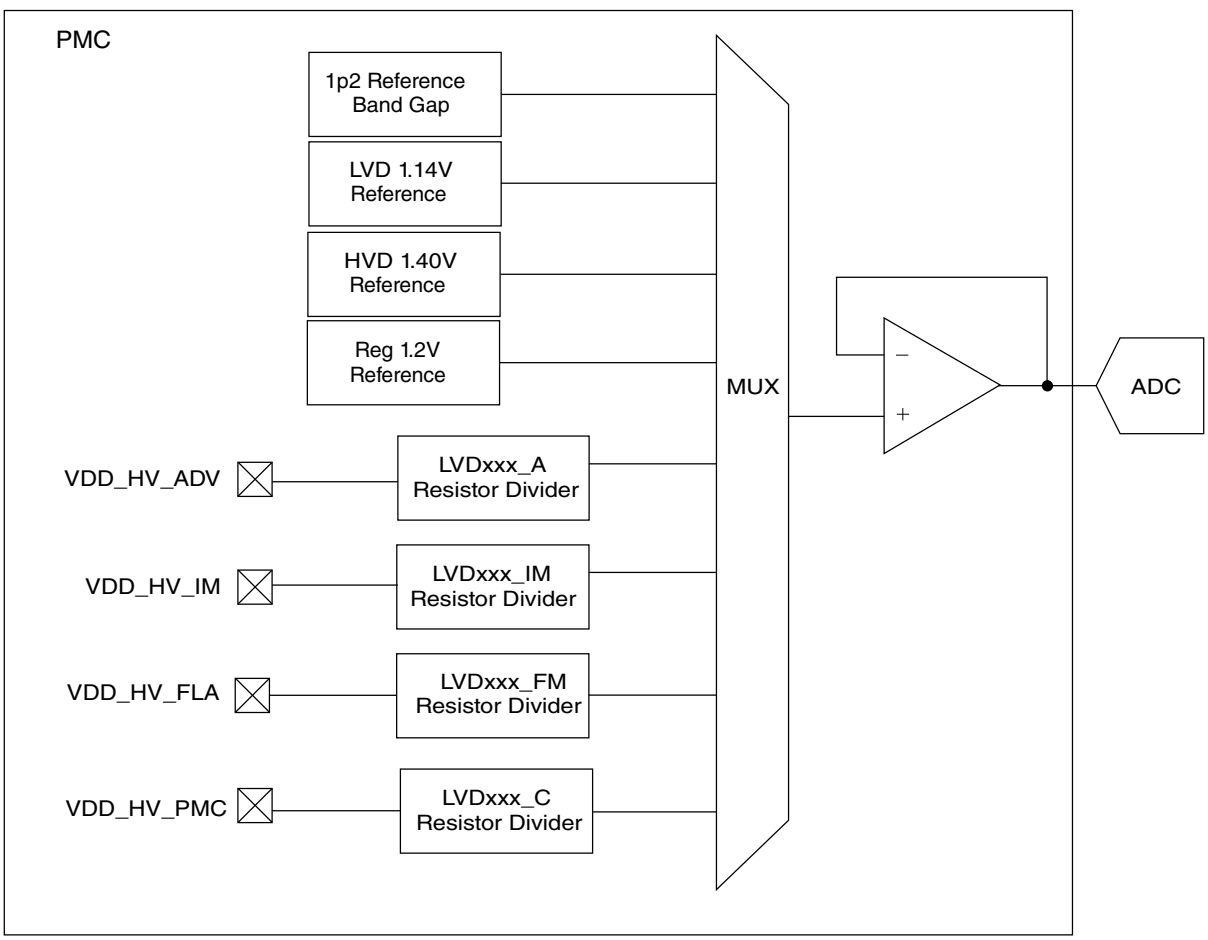

Figure 7-22. Simplified PMC ADC test multiplexer block diagram

The table below lists the parameters that can be monitored, the ADC channel select register value, and reference to the expected nominal value. Use maximum ADC sample time for most accurate results.

Table 7-67. Parameter monitoring via ADC channel

PMC ADC Mode Signal Description	ADC Channel Select Register	ADC Mode Description	Nominal value expected
Internal Voltage[1]	6b101000	Internal Voltage	0.855V
POR for security[1]	6b000001	Power-On-Reset on LV core supply for security	1.0V
POR for security[1]	6b011111	Power-On-Reset on LV flash supply for security	1.0V

1. When doing conversions on this channel, it is recommended to mask the corresponding HVD/LVD from generating a reset for the duration of the conversion when this channel is enabled.
2. Refer DS, 'Voltage monitor electrical characteristic Table (footnote 6)' for their values.
3. Bandgap trimmed reference voltage

For additional information see Analog-to-Digital Converters (ADC) Configuration, for an overview of the ADC subsystem, including a block diagram and a summary of analog input pin multiplexing. The chapter also provides configuration details for the SARADCs.

7.12.2 LVD / HVD self test

A self test functionality exists for each LVD / HVD. Programming LVD / HVD self test register to a specific value designated to a LVD /HVD will start the self test for that LVD / HVD. During the self test, the voltage sense input of the LVD /HVD comparator is connected to an internal voltage which is lower than the LVD reference for LVD test (higher than HVD reference for HVD test), so that an artificial assertion of the LVD /HVD comparator can be triggered. After the comparator is triggered, the voltage sense input will be re-connected to the supply it monitors automatically.

>The self test takes less than 5µs from a self test register programmed to start the test to LVD / HVD comparator output changing.

While programming the self test register bits, a timer should be started. If the LVD / HVD status has not been updated when the timer runs out, this indicates the LVD / HVD self test failed. The figure below shows a block diagram of the LVD self test. The table below provides LVD/HVD self test decoding.

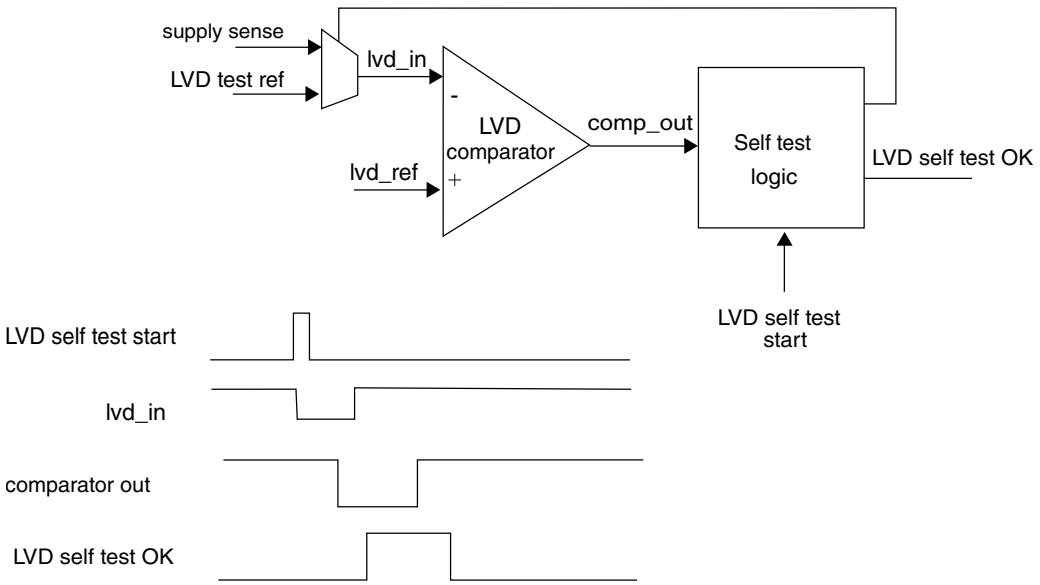

Figure 7-23. LVD self test simplified diagram

7.13 Safety modules

7.13.1 CRC – Number Of Contexts

The number of contexts available for the current CRC computation of multiple data streams of CRC are listed below:

Table 7-69. CRC Contexts

Signal name	Description	crc_0	crc_1
CRC_CNTX_NUM (N)	Number of contexts available for the current CRC computation of multiple data streams	1	1

7.13.2 MEMU configuration

The MEMU is responsible for collection and reporting of error events associated with ECC (Error correction code) logic used on SRAMs and FLASH. When any of the following events occur the MEMU receives an error signal that causes an event to be recorded and corresponding error flags to be set and reported to the FCCU.

7.13.2.1 MEMU system connections

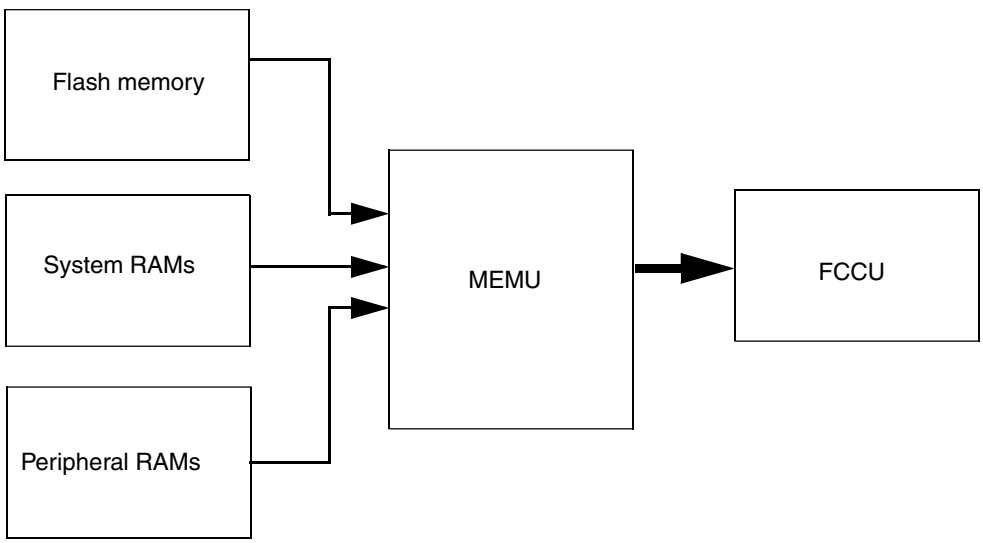

Figure 7-24. MEMU system connections

7.13.2.2 MEMU error sources

The following table shows the MEMU error sources for each instance configured on this chip.

Table 7-70. MEMU error sources

Instance	Value
Number of system RAM unique error sources	102
Number of peripheral RAM unique error sources	33
Number of flash memory unique error sources	3

7.13.2.3 Reporting tables implementation

There are three categories of error reporting for the MEMU:

- Flash memory error reporting
- System RAM error reporting (any RAM that is CPU accessible falls into this category)
- Peripheral RAM error reporting (any RAM that is not CPU accessible falls into this category)

Each category of error reporting has the following tables associated with it:

- Correctable error reporting table
- Uncorrectable error reporting table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 7-71. Number of entries in each reporting table

Error source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash memory	20	1
System RAM	10	1
Peripheral RAM	2	1

When accessing flash memory, the following cases apply:

- Case 1: In the case where a flash memory location has an uncorrectable ECC error, and this location is read by the core, then the error is signaled to the MEMU as two errors:

  a. Flash memory uncorrectable error
  b. RAM uncorrectable error

  In this case, ECC error reporting is performed by the masters, not the slaves. Therefore, in the case of the core reading from memory with the uncorrectable ECC error, the error is reported as a SYSTEM_RAM_UNCERR uncorrectable error. In addition to the core reporting a SYSTEM_RAM error, the flash memory module does its own reporting, indicated by a MEMU FLASH_UNCERR uncorrectable error.

- Case 2: In the case where a flash memory location is read by the eDMA, and an uncorrectable ECC error is encountered, then this error is signaled to the MEMU also as two errors:

  a. Flash memory uncorrectable error
  b. Peripheral uncorrectable error

  In this case, the eDMA is the master, and it reports its errors in the PERIPHERAL_RAM MEMU error reporting tables. Since flash memory is being accessed, the flash memory module also reports a MEMU error in the FLASH_UNCERR table.

- Case 3: In the case where a correctable error in the flash memory is read by a CPU core or the eDMA module, the following occurs:

  - No MEMU reporting by the core or the eDMA
  - Correctable flash memory error signaled to the MEMU

  When the flash memory controller detects a single-bit inversion, it signals the event to the MEMU and corrects the data before providing it back to the system (core or eDMA). So, as far as the requesting master is concerned, it should only “see” correct data, with no indication on their part that a single-bit correction occurred.

7.13.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from these categories:

- Flash memory
- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Positions not explicitly listed in the tables below are reserved.

Table 7-72. Corresponding error sources for system RAM OFLW0 register

7.13.3 Indirect Memory Access (IMA) configuration

The IMA refers to the alteration of memory data values during system development and test activities. This section provides details about what memory locations can be accessed —either via processor core access or via the IMA module—and how they are configured.

Note

See the *Microcontroller Security Reference Manual* for the HSM IMA details.

7.13.3.1 SRAM Arrays accessible by processor cores

All the SRAM arrays in Table 7-81 can be accessed by the main CPUs (CPU0 & CPU1) and the IOP (CPU2).

Table 7-81. SRAM with processor Core access

Block	Function	Words	Bits	ECC Bits
Safety Core	IMEM	2048	72	—
	DMEM	8192	40	—

FCCU_RF_TOE3	0x0000_0000

7.13.4.2 FOSU parameters

The FOSU_COUNT, or FOSU time out response time, is 8000 safe clock cycles.

7.13.4.3 Available FCCU output signals

Table 7-85 shows the available FCCU output signals implemented on this chip.

For more details refer to FCCU failure inputs.

Table 7-85. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0]	F0
EOUT[1]	F1

7.13.4.4 Error signal flow diagram

In the following diagram, the FCCU_RF registers are labeled as FCCU_NCF registers.

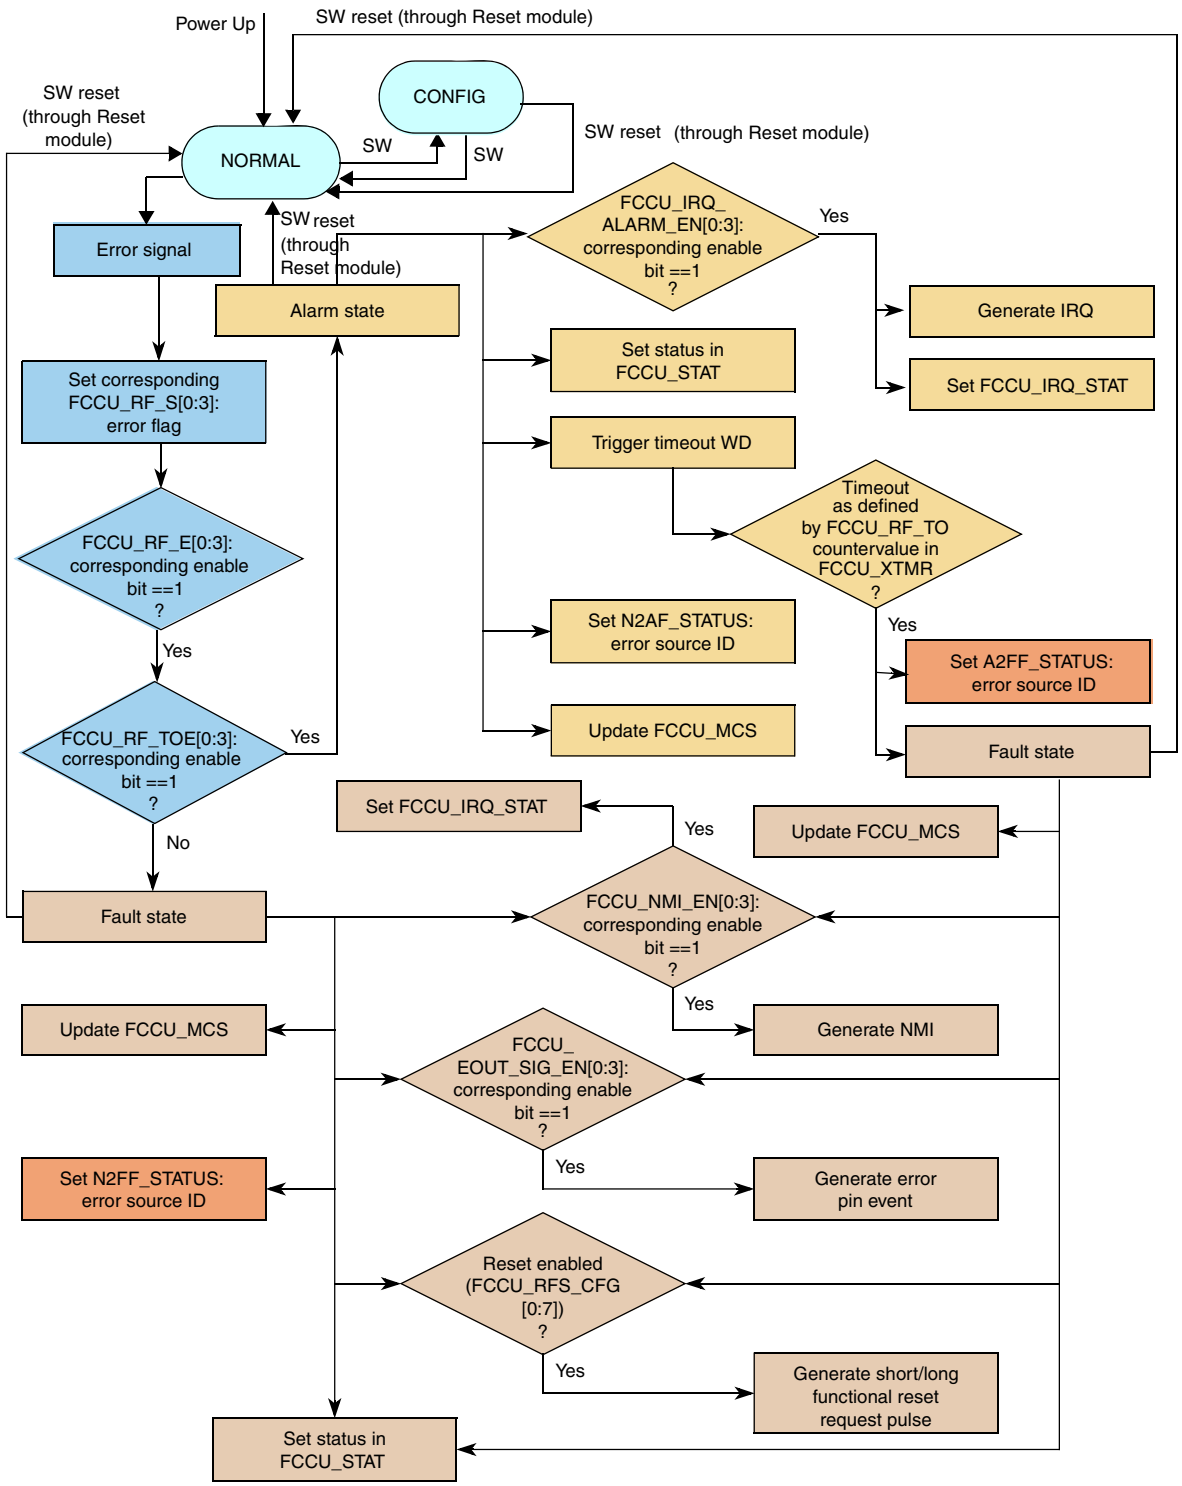

Figure 7-25. Error signal flow

7.13.4.5 FCCU failure inputs

Table 7-86 shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset[1].

1. All of these faults require a long functional reset.

Table 7-86. FCCU failure inputs[1]

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
0	TEMP_ERROR	Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_dig_EPR_TD, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	Not testable	No reaction	PMC_dig_EPR_TD Event Pending Register (PMCDIG_EPR_TD)	Correction of violating condition and power reset cycle
1	LVD_ERROR	Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VD*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LVD assertion test by tap point manipulation	No reaction	PMC_dig_EPR_VD3 PMC_dig_EPR_VD4 PMC_dig_EPR_VD9 PMC_dig_EPR_VD10 PMC_dig_EPR_VD13 PMC_dig_EPR_VD14 PMCDIG_memoryMap	Correction of violating condition and power reset cycle
2	HVD_ERROR	Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VD*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	HVD assertion test by tap point manipulation	No reaction	PMC_dig_EPR_VD7 PMC_dig_EPR_VD8 PMC_dig_EPR_VD12 PMC_dig_EPR_VD15 PMCDIG_memoryMap	Correction of violating condition and power reset cycle
3	DPMC_DCF_SAFETY_ERR	Digital PMC initialization error during DCF data load (triple-vote mismatch). The fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The status gets cleared if the fault is not persistent.	LBIST	No reaction	Power Management Controller digital interface (PMC_dig)	POR, Destructive Reset
4	MEMORY_DCF_SAFETY_ERR	Indication of fault during timing/ repair configuration initialization by SSCM of different memories. The status is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The	LBIST	No reaction	SSCM_memoryMap	POR, Destructive Reset

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
		status gets cleared if the fault is not persistent. Additionally, this error will cause an MBIST to fail.				
5	SSCM_XFER_FLASH_ERR	SSCM transfer error (during the SSCM and STCU DCF loading), or flash memory initialization error.	Testable (and wrong DCF configuration or spurious data from Flash can trigger other failures)	No reaction	SSCM_memoryMap	POR, Destructive Reset
6	STCU_UF	STCU2 unrecoverable fault indication during self-test. It is simultaneously reported to the MC_RGM which will initiate a destructive reset in case of an offline self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	Destructive reset by MC_RGM directly, during offline self-test	ERR_STAT Reset sources 'Destructive' Event Reset Disable Register (MC_RGM_DERD)	POR, Destructive reset. During offline test, assertion of this fault will automatically cause a destructive reset request by MC_RGM.
7	STCU_RF	STCU2 recoverable fault indication during self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing	SW check of BIST MISR or Feedback loop via FCCU Fake bit	No reaction	ERR_STAT	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
		STCU2_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].				
8	STCU_LMBIST_USR_ERR [4]	Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The status will clear if the fault is not persistent.	Feedback loop via FCCU Fake bit.	No reaction	—	Long Functional Reset to reset STCU, POR, Destructive Reset
9	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG, NPC or Debug functionality moved out of reset when JCOMP is low or activation of SSCM or DCF client during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit	No reaction	—	Long Functional Reset
10	RCCU_0	Safety cores out of sync during lockstep (RCCU0a). Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	Redundancy Control and Checker Units (RCCUs)	Functional Reset
11	RCCU_1	Safety cores out of sync during lockstep ((RCCU0b ... RCCU0e, RCCU1)). Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	Redundancy Control and Checker Units (RCCUs)	Functional Reset

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
12	SWT2_ResetReq	Reset request from Software Watchdog of Peripheral Core_2 domain. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared inside SWT2.	LBIST + SW test by not triggering SWT during startup	Long Reset	Software Watchdog Timer (SWT)	Functional Reset (application dependent)
13	SWT1_ResetReq	Reset request from Software Watchdog of Main Core_1 domain. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared inside SWT1.	LBIST + SW test by not triggering SWT during startup	No reaction	Software Watchdog Timer (SWT)	Functional Reset (application dependent)
14	SWT0_InterrutpReq	First timeout interrupt request from Software Watchdog of Safety Core (Main Core_0). Fault is cleared by clearing SWT0_SWT_IR[TIF], followed by clearing the FCCU channel status FCCU_RF_S*n*[RFS*m*].	LBIST + SW test by not triggering SWT during startup	No reaction	Software Watchdog Timer (SWT)	Functional Reset (application dependent)
15	SWT0_ResetReq	Second timeout (reset) request from Software Watchdog of Safety Core (Main Core_0). The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared inside SWT0.	LBIST + SW test by not triggering SWT during startup	No reaction	Software Watchdog Timer (SWT)	Functional Reset
16	MEMU_RAM_CE	Indication by MEMU of occurrence of correctable errors in system RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[SR_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Injection of RAM ECC error via ECC bit access and later reading	No reaction	Error flag register (MEMU_ERR_FLAG)	—

Table continues on the next page...

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
21	MEMU_PER_BOV[5, 6]	Indication of overflow of peripheral RAM ECC buffer or table in MEMU. The fault is cleared by clearing MEMU_ERR_FLAG[PR_EBO, PR_CEO or PR_UCO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Functional test [10]	No reaction	Error flag register (MEMU_ERR_FLAG)	—
22	MEMU_FLS_CE[6]	Indication by MEMU of occurrence of correctable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Reading preprogrammed correctable ECC error from UTEST flash memory	No reaction	Error flag register (MEMU_ERR_FLAG)	—
23	MEMU_FLS_UCE[6]	Indication by MEMU of occurrence of uncorrectable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_UCE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Reading preprogrammed uncorrectable ECC error from UTEST flash memory	No reaction	Error flag register (MEMU_ERR_FLAG)	—
24	MEMU_FLS_BOV[5, 6]	Indication of overflow of flash memory ECC buffer or table in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[F_EBO, F_CEO or F_UCO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Functional test[11]	No reaction	Error flag register (MEMU_ERR_FLAG)	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
25	IMA_SOC	MCU IMA active . Fault is cleared by selecting zero for IMA_SLCT[ARRAY_SLCT], followed by clearing FCCU_RF_Sn[RFSm].	LBIST + IMA read	No reaction	—	—
26	SMPU_MONITOR	Indication of fault in SMPU_0 or SMPU_1 logic fault resulting in an incorrectly refused access, but failure to indicate the error to the requesting bus master. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	LBIST	No reaction	—	—
27	Reserved	—	—	—	—	—
28	Reserved	—	—	—	—	—
29	FM_PLL_0	PLL0 loss of lock. In order for this fault source to be asserted in the event of loss of lock, the Loss of Lock needs to be enabled by writing (PLLDIG_PLL0CR[LOLIE]) = 1. Fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_RF_S*n*[RFS*m*].	LBIST + Forced loss by PLL reconfiguration	No reaction	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	application integrity checks
30	FM_PLL_1	PLL1 loss of lock. In order for this fault source to be asserted, the Loss of Lock indication needs to be enabled by writing PLLDIG_PLL1CR[LOLIE] = 1. Fault is cleared by clearing PLLDIG_PLL1SR[LOLF], followed by clearing FCCU_RF_S*n*[RFS*m*].	LBIST + Forced loss by PLL reconfiguration	No reaction	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)	application integrity checks
31	CMU_0_OSC [-1, 12]	Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0,	LBIST	No reaction	CMU Interrupt Status Register (CMU_ISR)	Functional reset

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
		followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].				
32	CMU_0_PLL [15][12]	SYSCLK frequency out of range. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by misconfiguration [15]	No reaction	CMU Interrupt Status Register (CMU_ISR)	Functional reset
33	CMU_comp_subsys[12], [16]	Exception from monitoring internal clocks of comp_subsys. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by misconfiguration [15]	No reaction	CMU Interrupt Status Register (CMU_ISR)	Functional reset
34	CMU_other [12, 17]	Exception from monitoring internal clocks of other subsystems. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by misconfiguration [15]	No reaction	CMU Interrupt Status Register (CMU_ISR)	Functional reset
35	PERIPH_XBIC_GASKET_MONITOR	Indication of a hardware fault (detected by the EDC_after_ECC) resulting in corrupted transaction through the peripheral XBAR or gaskets handling communication from Safety core to PERIPH_XBAR and back. Fault is	LBIST	No reaction	Crossbar Integrity Checker (XBIC)	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
		cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].				
36	EDC_ECC_FLASH	Indication of a hardware fault (detected by the EDC_after_ECC) in the ECC logic of the flash memory resulting in corrupted ECC detection/correction. Fault is cleared by a dummy read of the flash memory followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	Module Configuration Register (C55FMC_MCR)	—
37	EDC_ ECC_FLASH_C	Indication of hardware fault in the flash memory controller resulting in corrupted ECC detection / correction. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	e2eECC and flash accesses	—
38	ENC_ERR_FLASH	Indication of hardware fault resulting in corrupted flash memory access, or Read Voltage or Read Reference were out of range for a previous read. Fault is cleared by clearing MCR[RVE] and MCR[RRE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
39	ADDR_FDBK_ERR_FLASH_C	Indication of an addressing error in the flash memory controller resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
40	COMP_XBIC_DSMC_Monitor	Indication of an addressing or control fault resulting in corrupted transaction through the computational XBAR or interference by system RAM DSMC. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	Crossbar Integrity Checker (XBIC)	—
41	ADDR_FDBK_ERR_CAL_RAM[4]	Indication of an addressing error in the on-chip overlay RAM resulting in corrupted access to on-chip overlay RAM. Status should be cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	Flash address generation check	—
42	SAFE_CAL_ERR	Indication of hardware fault in the flash memory controller resulting in corrupted overlay remap evaluation. Status should be cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	Flash address generation check	—
43	ADDR_FDBK_ERR_PRAM + RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	Transaction monitor	—
44	SMPU_ERROR	Indication of the prevention of an unauthorized access by SMPU_0 or SMPU_1. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + willfully causing an access to an unauthorized location	No reaction	System Memory Protection Unit (SMPU)	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
45	EDC_ERR_PRAM	Indication of a fault in the controller PRAM of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction		—
46	DFT1	Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
47	DFT2	Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
48	DFT3	Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
49	DFT4	Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
50	Safety Core Machine Check Exception[18]	Safety Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Willfully cause an appropriate exception (for example, access a non-existing address)	No reaction		—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
51	Lockstep mode	Indication of disabled Checker Core or RCCUs.Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit	No reaction	Dual-core lockstep	—
52	Safe_Mode	Indication of safe mode request assertion from MC_RGM. The event is also captured in MC_ME and available as status for crosscheck. Status should be cleared first in the MC_RGM_FES, then followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + (in principle requesting an RGM "safe mode" though that is not typical, and should be avoided)	No reaction	'Functional' Event Status Register (MC_RGM_FES)	—
53	Compensation Disable	Indication of undesired deactivation of pad compensation. Fault may effect a distorted transmissions on I/Os associated with VDD_HV_IO_EBI, VDD_HV_IO_FLEX, and VDD_HV_IO_FLEXE. The indication is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	—	No reaction	—	—
54	EIN_ERR[19, 20]	Error input pin (FI[0], external of the MCU) signalling an error condition. The fault is cleared by clearing the fault driving FI[0] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	External activation of EIN. External entity has to pull the error input low.	No reaction	—	—

Table continues on the next page...

Table 7-86. FCCU failure inputs[1] (continued)

FCCU channel [2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
55	SWT3_ResetReq	Reset request from Security Watchdog. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared in the SWT3.	LBIST+ SW test by not triggering SWT during startup	No Reaction		—

1. All of these faults require a long functional reset.
2. See "Fault Collection and Control Unit (FCCU)" chapter for channel mapping details.
3. During execution of the safety function. Application level reactions not limited to FCCU reactions
4. Failure will be asserted during on-line MBIST.
5. Error reaction path check contents subject to change.
6. Fake fault cannot be generated for FCCU channel (these faults are injected only through the MEMU).
7. Assert the fault line by writing 1, followed by 0, to MEMU_DEBUG[FR_SR_EBO]. Deassert by writing 1 to MEMU_ERR_FLAG[SR_EBO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].
8. Assert the fault line by writing 1, followed by 0, to MEMU_DEBUG[FR_PR_CE]. Deassert by writing 1 to MEMU_ERR_FLAG[PR_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].
9. Assert the fault line by writing 1, followed by 0, to MEMU_DEBUG[FR_PR_UCE]. Deassert by writing 1 to MEMU_ERR_FLAG[PR_UCE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].
10. Assert the fault line by writing 1, followed by 0, to MEMU_DEBUG[FR_PR_EBO]. Deassert by writing 1 to MEMU_ERR_FLAG[PR_EBO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].
11. Assert the fault line by writing 1, followed by 0, to MEMU_DEBUG[FR_F_EBO]. Deassert by writing 1 to MEMU_ERR_FLAG[F_EBO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].
12. See Clock generation figure (Figure 1) in the Clocking chapter ().
13. CMU_0 OLR event.
14. CMU_0 OLR event.
15. CMU_0 FLL and FHH events.
16. CMU_1, CMU_2, CMU_3, CMU_11, FLL, and FHH events.
17. CMU_4, CMU_5, CMU_6, CMU_7, CMU_8, CMU_9, CMU_10, FLL and FHH events.
18. Alarm #50 is asserted by Main Core_0 when a machine check condition has caused an “Async Mchk” or “Error Report” type syndrome bit to be set in the Machine Check Syndrome register (Refer to Section 14.7.4, “Machine Check Syndrome Register (MCSR)”). See "Exceptions and Conditions" table in the *e200z4 Core Reference Manual* for all exceptions which can occur in the core and table "Error report machine check exceptions" for errors indicated by a machine check exception. Note that the following do not cause a machine check and thus do not signal to the FCCU: access blocked by MPU, wrongly aligned access, execution of a privileged or trap instruction, FPU exceptions. Such errors will have to be handled by the respective exception handler if they are safety-relevant.
19. EIN_ERR can be used only when bistable protocol is selected for external error indication, and the FI[0] pin is configured as open drain.
20. Fake fault cannot be generated for FCCU channel (requires 50 us delay to be active).

7.13.5 STCU2 configuration

7.13.5.1 Wait time for writing to the online registers

When writing to the online registers, the user must wait for the expiration of the offline key. The time the user should wait is (IPS_CLK)*4096 clock periods. If the IPS_CLK is 66.5 Mhz then the user must wait (1/66.5)*4096 = 61.6 µs.

7.13.6 Register protection (REG_PROT) configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software-controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the Register Protection (REG_PROT).

Register	Register Size (bits)	Offset from Module Base Address	Protected Size (bits)
JTAGM_MCR	32	0x00	32

7.13.7 Security modules

The modules described in this section provide a basic set of customer-configurable security features designed to protect code and data from unauthorized access and to provide a way implement an audit trail to identify accesses to specific blocks of flash memory.

Table 7-101. Reference links to related information

Topic	Related module	Reference
Security overview	—	Security
Password protection of flash memory blocks	PASS	Flash Memory Programming and Configuration
	PASS	Password and Device Security Module (PASS)
Tamper Detection	TDM	Tamper Detection Module (TDM)
Detailed information on advanced security features	—	See the Microcontroller Security Reference Manual

7.13.8 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks on the MCU. Up to 4 levels of password protection can be implemented for each flash block.

Note

The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See the Password and Device Security Module (PASS) chapter for further details.

7.13.8.1 PASS_LOCK*n*_PGn register bit mapping

As described in Flash Memory Programming and Configuration, each password group defined in the DCF records has a set of 4 LOCKn registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note

The mapping of various LOCK register bits to flash blocks in the MPC5777M microcontroller is very similar, but not identical. The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

Refer to Secure read protection for details of flash read lock protection.

Figure 7-29. PASS_LOCK3_PG*n* Register

7.13.8.2 PASS Module DCF Records

The records required to configure the initial values for the PASS module password group registers is shown in Table 7-102. These values provide the following capabilities:

- Set the current life cycle state
- Set flash memory to censored/uncensored state (censorship also depends on lifecycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part.

Most DCF records represent an initial value or reset value for a module register. See the relevant register documentation for details on values that can be assigned.

2. See External Bus Interface (EBI) Support for values.
3. See External Bus Interface (EBI) Support for values.

7.13.9 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), i.e., write once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

Warning

The TDM configuration registers detailed in this section are DCF clients. In general, DCF clients can only be written once —their intended values must be carefully selected beforehand.

See the Tamper Detection Module (TDM) chapter for further details on the TDM, including the DCF clients and two additional memory-mapped registers.

7.13.9.1 Diary Base Address (DBA) DCF client

The TDM_DBA register holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations. This register is more fully described in the TDM chapter.

7.13.9.2 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. This DCF client is more fully described in the TDM chapter. The mapping is shown below.

Offset: 0x01 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

This DCF client is more fully described in the TDM chapter

7.13.9.3 OTPEN*n* DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPEN*n* DCF clients.Each mapped bit is associated with a specific flash block. A "1" bit value indicates a block is OTP.

The mapping is shown in Figure 7-31 - Figure 7-34.

Figure 7-34. TDR*x*_LOCK3/OTPEN3 DCF client

7.13.9.4 TDR*x*_LOCK*n* DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A "1" in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDM_LOCKn DCF client bits to flash blocks is identical to the OTPEN*n* mapping and is shown in Figure 7-31 - Figure 7-34. Any available flash block can be mapped to any tamper protection region.

7.13.9.5 DCF client details

Table 7-104 contains the DCF client information.

1. OTP DCF clients have the same structure and mapping as the write-protect bits of the flash and PASS module LOCK DCF clients. A value of '1' in an OTP bit indicates a block is programmable only once. Note that a block cannot be reconfigured as non-OTP after it has been configured as OTP.
2. There are no flash memory blocks mapped to the OTPEN3 DCF client.

7.13.10 Production device vs. emulation device

MPC5777M microcontrollers have a comprehensive feature set to assist debug and calibration. Specialized variants, referred to as Emulation Devices (EDs), include additional calibration and debug features. An ED chip consists of the normal production die plus an additional die, called a Buddy die or Buddy Device (BD), bonded together in the same chip package. A Production Device (PD) includes a production die only and no buddy die.

Note

All features and modules included in the PD are also included in the ED.

The following table lists the key differences between the ED and PD of the MPC5777M microcontroller.

Table 7-105. Debug and calibration features per MPC5777M type

Debug or calibration feature	MPC5777M PD	MPC5777M ED
Internal Overlay Memory	16 KB	16 KB
Extended Overlay Memory	—	2 MB
Debug Interface	JTAG / LFAST	JTAG / LFAST
Trace Interface	—	Aurora (1.25 GHz, Lane)
Trace Sources	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA and GTM	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA and GTM
Trace Destination	Internal Overlay	Internal Overlay, Extended Overlay, Aurora Trace Port
Calibration Remap capabilities	32 Region	32 Region
System Level Performance Monitor Counters[1]	16 × 32 bits	16 × 32 bits
CPU Level Performance Monitor Counters	12 × 32 bits (4 × 32 bits per z4 CPU)	12 × 32 bits (4 × 32 bits per e200z4 CPU)

1. All system level PMCs can also be configured for use as debug timers. System level PMCs can also be configured as timers.

The following figure shows the top-level block diagram of the MPC5777M ED, which consists of the production die packaged together with the 2 MB Buddy die (BD2M). The figure shows the general interconnection of functional debug modules including interconnections between the two devices. All functional blocks are shown for the BD, but for clarity only blocks relevant to the debug and calibration system are shown for the PD.

Acronyms used in the block diagram include:

- BD_SIU — BD System Integration logic
- BD_XBS_RAM — Buddy Device RAM Crossbar
- DCI — Debug and Calibration Interface
  - JTAGC — JTAG Controller
  - M.JTAG — Mastered JTAG
  - P.JTAG — Peripheral JTAG
  - I.JTAG — Inter-die JTAG
  - DCU — Debug Control Unit
- DTS — Development Tool Semaphore

- JTAGM — JTAG Master
- SPU — Sequence Processing Unit
- NAR — Nexus Aurora Router
- NAL — Nexus Aurora Link
- Nexus RWA — Nexus Read/Write Access client

On ED devices, the device packaging routes the tool interface to the interface logic on the BD. On standard production devices packages the device packaging routes the tool interface to the interface logic on the PD.

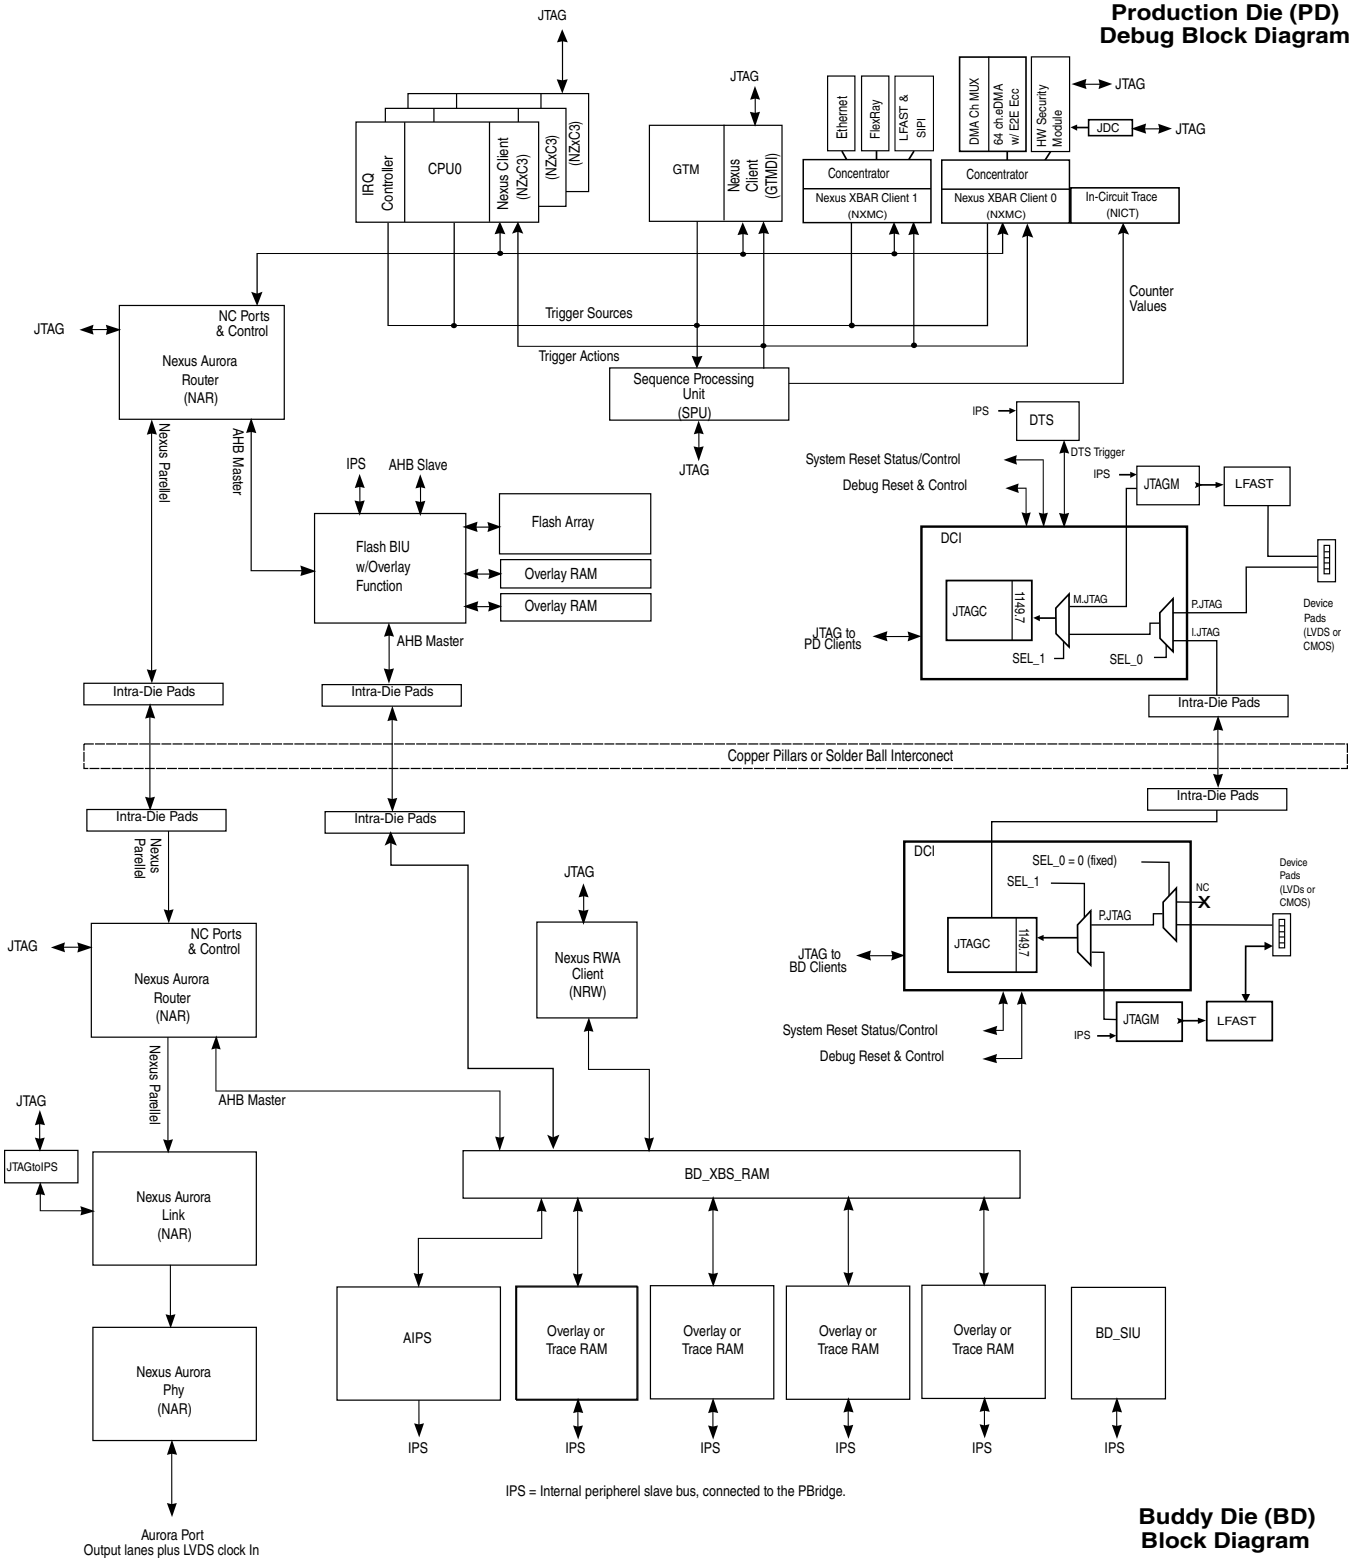

Figure 7-35. Debug and calibration architecture for MPC5777M ED

Chapter 8
Reset and Boot

8.1 Introduction

Resetting the MPC5777M starts with the application of power and ends with fetching the first instruction of the user's application code. A review of chip architecture is helpful to appreciate reset.

The processor cores on the MPC5777M are:

- Core_0 and Core_1 based on the e200_z710 architecture, generally execute user application code.
- Checker Core_0 executes the same instruction stream as Core_0. The results of each instruction execution are compared between the two cores and mismatches are flagged.
- Peripheral Core_2 (IOP or I/O Processor) is implemented using an e200_z425 core. It is intended to control the various peripherals on the chip, but may be used to execute any user code.
- A Hardware Security Module (HSM) with an embedded e200_z0 core is also included. The HSM executes factory-written code stored in Secure Flash only accessible to the HSM. Like the other processor cores, the HSM can access other memory elements on the chip.

Memory elements involved in the boot-up process include:

- UTEST flash memory
- TEST flash memory
- Boot Assist Flash (BAF).

8.1.1 Boot Assist Flash

The Boot Assist Flash (BAF) contains factory code to facilitate the boot-up procedure.

If the BAF code does not locate a valid boot header, it runs the Serial Boot Loader which receives files from an external serial link controlled by the internal LINFlexD module. The received file is placed in RAM and program execution begins at the start address specified in the received file.

The Serial Boot Loader is only an option in the early stages of the device life cycle. In later stages (for example, FIELD) the device waits for the watchdog to reset the device if no boot header is found.

8.1.2 TEST flash memory block

The TEST flash memory block contains Device Configuration Format (DCF) records used to hold trim values and other variables, as well as general device configuration information.

The trim values are for:

- Adjusting low-voltage and high-voltage detect circuit trip points
- Temperature sensor adjustments
- Power-on reset voltage trip point
- Analog-to-digital adjustments
- Internal RC oscillator (IRCOSC) trim values

NOTE

The DCF records are written by the device manufacturer and programmed into TEST flash memory during production testing. Further programming of the TEST flash is disabled at the end of the factory test cycle.

8.1.3 UTEST flash memory block

The UTEST flash memory block also contains DCF records. Some UTEST DCF records are written by the factory and programmed during production testing. Others are written by the end user and programmed at the same time application code is programmed into the flash memory. UTEST DCF records are used to set up various control and configuration registers, including the Self-Test Control Unit (STCU2) and default memory configuration.

8.1.4 Boot header

A boot header is used to supply the start address for code execution for Core_0, Core_1 and Checker Core_0s. It is written by the application programmer and loaded into specific flash memory locations. It contains the reset vectors for the various cores and specifies the BOOT CPU to execute application code.

8.2 Modules used in reset sequence

The modules involved in the reset sequence are:

- Power Management Controller (PMC)
- Reset Generation Module (MC_RGM)
- Mode Entry Module (MC_ME)
- System Status and Configuration Module (SSCM)
- Self-Test Control Unit (STCU2)

8.2.1 Power Management Controller

The Power Management Controller (PMC) controls and monitors:

- Its own supply voltage
- The supply voltages to all the high- and low-voltage detect circuits
- The trip points for all the high- and low-voltage detect circuits
- The power supplies and reference voltages to the Analog-to-Digital Converter
- The major power supplies to the chip

8.2.2 Reset Generation Module

The Reset Generation Module (MC_RGM) is a complex state machine that begins sequencing the chip through the initial steps of the reset process. The MC_RGM does not execute program code, it is a state machine that centralizes the different reset sources and manages the reset sequence. Reset sources are organized into two categories: destructive and functional.

See Figure 8-1 for more information on the MC_RGM reset sequence.

8.2.2.1 Destructive resets

A destructive reset source is related to a critical error or dysfunction, usually caused by a hardware malfunction. When a destructive reset event occurs, software recovery is not possible and the contents of memory are assumed unknown. A full device reset sequence starting from PHASE0 is therefore applied to the device, ensuring a safe startup state for both digital and analog modules.

Examples of destructive resets are:

- Power-on reset
- Low voltage detection
- Reset escalation (when too many functional resets occur simultaneously)

8.2.2.2 Functional resets

A functional reset source is related to a less critical error or dysfunction not usually not associated with hardware malfunction. When a functional reset event occurs, a partial reset sequence is applied to the device starting with PHASE1[FUNC]: most digital modules are reset normally and the state of analog modules, specific digital modules (for example, debug and flash memory modules) and system memory content is preserved.

Examples of functional resets are:

- External reset
- Machine check
- Software reset from mode entry
- Boundary scan instructions

8.2.3 Mode Entry module

The Mode Entry module (MC_ME) is responsible for delivering initial values to many registers, including the reset vectors to all the cores.

During the power-up sequence, the System Status and Configuration Module (SSCM) searches for a boot header at defined locations in the flash memory, derives the necessary reset vectors from the boot header and then writes these vectors to their respective locations in the Mode Entry module.

The SSCM also interprets the DCF records which contain further information that is written to the MC_ME. As the boot-up sequence progresses, the SSCM instructs the MC_ME to transfer the reset vectors to the respective processor cores.

Even though the reset vectors are in the boot header located in flash memory, the Mode Entry module always provides them to the CPU cores.

8.2.4 System Status and Configuration Module (SSCM)

During the reset sequence, the Reset Generation Module (MC_RGM) enables the SSCM state machine which reads the DCF records in the TEST and UTEST flash memory areas for device setup information to be written to various registers in the chip.

The DCF records are primarily for setting up the memory, configuring the Self-Test Control Unit (STCU2), and providing initial device configuration values.

The SSCM continues with the reset or boot-up sequence by locating boot vectors for the various cores. Once the SSCM locates the boot header, the SSCM writes the start address information for the CPU cores to special locations in the Mode Entry Module (MC_ME). For all cores enabled by the boot header, the MC_ME feeds a reset vector to each enabled core and the respective cores begins program execution at the specified address.

The SSCM starts up the IOP and the HSM in different ways depending on whether there is valid code in the Boot Assist Flash (BAF).

The boot-up sequence ends when the SSCM starts up the Core_0 or Core_1 boot CPU.

8.2.5 Self-Test Control Unit (STCU2)

The Self-Test Control Unit (STCU2) is a self-contained module that runs a Logic Built-In Self Test (LBIST) and a Memory Built-In Self Test (MBIST). The DCF record can be used to select which individual tests are run for LBIST and MBIST and disable tests for modules and memory elements that are not going to be used in user applications, thus shortening device boot-up time.

8.3 Reset sequence

The power-up reset sequence always begins with the application of power and follows different sequences depending on the condition of the MPC5777M chip and whether various modes are enabled from settings in the DCF records. For instance, the chip enters serial boot mode (the Serial Boot Loader receives startup code and begins program execution) if a valid boot header file is not found.

If an emulation and debug device is detected during the reset sequence, the device enters the calibration sequence. The calibration sequence is not a user mode and is only used for code development.

Another reset outcome is that the Hardware Security Module, the IO Processor, and the boot CPU are all properly started and begin executing their respective program code.

8.3.1 Power-on and the Reset Generation Module

When power is applied to the chip, the Reset Generation Module (MC_RGM) advances the device through a series of steps shown in Figure 8-1.

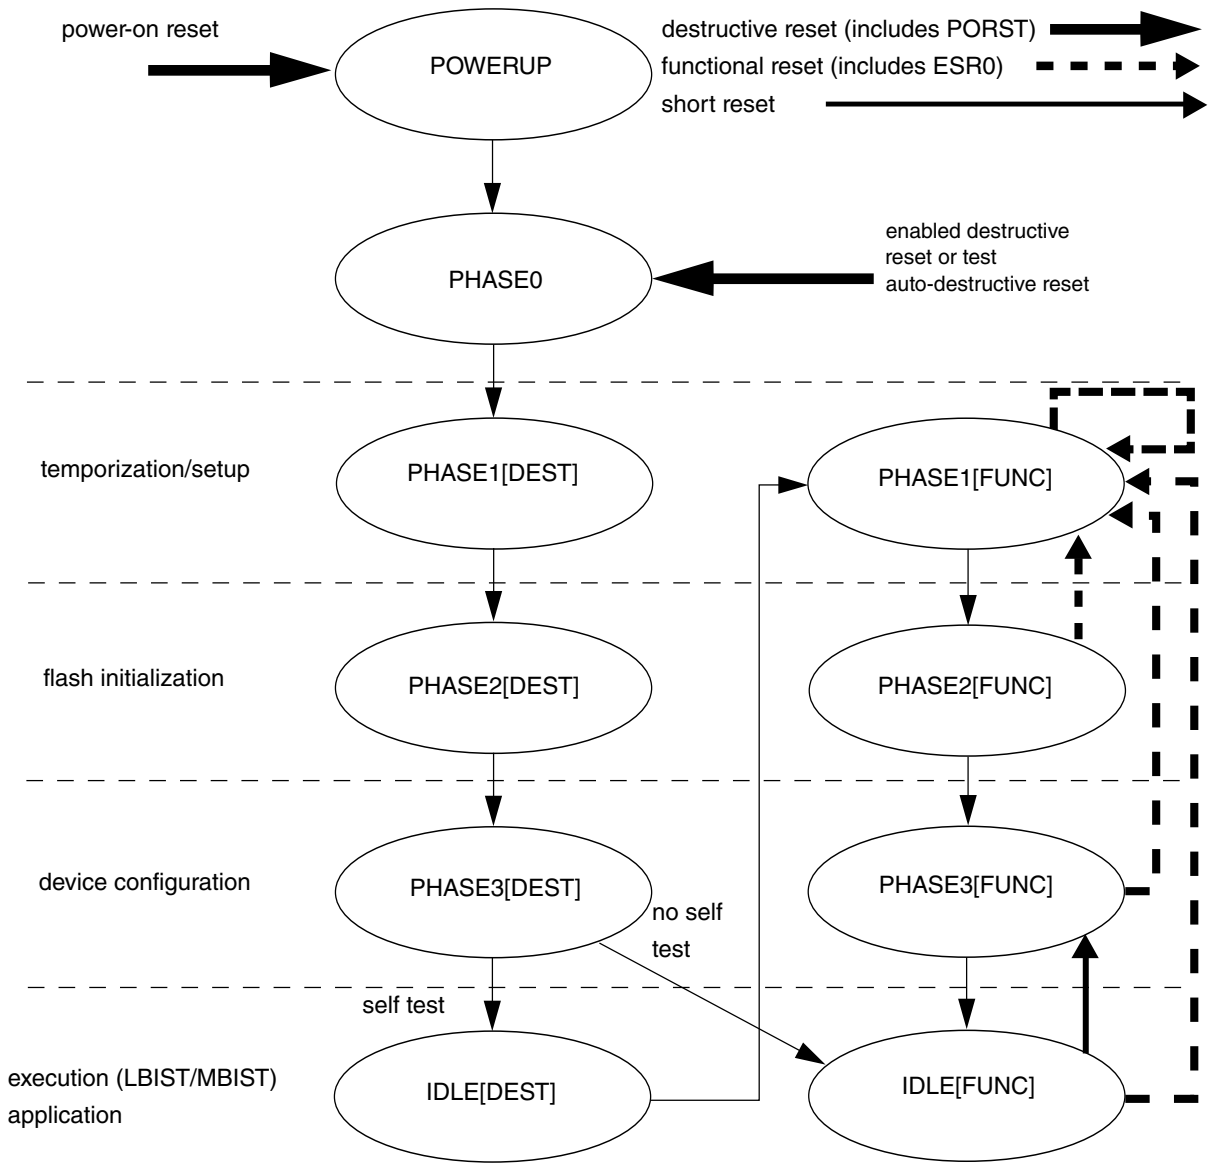

Figure 8-1. Reset Generation Module Reset Sequence

The MC_RGM starts the System Status and Control Module (SSCM), which continues the boot-up process detailed in Figure 8-2 through to Figure 8-6 after the MC_RGM enters the IDLE state.

The STCU is reset on any power-on, 'destructive,' or long external reset (external reset in this case is ESR0).

Table 8-1. Module status during reset phases

Module	PHASE								
	P0	P1 [DEST]	P2 [DEST]	P3 [DEST]	IDLE [DEST]	P1 [FUNC]	P2 [FUNC]	P3 [FUNC]	IDLE [FUNC]
IRCOSC	ON	ON	ON	ON	ON	ON	ON	ON	ON
PMC	ON	ON	ON	ON	ON	ON	ON	ON	ON
MC_RGM	ON[1]	ON	ON	ON	ON	ON	ON	ON	ON

Other modules including cores	RESET	RESET	RESET	RESET	LBIST	RESET	RESET	RESET	ON[9]
								Short functional reset	
						functional reset			
	destructive reset								

1. RESET only during POR
2. STCU time-out monitoring LBIST/MBIST execution
3. Depending on flash configuration
4. FCCU remains ON during functional reset; it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST]. FCCU is reset whenever the STCU is reset plus the STCU's post self-test functional reset request plus the individual peripheral reset from the RGM_PRSTn registers.
5. The STCU remains idle during functional reset; it is instead reset on long external reset (external reset here is ESR0).

6. Can be triggered by SW. Please refer to the STCU2 chapter.
7. MEMU is reset whenever STCU is reset.
8. LBIST is optionally triggered depending on safety execution directives
9. LBIST is optionally triggered depending on safety execution directives after enabling from IOP. Please refer to the BAF chapter.

8.3.2 Power-up phase: power stabilization

When a power-on reset event occurs (initial application of power), the reset generation module (MC_RGM) causes the device to enter the power-up phase of the reset sequence (See Figure 8-1). The only method to enter the power-up phase is from a power-on reset event.

The device remains in the power-up phase until the Power Management Controller module (PMC) determines that all power supplies are in their respective operational ranges.

The supplies for initial configuration are:

- VDD_HV_CORE: high voltage supply for core module, including power management unit, internal RC oscillator (IRCOSC), external oscillator (XOSC) driver
- VDD_LV_CORE: low voltage supply for digital module
- VDD_HV_FLA: high voltage supply for flash module
- VDD_LV_FLA: low voltage supply for flash module
- VDD_HV_IO_IM: high voltage supply associated with system pins (PORST, ESR0, TEST Mode)

Peripheral supplies, such as VDD_HV_IO_JTAG, VDD_HV_IO_FLEX, or VDD_HV_ADC, do not gate the power-up process. The low- and high-voltage detect circuits for these and other power supplies are managed by the PMC, which provides enable and status bits for these voltage detection circuits.

The PMC sends a signal to the Reset Generation Module when power stabilization has been achieved. The Reset Generation Module then advances to the PHASE0 state (see Figure 8-1). During the power-up phase, the PMC does the following:

- Drives to a logic 0 all LVDxx (low-voltage detect) and HVDxx (high-voltage detect) signals monitored by the Power Management Control (PMC) module.
- Monitors its own power supply voltage (VDD_HV_PMC) to determine that the applied voltage is within a specified range.

- Monitors the core power supply voltage (VDD_LV_CORE) to determine that the applied voltage is within a specified range.
- Monitors the low- and high-voltage detect circuit power supply voltage to determine that the applied voltage is within a specified range.
- Holds the outputs of the internal low- and high-voltage detect circuits at a ground state until the PMC determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Enables all low- and high-voltage detect circuits once all power supplies are at their functional levels.
- Begins to monitor the various power supplies using the high- and low-voltage detect circuits.
- Provides status information to the Reset Generation Module (MC_RGM) indicating whether or not power is properly applied.

To exit power-up and enter PHASE0:

- All enabled destructive resets must be processed.
- All power supplies must be at their functional voltages.
- The PMC must signal the MC_RGM that all power supplies are at the required levels.

8.3.3 *PHASE0* Phase: analog supply initial configuration

This phase is entered:

- On exit from power-up phase.
- On PORST pin falling edge detection except for the initial power-up sequence.
- Immediately from PHASE2[DEST], PHASE3[DEST], IDLE[DEST], PHASE1[FUNC], PHASE2[FUNC], PHASE3[FUNC] or IDLE[FUNC], on the occurrence of a PORST falling edge event other than power-on reset.

During PHASE0:

- All digital modules are reset, including safety, security, and test modules.
- All trimming bits for analog modules are reset.
- Startup of the internal analog modules (PMC, IRCOSC, Flash memory, and I/Os) begins:
  - PMC determines that proper voltages are applied.
  - Flash memory performs internal self test and initialization.
  - I/O pins are ensured correctly configured: outputs are driven to known levels, inputs ignored.

To exit PHASE0 and enter PHASE1[DEST]:

- All enabled destructive resets must be processed.
- Gating PHASE0 must be released. See Table 10-4
- All processes initiated in ***PHASE0*** must be completed. This generally includes startup of the internal analog modules: PMC, IRCOSC, flash memory and I/Os.

This phase is typically completed in less than 20 µs. The chip is guaranteed to remain in this phase for at least 0.5 µs.

Note

The core voltage must rise above LVD112 upper threshold to exit PHASE0. This ensures significant hysteresis on low voltage supply avoiding spurious low voltage detection during the power-up process.

8.3.4 *PHASE1[DEST]* Phase: temporization and monitoring setup

This phase is entered on exit from PHASE0.

During PHASE1[DEST]:

- Initial configuration of the watchdog to monitor the reset sequence
- Temporization for reset signal propagation in case of reset

This phase is completed in less than 1 µs and corresponds to eight IRCOSC clock cycles.

Test modules are available during PHASE1[DEST], but their functionality is limited by the security module (no security waiver granted at this phase).

All PHASE1[DEST] tasks must be completed before entering PHASE2[DEST].

8.3.5 PHASE2[DEST] Phase: flash initial configuration

This phase is entered on exit from PHASE1[DEST].

During PHASE2[DEST]:

- Reset is released to the flash memory module by the Reset Generation Module.
- The flash memory module starts its initial configuration process.
- The flash memory initialization is performed by a state machine internal to the flash module.
- The system watchdog starts monitoring flash memory configuration execution so that a reset occurs in the event of configuration failure.

Note

System Watchdog is configured to generate destructive reset in case of flash memory failure during boot process. If, on boot completion, the watchdog event is converted to generate an FCCU fault only, application software should re-configure the MC_RGM watch-dog register bit to prevent destructive reset from being triggered.

All PHASE2[DEST] tasks must be completed before entering PHASE3[DEST].

This phase is completed in less than 200 µs.

8.3.6 PHASE3[DEST] Phase: device configuration

This phase is entered on exit from PHASE2[DEST].

During PHASE3[DEST], the System Status and Configuration Module (SSCM) starts by retrieving the Device Configuration Format (DCF) record from the TEST and UTEST flash memory areas, and uses the configuration and initialization information therein to:

- Configure the Self-Test Control Unit (STCU2) and the initial memory map of the device.

- Transfer reset vectors for the various cores to the Mode Entry Module (MC_ME). This information enables tests that the STCU runs and also provides the memory map setup information so that the STCU can test memory.
- Write trim values for analog modules including the Analog-to-Digital Converter, low- and high-voltage detect circuits, and the temperature sensor to their respective registers.

The DCF record programmed into the TEST flash memory area is generally written by the manufacturer. The portion of the DCF record programmed into the UTEST flash memory is usually written by the customer, although there is a default DCF record programmed into both the TEST and the UTEST flash memory areas during device production testing. In general, you write your own DCF record for the UTEST area to replace the default DCF.

The DCF record also provides configuration information for the following:

- Trimming of the analog modules (for example, voltage regulator, voltage detectors, I/Os, and oscillator)
    - Trim values are in DCF records in the TEST flash memory area.
    - Trim values are determined during production test and programmed into the TEST flash memory area.
- Device life cycle information:
    - Censorship configuration.
    - Debug security configuration.
    - Functional security configuration.
- Application configuration bits:
    - Watchdog configuration.
    - Safety execution directives (self test, LBIST/MBIST).
    - Boot Assist Flash options.
    - Oscillator startup during reset sequence configuration.

To exit PHASE3[DEST]: All processes that need to be completed in PHASE3[DEST] must be finished.

This phase depends on actual trim values, especially those used for safety execution directives. This device configuration is maintained until the next internal power-on reset. Each time a destructive reset event occurs, the SSCM takes values from the DCF record and writes them to the applicable registers.

During this phase, the internal STCU watchdog is started and is only cleared after completion of STCU configuration.

If self-test execution is the configuration information from the DCF record requests , the device moves to IDLE[DEST] and the STCU2 begins self-test. At the end of the test, the STCU2 asserts a functional interrupt causing the Reset Generation Module to move to PHASE1[FUNC]. If self-test execution is not requested, the device moves directly to IDLE[FUNC]. The Reset Generation Module determines whether self-test execution is enabled or not by examining an entry in the DCF record stored in the UTEST flash memory.

Note

When self-test execution is not requested, it is possible to maintain the device in PHASE3[DEST] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.

8.3.7 IDLE[DEST] Phase: self-test execution

This phase is entered upon exit from PHASE3[DEST] if the execution of self test is enabled.

During the IDLE[DEST] phase:

- Dedicated watchdog is configured to monitor self-test execution completion within expected time. The length of this phase is variable depending on the self-test requirements.
- The Self-Test Control Unit (STCU2) executes all tests specified by the DCF information retrieved in PHASE3[DEST].
- The self-test engine updates the self-test completion flag and triggers an associated functional reset on completion of self test.

The length of this phase is variable depending on the self-test requirements.

Note

When the SSCM is decoding the Device Configuration field, it sets and clears various flags in STCU registers and memory that can later be examined by the SSCM to determine which self-test directives must be run.

Exiting IDLE[DEST] and moving to PHASE1[FUNC]:

- The IDLE[DEST] phase is automatically exited when the self-test code generates a functional reset on completion.
- The functional reset causes the reset generation module to move to the PHASE1[FUNC] phase.

Note

In case of unrecoverable fault detection during STCU execution, unrecoverable fault reset is triggered and the chip re-enters PHASE1[DEST] .

8.3.8 PHASE1[FUNC] Phase: temporization and monitoring setup

This phase is entered either:

- On exit from IDLE[DEST]
- Immediately from PHASE2[FUNC], PHASE3[FUNC], or on IDLE[FUNC] when a non-masked external or "functional" reset event occurs, providing the source of the reset event has not been configured to trigger a short reset sequence

During PHASE1[FUNC]:

- Initial configuration of the watchdog to monitor reset process
- Temporization for reset signal propagation in case of reset

To exit PHASE1[FUNC] and enter PHASE2 [FUNC]:

- All enabled, non-shortened functional resets must be processed.
- All processes started in PHASE1[FUNC] must be completed.
    - Initial configuration of the watchdog to monitor reset process
    - Temporization for reset signal propagation in case of reset

This phase is completed in ~1 µs or less. During this phase, test modules are available.

8.3.9 PHASE2[FUNC] Phase: flash initial configuration

This phase is entered on exit from PHASE1[FUNC].

During the PHASE2[FUNC] phase:

- The reset signal is released to the flash memory.
- Flash initialization and configuration begins using a state machine that is internal to the flash memory module.
- A watchdog monitors flash initialization to ensure a reset in case of flash memory configuration failure.

The reset state machine exits PHASE2[FUNC] and enters PHASE3[FUNC] on verification that all processes started in PHASE2[FUNC] are completed.

This phase is completed in ~200 µs .

8.3.10 PHASE3[FUNC] Phase: device configuration monitoring

PHASE3[FUNC] is entered:

- On exit from PHASE2[FUNC]
- Immediately from IDLE[FUNC] when an enabled, short functional reset event occurs.

During PHASE3[FUNC], configuration information contained within the UTEST flash memory sector is checked against information extracted during PHASE3[DEST] and written to the Self-Test Control Unit (STCU2). In case of mismatches, a dedicated boot fault is triggered within the FCCU which, if enabled, can cause a system reset. The purpose of PHASE3[FUNC] is to verify that the DCF information transferred to the STCU, MC_ME and other modules, in PHASE3[DEST], was performed correctly and has not been corrupted.

The Reset Generation Module exits PHASE3[FUNC] and enters the IDLE [FUNC] on verification of the following:

- All processes started in PHASE3[FUNC] are completed.

- PORST and ESR0 pin are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened functional reset event.

After all PHASE3[FUNC] internal actions have been completed, it is possible to maintain the device within PHASE3[FUNC] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes in order to connect through the JTAG port to the internal debugger. In the case of a secured device, it is possible to submit the debug password to access device and/or HSM debug through the JTAG module. The HSM responds by performing certification of the provided password and eventually may enable debug access to the different cores.

8.3.11 IDLE[FUNC] Phase

This is the Reset Generation Module's final phase of the reset sequence. It is entered either on exit from PHASE3[DEST] (if self test was not enabled) or at the completion of PHASE3[FUNC]. When the IDLE[FUNC] phase is reached, the MC_RGM releases control of the system to the System Status and Control Module. The SSCM, which started in PHASE3[FUNC], runs and waits for a signal from the MC_RGM indicating that the MC_RGM is now in the IDLE state. The MC_RGM then waits for new reset events that can trigger a reset sequence. The SSCM continues with the system boot-up sequence.

8.4 MC_RGM passes boot sequence control to the System Status and Control Module

The SSCM continues the boot-up sequence after the Self-Test Control Unit (STCU2) finishes executing the MBIST and LBIST functions that were initiated by the MC_RGM during the IDLE[DEST] state.

A flow chart of the boot-up sequence is shown in Figure 8-2, Figure 8-3, Figure 8-4, Figure 8-5, and Figure 8-6.

8.4.1 Reset sequence flow based on initial device condition

The boot-up sequence takes different paths depending on which modules are enabled and which header files are present. For instance, a device shipped from the factory has pre-installed programs in the Boot Assist Flash and the Boot Assist ROM. Also DCF records are programmed into the TEST flash memory area and the UTEST flash memory area.

- Boot Assist Flash contains factory code which cannot be modified by user.
- Boot Assist ROM contains factory code which cannot be modified by user.
- TEST DCF record cannot be modified by user.
- UTEST flash memory contains a default DCF record which can be replaced with a user file.

After the chip's flash memory has been programmed, it contains the CPU boot header file, and, if required, an HSM boot header file, together with the user application. This boot header is used by the boot-up sequence flow managed by the SSCM module.

8.4.2 Possible boot-up sequences

This section describes possible boot-up sequences.

8.4.2.1 Enter JTAG test mode

- Used for JTAG testing (non-user mode)
- Interface to JTAG port Development Equipment for Code Development

8.4.2.2 Enable IOP and Boot CPU (CPU_0 or CPU_1)

- Normal operation for I/O Processor (IOP)
- Normal operation for the selected boot CPU

8.4.2.3 Enable IOP, HSM and enable the Boot CPU (CPU_0 or CPU_1)

- Normal operation for I/O Processor (IOP)
- Normal operation for selected boot CPU
- Normal Hardware Security Module (HSM) operation

8.4.2.4 Enable IOP and/or HSM and enter serial boot mode if no application code is present

- Mode used to download program code and place it in RAM
- Mode used to start downloaded application program

The following sections detail the exact flow through the reset sequence to achieve the various outcomes.

8.4.3 Sequence from MC_RGM IDLE to IOP, HSM, and boot CPU running code

Here the operation of the IOP and HSM is desired. A boot CPU is selected and starts executing application code; all of the processor cores are also started: CPU_0, CPU_1, Checker Core_0s, HSM, and IOP.

8.4.3.1 Initial conditions

- Boot Assist Flash bypass mode is NOT enabled (execute BAF code).
- HSM is enabled.
- Application code for the IOP is programmed into Boot Assist Flash memory.
- Application code for the HSM is programmed into flash memory.
- Application code for the boot CPU is programmed into flash memory.
- A valid boot header for CPU_0, CPU_1, and the Checker Core_0s has been programmed into flash memory with:
  - Boot Header_ID
  - Boot CPU selection
  - Boot CPU start address (address of first instruction in application code)
  - CPU_0 reset vector
  - CPU_1 reset vector
  - Checker Core_0s reset vector
- A valid boot header for HSM has been written into flash memory with:

- HSM_Boot_Header_ID
- Start address of HSM application code

- The Reset Generation Module (MC_RGM) has passed control to the SSCM during the IDLE[FUNC] state.

8.4.3.2 Reset Generation Module has entered idle state

The MC_RGM enters the IDLE[FUNC] state and completes all the tasks in defined the IDLE[FUNC] state. It then signals the SSCM that it has become idle and the SSCM can take control of boot-up.

8.4.3.3 LBIST and MBIST start execution (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. It then signals the SSCM that it has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.3.4 Is a JTAG request pending? (state A)

The SSCM now controls the boot-up sequence and begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.3.5 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM determines whether or not the Boot Assist Flash bypass mode is enabled. If enabled, any eventual code in the BAF is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the BAF bypass mode. With the BAF bypass mode disabled, code in the Boot Assist Flash is always executed during a boot-up sequence.

The factory BAF code also runs the Serial Boot Loader, setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins IOP (I/O Processor) execution at the start address specified in the file header.

8.4.3.6 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the Hardware Security Module (HSM) is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.3.7 Locate HSM Boot Header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_C000, 0x61_0000 and 0x62_0000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a start address for the HSM application code, and a third word that is reserved for future use. By definition a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

If a valid HSM_Boot_Header_ID is found, the SSCM transfers the start address to the Mode Entry Module (MC_ME). When reset is released to the HSM, the HSM start address is transferred from the MC_ME to the HSM and HSM code execution begins at that point.

8.4.3.8 Valid Hardware Security Module header file? (state D)

In the present scenario, a valid HSM boot header is present as determined in state 44.

8.4.3.9 Provide reset vectors to IOP and HSM (state 25—go to state 22 and 26)

Under the control of the SSCM, the HSM start address obtained from the HSM boot header is transferred to the MC_ME.

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code is transferred to the MC_ME. The SSCM releases reset to the IOP and HSM and then turns on the clock to both modules. The BAF code start address is transferred from the MC_ME to the IOP. At this time, the HSM code start address is also transferred from the MC_ME to the HSM under the control of the SSCM.

8.4.3.10 HSM code and BAF code execution begins (state 26)

After the reset signal is released and the respective clock is turned on to the HSM and the IOP, code execution begins. The HSM begins executing its application code and the IOP begins execution of code in the Boot Assist Flash.

8.4.3.11 Verification of HSM host boot block (state 27)

HSM applications code can optionally be written to confirm that the correct start address for the HSM applications code was obtained from the HSM boot header file. This step is optional and requires that the HSM applications code and the HSM boot header file match.

If a new revision of the HSM code is created with a start address that is different from the prior revision, the HSM applications code must be modified to take into account that there is a different start address. The HSM Boot Header must also be appropriately modified.

8.4.3.12 Set HSM Boot Ready flag (state 28)

The HSM hardware sets the HSM Boot Ready flag when the HSM becomes fully initialized.

8.4.3.13 Execution of HSM application code begins (state 29)

The HSM has been properly enabled, a valid start address for code execution has been supplied and the HSM begins normal code execution.

8.4.3.14 IOP begins BAF code execution (state 22)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.3.15 IOP applies device settings (state 23)

The IO Processor, executing code in the Boot Assist Flash, configures the MPC5777M with various initialization parameters. The System Status and Configuration Module (SSCM) has already applied some configuration information from the DCF record.

8.4.3.16 Calibration Sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production MPC5777M (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The emulation and debug device (ED) consists of a regular production MPC5777M (PO) and a special Buddy Device (BD) in a single package.

The I/O Processor (IOP) executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is detected, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of MPC5777M reset.

In this example, it is assumed that an emulation and debug device (ED) is not being used in place of a regular production MPC5777M.

8.4.3.17 Is HSM enabled? (decision point E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In this example, it is assumed that the HSM is enabled.

8.4.3.18 Wait for HSM to set HSM_Boot_Ready flag? (decision point F)

The IOP determines whether it must wait until the HSM becomes ready before the IOP begins a search for the boot header file. If the IOP is directed to wait for the HSM to set its HSM_Boot_Ready flag, the IOP goes to state 30 until the "HSM_Boot_Ready" flag is set. Afterwards, the IOP begins a search for the Boot Header file in state 31.

If the IOP is not directed to wait for the HSM to set its HSM_Boot_Ready flag, the IOP immediately begins a search for the boot header file in state 31.

8.4.3.19 Wait until HSM_Boot_Ready flag sets (state 30)

The IOP waits until the HSM_Boot_Ready flag is set.

8.4.3.20 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. This is the header file for the CPU that starts executing the your application code. Generally, the BOOT CPU is either Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time your application program is programmed into flash memory. The IOP searches for the boot header file which can be located at one of eight addresses:

Note

Addresses are searched in the following order.

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid boot header begins with the value 0x005A.

The boot header structure consists of seven words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector

- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit 0 selects the I/O Processor
- Bit 1 selects CPU_0
- Bit 2 selects CPU_1
- Bit 3 selects the Checker Core_0s
- Bits 4–15 are not implemented

Note

Checker Core_0s can only be used if CPU_0 is also used. Both cores must have the same reset vector.

8.4.3.21 Valid boot header is found (state N)

In the present example, a valid boot header is assumed to be present in flash memory.

8.4.3.22 Decode boot CPU (state 32)

The IOP decodes the boot header and then writes the reset vectors for CPU_0, CPU_1, and the Checker Core_0s to the Mode Entry Module.

8.4.3.23 Lock BAF access (state 33)

Further access to the BAF is locked against further code execution, but it is readable.

8.4.3.24 Boot From Internal flash (state 34)

The MC_ME transfers the reset vectors to the respective CPUs and code execution for each of the cores begins at their respective reset vector address.

8.4.4 Sequence from MC_RGM IDLE to IOP and Boot CPU running code (HSM disabled)

Here the IOP is desired, but not the HSM. A Boot CPU is selected and starts executing application code; it also starts all of the processor cores except HSM: CPU_0, CPU_1, Checker Core_0s, and IOP.

8.4.4.1 Assumptions

- Boot Assist Flash bypass mode is not enabled (execute BAF code).
- HSM is not enabled.
- Application code for the IOP is programmed into Boot Assist Flash memory.
- Application code for the Boot CPU is programmed into flash memory.
- A valid boot header for CPU_0, CPU_1 and Checker Core_0s has been programmed into flash memory.
    - Boot Header_ID
    - Boot CPU selection
    - Boot CPU start address (address of first instruction in application code)
    - CPU_0 reset vector
    - CPU_1 reset vector
    - Checker Core_0s reset vector
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.4.2 Reset Generation Module has entered idle state (state 1 and 2)

The Reset Generation Module (MC_RGM) enters the IDLE[FUNC] state and completes all tasks. The MC_RGM then signals the System Status and Control Module (SSCM) that it has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.4.3 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining whether a JTAG request is pending. The JTAG test circuitry is for production test and used by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.4.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the Boot Assist Flash bypass mode is enabled. If this mode is enabled, any eventual code in the BAF is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the Boot Assist Flash is always executed during a boot-up sequence.

The factory BAF code also runs the serial boot loader, setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins IOP execution at the start address specified in the file header.

8.4.4.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is not enabled.

8.4.4.6 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code is transferred to the MC_ME.

The SSCM releases reset to the I/O Processor (IOP) and then turns on the clock to the IOP. The BAF code start address is transferred to the IOP at this time under the control of the SSCM. Execution of the Boot Assist Flash code begins.

8.4.4.7 BAF code execution begins (state 22)

After the reset signal is released to the IOP, BAF code execution begins.

8.4.4.8 The IOP executes code to apply device setting (state 23)

The IOP executes BAF code, written by the manufacturer, to apply specific device settings to the MPC5777M.

The BAF code begins by initializing registers and applying device settings. The BAF code, written by the device manufacturer, changes from device to device.

8.4.4.9 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production MPC5777M (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of MPC5777M reset.

In this example, it is assumed that an ED is not being used in place of a regular MPC5777M production device.

8.4.4.10 Is HSM enabled? (decision point E)

The IOP determines whether the HSM is enabled by examining a status bit in the HSM. In the present example, it is assumed that the HSM is not enabled.

8.4.4.11 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that a valid Boot Header is present.

This is the header file that specifies which Boot CPU starts executing the user application code. Generally, the Boot CPU is Core_0 or Core_1. The boot header file also contains the reset vector addresses for Core_0, Core_1, and the Checker Core_0s.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘2’ selects CPU_1,
- Bit ‘3’ selects the Checker Core_0s.
- Bits ‘4–15’ are not implemented.

8.4.4.12 Is a valid boot header present? (decision point N)

In the present example, a valid boot header is assumed to be present in flash memory.

8.4.4.13 Decode boot CPU (state 32)

The I/O Processor decodes the boot header and then writes the reset vectors for CPU_0, CPU_1, and the Checker Core_0s to the Mode Entry Module (MC_ME).

8.4.4.14 Lock BAF access (state 33)

Further access to the Boot Assist Flash is locked.

8.4.4.15 Boot from internal flash (state 34)

The MC_ME transfers the reset vectors to the respective CPUs and code execution for each of the cores begins at their respective reset vector.

8.4.5 Path from MC_RGM IDLE to serial boot mode

Here no application program or valid boot headers for the HSM or CPU_0, CPU_1, or Checker Core_0s is programmed into flash memory. It is an unusual scenario, but it is shown here for illustrative purposes.

8.4.5.1 Initial conditions

- No valid boot header for CPU_0, CPU_1, and Checker Core_0s has been programmed into flash memory.
- BAF bypass mode is NOT enabled (execute BAF code).
- The HSM is enabled.
- Application code for the IOP is programmed into the BAF.
- Application code for the HSM is not programmed into secure flash memory.
- Application code for the Boot CPU is not programmed into flash memory.

- A valid boot header for the HSM has not been written into flash memory.
- The Life Cycle variable is set to FACTORY, indicating an unprogrammed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.5.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. The MC_RGM then signals the SSCM that it has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.5.3 Is a JTAG request pending? (state A)

The SSCM now controls the boot-up sequence and begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.5.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the BAF bypass mode is enabled. If enabled, any code in the BAF is not executed. The BAF bypass mode is enabled/ disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the BAF is always executed during a boot-up sequence.

The BAF code written by the device manufacturer also runs the serial boot loader. This involves setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins the IOP execution at the start address specified in the header portion of the program file.

8.4.5.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.5.6 Locate HSM boot header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_C000, 0x61_0000 and 0x62_0000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a Start Address for the HSM application code, and a third word that is reserved for future use. By definition, a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

8.4.5.7 Valid Hardware Security Module header file? (state D)

In the present scenario, no valid HSM boot header is present. In this case, the System Status and Control Module takes the same path as if the HSM was not enabled at decision point C.

8.4.5.8 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME by the SSCM.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The clock to the HSM is turned off in this state even though the HSM was originally enabled. Because no valid header file for the HSM is found, the IOP goes to state 21 from decision point D, which turns the HSM clock off. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the BAF code.

8.4.5.9 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.5.10 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.5.11 Calibration Sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production MPC5777M (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of MPC5777M Reset.

In this example, it is assumed that an ED is not being used in place of a regular MPC5777M production device.

8.4.5.12 IOP checks to determine if HSM is enabled (state E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In the present case, the SSCM has already disabled the clock to the HSM. Therefore, the HSM is not enabled.

8.4.5.13 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘2’ selects CPU_1,
- Bit ‘3’ selects the Checker Core_0s.
- Bits ‘4–15’ are not implemented.

8.4.5.14 Valid boot header is not found (decision point N)

The IOP, executing code in the BAF, does not find a valid boot header file in flash memory. Because there is no valid boot header, serial boot mode must be entered to obtain an application program.

Note

This mode uses a defined protocol to receive a program over a serial port via the LINFlexD port. The IOP then jumps to the start address of the program and begins execution.

8.4.5.15 Initialize RAM (state 35)

The IOP, executing code in the Boot Assist Flash, initializes RAM in preparation for entering serial boot mode. Serial boot mode configures the LINFlexD port to receive code from an external source. The LINFlexD port comes in a number of hardware configurations. The chip uses LINFlexD, which implements a basic UART. Code in the BAF operates the LINFlexD module and implements the protocol.

8.4.5.16 Enter serial boot mode (state 14)

Figure 8-6 shows the boot loader flow.

8.4.5.17 Life Cycle check indicates FACTORY (decision point G)

There are two possible settings for the Life Cycle parameter:

- FIELD indicates that application code has been programmed into the flash memory of the device. Serial boot mode is exited and IOP enters a ‘wait’ mode until a watchdog reset occurs.
- FACTORY means that there is no application code programmed into the flash memory. For the present example a setting of FACTORY is assumed.

8.4.5.18 Receive and install application code

In general, a serial link is implemented using the LINFlexD port and a particular protocol for data transmission has been defined and implemented in the Boot Assist Flash code. Once the LINFlexD port is configured, the serial boot loader waits to receive the code.

Note

There is a software watchdog timer that is started by the BAF code. If a program is not received before the watchdog timer timeout, a reset occurs.

- Configure LINFlexD module and external pins (state 37)
- Wait for START WORD (state 38)
- Receive START WORD (state 39)
- Receive START ADDRESS (state 40)
- Receive DOWNLOAD SIZE (state 41)
- Receive CODE (state 42)
- Branch to START ADDRESS (state 43)

Application code, using the IOP, begins at the received START ADDRESS.

8.4.6 Path from MC_RGM IDLE with IOP and HSM enabled to watchdog timer timeout

Here the operation of the IOP and the HSM is desired but there is no valid boot header file or HSM header file and the Life Cycle variable is set to FIELD, indicating that the device was programmed with application code and the appropriate boot header files.

This path is only taken if a catastrophic event has occurred or the device is improperly programmed.

8.4.6.1 Initial conditions

- BAF bypass mode is not enabled (execute BAF code).
- The HSM is enabled.
- A valid boot header for the HSM has not been programmed into flash memory.
- A valid boot header for CPU_0, CPU_1 and Checker Core_0s has not been programmed into flash memory.
  - Boot Header_ID
  - Boot CPU selection

- Boot CPU start address (address of first instruction in application code)
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

- The Life Cycle variable is set to FIELD, indicating a programmed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.6.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. It then signals the SSCM that the MC_RGM has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.6.3 Is a JTAG request pending? (state A)

The SSCM now controls the boot-up sequence and begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.6.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether or not the boot assist flash bypass mode is enabled. If this mode is enabled, any eventual code in the Boot Assist Flash is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the BAF is always executed during a boot-up sequence.

The factory BAF code also runs the serial boot loader, setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins IOP execution at the start address specified in the file header.

8.4.6.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.6.6 Locate HSM boot header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_C000, 0x61_0000 and 0x62_0000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a Start Address for the HSM application code, and a third word which is reserved for future use. By definition, a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

8.4.6.7 Valid Hardware Security Module header file? (state D)

In the present scenario, no valid HSM boot header is present. In this case, the SSCM takes the same path as if the HSM was not enabled at decision point C.

8.4.6.8 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The clock to the HSM is turned off in this state even though the HSM was originally enabled. Because no valid header file for the HSM is found, the IOP goes to state 21 from decision point D, which turns the HSM clock off. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the Boot Assist Flash code.

8.4.6.9 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.6.10 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.6.11 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production MPC5777M (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of MPC5777M reset.

In this example, it is assumed that an ED is not being used in place of a regular MPC5777M production device.

8.4.6.12 IOP checks to determine if HSM is enabled (state E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In the present case, the SSCM has already disabled the clock to the HSM. Therefore, the HSM is not enabled.

8.4.6.13 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘2’ selects CPU_1,
- Bit ‘3’ selects the Checker Core_0s.
- Bits ‘4–15’ are not implemented.

8.4.6.14 Valid boot header is not found (decision point N)

The IOP, executing code in the BAF, enters serial boot mode to obtain an application program as it does not find a valid boot header file in flash memory.

Note

This mode uses a defined protocol to receive a program over a serial port via the LINFlexD port. The IOP then jumps to the start address of the program and begins execution.

8.4.6.15 Initialize RAM (state 35)

The IOP, executing code in the BAF, initializes RAM areas in preparation for serial boot mode. This mode configures the LINFlexD port to receive code from an external source using a basic UART protocol.

8.4.6.16 Enter serial boot mode (state 14)

Figure 8-6 shows the boot loader flow.

8.4.6.17 Life Cycle check indicates FIELD (decision point G)

There are two settings for the Life Cycle parameter: FIELD and FACTORY.

FIELD indicates that application code has been programmed into the flash memory. In this case, the IOP enters a ‘wait’ mode until a watchdog reset occurs.

8.4.6.18 Stop—wait for watchdog (state 36)

This state is entered when the chip’s program flash memory is incorrectly programmed.

Chapter 9
Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record consists of a pointer to the location of a register internal to the device and the respective data.

There are two broad categories of DCF records, TEST DCF Records and UTEST DCF Records:

- TEST DCF records are developed by the factory. They can be used to write any DCF client, but are used mainly to:
  - Program registers involved in trimming trip points for voltage comparators
  - Adjusting analog to digital voltage supplies
  - Trim oscillator frequencies
  - Enable RAM repair

NOTE

The TEST DCF Records are programmed into TEST flash during production and cannot be modified. TEST flash is not visible to the user.

- UTEST DCF records can be either:
  - Factory programmed during production testing (see “UTEST flash memory map” table in Flash memory maps).
  - User programmed when application code is written to the flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the factory UTEST DCF records. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) runs during the boot sequence, enable the HSM, assign flash memory blocks to specific tamper detect regions, assign memory blocks as OTP and assign flash blocks to be associated with specific password groups.

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective flash memories.

When power is applied to a properly programmed device:

1. The Power Management Controller (PMC) takes control of the device until the system power supplies have reached predefined levels.
2. The PMC then signals the Reset Generation Module (RGM) to begin the boot sequence.
3. During boot, the RGM enables the System Status and Control Module (SSCM) to read the device configuration records and write information to specific registers.
4. After the reset process has completed, the STCU, depending on its DCF values, may start the self test.

9.2 DCF clients

DCF clients are 32-bit hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written, and may have special writing constraints, such as 'Write Once' or only allowing bits to be written from '1' to '0' or vice versa. DCF clients need not implement all 32 bits. DCF clients may be designated 'TEST DCF record only', so that only DCF Records stored in TEST flash can write to the DCF Client.

A list of DCF clients is shown in Table 9-6. (TEST DCF Record Only Clients are not shown as these are not accessible by the user).

The DCF Records select the target DCF client via a 30-bit field in the DCF Record consisting of:

- A 15-bit Chip-Select field—each module that includes DCF clients is assigned a Chip Select during chip definition.
- A 15-bit Address field—the address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory beginning at 0x0040_0300.

The structure of a DCF Record is shown in Table 9-1.

Table 9-1. DCF Record Structure

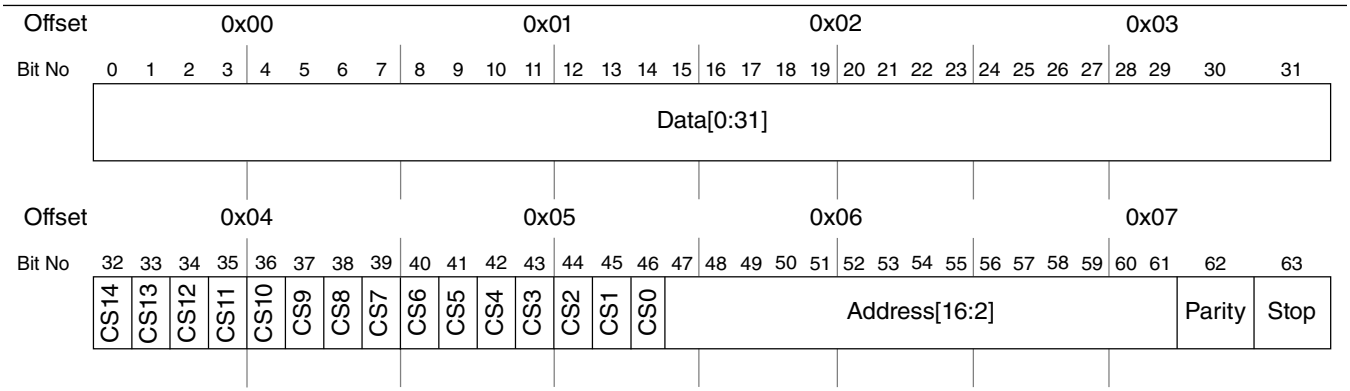

Figure 9-1. DCF Record Structure

Table 9-2. DCF Record Field Description

Field	Name	Description
0–31	Data[0:31]	32 bits of data that is to be written to the DCF Client
32–46	CS*n*	Chip Select *n*. **NOTE:** Only assert one chip per DCF record to select the target module for the DCF client. All other Chip Selects should be negated. 0 Chip Select is asserted 1 Chip Select is negated
47–61	Address[16:2]	Address of the DCF client within the selected module. **NOTE:** Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter
62	Parity	Parity Bit for the DCF Record. **NOTE:** This bit is NOT implemented for DCF Client written from UTEST
63	Stop	Stop bit. This bit indicates the end the list of DCF Records. **NOTE:** The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list. 0 Not the end of the list. 1 End of the list.

The following structure must be present:

- The first record must be a start record.

- DCF records containing configuration data must immediately follow the start record with no blank records between—an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a stop record.

Each record is 64 bits in length. Table 9-3 shows the DCF start record.

Warning

The start record must be placed at the beginning of the DCF area in UTEST flash memory to indicate to the device that the following data records must be processed.

Table 9-3. DCF start record

0x00 0:31	0x04 32:63
0x05AA55AF	0x00000000

During system boot, while the reset signal is asserted, the SSCM reads the device configuration records and writes the data to the appropriate internal module registers. Many operational aspects of the device are therefore already configured when the reset signal is released and normal device operation begins.

Some device configuration records are calculated during production testing and programmed into the TEST flash memory area. Other DCF records are developed by the user and programmed into the UTEST flash area.

The stop bit designates the last device configuration record in a set of records. It is not normally set in a valid UTEST DCF record programmed during production as this prevents additional UTEST records from being appended to the factory programmed UTEST DCF records. However, the flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location whose contents is 0xFFFF_FFFF_FFFF_FFFF. The stop bit location in this unprogrammed flash memory location is therefore a logic 1, signifying that this is the last DCF record and not to be acted on.

The general format of the stop record is shown in Table 9-4. Only the stop bit needs to be 1 in order to form a stop record—all other bits are ignored. An unprogrammed location in UTEST flash is interpreted as a stop record.

Table 9-4. DCF stop record

0:31	32:62	63
Reserved	Reserved	1

If *n* data records are to be stored in UTEST, the data structure must be as shown in Table 9-5.

Table 9-5. Series of DCF records in UTEST flash memory

ADDR offset	DATA			
0x00	0x05AA55AF			
0x04	0x00000000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
…	…			
8n + 0x0	reserved			
8n + 0x4	Reserved			STOP=1
8(n+1) + 0x0	—			
8(n+1) + 0x4				

Warning

There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored. Records to be programmed in several sessions, appending new records to the end of the list each time, is shown in Figure 9-2

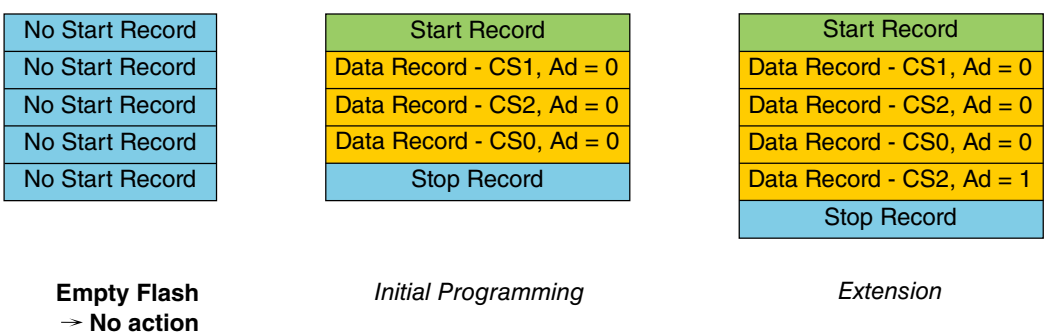

Figure 9-2. Appending DCF records

It is possible for more than one DCF Record to write to the same DCF client. The later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST flash memory area (refer to UTEST flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory and the user may add USER DCF records from the first unprogrammed location following the factory programmed UTEST DCF records. An unprogrammed location in flash memory contains 0xFFFF_FFFF.

When programming UTEST DCF records, the records must start at the first address in the UTEST flash memory area and be continuous; that is, one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module.

9.4 DCF client table

A list of DCF clients is shown in DCF client list. Various attributes of the DCF clients are listed in these tables:

- DCF CS[14:0]

  The DCF Chip Select is a 15-bit field with each bit in the field acting as module-select signal for the internal modules. Only one bit in this field should be set in a DCF record.

- DCF address[16:2]

  The 15-bit ADDR field specifies an internal address for a DCF client. These addresses are only used by the SSCM when interpreting DCF records and writing data to specified modules.

- DCF client description

  The name of the DCF clients.

- Reset value of DCF client

  The reset value of DCF client before being written by the SSCM with the associated DCF record.

- IPS read

  This column specifies whether or not a DCF client can be read by user software after the release of reset.

- DCF client special strategy

  Registers are designated as DCF clients if they need to be written with a DCF record. Other features that must be designated for DCF clients include write strategies listed below. The following list defines the special strategies.

  - None

    No special DCF strategy is used.

  - Write Once

    A DCF client can be written only once. The DCF client ignores subsequent writes.

  - Triple Voted

    DCF clients have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows for a 'bit-flip' error tolerance without changing the DCF client output data.

  - Write 0 only

    A bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a bit to logic 1 is ignored.

  - Write 1 only

    A bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a bit to logic 0 is ignored.

- DCF order dependency in flash memory

  This column details whether or not there are special conditions on the location of a particular DCF record in flash memory.

9.4.1 DCF client list

The DCF client list is provided in the following table:

Table 9-6. DCF client list

DCF CS[14:0][1]	DCF address [16:2] (binary)	DCF client description	Reset value of DCF client	IPS read	DCF client special strategy	DCF order dependency in flash memory
STCU - Support for 10 LBIST partitions; 78 Memories; 32-bit PRPG; 64-bit MISR						

Table continues on the next page...

LVD assertion on the supply of the cold point causes system reset.

Chapter 10
Power management

10.1 Overview

MPC5777M microcontrollers include a robust power management infrastructure that enables applications to select among various operational and low-power modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave reset. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Clock Generation Module (MC_CGM)
- Mode Entry Module (MC_ME)

This chapter describes these modules in brief. For complete details, see the respective module chapters.

The MC_CGM generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement low power modes.

The MC_PCU provides a status register and a submodule, the PMC_dig (Power Management Control Digital Interface), provides an interface to configure and control internal voltages.

The MC_ME module controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application.

The MPC5777M has two types of modes, SYSTEM modes and USER modes.

SYSTEM modes:

- SYSTEM modes are entered automatically on system events or on application request.
- The SYSTEM modes are: RESET, SAFE, TEST and DRUN.

Table 10-1. SYSTEM modes

Mode	Description	Entry	Exit
RESET	System remains in this mode until all resources are available for S/W to take device control. RESET manages H/W initialization of chip configuration, voltage regulators, oscillators, PLLs, and flash.	System reset assertion from RGM	System reset deassertion from RGM
SAFE	May be entered on detection of a recoverable error. Forces system into predefined safe configuration from which the system may try to recover.	H/W fail, S/W request from DRUN, TEST and RUNx	System reset assertion, DRUN through S/W
TEST	Control environment for device self-test. Allows application to run its own self-test like flash checksum and RAM BIST.	Software request from DRUN	System reset asserted, DRUN through S/W
DRUN	Entry mode for the embedded software. Provides full system accessibility and enables system configuration. Provides gate to enter USER modes. BAF, when present, is executed in DRUN mode.	Reset removed, from SAFE, TEST and RUNx through S/W, STANDBY wakeup	Reset applied, RUNx, TEST through S/W, SAFE through S/W or H/W fail

USER modes:

- USER modes control performance and consumption during normal application operation. The modes are organized according to the performance provided.
- The USER modes are RUNx, HALT, STANDBY, and STOP.
- Each mode is entered by writing a dedicated register protected by a key, to avoid unwanted transition.
- Figure 10-1 shows the mode relationships.

Table 10-2. USER modes

Mode	Description	Entry	Exit
RUNx	These are software running modes where most of the processing activity is done. These run modes allow the user to enable different clock and power configurations of the system with respect to each other.	Software request from DRUN, interrupt event from HALT, wakeup request from STOP	Reset asserted, SAFE through S/W or H/W fail, RUNx, HALT, STOP, STANDBY through S/W
HALT	Reduced-activity low-power mode during which the core clock is disabled. It can be configured to switch off analog peripherals like PLL, flash, main voltage regulator, etc., for efficient power management at the cost of higher wakeup latency.	Software request from RUNx	Reset asserted, SAFE on hardware failure, RUNx on interrupt event

Table continues on the next page...

Table 10-2. USER modes (continued)

Mode	Description	Entry	Exit
STOP	Advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including the oscillator for efficient power management at the cost of higher wakeup latency.	Software request from RUNx	Reset asserted, SAFE on hardware failure, RUNx on wakeup event
STANDBY	Reduced-leakage low-power mode during which power is cut off from most of device. Wakeup takes a relatively long time, and content is lost or must be restored from backup	Software request from RUNx modes	Reset asserted, INIT on wakeup event

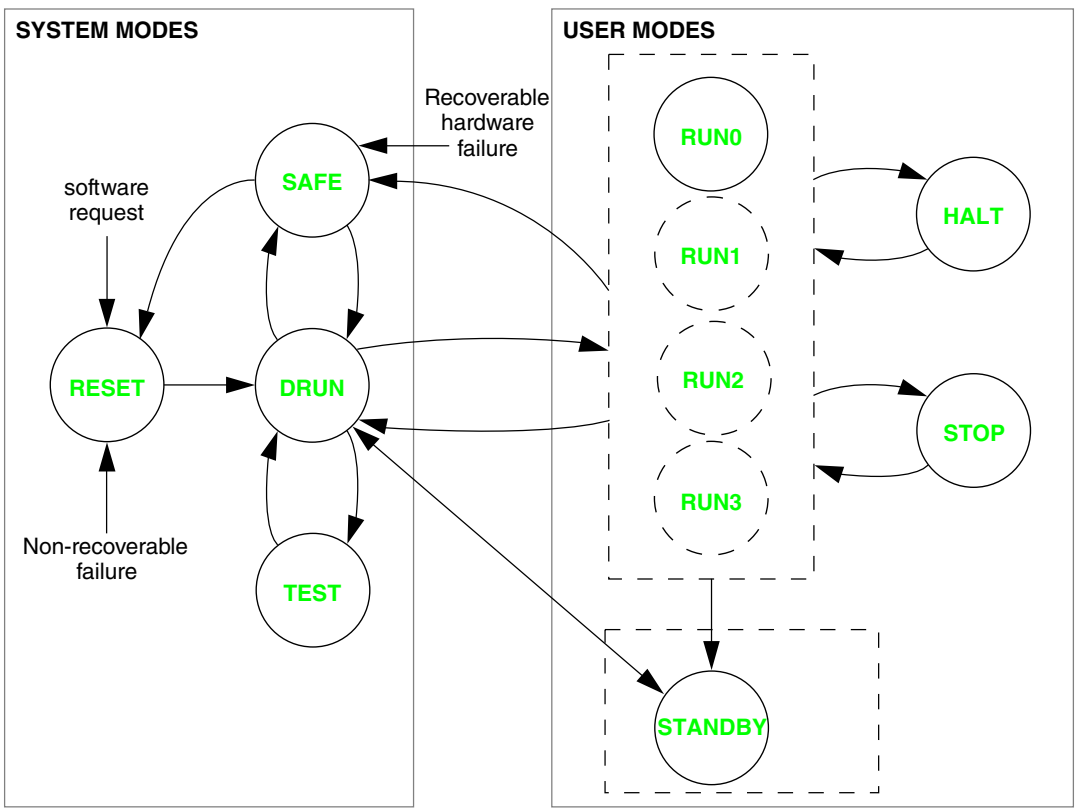

Figure 10-1. Mode relationships

10.1.1 Power management framework

The power management framework supports a variety of configuration options. See the following figure for more details. MPC5777M implements a unique core voltage power domain. There are no separate functional power domains.

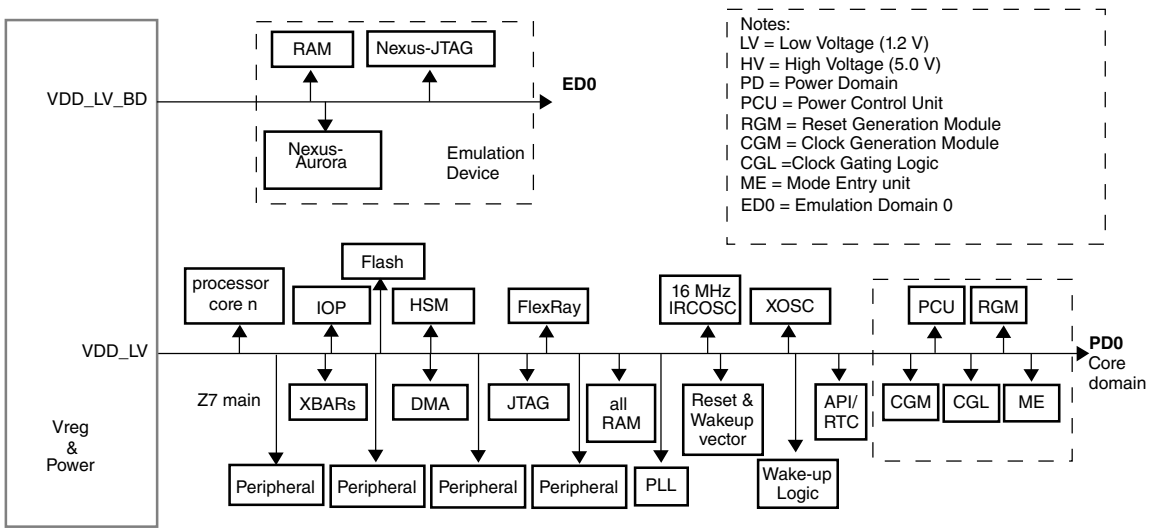

Figure 10-2. Device power management framework

10.1.2 Power management supply description

The following table provides an overview of the PMC supply signals.

Table 10-3. Device power management controller external signals

Name	Type	Description
VDD_HV_ADR_D	Reference	Voltage reference of ADC Σ/δ module
VDD_HV_ADR_S	Reference	Voltage reference of ADC SAR module
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_FLA	Decoupling	Decoupling supply pin for Flash
VDD_HV_IO	Supply	High voltage power supply for the I/Os
VDD_HV_IO_FLEX	Supply	FlexRay/Ethernet 3.3 V I/O supply
VDD_HV_IO_JTAG	Supply	Oscillator and JTAG pin supply
VDD_HV_PMC	Supply	High voltage power supply for internal power management unit
VDD_LV	Supply	Low voltage power supply for the core area
VDD_LV_BD	Supply	Low voltage power supply for the buddy device
VSS	Ground	Ground supply for the device / I/O. This is covering both VSS_LV and VSS_HV in case of exposed pad device.
VSS_HV_ADR_D	Reference	Ground reference of ADC Σ/δ module
VSS_HV_ADR_S	Reference	Ground reference of ADC SAR module
VSS_HV_ADV	Supply	Ground supply for the ADC modules

Warning

There are constraints on some input voltages relative to other input voltages. Please refer to the device data sheet for detailed information.

10.1.3 MPC5777M power management controller overview

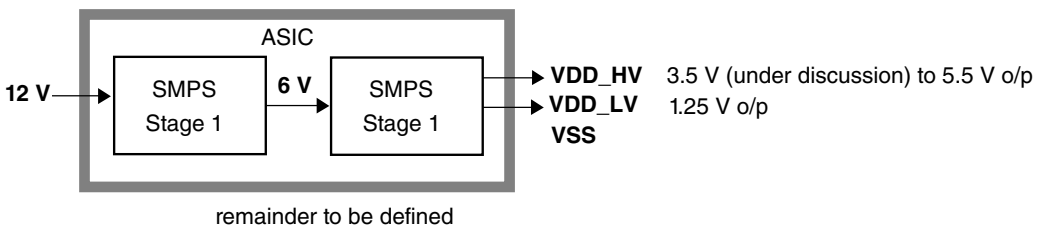

Figure 10-3. PMU MPC5777M (simplified)

VDD_HV_IO is redundant, ensuring that single pin failure does not prevent device from functioning correctly. Full specification may not be guaranteed.

VDD_LV is redundant, ensuring that single pin failure does not prevent the device from functioning correctly.

10.1.3.1 1.2 V safety/spike regulator specification

MPC5777M implements a 1.2 V safety/spike regulator. This regulator can be used to handle fast application current variation that cannot be fully handled by external regulator.

10.2 Low power mode support

The MPC5777M microcontroller supports low power modes.

Dedicated logic prevents uncontrolled activation of low-power mode. This is implemented using protected sequence from ME.

Any register leading to low power entry is triple-voted.

10.2.1 Low power support and STOP mode implementation

Low power mode may be used to control the engine during the power-up phase, as in a Start-Stop system or when the key has been turned off.

The device implements the equivalent of an idle or power-down mode through STOP and HALT mode configuration.

The microcontroller application code can be used to put the device or modules into STOP mode.

A combination of mode control and clock control allows the user to configure the STOP mode.

In Afterrun mode, peripheral modules can be enabled/disabled in STOP using the control described in the ME section. For alternate configurations, other modules can be enabled/disabled in STOP using the control described in the ME section. External interrupt request channels and external wake-up channels can be made active to wake-up the device in alternative to peripherals interrupts.

All pins associated to the active modules are functional.

Control of the pins is defined by user during run time. A wake-up line is associated to each selectable module.

One of the available modules can be configured to perform the wake-up task. For example, with five CAN modules on the chip, four modules are set completely to power down mode and only one is configured for wake-up message receive (any of the five modules can be configured to perform this task).

All CAN modules can be independently configured to receive messages and respond to wake-up messages. Control of the pins is defined by user during run time.

In idle mode these modules can also be idle, but able to wake-up as soon as activity is detected and wake the core.

All these modules can be configured to a low power state. Wake-up recovery is programmable, for instance depending on state or activity of associated pin.

All parts of the device can be disabled. Following modules are configurable:

- There is one CAN module, selectable from any of the CAN modules on the device. The others can be disabled.
    - The maximum CAN baud rate is 1 MBaud.
    - One CAN module is able to receive messages from the CAN bus and wake-up the controller if the received message contains the correct message identifier.

- One LIN/UART module is able to recognize special wake-up messages on the receive line and then wake up the controller.
- Some "request" pins are able to initiate a wake-up. Refer to the pinout chapter for more information.
- The system timer is able to initiate a wake-up.

Configurable modules (ASC, three CANs, timer) can all be off in STOP mode.

The CAN module recovers from wake-up instantaneously but its ability to capture the message depends on settings of certain peripherals such as the CAN protocol clock. Depending on recovery time this impacts whether the first message can be captured, hence software must be used as a workaround.

Device implements all three mechanisms to exit from stop mode: pin wakeup, CAN wake-up and timed wake-up.

10.2.1.1 After-run implementation

After-run mode is implemented mainly making use of clock gating, module disabling, reduced frequency, mode switching.

Assuming that the selected CAN is kept enabled (clocked and active) then it can maintain its synchronization with the CAN network. Assuming also that the supplied CAN module can buffer the received (first) message, the CAN is then able to interrupt the IOP. The IOP would execute from TCM (i.e., Flash is disabled) and use the internal RC oscillator (IRCOSC) or the external oscillator (XOSC). To support this would keep the PMC, LVD, temperature sensor, internal FIRC, XOSC and pads active. The PLL, Flash, and ADC would be disabled, with rest of part static and clock gated off.

10.2.1.2 Checker core disabling

The checker core is always in lock step with the main core — hence if the main core is clocked, the checker core is clocked (unless user intentionally disables checker clock, e.g. afterrun mode). Also if the main core is gated off, then the checker core is also gated off.

It is possible to disable the safety checker core to reduce current consumption.

The checker core can be placed in idle mode throughout the afterrun mode. By default the checker core mimics the main core, but it can be clock gated off during afterrun mode whilst continuing to clock the main core.

The checker core is implemented in such a way that its entire clock tree can be gated off while the core logic remains supplied.

The checker core (part of the Checker Logic) and the corresponding 'checked main' core share the same cache SRAM arrays and local SRAM arrays. Once the checker logic is disabled (i.e., its clock is gated) the SRAM array of the cache and the local memory of the main core are still usable by the main core.

10.3 Flash power requirements

During start-up operation, the flash module operates from an untrimmed regulator, which has a slightly larger variation than the ideal case. During this start-up phase, the flash can still be read, but it must be read at a slower rate. For MPC5777M, read is performed differentially, i.e., the data is duplicated / inverted across two locations. While operating in this slower read mode, the flash can operate at a much reduced voltage, and hence the untrimmed regulator should default to a < 3.3V average. This will help guarantee that the maximum value is not exceeded.

Following completion of the start-up phase, the regulator is in its trimmed condition, and subsequently the flash module reference current has also been trimmed. Therefore, when entering normal operation, the flash can be read in the normal access manner and support the full flash specification.

For MPC5777M, the flash is using the externally supplied 1.25 V for the low voltage supply, while high voltage (3.3 V) is generated by a dedicated internal regulator whose supply is VDD_HV_PMC. When the VDD_HV_PMC is below 3.5V, this regulator is in its bypass mode and can only support flash read.

10.4 Device trimming

During the initialization phase the device defaults to a pre-determined state for each of the LVDs, HVDs and the internal regulators. As the flash becomes available, the differential read process allows the trimmed data to be available for trimming the internal LVDs, HVDs and regulators.

Please refer to Power sequence for further details.

10.5 Supply monitoring (POR and LVDs)

The function of the POR and LVD circuits is to hold the device in reset regardless of how slow the supply voltage rise is, until the point at which the POR and LVDs are released.

The POR and LVD circuits function correctly even if the input voltage is non-monotonic.

10.5.1 Power-on reset (POR)

The PMC implements two internal power-on reset circuits:

- VPORUPLV monitors the voltage on the 1.2 V input supply. It is monitoring the VDD_LV_CORE pin. The VPORUPLV asserts a reset when the input supply is below defined values.
- VPORUPHV monitors the voltage on the 5.0 V input supply. It is monitoring the VDD_HV_PMC pin. The POR trip point is high enough to make sure all the LVD circuits are functional.

See Reset and Boot chapter for PORST/ESR0 pin functionality.

10.5.2 Behavior of device LVD / HVD

Although there is an option to disable the LVD and HVD following reset (see Low Voltage Detection (LVD) and High Voltage Detection (HVD)), they are capable of being used in a 'monitor' only mode and also capable of generating a safe / interrupt event. The diagram in the following figure illustrates the behavior of these internal LVD / HVD circuits during the power on phase, through into device initialization and subsequently in 'normal' run / operating mode.

The LVDs/HVDs can also be configured after device initialization preventing reset to happen when supply crosses the LVD threshold, effectively providing a higher voltage operating range. It is the responsibility of the application to ensure that the device remains in the functional range.

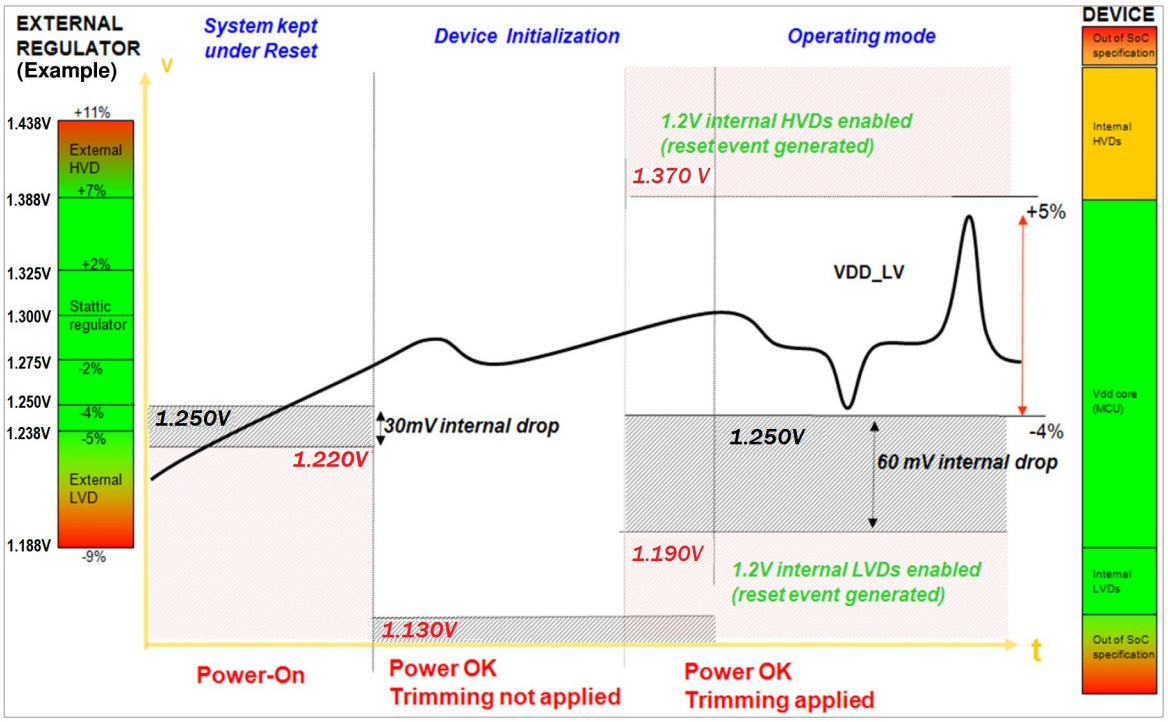

Figure 10-4. Internal LVD and HVD in configuration example during power-up

10.5.3 Low Voltage Detection (LVD) and High Voltage Detection (HVD)

The internal LVD circuits monitor when the voltage on the corresponding supply is below defined values and either assert a reset, an interrupt, or set a flag in a register. The LVDs also support hysteresis in the falling and rising trip points.

10.5.3.1 LVD and HVD implementation

- All LVDs and HVDs are capable of generating either an RGM and/or FCCU event, with the following exceptions:
  - The LVD270 (that is, the LVD monitoring the high voltage supply input) should be disabled only for test purpose and should otherwise always generate a reset when triggered.

WARNING

In case LVD270 are disabled, the device may not detect through internal monitor that VDD_HV voltage is outside functional range. If this event occurs, reset state must be ensured by assertion of external PORST pin from the user.

  - It is not possible to disable the LVD096 (that is, the LVD monitoring the internal core voltage) and they always generate a reset when triggered. This LVD096 is integral to the POR management.

- All LVDs and HVD configured for reset generation can cause functional or destructive resets. MC_RGM PHASE0 is not exited until all destructive reset conditions are cleared.
- The appropriate flag bits in the PMC registers are set by LVD and HVD events.
- The LVDs and HVDs control is protected by the SoC wide register protection scheme. Therefore it is configurable as long as the scheme is followed. Please refer to Chapter 81, Register Protection (REG_PROT).
- MPC5777M implements REE DCF records to allow to associated "configurable" LVDs/HVDs to a RESET event. When RESET event is enabled through REE DCF record, it cannot be changed until next RESET event. When RESET event is not enabled through REE DCF record, LVDs/HVDs trigger event default to FCCU event.

Note

The list of the "configurable" LVDs/HVDs is provided in Table 10-4 , in which the "User configurability" columns provide the possible user configuration.

- When the LVD or the HVD is enabled for destructive reset generation and a subsequent trigger event is detected, the external PORST pin is driven low.

Note

LVD096 and LVD270 (low range LVDs) cannot be disabled by DCF bits written by the user during boot sequence. These modules are used during power-up phase and must ensure that an absolute lowest threshold of operation is never crossed. This

is not a guarantee that the device will function down to this level. It is rather a guarantee that the device will recover if this level is crossed.

WARNING

The LVD270 can be disabled for test purpose through software accessing PMC_REE register. In case LVD270 are disabled, the device may not detect through internal monitor that VDD_HV voltage is outside functional range (below LVD270 threshold). If this event occurs, reset state must be ensured by assertion of external PORST pin from the user. When supply goes below the threshold of the POR240 (internal power-on state detector), device will be forced into reset and LVD270 is automatically re-enabled.

10.6 Power sequence

The following sections describe the power sequence and the relation between the different supplies during power-up and power-down.

The device is considered to be in a power sequence (or POWERUP state) when it is either not supplied or partially supplied. An internal power-on signal is used to identify POWERUP state. This signal is released high on exit of power sequence. The power-on signal is a combination of the LVDs monitoring the following supplies:

- VDD_LV
- VDD_HV_PMC
- VDD_HV_IO
- VDD_HV_FLA

The actual threshold use for each LVD is dependent on the configuration of the device. This is configurable by hardware (flash option bits content) or by software (LVD event configuration through register interface). Once power-on signal has been asserted, device configuration is reset to default power-up configuration.

10.6.1 Power-up sequence

In this section it is assumed that all supplies are low when entering the power-up sequence. Brown-out and power down sequences are managed in specific sections.

10.6.1.1 POWERUP state

At the beginning of power-up, the internal power-on signal remains low due to internal parasitics diodes. As soon as minimum threshold is reached on VDD_LV and VDD_HV supply, the internal power-on signal is forced low until power-up LVDs reach upper not trimmed threshold (refer to datasheet).

The different supplies can rise independently as long as the constraints described in the datasheet are met.

During power-up, all functional terminals are maintained into a known state as described in the following table.

Table 10-6. Functional terminal state during power-up and reset

Terminal type[1]	POWERUP[2] pad state	RESET pad state	DEFAULT pad state[3]	Comments
PORST	strong pull-down	weak pull-down	weak pull-down	Power-on reset pad
ESR0	strong pull-down	strong pull-down	weak pull-up[4]	Functional reset pad
ESR1	weak pull-up	weak pull-up	weak pull-up	Functional NMI/reset pad
TEST_MODE	weak pull-down	weak pull-down	weak pull-down	—
GPIO	weak pull-up	weak pull-up	weak pull-up	—
ANALOG	high impedance	high impedance	high impedance	—
ERROR	high impedance	high impedance	high impedance	During functional reset, pad state can be overridden by FCCU
JCOMP[5]	high impedance	weak pull-down	weak pull-down	—
TCK[5]	high impedance	weak pull-down	weak pull-down	—
TMS[5]	weak pull-up	weak pull-up	weak pull-up	—
TDI[5]	weak pull-up	weak pull-up	weak pull-up	—
TDO	high impedance	high impedance	high impedance	—

1. Refer to pinout information for terminal type
2. POWERUP state is maintained until supply cross the power-on reset threshold: V_{PORUP_LV} for LV supply, V_{PORUP_HV} for high voltage supply.
3. Before software configuration
4. ESR0 configuration move from strong pull-down to weak pull-up on completion of internal reset sequence (PHASE3[FUNC]).
5. JTAG interface implements build-in pull-up/pull-down configuration to ensure noise immunity. Worst case is boundary scan activation, requiring JCOMP to pulse high and following events to occur during JCOMP pulse high:
   - 23 TCK events corresponding to12 clock cycles.
   - 3 TMS events synchronous with TCK: sequence 0,1,1,0,0,0,0,0,0,0,0,1
   - 2 TDI events synchronous with TCK: sequence x,x,x,x,x,0,0,0,1,0,0,x

   TCK, TMS, TDI are implementing hysteresis requiring minimum variation

Digital reset is asserted, ensuring that all modules registers are reset to power-on value.

10.6.1.2 POWERUP exit

The POWERUP state can be exited when both VDD_LV and VDD_HV are above the internal LVD thresholds.

10.6.1.2.1 VDD_LV conditions and LVD trimming/enabling sequence

During POWERUP, only the following low voltage LVDs are enabled:

- LVD096_C

The VDD_LV conditions to exit POWERUP are the following:

- LVD096_C upper threshold is crossed

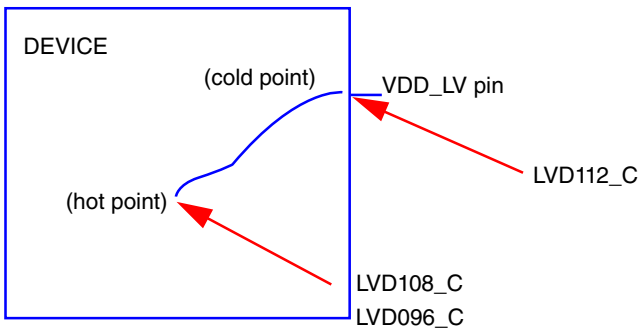

Figure 10-5. VDD_LV monitored voltages during power-up

After the POWERUP exit conditions (low voltage, high voltage conditions) have been verified, the internal power-on signal is released to all analog modules.

The internal RC oscillator module (IRCOSC) starts initialization and provides clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and the system counts a number of RC clocks. Once these clocks have completed and the LVD112_C has deasserted, the system will exit from PHASE0, LVD112_C is masked, and only LVD096_C remains active.

LVD096_C and LVD112_C share the same reference. LVD112_C – LVD096_C > 90 mV ± 5%. This difference provides margin with respect to maximum internal resistive drop (40 mV at I_{max}) and 50 mV hysteresis addressing external supply drop.

The device proceeds through the reset sequence through RGM phase, PHASE1[DEST], PHASE2[DEST] and PHASE3[DEST].

Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST]. Trimming of LVDs/HVDs are stored as internal DCF records. They are read by SSCM at low voltage, using the differential flash read accesses and applied to each LVDs/HVDs module. After a delay (including tLVDTRIM and other system operations) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold, the SSCM proceeds with the reset sequence, eventually running full speed accesses to the flash to read the option bits required to complete device configuration.

The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

When LVD108_C and LVD360_IM are masked by the application using the flash user option bits, the device should rely on PORST signal, being asserted by an external Voltage Detect circuit to detect a voltage failure during power-up. The device must wait for PORST to be released high before proceeding with the power-up sequence.This may increase the amount of time necessary to complete the reset sequence.

Figure 10-6 provides an example of VDD_LV power-up sequence from POWERUP to PHASE3[DEST].

Figure 10-7 illustrates threshold variation of VDD_LV LVD monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD108_C LVD and internal HVD140_C HVD are *enabled* during PHASE3[DEST].

Figure 10-8 illustrates threshold variation of VDD_LV LVD monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD108_C LVD and internal HVD140_C HVD are *disabled* during PHASE3[DEST]. The device relies on external voltage monitors.

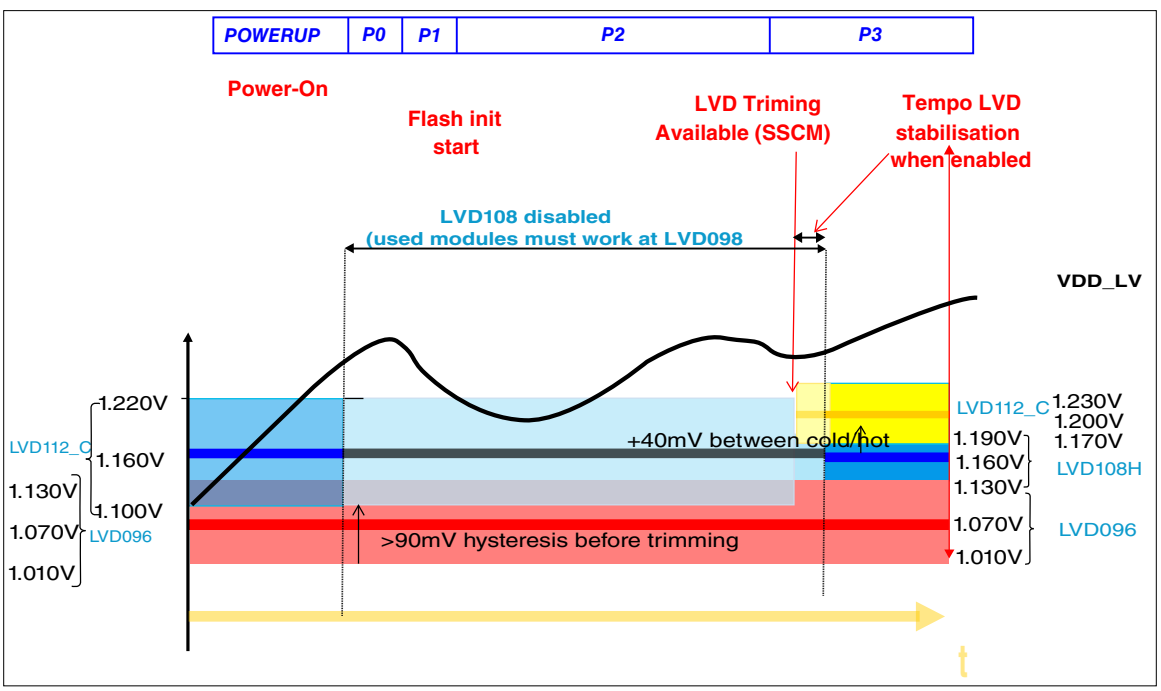

Figure 10-6. Example of VDD_LV power-up sequencing

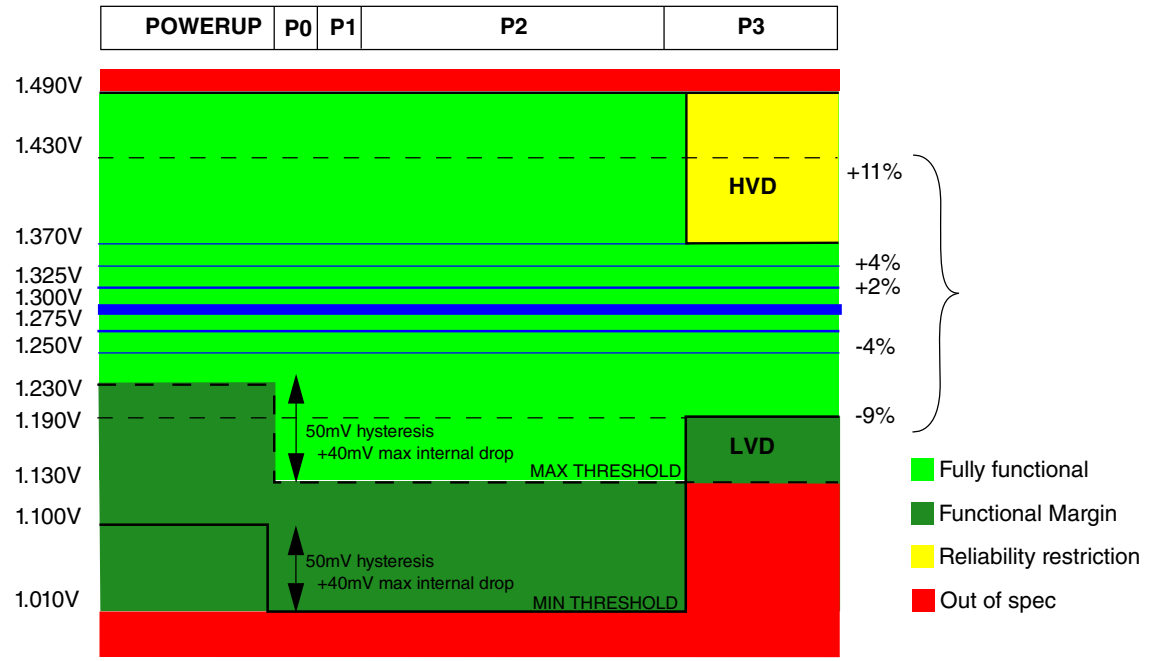

Figure 10-7. Threshold variation during power-up sequence: hot point LVD enabled

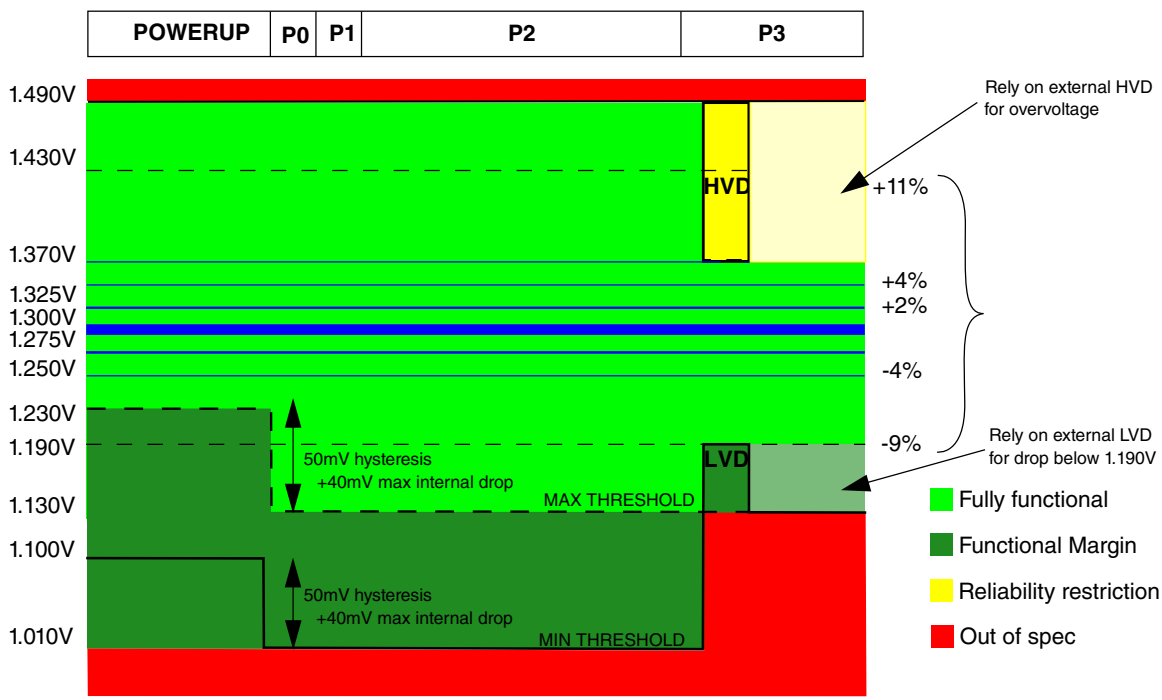

Figure 10-8. Threshold variation during power-up sequence: hot point LVD disabled

10.6.1.2.2 VDD_HV conditions and LVD trimming/enabling sequence

During POWERUP, the following high voltage LVDs are enabled:

- LVD295_A

- LVD295_F
- LVD270_xx

The VDD_HV conditions to exit POWERUP are the following:

- LVD295_A upper threshold is crossed.
- LVD295_F upper threshold is crossed.
- LVD270_xx upper threshold is crossed.

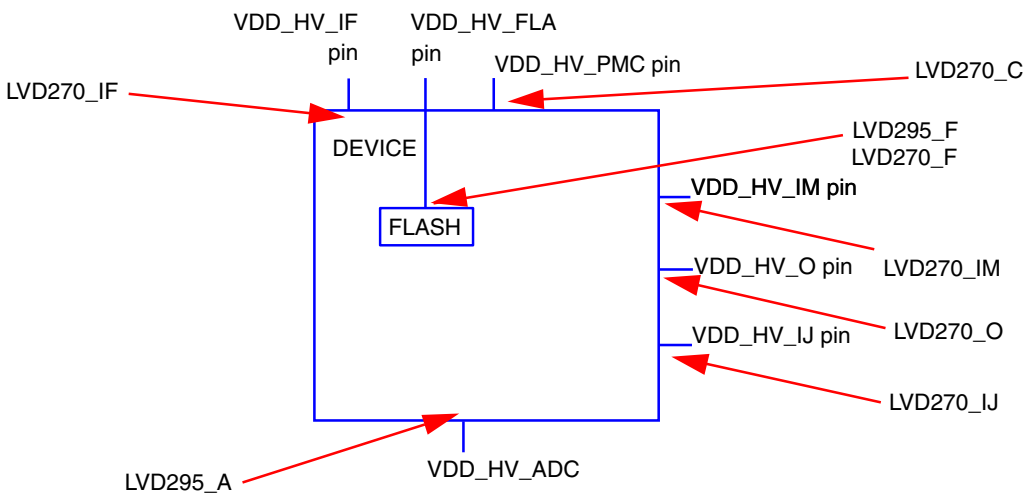

Figure 10-9. VDD_HV monitored voltages during power-up

After both LV and HV POWERUP exit conditions have been verified, the POR signal, ipg_por_b, is released to all analog modules.

The IRCOSC module starts initialization and provides the clock to the system after tRCSTARTUP. PMC digital interface reset is released after two RC clock cycles and the system counts a number of RC clocks. Once these clocks have completed and HVD600_C, LVD360_IM, and LVD400_IM have deasserted, the system will exit from PHASE0, and LVD295_A, LVD360_IM, and LVD400_IM are masked. All other HV LVDs remain active.

LVD360_IM and LVD400_IM share the same reference. LVD400_IM - LVD360_IM difference is implementing margin with respect to maximum internal resistive drop and hysteresis addressing external supply drop.

Device proceeds through the reset sequence through RGM phase, PHASE1[DEST], PHASE2[DEST], PHASE3[DEST]. PHASE2[DEST] will not be exited unless HVD600_C has deasserted.

LVD/HVD modules are trimmed at the beginning of PHASE3[DEST]. Trimming is done by SSCM at low voltage, using the differential flash read accesses. After LVD is completed, SSCM waits for PMC acknowledgement before proceeding with reset sequence.

Configurable LVD/HVD modules are optionally enabled at the end of PHASE3[DEST].

Figure 10-10 provides the threshold variation of VDD_HV LVDs monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD360_IM, LVD270_XX, LVD400_A, LVD400_IM LVDs and internal HVD600_IM, HVD600_C, HVD360_IM HVDs are *enabled* by default during PHASE3[DEST] although this can be controlled via the LVD/HVD enable DCF load.

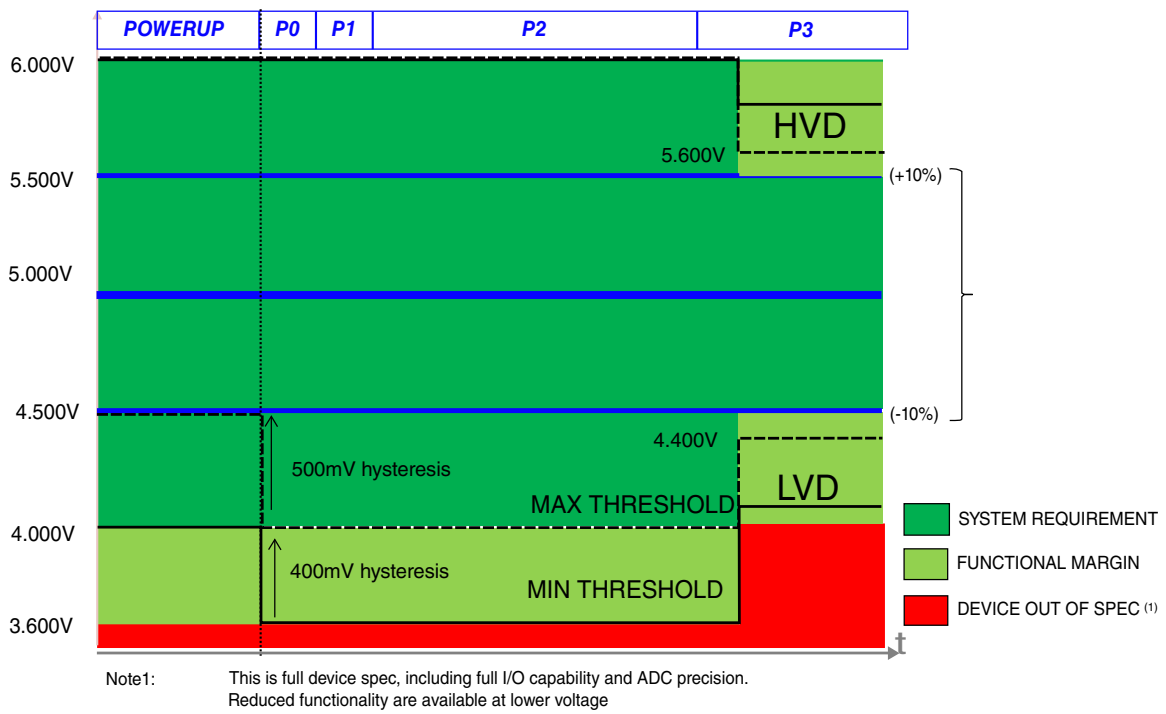

Figure 10-10. Threshold variation during power-up sequence — 2.7V–5.5V hot point LVD disabled, 4.5V–5.5V range

The device needs to fulfill all conditions described on Power-up sequence to recover.

10.6.2 Power-down sequence

In case the threshold of the higher ranges LVDs that are configured to generate destructive reset is crossed but neither LVD096 nor LVD270 threshold is crossed, the device enters PHASE0 phase.

Power-down sequence is actually entered as soon as the threshold of one of the LVD096 or LVD270 is crossed. The device enters the POWERUP state. The internal power-on signal ipg_por_b is asserted.

On ipg_por_b assertion, all analog modules reach their safe state.

Device supplies may then proceed to drop down to ground either through device leakage or external pull-down. During power-down, all supplies should comply with supply constraints.

In the case of an intentional power down of the Low Voltage supply (1.2V), the Auxillary Regulator should be disabled by writing a 1 to the bit VREG1P2_CTRL[VREG1P2_DIS].

10.6.3 Brown-out management

During brown-out, the device re-enters the POWERUP phase as soon as the threshold of either LVD096 or LVD270 is crossed. The internal power-on signal ipg_por_b is asserted.

Note

The device will correctly start independently from any residual voltage. Below LVD270 threshold the device is under POWERUP state. Above the LVD270 threshold, the device is into a RESET state as defined by Voltage monitor or external PORST pin or active state when all have been released.

WARNING

This mechanism is ensured when LVD270 are not disable by the user. In case LVD270 are disabled, reset state must be ensure by assertion of external PORST pin from the user. When supply goes below the threshold of the POR240 (internal power-on state detector), device will be forced into reset and LVD270 is automatically re-enabled.

On internal power-on signal assertion, all analog modules reach their safe state.

10.6.4 Low voltage requirement during crank

The device can continue operation to the minimum input voltage during crank.

In order to proceed with execution during cranking and prevent device reset, it is important to correctly configure the high voltage LVDs.

Internal LVDs that monitor the supply ensure that the flash content is protected.

Chapter 11
Security

11.1 Introduction

All MPC57xx family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations while other more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off; they require significant involvement for implementation. Consequently, they provide an important opportunity to define the security level of the device.

11.2 Basic security

All MPC5777M devices have the following basic set of security features.

- Device censorship based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
    - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection
    - SRAM and caches initialized to a constant value after reset (power-on reset, when in a test mode, when not booting from internal flash memory); MBIST functionality used in case of power-on and destructive resets to initialize RAMs selected via configuration in UTEST flash; BAF software routines to initialize RAMs when not booting from internal flash memory
- Monitoring of operating conditions

- Unique ID for each device: each MPC5777M device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device
- Secure watchdog timer
- Basic debugger restrictions (on/off via censorship mode)

11.3 Advanced security

Depending on the device configuration, the following features are available:

- Secure debugger interface
- Boot modes:
    - Trusted/secure boot support

11.4 Detailed security information

Details of most of the MPC5777M security features are published in a separate *MPC5777M Microcontroller Security Reference Manual*, which is only available to qualified customers.

Chapter 12
Calibration and Debug

12.1 Introduction

This chapter discusses the device-specific information for the debug and calibration modules. This device implements a high-speed serial Nexus trace auxiliary port. The Aurora interface allows the Nexus protocol information to be transmitted serially at high speed over four Aurora lanes. The Aurora protocol handles the encoding of the data and striping the information across the four Aurora lanes available on the device. In addition, the LFAST module, a high speed calibration interface, is supported for run control and memory access. The LFAST signals are alternate functions on the device's JTAG pins. The device starts up in JTAG mode and the tool can request that the JTAG interface be converted to the LFAST high-speed interface. All standards used have freely available specifications for tool developers.

The debug and calibration features for this device are provided in two separate dies: the Production die and the Buddy die, or Buddy Device (BD). The Production die is packaged alone in the Production Device (PD) package. The PD is also assembled into an Emulation and Debug Device (ED) package that consists of the Production die along with the Buddy die. The Buddy device supports additional debug capability. The Nexus Aurora interface is only available on the ED. The PD only supports trace to the internal trace/calibration memory.

The Event Out ($\overline{\text{EVTO}}$[0,1]) signals are connected to the external TGOUT[0,1] device pins and the Event In ($\overline{\text{EVTI}}$) signals are connected to the external TGIN[0,1] device pins.

12.2 Core debug support

Internal debug support in the e200z710n3 and e200z425n3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug

mode, such that no code runs. This allows debuggers to perform operations such as configuration of calibration remap or edit of overlay memory prior to user code execution.

For details, see e200z425Bn3 Core Debug Support and e200z710n3 Core Debug Support chapters.

12.3 Run control and memory access

Run control is any operation required to control device operation. Run control includes starting and stopping the processor's execution of code, as well as accessing memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both Boundary Scan and Debug modes. It is based on the IEEE 1149.1 and IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can either be fed directly from the JTAG pins or the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross-triggering of events from the device. The SPU can access some of the DCU run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the $\overline{\text{EVTI}}$ pins. Furthermore, the SPU can use system triggers to cause many different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

12.3.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug and calibration features. The DCI module includes the device JTAG Controller, the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tools or software
- Port-sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Simultaneous operation for debug and calibration features

12.3.1.1 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG Controller.

12.3.1.1.1 JTAGC ACCESS_AUX block instructions

The ACCESS_AUX instructions are described in these tables.

Table 12-2. Production die ACCESS_AUX 6-bit JTAG instructions

12.3.1.2 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

12.3.2 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows both JTAG and software access to two registers. These two registers are the challenge/response password authorization registers used by the Hardware Security Module (HSM).

12.3.3 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

12.4 Calibration interface

This device includes an alternate calibration interface for high-speed run control and advanced software control. This calibration interface is based on the LFAST interface. The LFAST based calibration has the ability to perform all of the functions that JTAG supports, only at a faster speed. The MCU implements the slave module, and the pins for the LFAST interface are multiplexed onto the same pins as the JTAG pins. Initially, the device powers up with the JTAG module in control of the pins. Under tool commands, the LFAST interface can be enabled and the pins become LFAST signals. Once the LFAST interface has been activated, all run control and other JTAG operations are converted in the MCU from LFAST messages into JTAG control operations of the JTAG Controller. The interface is supported entirely in hardware for both LFAST and JTAG modes, with no software or system overhead required to support interface traffic.

Table 12-4. Reference links to related information

Related module	Reference
JTAG Master (JTAGM)	JTAG Master (JTAGM)
LFAST Module—JTAGM	LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed debug
Development Tool Semaphore (DTS)	Development Tool Semaphore (DTS)

12.4.1 JTAG Master (JTAGM)

The JTAG Master (JTAGM) acts as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or through software.

The data transferred to this module is transformed to produce TCK, TMS, TDI, and TRST outputs and to accept TDO inputs. The module allows these five signals to connect to the JTAGC as if the JTAG data were coming from an external tool. The JTAGM generates all required JTAG scan chains to allow software and high-speed serial communication access to all JTAG-mapped resources.

12.4.2 Debug LFAST

The high-speed calibration interface provides up to a 320 Mbit/s interface between a calibration tool and the device. The calibration interface uses the LFAST as the physical layer between the tool and the JTAGM for access to debug resources. In addition, an LFAST switch allows direct access to read and write memory. The calibration debug LFAST module is one of two instantiations of the LFAST module on the device. The calibration LFAST is configured for slave-only operation and is meant to be used as a calibration interface to provide higher (than JTAG) speed debug and calibration operations. The calibration LFAST interface supports full duplex operation, where the available bandwidths for upstream and downstream traffic are independent.

12.4.3 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways that this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data-acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus auxiliary port.

12.5 Debug over CAN

As well as supporting debug via JTAG and LFAST interfaces, the device supports the use of a CAN interface for debug. This allows debug of application hardware where access to the dedicated JTAG/LFAST interface signals is not easily available. The debug over CAN mechanism is intended to provide basic debug functionality with some reduction in bandwidth and features compared to use of the dedicated JTAG or LFAST interfaces.

Use of the CAN interface for debug purposes requires the use of some M_CAN, eDMA and JTAGM resources. Some initialization of these resources via software is required, but once this initialization has completed, debug over CAN is possible without any further software overhead.

As the debug over CAN scheme generates internal JTAG messages based on received CAN data, all JTAG clients and included debug resources are accessible. Basic device trace capability is also possible by configuring the device trace hardware to stream to a device overlay/trace RAM, which can be read later using debug over CAN.

The debug over CAN scheme supports the following features:

- Supports operation through M_CAN_0 or MCAN_1 interfaces
  - Makes use of M_CAN debug enhancements
  - Debug message selected by filter configuration SFEC/EFEC=111
- Allows debug of hardware where JTAG access is not available
- Debug traffic carried over application CAN bus
- Debug traffic on CAN coexists with application traffic
- No software overhead after initialization
- Flexible selection of CAN identifiers for debug use
- Access to all JTAG debug facilities, includes CPU run control

12.6 Nexus Trace Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at high speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and the striping of information across the lanes. The Aurora interface is only available on the Emulation and Debug Device. Trace information is transferred to the Buddy Device for transmission via the Aurora interface.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the MCU. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client; generally, it can be individually enabled (both the type of message and the client). Table 12-5 shows a few examples of Nexus messages. All messages can be enabled to include a timestamp.

Table 12-5. Nexus message types

Message Type	Description
Program trace	Nexus program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership trace	Ownership trace provides information on process identification changes.
Watchpoint trace	Watchpoint messages are generated any time a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device identification	The device identification message allows information about the MCU to be transmitted upon startup to allow tools to identify the target system MCU type.
Debug status	Debug status messages provide additional information that may be needed to reconstruct software execution, such as whether the device has entered Debug or Low-power mode.
Data acquisition	Data acquisition messages are an optional feature that allows software control of information to be transmitted.
Error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory, or the parallel information can be serialized for transmission over a serial interface through the Nexus Aurora interface. Nexus trace information can also be routed through the Data Write Processing Unit (DWPU) as described in Data trace filtering.

The Nexus blocks do not have memory-mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The

enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 12-6. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Production Die		
Cores	CORE_ENABLE	0x7C (10 bits)
NXMC	NEXUS_ENABLE	0x0 (4 bits)
GTM		
NAR		
SPU		
Buddy Die		
RWA	CORE_ENABLE	0x7C (10 bits)
NAR	NEXUS_ENABLE	0x0 (4 bits)
NAL		
DWPU		

All of the internal JTAG modules are accessed through a single JTAG connection to the device. In the case of the ED, all JTAG communication is performed through the JTAG interface located in the BD. In the production package configuration, access is performed through the JTAG interface located in the PD.

With the hierarchical JTAG configuration, the BD JTAGC is considered the master JTAG TAP controller. The PD JTAGC TAP controller is selected via an AUX_ACCESS instruction. Other TAP controllers residing on the BD are also selected via AUX_ACCESS instructions (NAR, RWA, BD_DCI). Once control is transferred from the BD JTAGC to the PD JTAGC via the AUX_ACCESS instruction, all other PD TAP controllers are then selected via AUX_ACCESS instructions executed by the PD JTAGC. This is also referenced as TAP-sharing and is shown in the following figure.

NOTE

On the Emulation device, when the PAUSE-DR/UPDATE-DR state is executed to pass control of the JTAG TAP controller, control is always passed to the top level JTAG TAP controller, in other words, the DCI of the BD. For this reason, it is recommended that all JTAG operations, except when the BD clients need to be accessed, that all PD JTAG access be preceded with ACCESS_PD_JTAGC command. If the device is not an ED, the access is ignored.

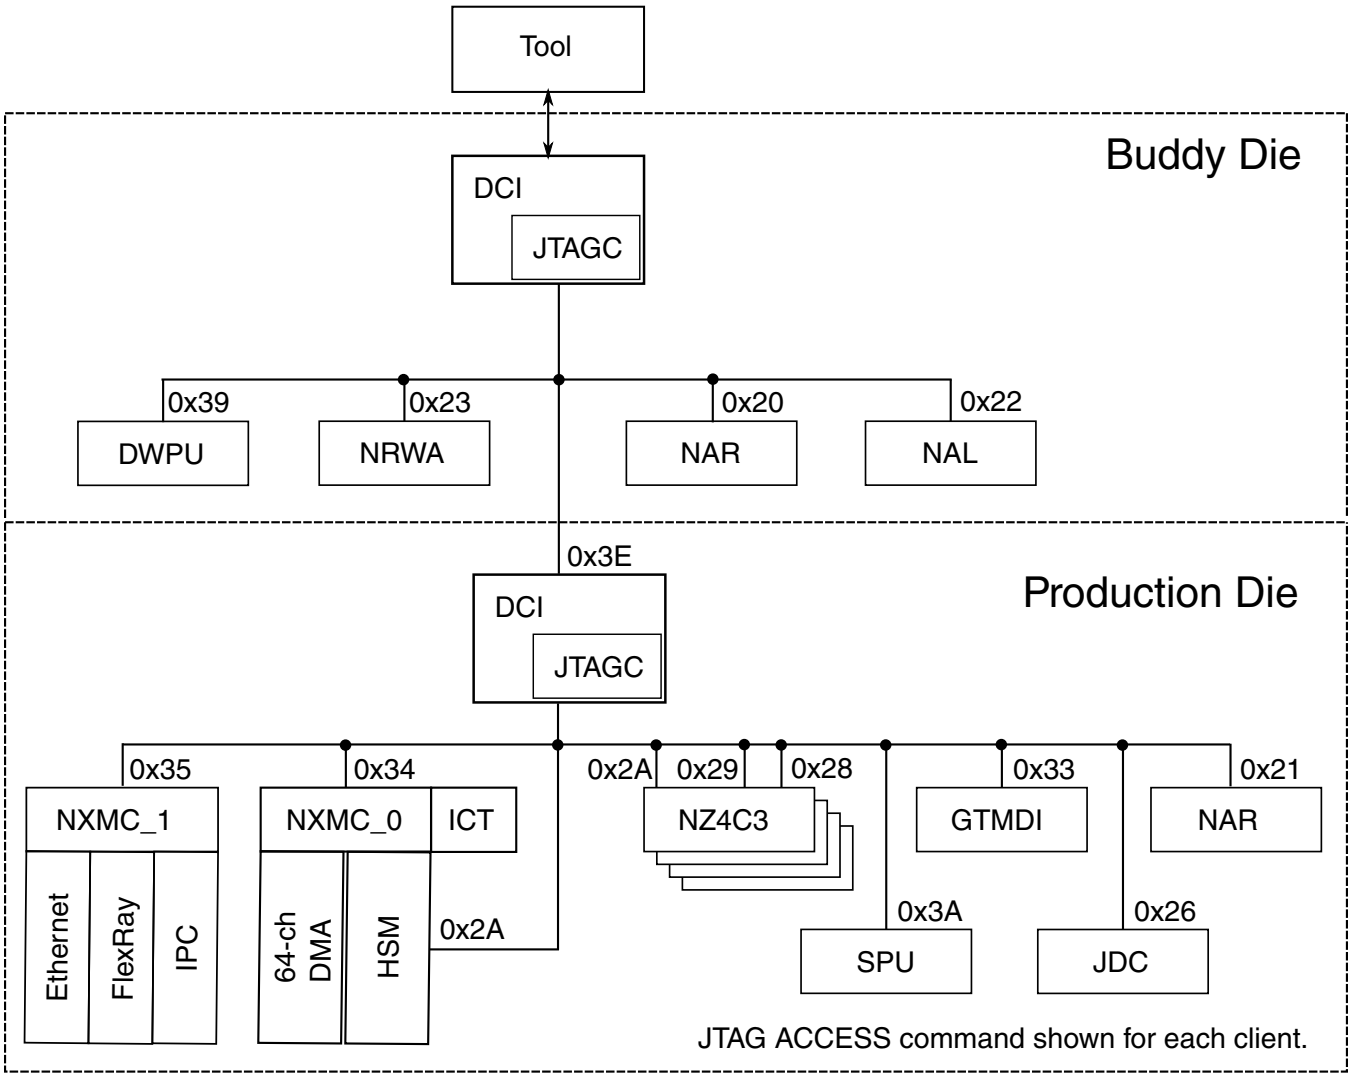

Figure 12-1. JTAG hierarchal view

Table 12-7. Reference links to related information

Production Device Nexus Aurora Router (NAR)	Production Device Nexus Aurora Router (NAR)

12.6.1 Nexus Aurora overview

The IEEE-ISTO 5001-2011 standard adds a new type of auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8b/10b encoded LVDS driver. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on the XAUI (10 Gigabit Attachment Unit Interface) standard used in communication protocols, which covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation uses a simplex output-only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC), and the Nexus Aurora Physical interface (NAP). Figure 12-2 shows the Aurora interface block diagram, where the number of lanes, n, is 4.

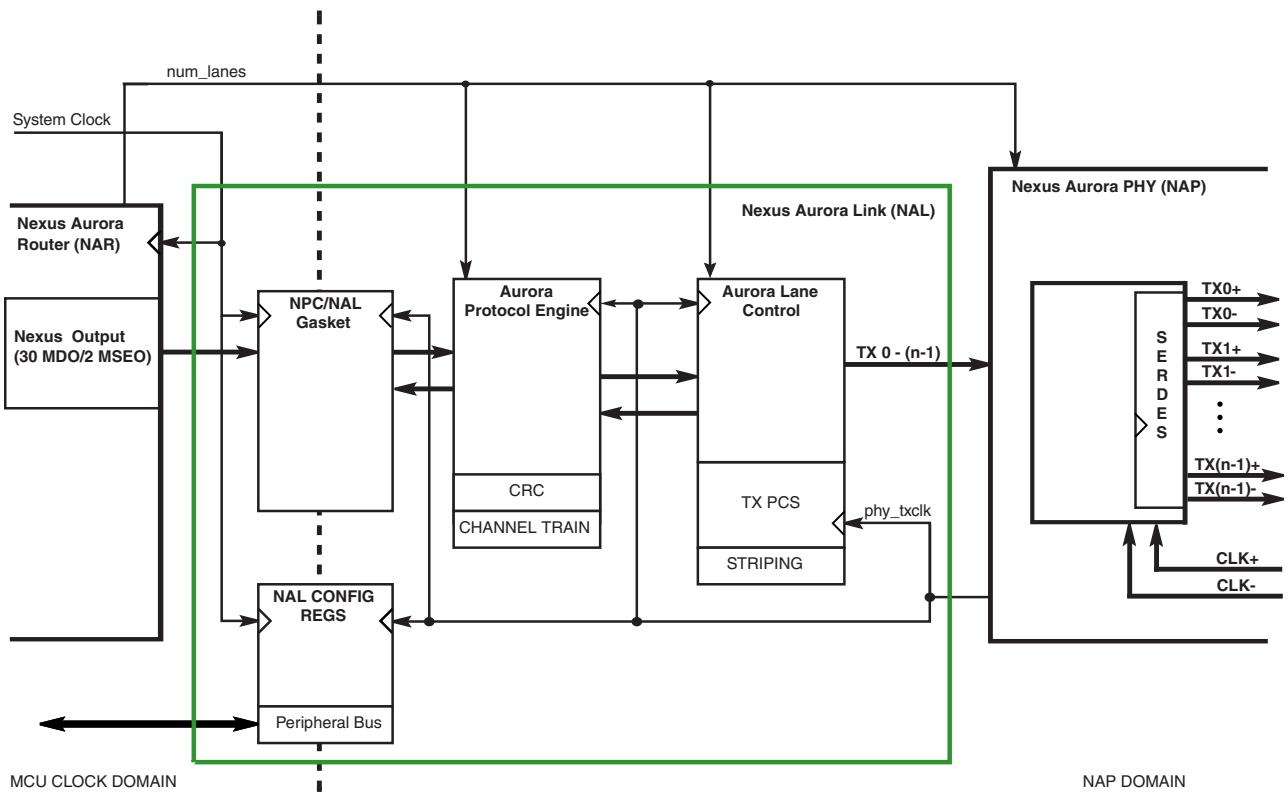

Figure 12-2. Aurora interface block diagram

12.6.2 Nexus Aurora Router (NAR)

The Nexus Aurora Router (NAR) manages the Nexus trace information from each of the Nexus clients. The NAR takes the parallel trace information from each of the connected clients, buffers it to avoid overruns, and routes it to either the internal overlay RAM or the Buddy Device, where it is stored in on-chip SRAM or transmitted out of the device through the Aurora interface.

16 KB of trace SRAM is available on the PD (located in the flash module), and 1 MB of trace SRAM is available in the ED. (Some of this SRAM may be used for calibration overlay content as well as trace content.) Similarly, a smaller NAR output queue is located on the PD (2 KB), and a much larger NAR output queue is located in the ED (8 KB). The physical Aurora pins are only available on the ED. Figure 12-3 shows the NAR block diagram.

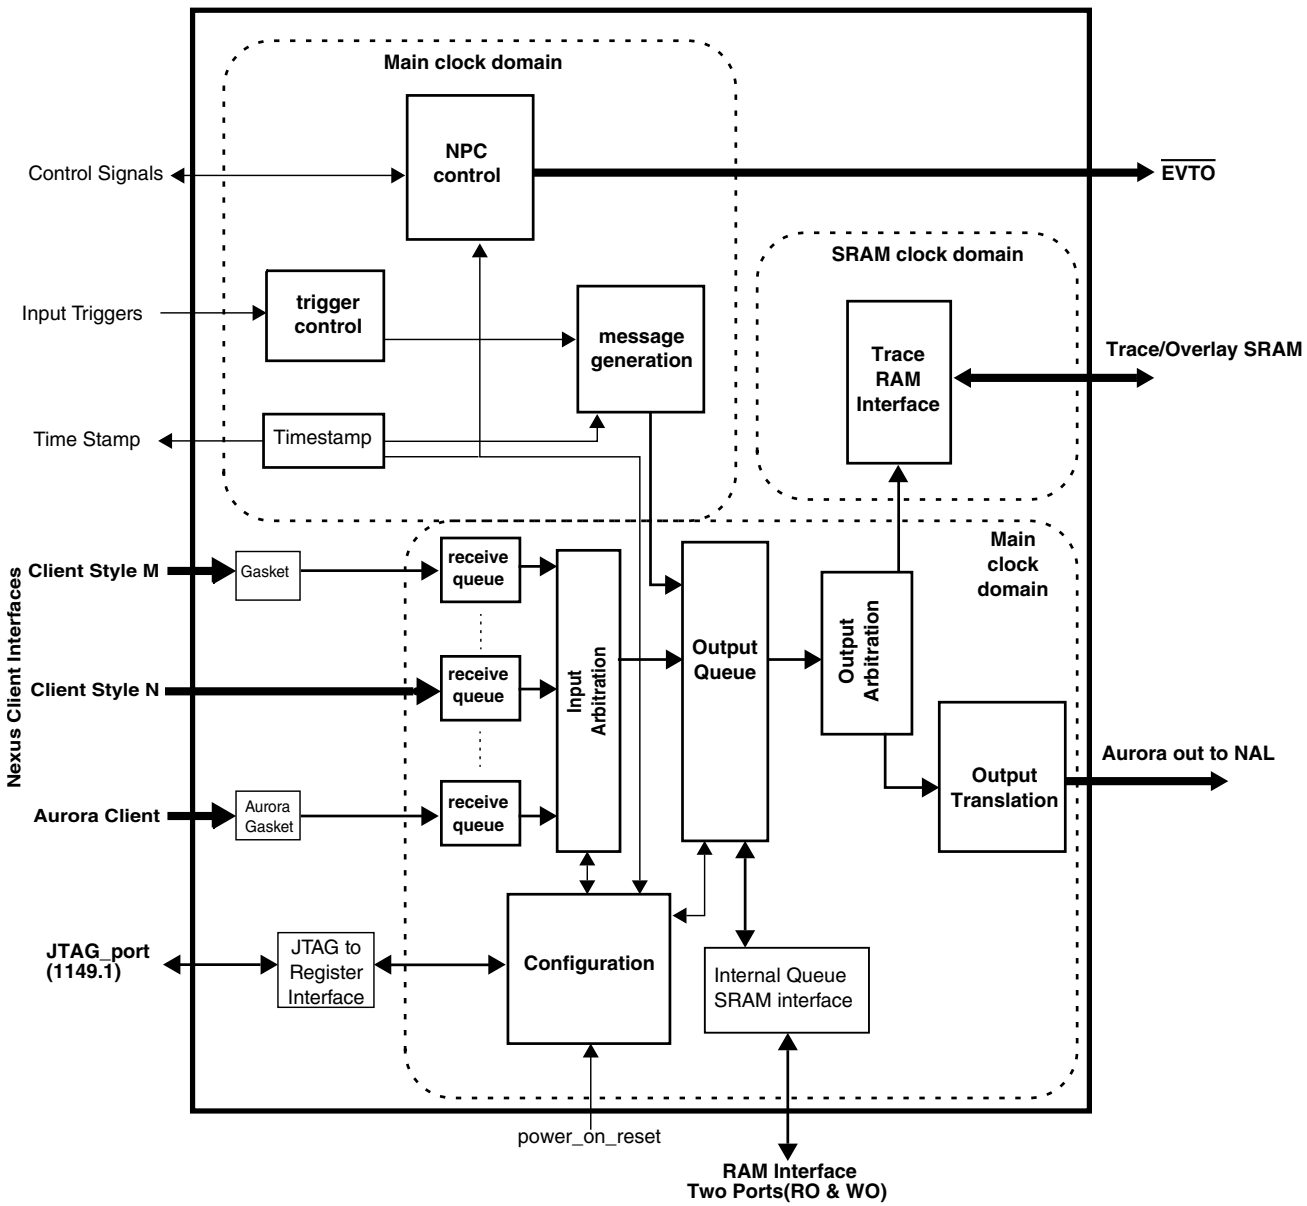

Figure 12-3. NAR block diagram

12.6.2.1 NAR clients

The PD NAR module has seven clients, with client index 1–7. Clients 8–16 are not connected. The client connections and the corresponding NAR client index are shown in the following table. The NAR client index is used in the NAR_STCR, NAR_CSSR, and NAR_CDR registers. The source trace ID is used in the NAR_SFR.

Table 12-8. PD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
—	NAR	0b1111 (0xF)	—
1	GTM	0b0111 (0x7)	3
2	HSM	0b0011 (0x3)	1
3	Core 0	0b0000 (0x0)	1
4	NXMC Client 0 Concentrator	0b1100 (0xC)	1
5	Core 1	0b0001 (0x1)	1
6	NXMC Client 1 Concentrator	0b1101 (0xD)	1
7	Core 2	0b0010 (0x2)	1
8	—	—	—
9	—	—	—
10	—	—	—
11	—	—	—
12	—	—	—
13	—	—	—
14	—	—	—
15	—	—	—
16	—	—	—

The BD NAR module has one client and the client connections and the corresponding NAR client index are shown in the following table.

Table 12-9. BD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
1	PD NAR	0b1110 (0xE)	2

The NAR is limited writing trace information to the overlay RAM. The PD NAR only has access to the 16 KB internal overlay RAM. Therefore, the PD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0D000000–0x0D003FFF. The BD NAR also has access to 1 MB of extended overlay RAM. Therefore, the BD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0C000000–0x0C1FFFFF.

The NUM_LANES field of the NAR_NAPCR is described in the following table.

Table 12-10. NAR_NAPCR field descriptions

Field	Description	
19–16	TX Lane Configuration. Number of enabled TX lanes.	
NUM_LANE	0000	Disable NAP and NAL
	0001	Reserved
	0010	Enable 2 lanes (Lane 0–1)
	0011	Reserved
	0100	Enable 4 lanes (Lanes 0–3)
	0101	Reserved
	0110	Reserved
	0111	Reserved
	1000	Reserved
	1001–1111	Reserved

12.6.3 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) is only included in the Emulation and Debug Device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into a 32-bit format by the clients and then collected by the NAR. The NAL encodes the message data (8b/10b), stripes it across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters, and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

12.6.4 Nexus Aurora PHY (NAP)

The Nexus Aurora PHY (NAP) is only included in the Emulation and Debug Device. The NAP, in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY lane's LVDS pads. The NAL performs lane striping with settings in the NAL and NAR specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator that registers the 10-bit character for that lane from the ALC on the rising

edge of the NAL clock. A serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called "lane alignment" in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

Figure 12-4 shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, n, is 4.

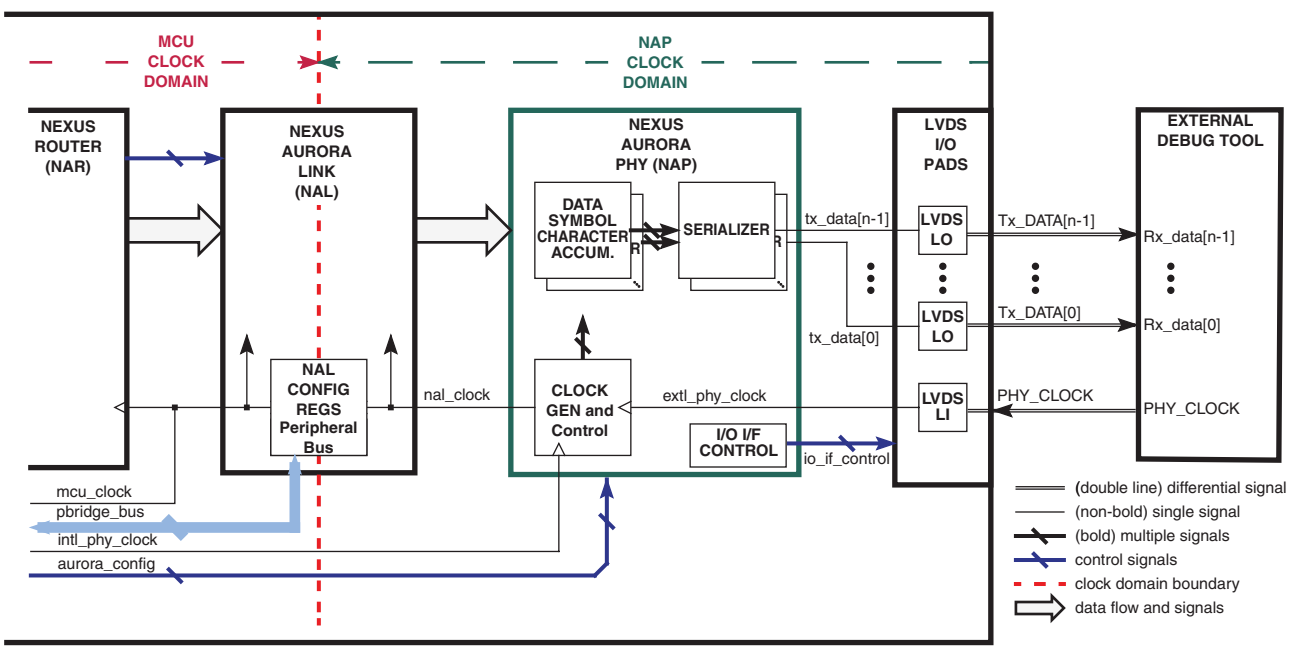

Figure 12-4. NAP block diagram

12.7 Nexus clients

Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the device.

GTM Development Interface (GTMDI)	GTM Development Interface (GTMDI
Nexus Crossbar Multi-Master Client (NXMC)	Nexus Crossbar Multi-Master Client (NXMC)

12.7.1 e200z Nexus 3

The e200z710n3 and e200z425n3 Nexus 3 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

12.7.2 GTM Development Interface (GTMDI)

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, Input Channel Filters trace, Output Timer channels, DPLL and Sensor Pattern Evaluation (SPE) module submodules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global timestamp that allows real-time trace for several GTM submodule events. The GTMDI implements a Nexus client standard interface and a JTAG standard port controller to provide communication capability via the JTAG port and the on-chip NAR.

12.7.3 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

12.7.3.1 NXMC block connections

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four total—two from each NXMC) for events from the SPU.

The following figure shows a block diagram illustrating the NXMC integration.

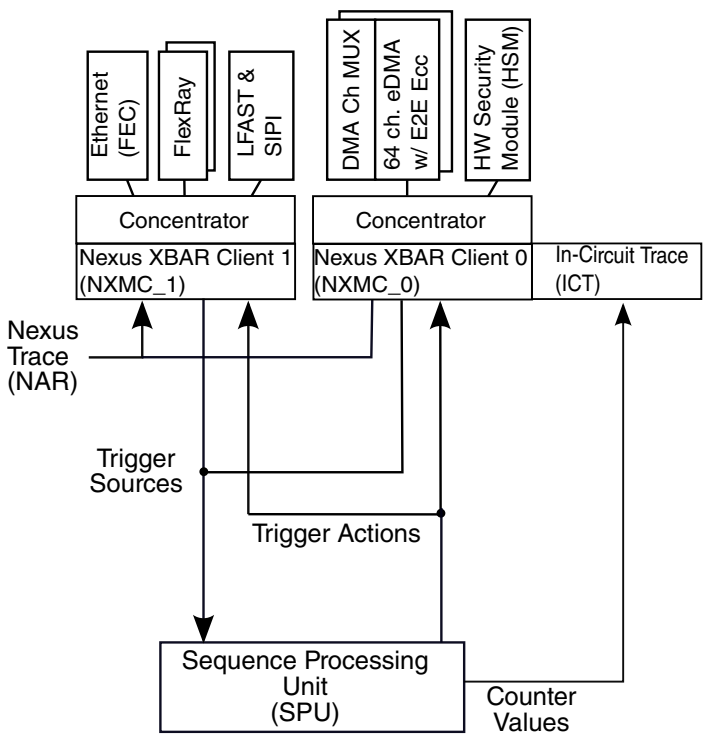

Figure 12-5. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 12-12. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
XBAR Client 0 Concentrator (fast masters)	Hardware Security Module (HSM)	0b1100	0b0000
	eDMA Controller 0		0b0001
	eDMA Controller 1		0b0010
	Reserved		0b0011 –0b0111
XBAR Client 1 Concentrator (slow masters)	System Bus	0b1101	0b1000
	FlexRay 0		0b1001

	FlexRay 1		0b1011
	Reserved		0b1100–0b1110
Data Write Processor Unit (DWPU)	e200zx core	—[1]	0b1111

1. The Nexus trace Source ID is the same as the original core SRC.

12.8 Data trace filtering

The Data Write Processing Unit (DWPU) supports data trace filtering as well as out of range parameter identification.

Table 12-13. Reference links to related information

Related module	Reference
Data Write Processing Unit (DWPU)	Data Write Processing Unit (DWPU)

DWPU operates in conjunction with the BD NAR and a small RAM array. DWPU receives its input trace stream from the BD NAR Nexus Out Link. The trace stream is initially decompressed (which includes conversion of relative address and data values to absolute values) to ease subsequent filtering and comparison operations. The decompression process tracks multiple contexts, with individual context tracking required for each supported Nexus client.

The processed stream then passes through an address compare block, that generates tag RAM addresses corresponding to a portion of each data write address within the trace stream. Another portion of the data write addresses is used to select a particular bit from the data word returned by the tag RAM, so that each tag RAM bit corresponds to a unique 64-bit data write address. The value of the selected bit determines whether the

data write trace occurrence is passed out of the DWPU back to the BD NAR, or is removed from the trace stream. DWPU returns the data trace filtered and re-formatted stream back to a secondary Nexus client input port on the BD NAR.

Chapter 13
Core Complex Overview

13.1 Introduction

The MPC5777M has four separate cores that perform various computational and control functions. The main computational shell consists of Main Core_0 and Main Core_1, both of which use an e200z710n3 core. These two cores are used for general computational functions. A third core, referred to as Checker Core_0s, uses an e200z709 core, which is a true subset of the e200z710n3 core. When enabled, Checker Core_0s operates in Lock Step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to ensure that Main Core_0 is executing correctly. There is no Lock Step function associated with Main Core_1. The fourth processor, Peripheral Core_2, employs an e200z425Bn3 core and is generally used to control various I/O modules.

NOTE

The processor ID for each CPU core is contained in its Processor ID Register (PIR).

This chapter provides overviews of the e200z710n3 core, the e200z709 core, and the e200z425Bn3 core.

13.2 Overview of the e200z710n3, e200z709, and e200z425Bn3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power Architecture. The e200z710n3, e200z709, and e200z425Bn3 cores are very similar. The register set for all three of these cores is identical. The e200z425Bn3 core differs in hardware from the e200z710n3 core in several ways. The e200z425Bn3 core and e200z710n3 core have different amounts of Instruction and Data Cache. The e200z425Bn3 has no Data Cache. Also, the e200z425Bn3 incorporates a Lightweight

Signal Processing Extension (LSP) APU to provide support for real-time SIMD fixed point embedded numeric operations. The e200z709 core has no Instruction Cache, Data Cache, I-memory, or D-memory.

13.3 Features

The following is a list of some of the key features of the e200z710n3, e200z709, and e200z425Bn3 processor cores:

- Two integer execution units
  - Branch control unit
  - Instruction fetch unit
  - Load/store unit
  - Multi-ported register file
    - Capable of sustaining six read and three write operations per clock
    - Most integer instructions execute in a single clock cycle.
  - Branch target prefetching is performed by the branch unit
    - Allows single-cycle branches in many cases.
- Dual-issue (e200z425Bn3), 32-bit *PowerISA 2.06*-VLE compliant CPU
  - VLE ISA for improved code density
  - *PowerISA 2.06* fixed length 32 bit instruction set is not directly supported
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General-Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit system buses

- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z710n3 core-16 KB IMEM, 64 KB DMEM
  - e200z425Bn3 core-16 KB IMEM, 64 KB DMEM
  - e200z709 core does not contain either Instruction or Data Memories
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
  - e200z710n3 core-16 KB ICache, 4 KB DCache
  - e200z425Bn3 core-8 KB ICache, no DCache
  - e200z709 core does not contain either Instruction or Data Cache
- Embedded Floating-point (EFPU2) APU
  - supports real-time single-precision embedded numeric operations
  - uses general-purpose registers
- Lightweight Signal Processing (LSP) APU (e200z425Bn3 core only) supporting fixed-point multiply/accumulate and integer/fixed-point operations using the 32-bit General-Purpose Register file.
- Performance Monitor APU supporting execution profiling
- Nexus Class 3+ Real-time Development Unit for e200z710n3 and e200z425Bn3
- Power management
  - Low power design with extensive clock gating
  - Power saving modes: DOZE, NAP, SLEEP, WAIT
  - Dynamic power management of execution units, caches, and local memories
- Testability
  - Synthesizeable, MuxD scan design
  - ABIST/MBIST for arrays
  - Built-in LBIST unit

13.4 Microarchitecture summary

The e200z710n3, e200z709, and e200z425Bn3 processor cores utilize a five-stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/EA Calc, Execute0/Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single-clock instruction execution for most instructions. Figure 13-1 shows a block diagram of the e200z architecture.

Each integer execution unit consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel Shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register Manipulation Unit (CRU), a Count Leading Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32 x 32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single-cycle with the exception of the multiply, which is implemented with a pipelined hardware array, and divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated branch address adders to minimize delays during change-of-flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clock cycles for correctly predicted branches. Conditional branches that are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal. These instructions can be pipelined to allow effective single-cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to optimize effective address generation.

The CRU supports the condition register (CR) and condition register operations defined by Power Architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

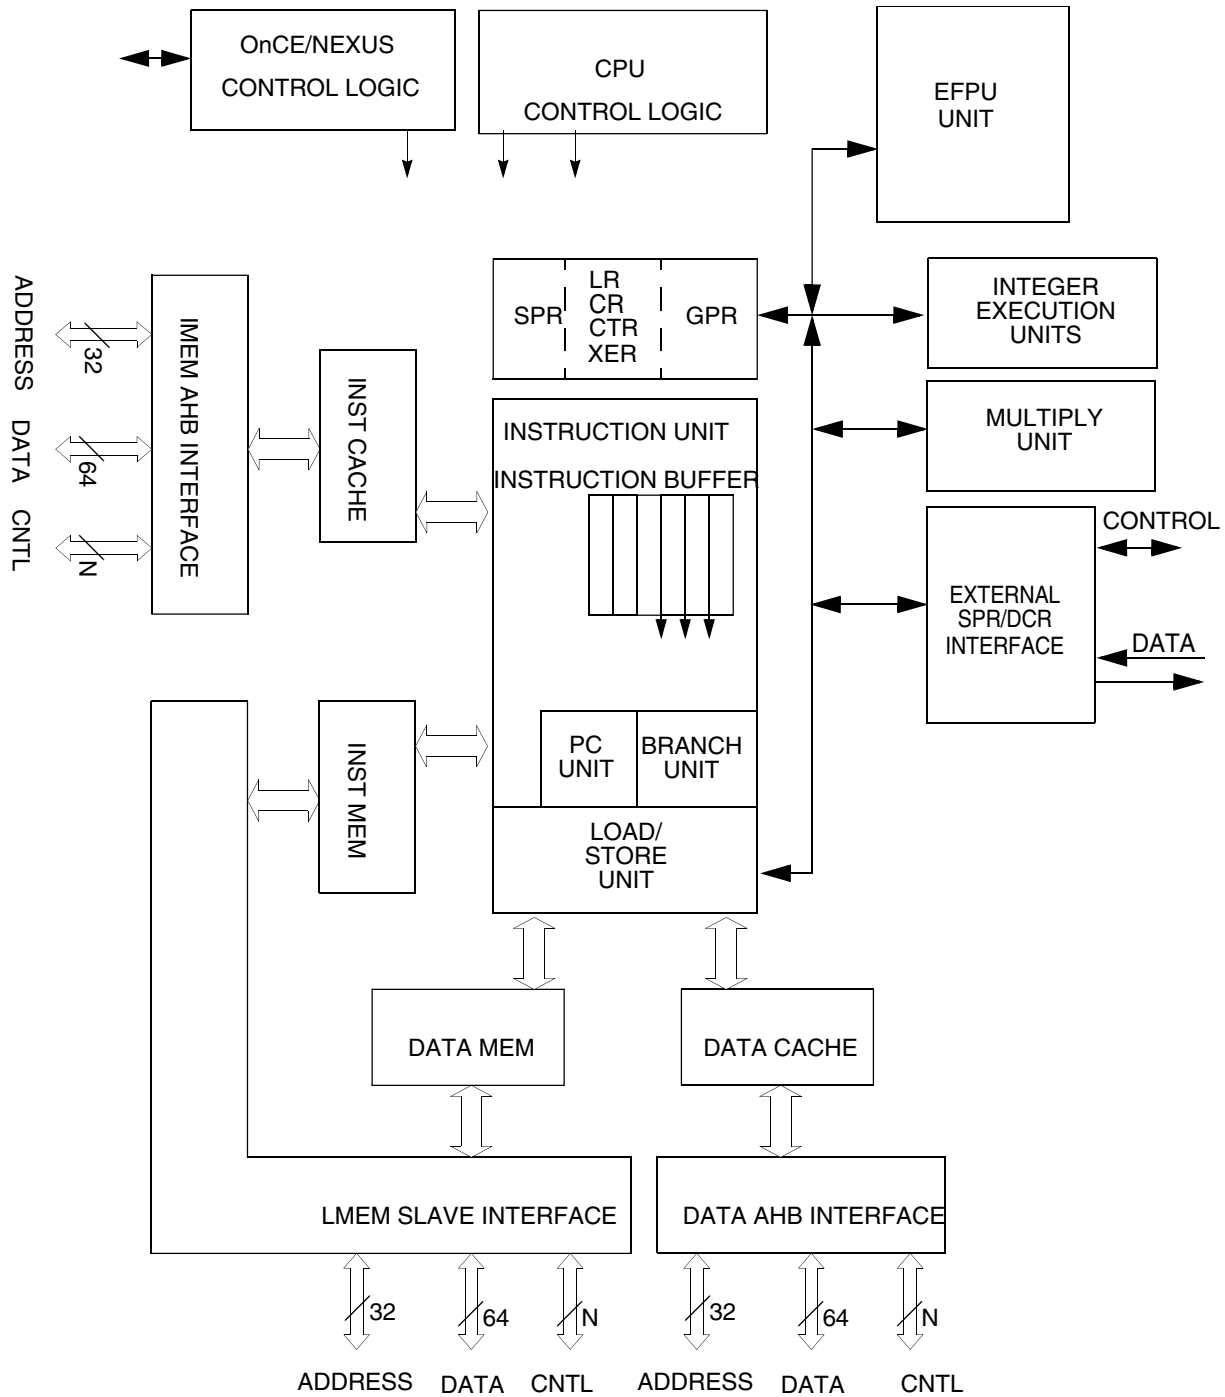

Figure 13-1. e200z block diagram

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The LSP APU (included only on the e200z425Bn3 core) supports vector instructions operating on 16-bit and 32-bit fixed-point data types. The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats and operates in a pipelined fashion. The

32-bit general-purpose register file is used for source and destination operands. There is a unified storage model for scalar single-precision floating-point data types of 32 bits and the normal integer type. Low latency floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided. Most operations can be pipelined.

13.4.1 Instruction unit features

The features of the e200z710n3, e200z709, and e200z425Bn3 instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds as many as eight 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single-cycle execution of successfully predicted branches

13.4.2 Integer unit features

The e200z710n3, e200z709, and e200z425Bn3 integer units support single-cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the Count Leading Zeros function
- 32-bit single-cycle Barrel Shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clock cycles with minimized execution timing (EU1 only)
- Pipelined 32 x 32 hardware multiplier array supports 32 x 32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

13.4.3 Load/Store unit features

The e200z710n3, e200z709, and e200z425Bn3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations

- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

13.4.4 EFPU2 Floating-Point Unit Features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion <-> single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 15 (FP sqrt) clock cycles

13.4.5 LSP Lightweight Signal Processing Unit Features

The LSP APU is designed to accelerate signal processing applications normally suited to DSP operation.

- LSP instructions operate on the 32-bit GPRs
- Supports SIMD integer operations - arithmetic, logical, shift
- Supports SIMD rounding, saturation, pack, unpack, merge, extract, select for efficient data manipulation
- Supports SIMD multiply/multiply accumulate/ dot product operations
- 16, 32, and (limited) 64-bit signed and unsigned integer data types
- 16-bit and 32-bit signed fractional support
- Guarded 32-bit and 64-bit signed fractional support
- Single-cycle throughput for all instructions (except fractional divide)
- Supports fractional divide operations (32/32->32)

- Specialized operations such as field manipulation, count-leading,
- Supports specialized load/store operations with integrated data manipulation
- Multiple addressing modes supported including circular and bit-reversed addressing
- Sustained throughput of up to 2 1 16x16-bit multiply/accumulate operations per cycle.

13.4.6 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit process identifier
- Bypass capability for individual access types
- Maskable process identifier and address
- Programmable memory attributes
- Entry invalidation protection
- Write-once option
- Alternate Debug Breakpoint/Watchpoint function

13.4.7 Cache features

The features of the caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
  - e200z710-16 KB ICache, 4 KB DCache
  - e200z425-8 KB ICache, No DCache
  - e200z709-No ICache, No DCache
- Writethrough support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Way locking support
- Write allocation policies

- Support for multi-bit EDC with correction/auto-invalidation capability for the instruction and data caches
- Hardware debug cache invalidate support for the data cach evia DBL1CCSR0 register
- Software and hardware debug access to cache tag, status, and data storage via CDANTL and CDADATA dedicated control registers

13.4.8 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z710n3-16 KB IMEM, 64 KB DMEM
  - e200z425Bn3-16 KB IMEM, 64 KB DMEM
  - e200z709-No IMEM, No DMEM
- I-MEM provides RAM storage for instructions allowing the CPU to execute these instructions with 0 wait-state delay.
- I-MEM includes a feature to allow the memory to be relocated in the memory map as seen by the local CPU, such that it overlays MCU code flash (The memory map to other bus masters is unchanged). This relocation of I-MEM into the flash region allows IMEM to be accessed directly from any location in flash with a single short branch instruction
- IMEM and DMEM are not duplicated on e200z709 core.
- Supports zero wait-state access relative to cache hit timings
- Supports multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC RMW Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

13.4.9 Performance Monitor Unit Features

The features of the e200z710n3 performance monitor include:

- Four configurable 32-bit performance monitor counters each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including # of clock cycles, CPU stall cycles, # of instructions completed, # of interrupts taken, # of memory accesses (by type), # of instruction or data cache misses, # of cycles with 0, 1, or 2 instructions issued, # of instructions in a given class completed (ldst, branch, integer, FP, etc.), cache linefills, and many other event types

13.4.10 e200z710n3 and e200z425Bn3 system bus features

The features of the e200z710n3 and e200z425Bn3 system bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

13.4.11 e200z709 system features

Checker Core_0 is implemented using an e200z709 core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z709 core can only be enabled or disabled by the user. For the MPC5777M device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z709 core is identical to the e200z710n3 with five exceptions:

- IMEM memory array is not present
- ICache memory array is not present
- DMEM memory array is not present
- DCache memory array is not present
- The e200z709 has a pair of system bus interfaces, which are driven/sampled by the delayed Lock Step logic

13.5 Availability of detailed documentation

Detailed documentation of the e200z4xxd and e200z7xxd cores are provided in separate core reference manuals (CRMs). The CRMs are available online at http://www.freescale.com.

Chapter 14
Core description

14.1 Overview of the e200z425Bn3 core

The e200z425Bn3 is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z425Bn3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver 16-bit vector and 32-bit scalar results. A wide variety of data manipulation, multiply, multiply/accumulate, and dot product instructions along with specialized memory access instructions allow a sustained throughput of up to two 16x16-bit multiply/accumulate operations per cycle.

The e200z425Bn3 core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z425Bn3 core contains an 8 KB Instruction Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

14.2 Register model

This section describes the registers implemented in the e200z425Bn3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z425Bn3 extends usage of the general purpose registers to support EFPU /LSP APU operations on the 32-bit GPR registers.

Figure 14-1 and Figure 14-2 show the complete e200z425Bn3 register set, all of which are accessible in supervisor mode. Figure 14-3 and Figure 14-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

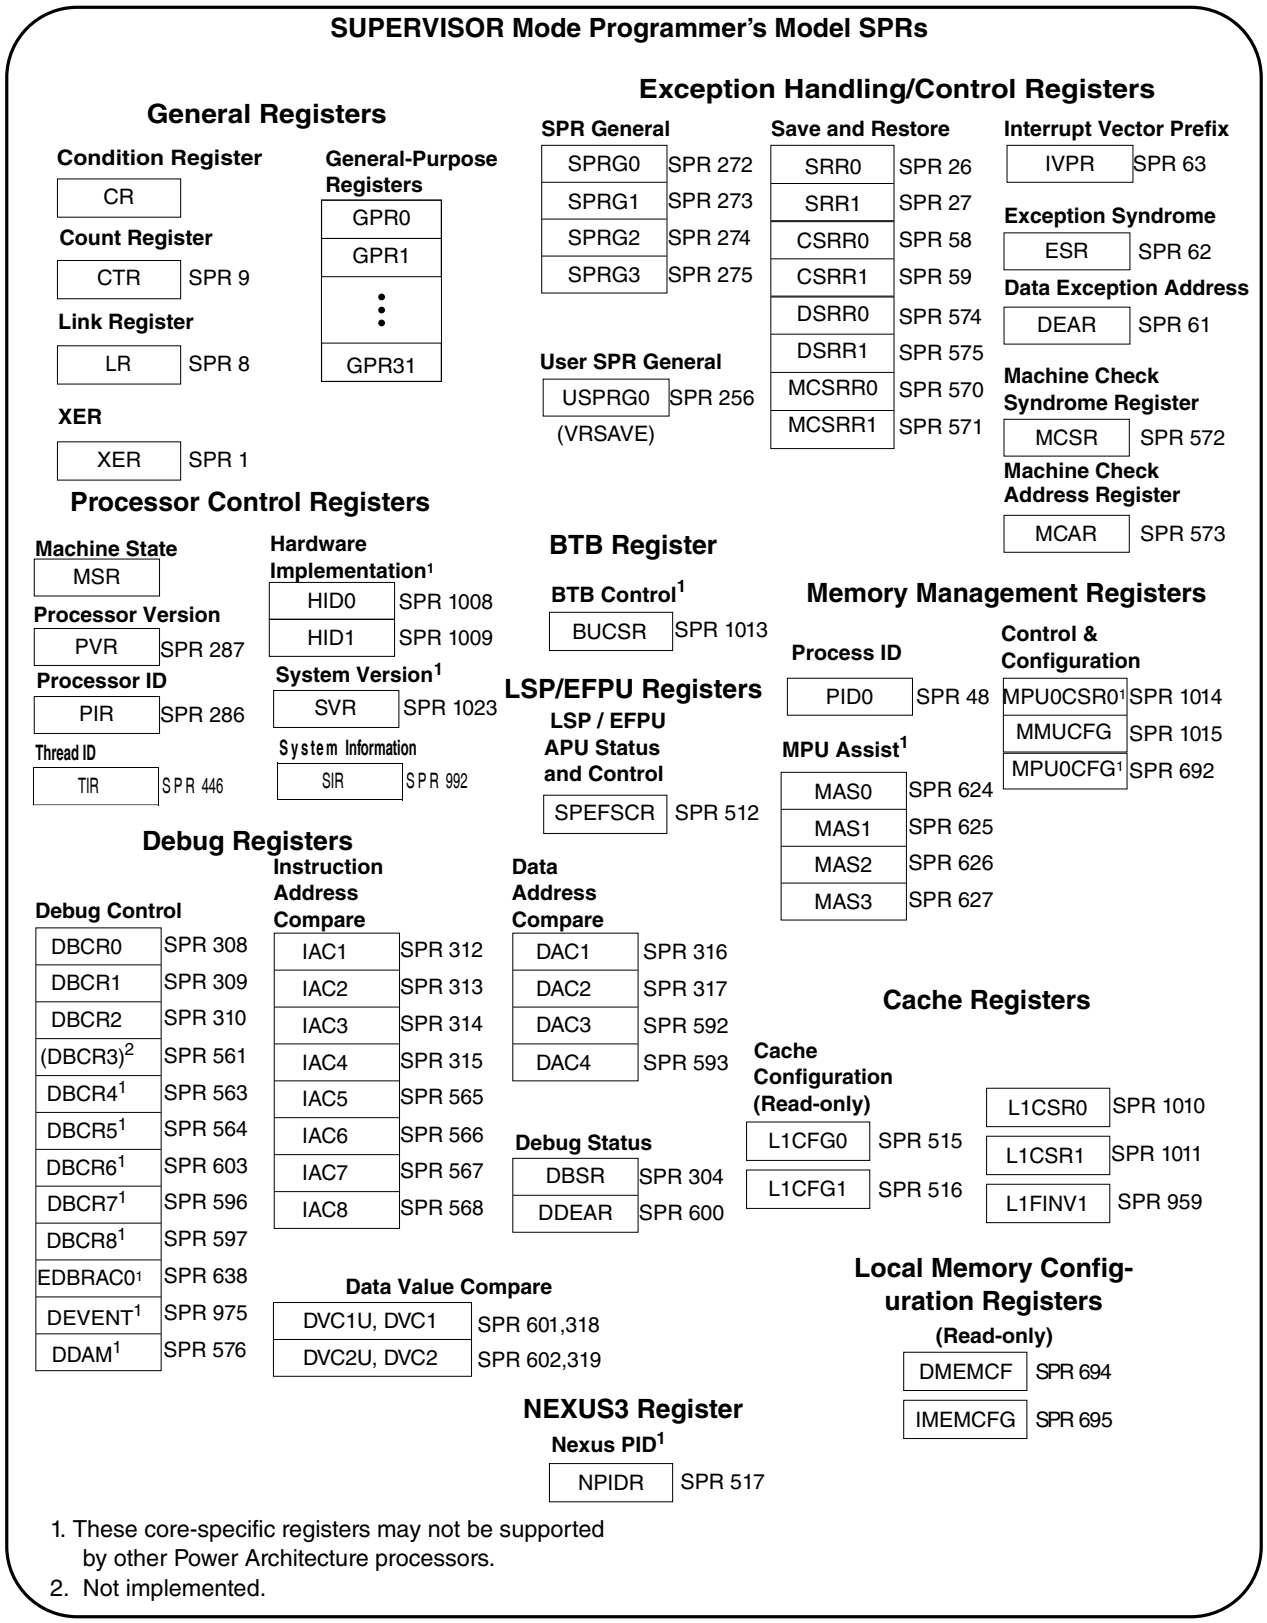

Figure 14-1. e200z425Bn3 Supervisor Mode Programmer's Model SPRs

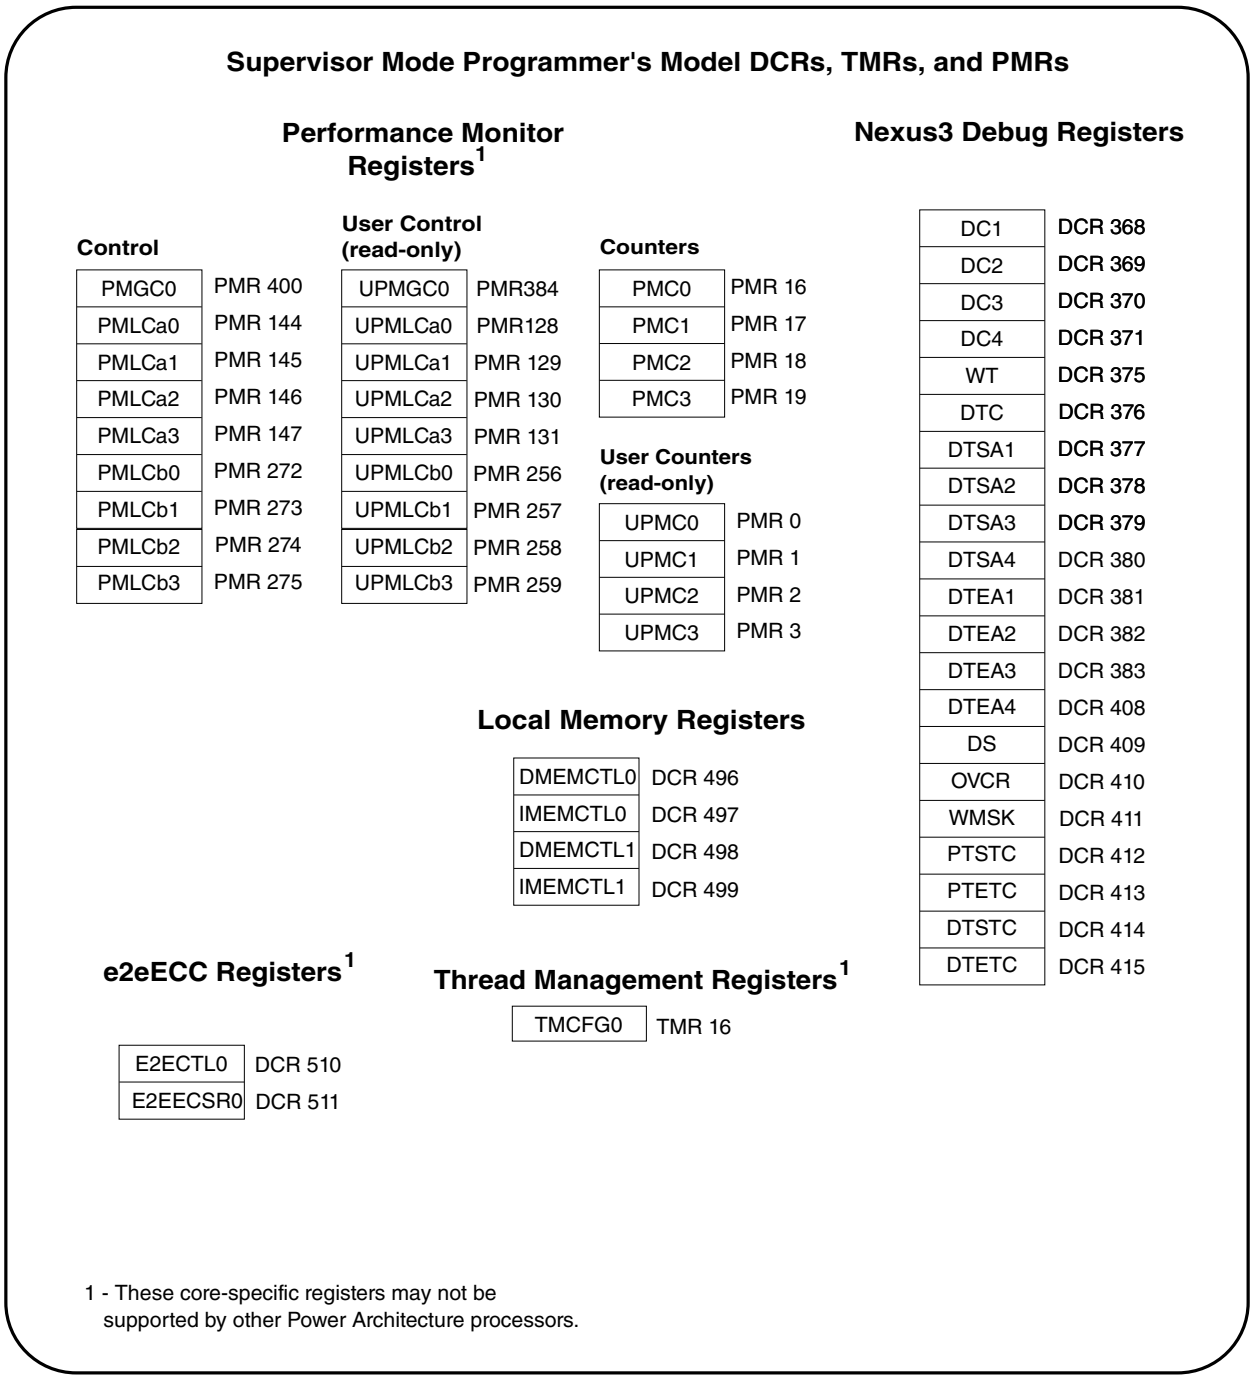

Figure 14-2. e200z425Bn3 Supervisor Mode Programmer's Model DCRs and PMRs

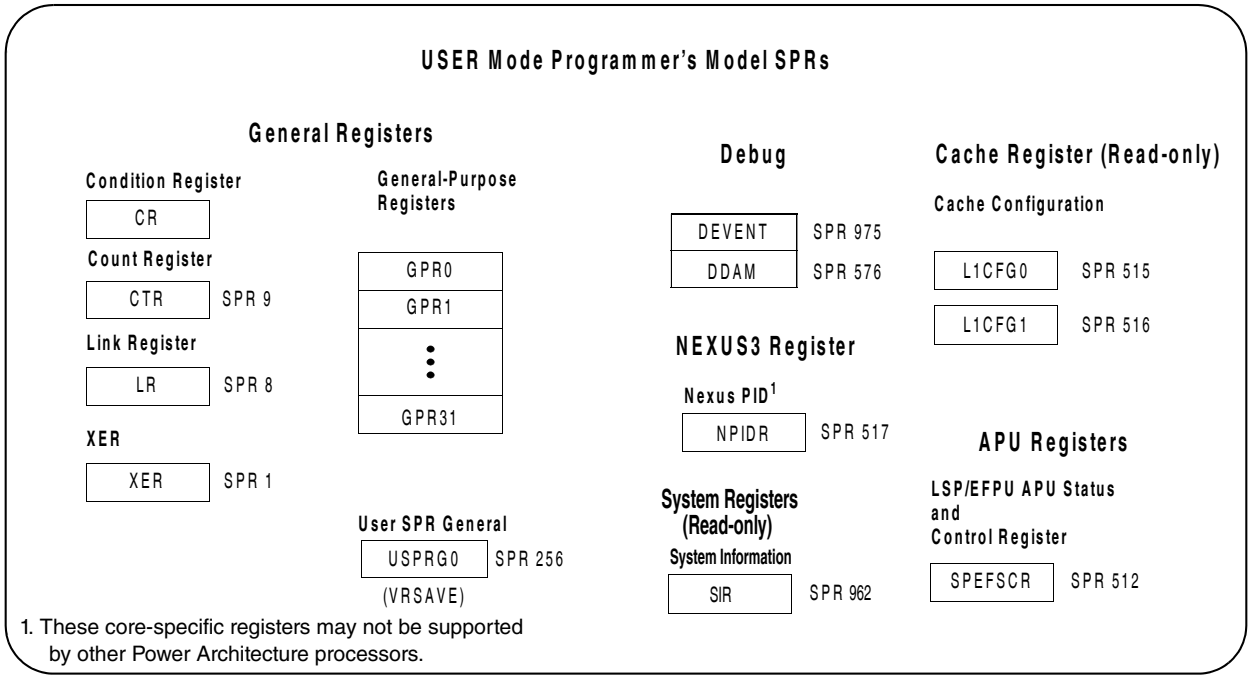

Figure 14-3. e200z425Bn3 User Mode Programmer's Model SPRs

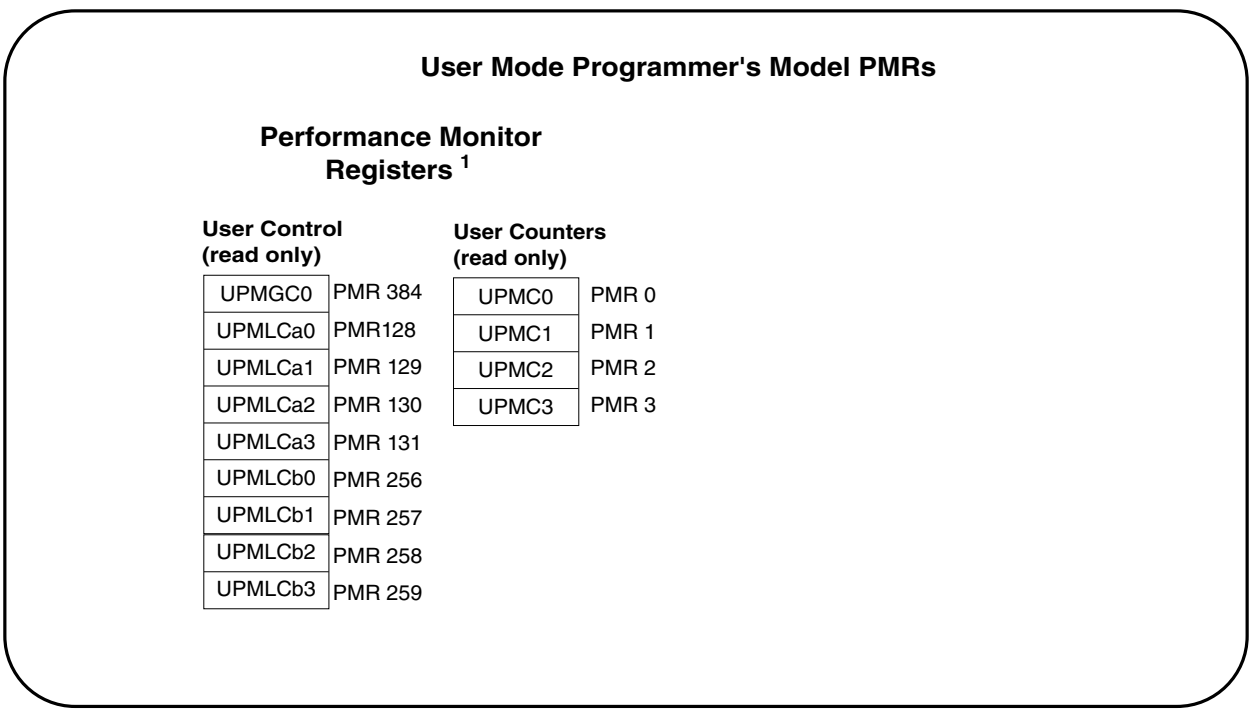

Figure 14-4. e200z425Bn3 User Mode Programmer's Model PMRs

14.2.1 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a core implementation dependent register used for various configuration and control functions. It is shown in the following figure.

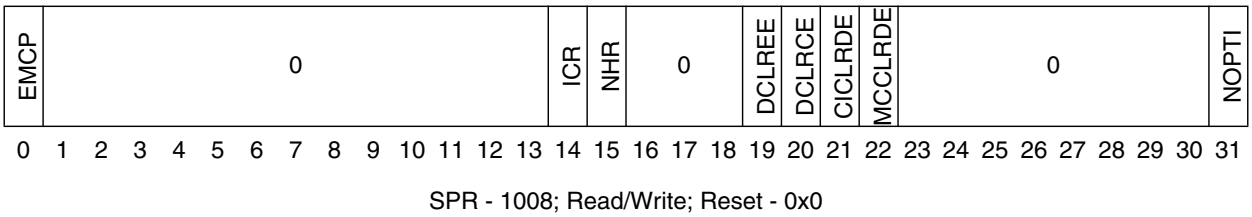

Figure 14-5. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 14-1. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit 1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18 [48:50]	-	Reserved
19 [51]	DCLREE	Debug Interrupt Clears MSR_{EE} 0 MSR_{EE} unaffected by Debug Interrupt 1 MSR_{EE} cleared by Debug Interrupt This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSR_{CE} 0 MSR_{CE} unaffected by Debug Interrupt 1 MSR_{CE} cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Critical class interrupt

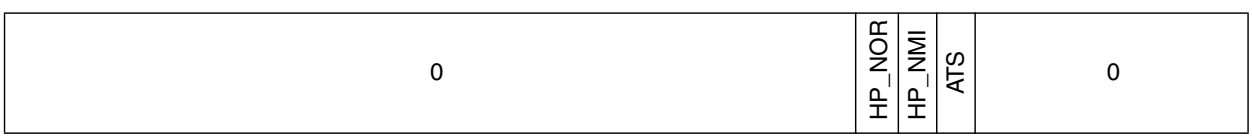
Table continues on the next page...

Table 14-1. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
		1 MSR_{DE} cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit. Note that if Critical Interrupt Debug events are enabled ($DBCR0_{CIRPT}$ set), and MSR_{DE} is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, $DSRR0_{DE}$ will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSR_{DE} enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Machine Check interrupt 1 MSR_{DE} cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [55:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

14.2.2 Hardware Implementation Dependent Register 1 (HID1)

The HID1 register is used for bus configuration and system control. It is shown in the following figure.



SPR - 1009; Read/Write; Reset - 0x0

Figure 14-6. Hardware Implementation Dependent Register 1 (HID1)

The HID1 fields are defined in the following table.

Table 14-2. Hardware Implementation-Dependent Register 1

Bits	Name	Description
0:21 [32:53]	-	Reserved

Table continues on the next page...

Table 14-2. Hardware Implementation-Dependent Register 1 (continued)

Bits	Name	Description
22 [54]	HP_NOR	High priority elevation for normal and external interrupts 0 - High priority elevation for normal and external interrupts is disabled 1 - High priority elevation for normal and external interrupts is enabled The HP_NOR bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided. These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
23 [55]	HP_NMI	High priority elevation for NMI and critical interrupts 0 - High priority elevation for NMI and critical interrupts is disabled 1 - High priority elevation for NMI and critical interrupts is enabled The HP_NMI bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
24 [56]	ATS	Atomic status (read-only) Indicates state of the reservation bit in the load/store unit.
25:31 [57:63]	-	Reserved

14.3 Dual-issue operation

The instruction issue unit attempts to issue two instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as three results can be simultaneously written.

14.4 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 14-3. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during execution.

Timing for EFPU instructions is detailed in Table 14-6.

Timing for LSP instructions is detailed in:

- LSP simple instruction timing—Table 14-7
- LSP complex instruction timing—Table 14-8
- LSP shift/rotate instruction timing—Table 14-9
- LSP vector compare instruction timing—Table 14-10
- LSP vector select instruction timing—Table 14-11
- LSP vector data arrangement instruction timing—Table 14-12
- LSP multiply and multiply/accumulate instruction timing—Table 14-13
- LSP dot product instruction timing—Table 14-14
- LSP miscellaneous vector instruction timing—Table 14-15
- LSP load and store instruction timing—Table 14-16

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 14-3. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**	1	1	—
Branch	3/2/1	3/2/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 3 cycles.
multiply (saturating/non-saturating)	2	1	—
divide	4–14	4–14	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	2	1	—
load multiple	2 + n/2 (max)	2 + n/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	2	1	—

Instruction	Latency	Throughput
all **z[v]dotp** instructions	—	1

Instruction timing for LSP miscellaneous instructions is shown in Table 14-15.

Table 14-15. LSP miscellaneous vector instruction timing

Operation	Instruction	Latency	Throughput
Circular increment	**zcircinc**	1	1
Bit reversed increment	**zbrminc**	1	1

Instruction timing for LSP load and store instructions instructions is shown in Table 14-16.

Table 14-16. LSP load and store instruction timing

Instruction	Latency	Throughput
all **zv** loads	—	1
all **zv** stores	—	1

14.5 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

14.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. This register is also used by the LSP APU. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.

SPR - 512; Read/Write; Reset - 0x0

Figure 14-7. LSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 14-17. LSP/EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z425Bn3 Supports only mode 0.

Table continues on the next page...

Table 14-17. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by e200 core)
16 (48)	SOV	Summary integer overflow Defined by LSP APU.
17 (49)	OV	Integer overflow Defined by LSP APU.
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled

Table continues on the next page...

Table 14-17. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 (62:63)	FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

14.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

14.7.1 Cache overview

The e200z425Bn3 processor supports an 8 KB 2-way set-associative instruction cache with a 32-byte line size. The cache improves system performance by providing low-latency data to the e200z425Bn3instruction pipeline, which decouples processor performance from system memory performance.

The e200z425Bn3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

14.7.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. L1CSR0 implements the WID control field for instruction cache way disabling. The other fields are reserved. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

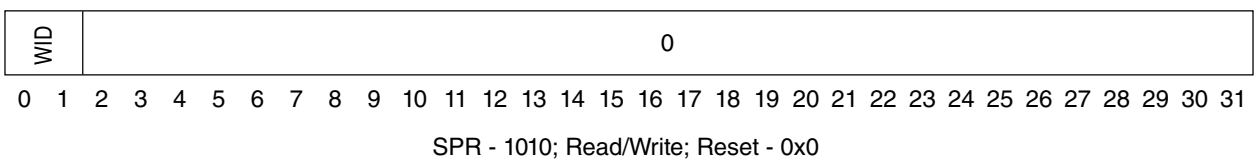

Figure 14-8. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 14-18. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:31	—	Reserved[1]

1. These bits are not implemented and should be written with zero for future compatibility.

14.7.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.

SPR - 1011; Read/Write; Reset - 0x0

Figure 14-9. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 14-19. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits.
17:18	ICLOC	Instruction Cache Lockout Control **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. See ECC/EDC Error Handling for Cache Control Operations and Instructions. **Note:** When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one.

Table continues on the next page...

Table 14-19. L1CSR1 field descriptions (continued)

Bits	Name	Description
		11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses.

Table 14-19. L1CSR1 field descriptions

Bits	Name	Description
		Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.7.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z425Bn3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The L1CFG0 register is shown in the following figure.

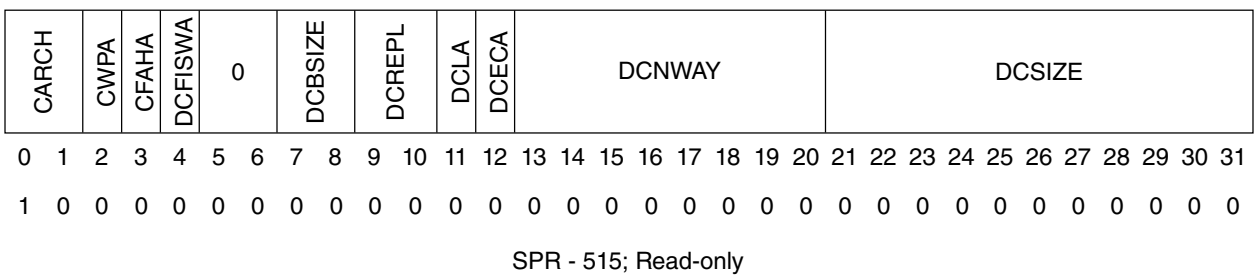

Figure 14-10. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 register indicates a cache architecture value (CARCH) of 2'b10, indicating that an I-Cache but no D-Cache is present.

14.7.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z425Bn3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The L1CFG1 register is shown in the following figure.

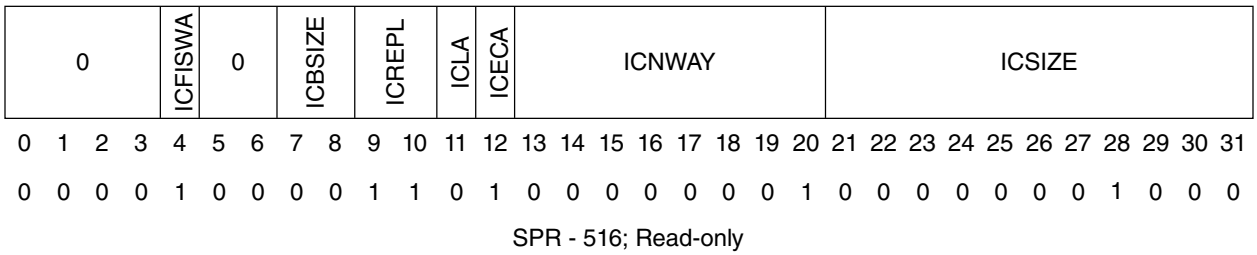

Figure 14-11. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 14-20. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

14.7.6 Cache Invalidate by Set and Way

e200z425Bn3 supports cache set/way invalidation under software control. The instruction cache may be invalidated by index and way through a **mtspr l1finv1** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV1) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when the instruction cache is disabled.

14.7.7 L1FINV1

The L1FINV1 register is shown in following figure.

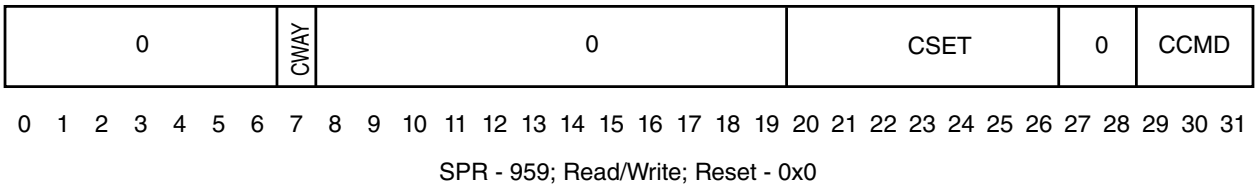

Figure 14-12. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 14-21. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8: 19	—	Reserved[1] for set extension
20 :26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.7.8 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of the instruction cache. Seven parity check bits are provided for each tag entry for the tag array to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for

each doubleword in the data arrays of the I-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR1[ICECE] control field. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the instruction cache when cache error checking is disabled ($L1CSR1_{ICECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

14.7.8.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the cache, each cache line in the I-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR1_{ICLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on instruction fetch, accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR1_{ICLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch , if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, cache contents are ignored for lines with those errors. Cache invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable access will perform the lockout function if required.

14.7.9 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi** instruction or an L1FINV1 invalidation operation.

14.8 Exceptions

Interrupts implemented in e200z425Bn3 and the exception conditions that cause them are listed in the following table.

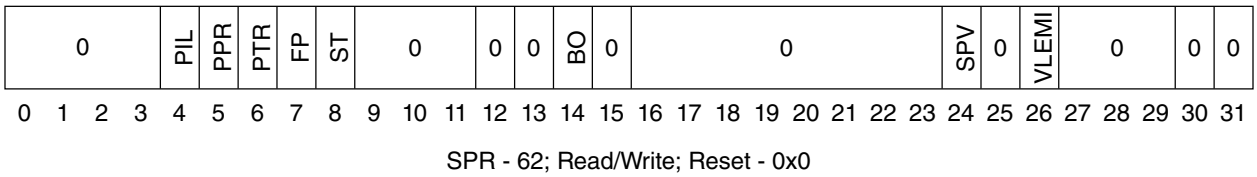
Table 14-22. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. LSP ld and st instructions not properly aligned 4. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

14.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.



SPR - 62; Read/Write; Reset - 0x0

Figure 14-13. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 14-23. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For e200z425Bn3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	—	Reserved	—
13	—	Reserved	—
14	BO	Byte Ordering exception Mismatched Instruction Storage exception	Instruction Storage
15	—	Reserved	—

24	SPV	EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
25	—	Reserved	—
26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—

Table continues on the next page...

Table 14-23. ESR field descriptions (continued)

Bit(s)	Name	Description	Associated interrupt type
31	—	Reserved	—

14.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z425Bn3 MSR is shown in the following figure.

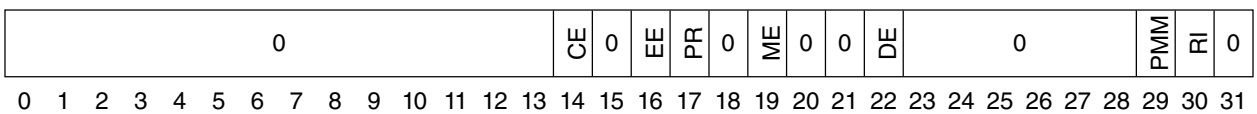

Figure 14-14. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 14-24. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled.

Table continues on the next page...

Table 14-24. MSR field descriptions (continued)

Bit(s)	Name	Description
		1 Debug interrupts are enabled.
23:28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

14.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

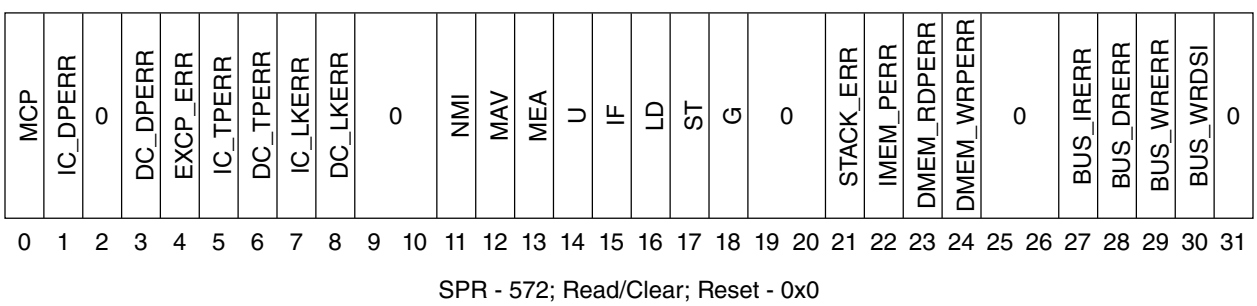

Figure 14-15. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 14-25. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR[2]	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR[2]	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1,MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[3]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise

Table continues on the next page...

Table 14-25. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

- "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
- "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

2. Will not be set by e200z425Bn3-1 since no data cache is present.
3. Note that since no address translation mechanism is present on e200z420n3, the MEA value is always set to \0'.

14.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

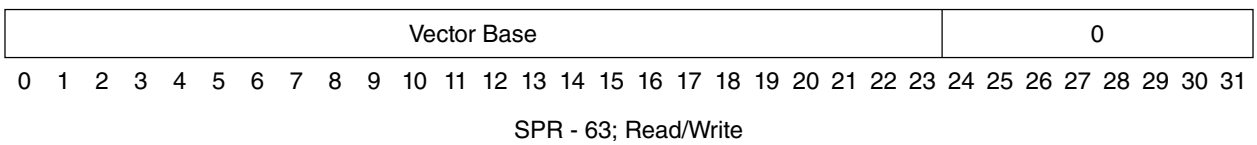

Figure 14-16. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 14-26. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

14.8.5 Interrupt Definitions

14.8.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 14-27. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored)					
	$IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

14.8.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 14-28. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

14.8.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 14-29. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

14.8.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 14-30. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

14.8.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 14-31. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0

Table continues on the next page...

Table 14-31. External Input Interrupt—Register Settings (continued)

Register	Setting description					
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x40 (autovectored) IVPR0:15 || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

14.8.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of an LSP APU load or store instruction that is not properly aligned.

The following table lists register settings when an alignment interrupt is taken.

Table 14-32. Alignment Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	[ST], [SPV], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	$IVPR_{0:23}$ || 0x50					

14.8.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z425Bn3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z425Bn3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z425Bn3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 14-33. Program Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the excepting instruction.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table continues on the next page...

	Trap:		PTR, VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x60					

14.8.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 14-34. Performance Monitor Interrupt—Register Settings

Register	Setting description
SRR0/ DSRR0	Set to the effective address of the next instruction to be executed.
SRR1/	Set to the contents of the MSR at the time of the interrupt.

Table continues on the next page...

3. EE is not cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLREE}$ = 0
4. DE is cleared if $PMGC0_{UDI}$ = 1

14.8.5.9 System Call Interrupt (offset 0x80)

A System Call interrupt occurs when a System Call (**se_sc**) instruction is executed and no higher priority exception exists.

The following table lists register settings when a System Call interrupt is taken.

Table 14-35. System Call Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the instruction *following* the system call instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x80					

14.8.5.10 Debug Interrupt (offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both $DBCR0_{IDM} = 1$ (internal debug mode) and $MSR_{DE} = 1$).

The following table lists register settings when a Debug interrupt is taken.

Table 14-36. Debug Interrupt—register settings

Register	Setting description					
DSRR0[1]	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP.Set to the effective address of the next instruction to be executed *following* the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
DSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—/0	FE0	0	DS	0
	EE	—/0[2]	DE	0	PMM	0
	PR	0			RI	—
DBSR[3]	Unconditional Debug Event:		UDE

2. Conditional based on control bits in HID0
3. Note that multiple DBSR bits may be set

14.8.5.11 Embedded Floating-point Data Interrupt (offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

The following table lists register settings when an EFPU Floating-point Data interrupt is taken.

Table 14-37. Embedded Floating-point Data Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting EFPU instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0

MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0xB0					

14.8.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 14-39. System Reset Interrupt—register settings

Register	Setting description

14.9 Memory Protection Unit (MPU)

14.9.1 MPU Overview

The e200z425Bn3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

14.9.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

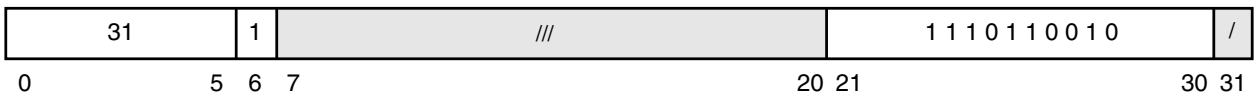
14.9.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

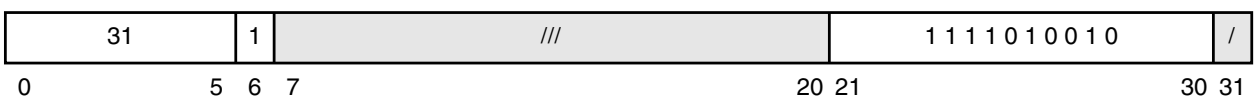
14.9.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

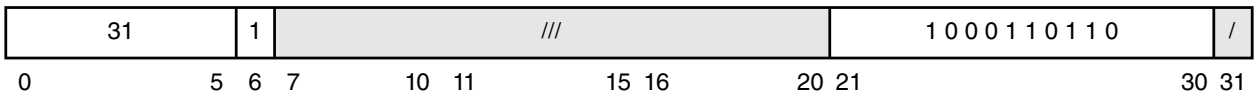
14.9.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the core.

mpusync

MPU Synchronize
mpusync

mpusync



14.9.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z425Bn3 MPU design. The MMUCFG register is shown in the following figure.

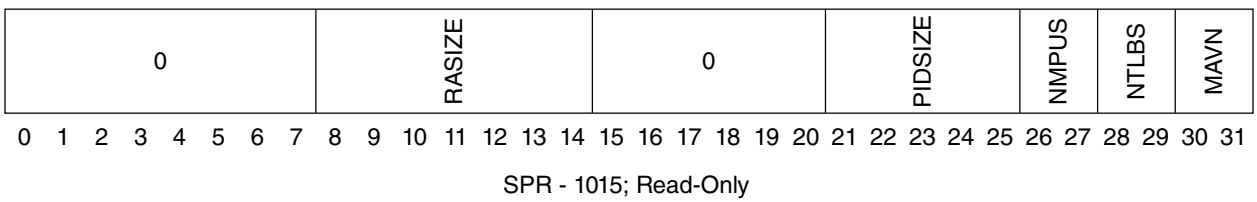


Figure 14-17. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 14-40. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

14.9.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z425Bn3 MPU. The MPU0CFG register is shown in following figure.

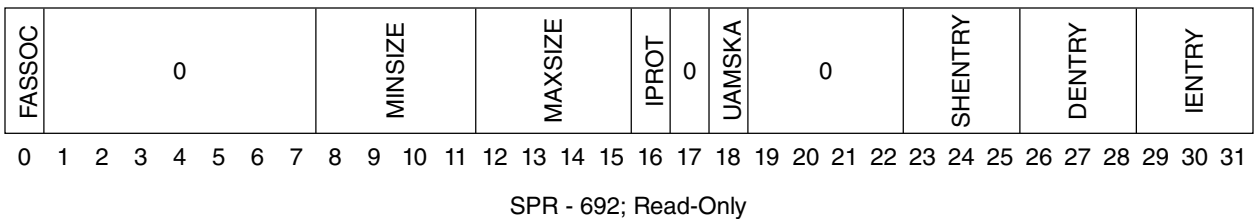

Figure 14-18. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in the following table.

Table 14-41. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

14.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.

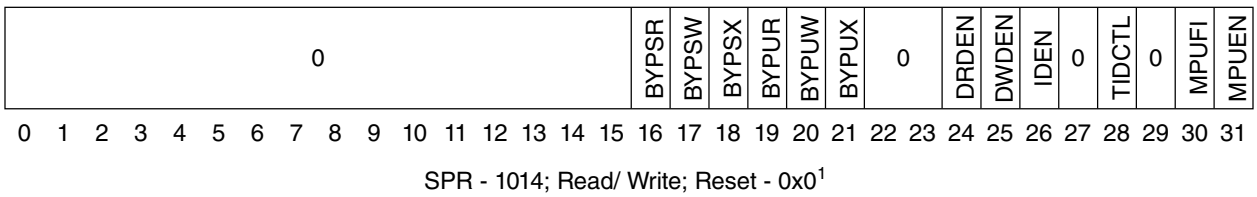

Figure 14-19. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM} = 0$, as well as unconditionally by an internal power-on reset signal. If $EDBCR0_{EDM} = 1$, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 14-42. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses

Table continues on the next page...

Table 14-42. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses

Table continues on the next page...

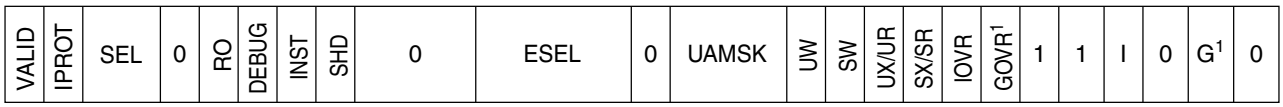
Table 14-42. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

14.9.9 MPU Assist Registers (MAS)

The core uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 14-20. Fields are defined in Table 14-43.



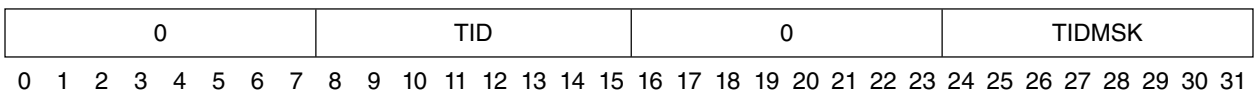
SPR - 624; Read/ Write; Reset - Unaffected

Figure 14-20. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

The MAS1 register is shown in Figure 14-21. Fields are defined in Table 14-43.



SPR - 625; Read/Write; Reset - Unaffected

Figure 14-21. MPU Assist Register 1 (MAS1)

Table 14-43. MAS1—Descriptor Context and Configuration Control

Bit	Name	Comments, or Function when Set
0:7	—	Reserved
8:15	TID	Region ID bits This field is compared with the current process ID of the access address. A TID value of 0 defines an entry as global and matches with all process IDs.
16:23	—	Reserved
24:31	TIDMSK	Region ID mask 0xxxxxxx = TID[0] comparison to PID0[0] not masked 1xxxxxxx = TID[0] comparison to PID0[0] is masked x0xxxxxx = TID[1] comparison to PID0[1] not masked x1xxxxxx = TID[1] comparison to PID0[1] is masked xx0xxxxx = TID[2] comparison to PID0[2] not masked xx1xxxxx = TID[2] comparison to PID0[2] is masked xxx0xxxx = TID[3] comparison to PID0[3] not masked xxx1xxxx = TID[3] comparison to PID0[3] is masked xxxx0xxx = TID[4] comparison to PID0[4] not masked xxxx1xxx = TID[4] comparison to PID0[4] is masked xxxxx0xx = TID[5] comparison to PID0[5] not masked xxxxx1xx = TID[5] comparison to PID0[5] is masked xxxxxx0x = TID[6] comparison to PID0[6] not masked xxxxxx1x = TID[6] comparison to PID0[6] is masked xxxxxxx0 = TID[7] comparison to PID0[7] not masked

Table 14-43. MAS1—Descriptor Context and Configuration Control

Bit	Name	Comments, or Function when Set
		xxxxxxx1 = TID[7] comparison to PID0[7] is masked This field controls whether bits within the TID to PID0 comparison are masked for determining a range match. When a bit is masked, the value of that TID and PID0 bit is ignored for matching purposes.

The MAS2 register is shown in Figure 14-22. Fields are defined in Table 14-44.

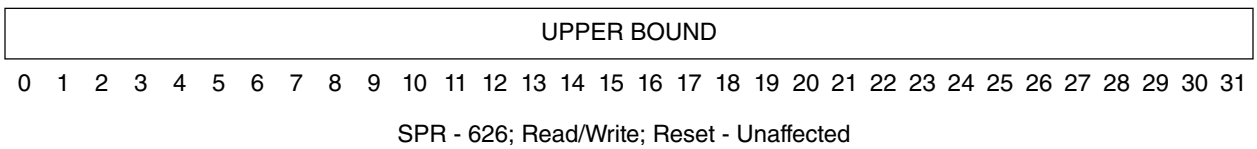


Figure 14-22. MPU Assist Register 2 (MAS2)

Table 14-44. MAS2—Upper Bound Control

Bit	Name	Comments, or Function when Set
0:31	UPPER BOUND	Upper bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

The MAS3 register is shown in Figure 14-23. Fields are defined in Table 14-45.

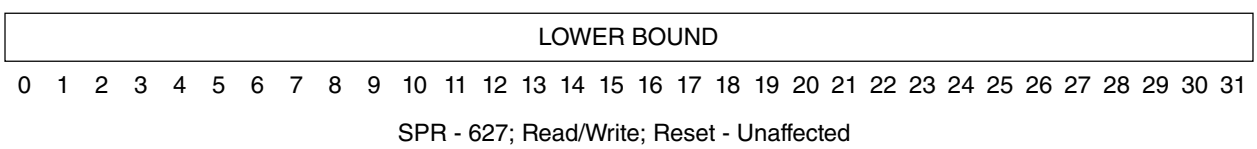

Figure 14-23. MPU Assist Register 3 (MAS3)

Table 14-45. MAS3—Lower Bound Control

Bit	Name	Comments, or Function when Set
0:31	LOWER BOUND	Lower bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

14.9.10 MAS Registers Summary

The MAS registers are summarized in the following figure.

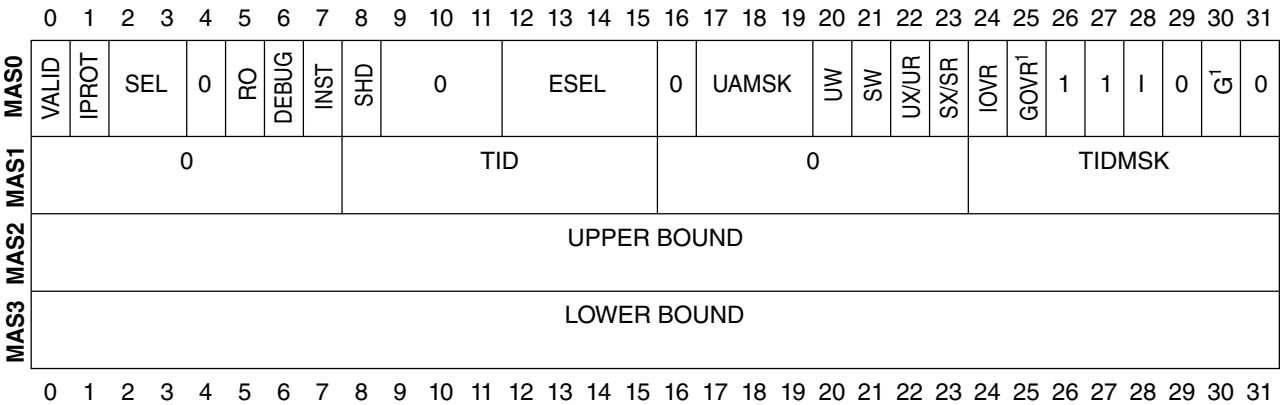

Figure 14-24. MPU Assist Registers Summary

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

14.10 Local memories

14.10.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

14.10.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

14.10.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z425Bn3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

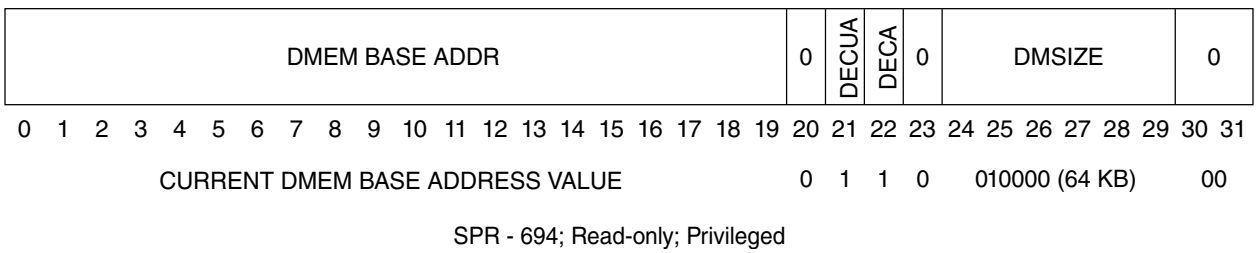

Figure 14-25. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 14-46. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

14.10.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

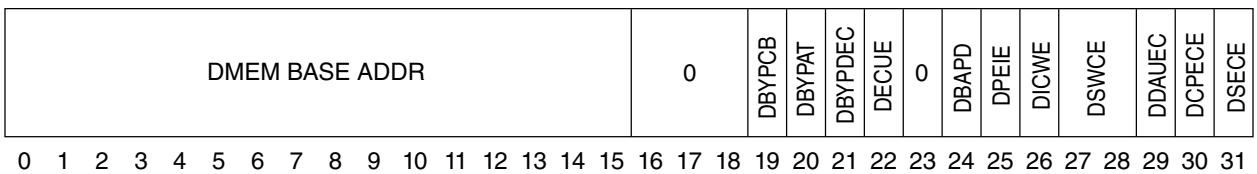

Figure 14-26. DMEM Control Register 0 (DMEMCTL0)

Note

[1] Reset by an internal power-on reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 14-47. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16 :18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[8]** input, which is internally hard coded.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by

Table continues on the next page...

Table 14-47. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[6]** input, which is internally hard coded.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[7]** input, which is internally hard coded.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[0]** input which is internally hard coded.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled.

Table continues on the next page...

Table 14-47. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits.
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1-, 2-, or 3-byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the values of the **p_dmem_rstcfg[1:2]** inputs, which are internally hard coded.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[3]** input, which is an internally hardcoded signal.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[4]** input, which is internally hard coded.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written.

Table 14-47. DMEMCTL0 field descriptions

Bits	Name	Description
		1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[5]** input, which is an internally hard coded signal.

14.10.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed. All other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB,\ DBYPATF,\ DBYPDEC}$.

14.10.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the e200z425Bn3 local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in the following figure.

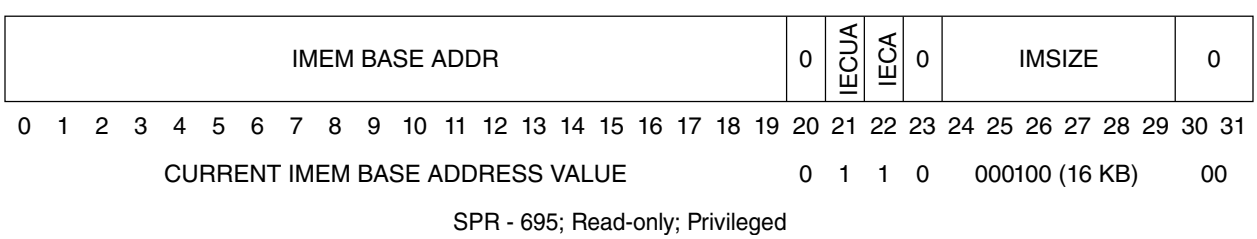

Figure 14-28. IMEM Configuration Register 0 (IMEMCFG0)

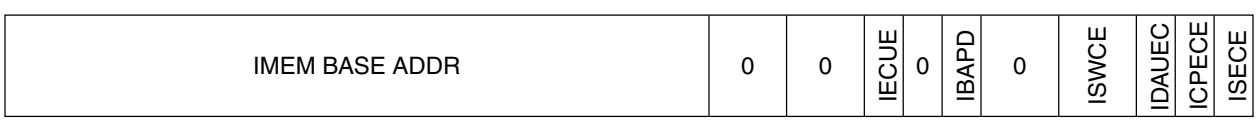
The IMEMCFG0 fields are described in the following table.

Table 14-49. IMEMCFG0 field descriptions

Bits	Name	Description
0:19	IMEM BASE ADDR	IMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the IMEM. This field reflects the value of the external IMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of IMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0's when the IMEM size is > 4 KB
20	—	Reserved
21	IECUA	IMEM Error Correction Update Available IECUA indicates an error scrubbing function for the IMEM is available. 0 Error Correction Update is not available 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access
22	IECA	IMEM Error Correction Available IECA indicates an error correction function for the IMEM is available. 0 Error Correction is not available 1 Error Correction is available
23	—	Reserved
24:29	IMEM Size	IMSIZE - IMEM Size 000100 The size of the IMEM is 16 KB
30:31	—	Reserved

14.10.2.5 IMEM Control Register 0 (IMEMCTL0)

The IMEM Control Register 0 (IMEMCTL0) controls operation of certain functions of the IMEM logic.



DCR - 497; Read/Write; Reset[1] - 22'b0 ||| p_imem_rstcfg[0] || 4'b0 || p_imem_rstcfg[1:5]; Privileged

Figure 14-29. IMEM Control Register 0 (IMEMCTL0)

Note

[1] Reset by an internal Power-On-Reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 14-50. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.
18:19	—	Reserved for Base Address extension
20:21	—	Reserved
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[0]** input, an internally hard coded signal. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the values of the **p_imem_rstcfg[1:2]** inputs, which are internally hard coded signals.
29	IDAUEC	IMEM Disable Address Use in Error Check

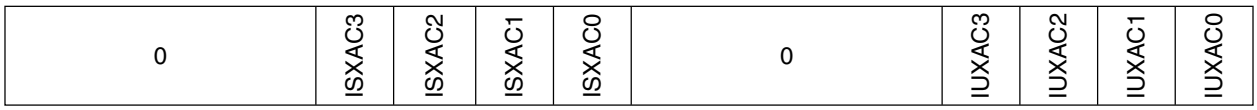
Table continues on the next page...

Table 14-50. IMEMCTL0 field descriptions (continued)

Bits	Name	Description
		This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[3]** input, which is an internally hard coded signal.
30	ICPECE	IMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[4]** input, which is an internally hard coded signal.
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[5]** input, which is an internally hard coded signal.

14.10.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.



DCR - 499; Read/Write; Reset [1] - 32‘b0; Privileged

14.11 End-to-End ECC Support

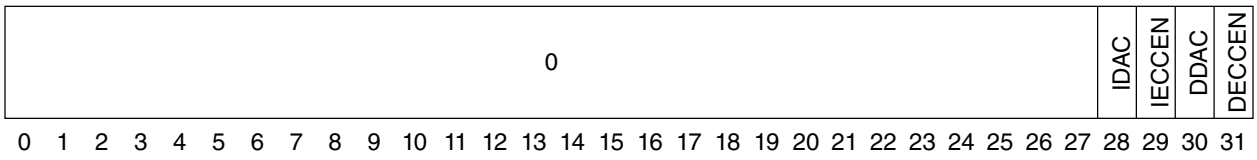
This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

14.11.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

14.11.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.



DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 14-31. e2eECC Control Register 0 (E2ECTL0)

Table 14-52. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

14.11.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/ correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 14-32. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 14-53. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection:

Table 14-53. E2EECSR0 field descriptions

Bits	Name	Description
		0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 15
Core description

15.1 Overview of the e200z710n3 core

The e200z710n3 is a single-issue 32-bit *Power ISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z710n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *Power ISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z710n3 core integrates an integer execution unit, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining three read and two write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z710n3 core contains a16 KB Instruction Cache, and a 4 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

15.2 Register model

This section describes the registers implemented in the e200z710n3 core. The *Power ISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z710n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 15-1 and Figure 15-2 show the complete e200z710n3 register set, all of which are accessible in supervisor mode. Figure 15-3 and Figure 15-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

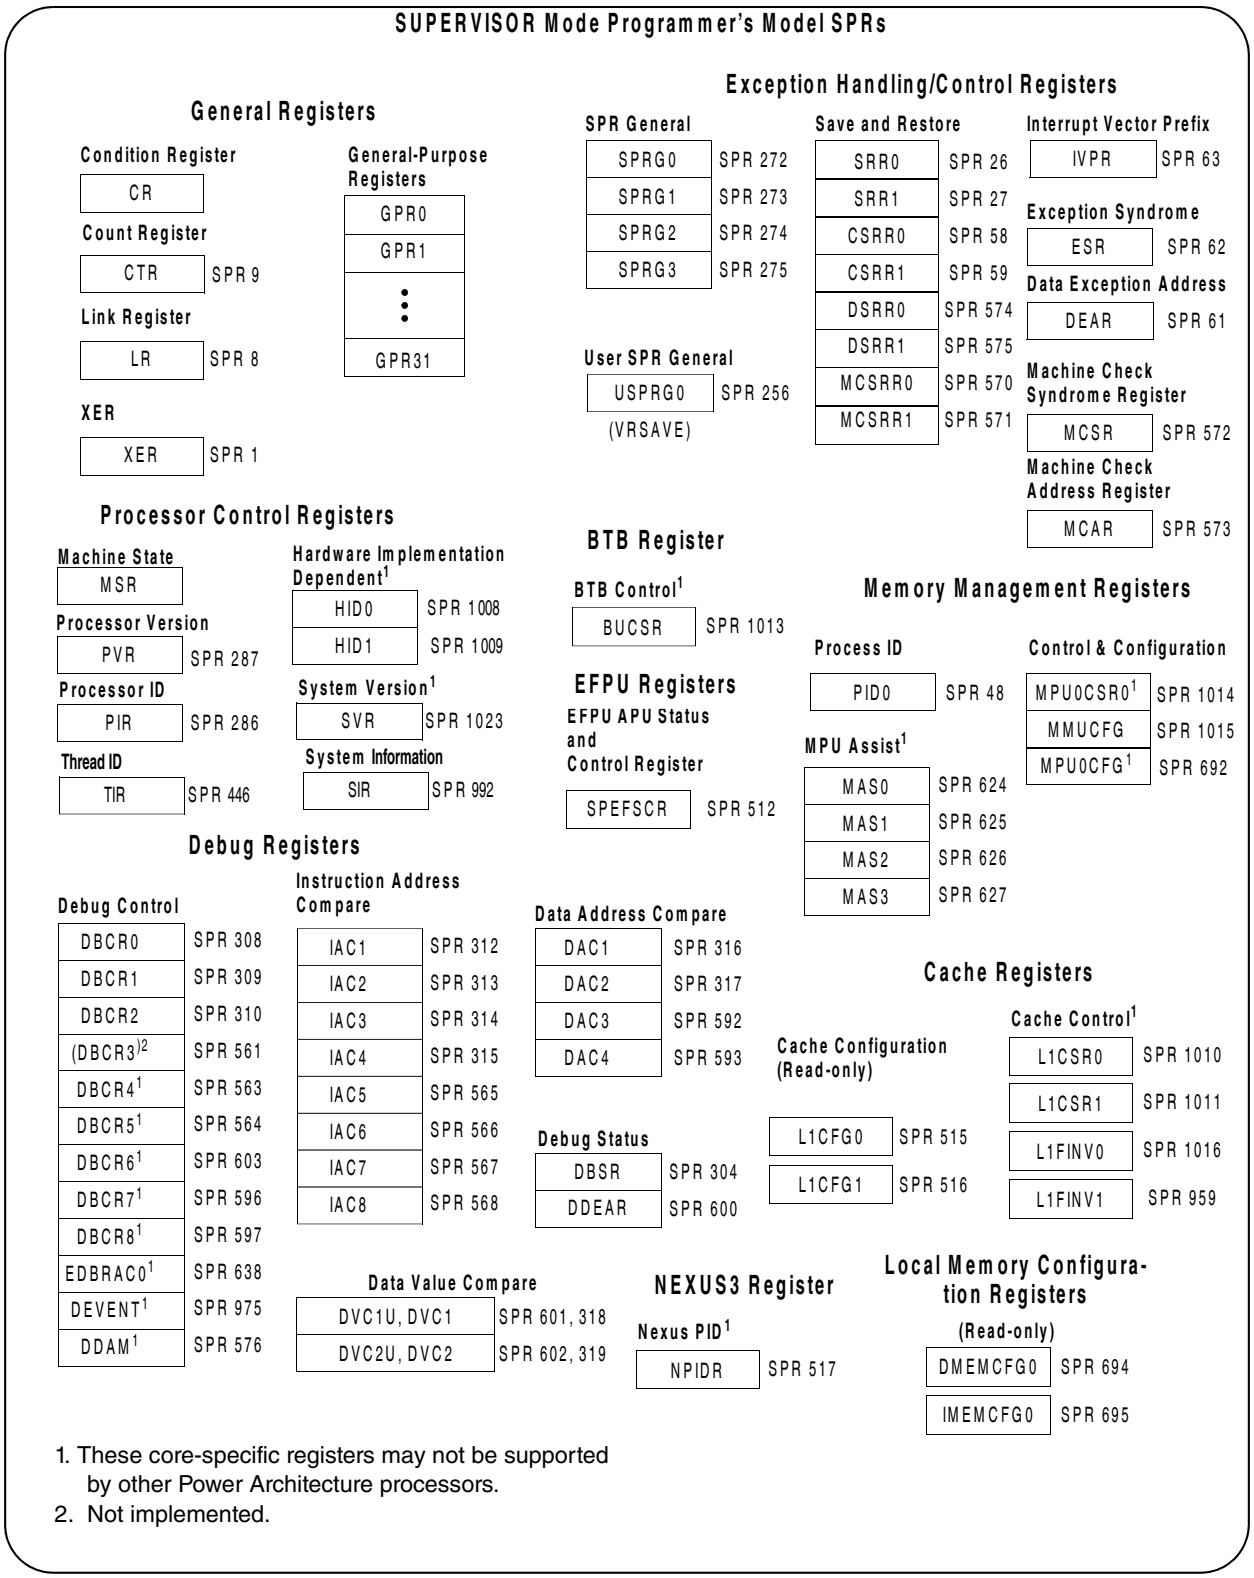


Figure 15-1. e200z710n3 Supervisor Mode Programmer's Model SPRs

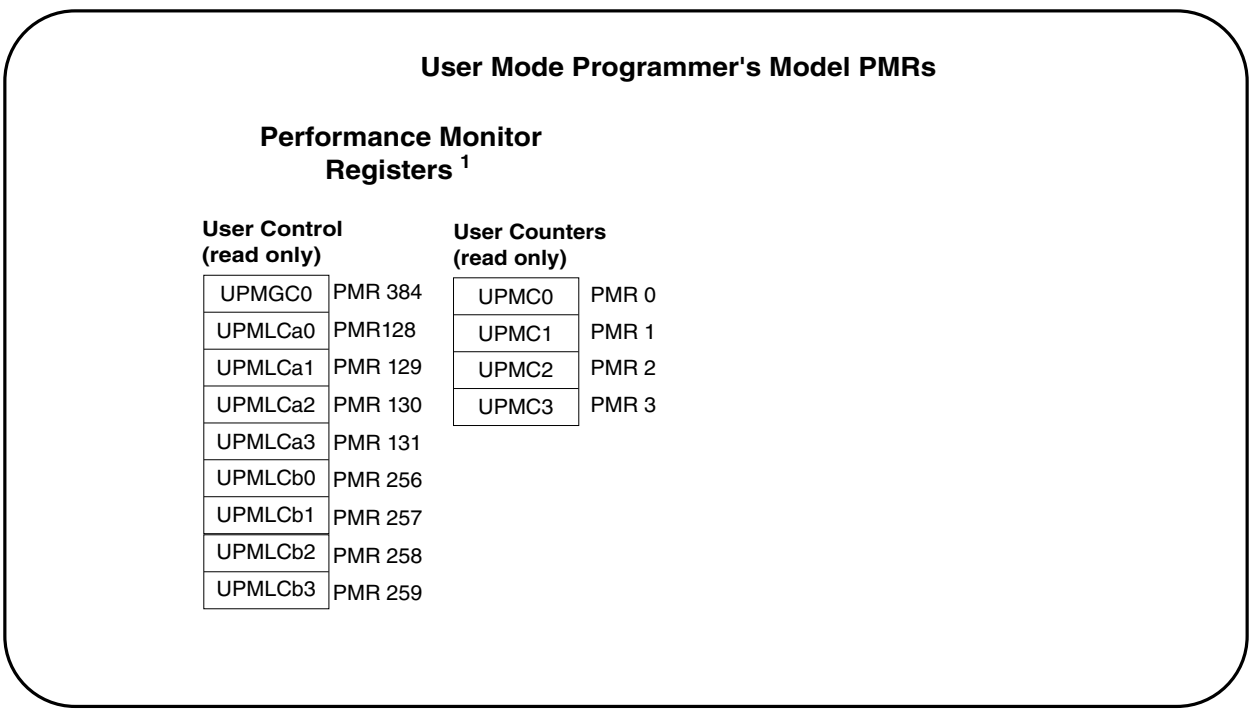

Figure 15-4. e200z710n3 User Mode Programmer's Model PMRs

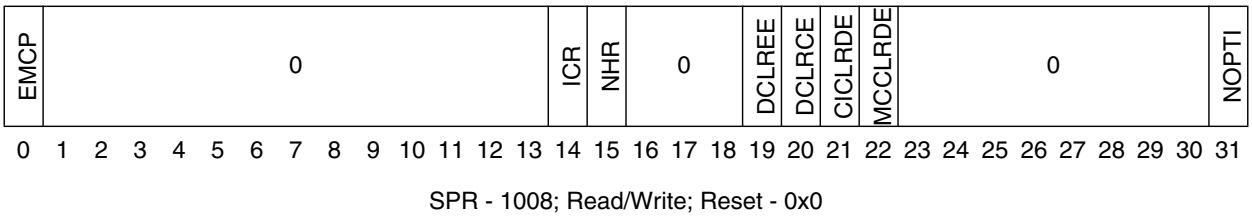
15.2.1 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a core implementation dependent register used for various configuration and control functions. It is shown in the following figure.



SPR - 1008; Read/Write; Reset - 0x0

Figure 15-5. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 15-1. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit 1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18 [48:50]	-	Reserved
19 [51]	DCLREE	Debug Interrupt Clears MSR_{EE} 0 MSR_{EE} unaffected by Debug Interrupt 1 MSR_{EE} cleared by Debug Interrupt This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSR_{CE} 0 MSR_{CE} unaffected by Debug Interrupt 1 MSR_{CE} cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Critical class interrupt

Table continues on the next page...

Table 15-1. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
		1 MSR_{DE} cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit. Note that if Critical Interrupt Debug events are enabled ($DBCR0_{CIRPT}$ set), and MSR_{DE} is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, $DSRR0_{DE}$ will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSR_{DE} enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSR_{DE} 0 MSR_{DE} unaffected by Machine Check interrupt 1 MSR_{DE} cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [58:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

15.2.2 Hardware Implementation Dependent Register 1 (HID1)

The HID1 register is used for bus configuration and system control. It is shown in the following figure.

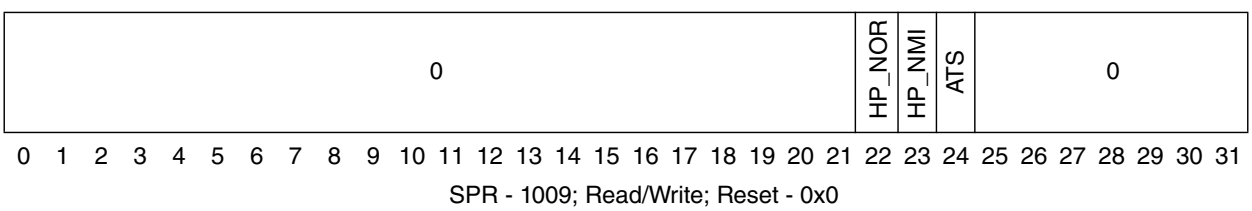


Figure 15-6. Hardware Implementation Dependent Register 1 (HID1)

The HID1 fields are defined in the following table.

Table 15-2. Hardware Implementation-Dependent Register 1

Bits	Name	Description
0:21 [32:53]	-	Reserved

Table continues on the next page...

Table 15-2. Hardware Implementation-Dependent Register 1 (continued)

Bits	Name	Description
22 [54]	HP_NOR	High priority elevation for normal and external interrupts 0 - High priority elevation for normal and external interrupts is disabled 1 - High priority elevation for normal and external interrupts is enabled The HP_NOR bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided. These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
23 [55]	HP_NMI	High priority elevation for NMI and critical interrupts 0 - High priority elevation for NMI and critical interrupts is disabled 1 - High priority elevation for NMI and critical interrupts is enabled The HP_NMI bitfield enables temporary elevation of the processor's crossbar priority. The relevant Master x field for the processor must also be enabled in the XBAR_CRSn HPEx bitfield. The platform logic elevates the processor's crossbar priority from the time of the IRQ assertion until the appropriate return instruction has been executed. For normal interrupts , the hardware supports the stacking of up to 4 interrupts. No hardware support of stacking for critical or NMI interrupts is provided These bits may need external synchronization. **NOTE:** Must be used in conjunction with the XBAR_CRSn HPEx setting
24 [56]	ATS	Atomic status (read-only) Indicates state of the reservation bit in the load/store unit.
25:31 [57:63]	-	Reserved

15.3 Single-issue operation

The instruction issue unit attempts to issue an instruction to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as two results can be simultaneously written.

15.4 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 15-3. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during execution.

Timing for EFPU instructions is detailed in Table 15-6.

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 15-3. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**	1	1	—
Branch	6/4/1	6/4/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 6 cycles.
multiply (saturating/non-saturating)	2/3	1	Result data is available after 2 cycles for non-saturating forms, and 3 cycles for saturating forms, and record form conditions are available after 3 cycles for both forms.
divide	4–15	4–15	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	3	1	—
load multiple	4 + *n*/2 (max)	4 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	3	1	—
store multiple	4 + *n*/2 (max)	4 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
mtmsr, **wrtee**, **wrteei**	6&	6&	—
mcrf	1	1	—
mfspr, **mtspr**	4&	4&	Applies to Debug SPRs, optional unit SPRs
mfspr, **mfmsr**	1	1	Applies to certain limited internal, non Debug SPRs

efssub	4	1	—
efststeq	4	1	—
efststgt	4	1	—
efststlt	4	1	—

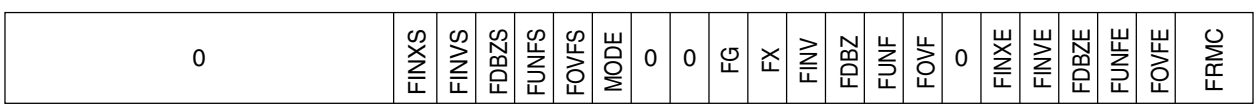
1. Destination register is also a source register, so for full throughput, back-to-back operations must use a different destination register.

15.5 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

15.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.



SPR - 512; Read/Write; Reset - 0x0

Figure 15-7. EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 15-7. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved

Table continues on the next page...

Table 15-7. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z710n3 Supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by e200 core)
16 (48)	—	Reserved
17 (49)	—	Reserved
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21	FDBZ	Embedded Floating-point Divide by Zero

Table continues on the next page...

Table 15-7. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
(53)		The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22	FUNF	Embedded Floating-point Underflow
(54)		The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23	FOVF	Embedded Floating-point Overflow
(55)		The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24	—	Reserved
(56)		
25	FINXE	Embedded Floating-point Inexact Exception Enable
(57)		If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG l FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable
(58)		If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27	FDBZE	Embedded Floating-point Divide by Zero Exception Enable
(59)		If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28	FUNFE	Embedded Floating-point Underflow Exception Enable
(60)		If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29	FOVFE	Embedded Floating-point Overflow Exception Enable
(61)		If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31	FRMC	Embedded Floating-point Rounding Mode Control
(62:63)		00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity

15.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.7.1 Cache overview

The e200z710n3 processor supports a16 KB 2-way set-associative instruction and 4KB 2-way set-associative data cache with a 32-byte line size. The caches improves system performance by providing low-latency data to the e200z710n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z710n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

15.7.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

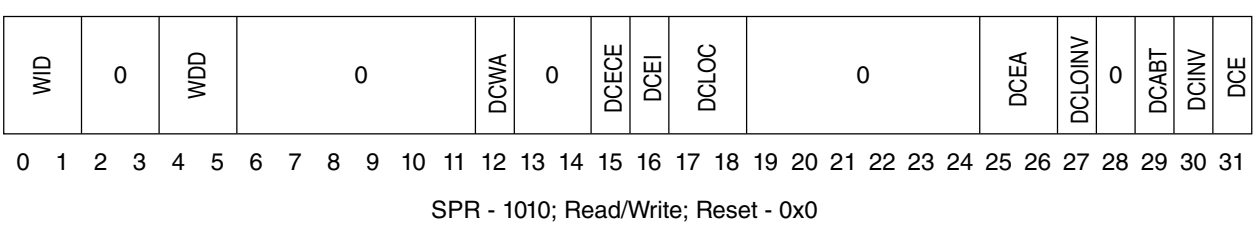

Figure 15-8. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 15-8. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved[1]
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved[1]
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[1]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled.

Table continues on the next page...

Table 15-8. L1CSR0 field descriptions (continued)

Bits	Name	Description
		Note: When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table continues on the next page...

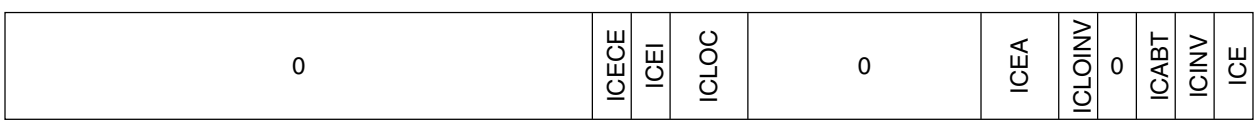
Table 15-8. L1CSR0 field descriptions (continued)

Bits	Name	Description
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses.Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

15.7.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.



SPR - 1011; Read/Write; Reset - 0x0

Figure 15-9. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 15-9. L1CSR1 field descriptions

Bits	Name	Description

Bits	Name	Description
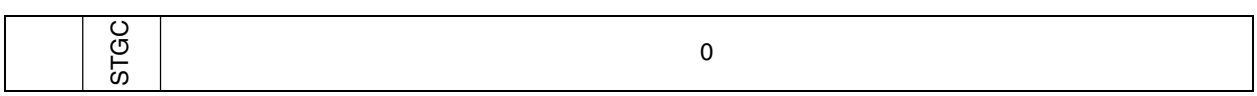
		operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 258 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

15.7.4 L1 Cache Control and Status Register 2 (L1CSR2)

The L1 Cache Control and Status Register 2 (L1CSR2) is a 32-bit register used for extended cache control. The L1CSR2 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR2 is 606 in decimal, and is shown in the following figure.



SPR - 606; Read/Write; Reset - 0x0

Figure 15-10. L1 Cache Control and Status Register 2 (L1CSR2)

The L1CSR2 bits are described in the following table.

Table 15-10. L1CSR2 field descriptions

Bits	Name	Description
0:1	—	Reserved
2:3	STGC	Store Gather Control 00 - Default Operation - Implementation defined. for e200 store gathering is disabled. 01 - Store Gathering is enabled. No constraints on alignment or requirement to be contiguous. External bus write accesses for gathered stores may have non-contiguous byte strobes asserted. 10 - Store Gathering is enabled. Gathered stores are required to be contiguous once gathered. Cache hit data from a store access lookup may be used to provide adjacent store data to increase gathering opportunities. External bus write accesses for gathered stores will not have non-contiguous byte strobes asserted. 11 - No Store Gathering is Performed
4:31	—	Reserved

15.7.5 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z710n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The L1CFG0 register is shown in the following figure.

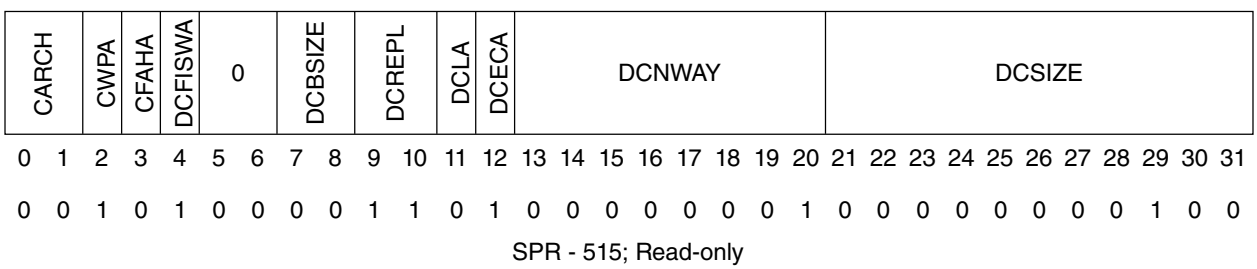


Figure 15-11. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in the following table.

Table 15-11. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available

Table continues on the next page...

Table 15-11. L1CFG0 field descriptions (continued)

Bits	Name	Description
		1 The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 The size of the data cache is 4 KB

15.7.6 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z710n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The L1CFG1 register is shown in the following figure.

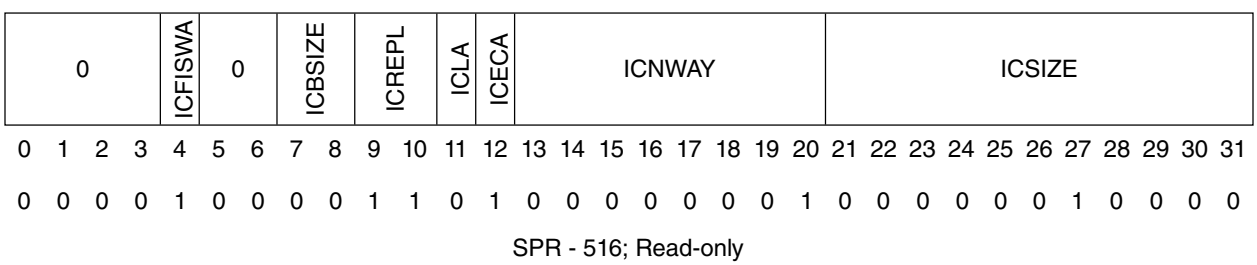

Figure 15-12. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 15-12. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x010 The size of the instruction cache is 16 KB

15.7.7 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

15.7.8 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

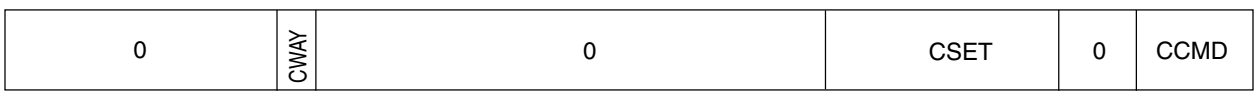
15.7.9 Cache Invalidate by Set and Way

e200z710n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

15.7.9.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in the following figure.



SPR - 1016; Read/Write; Reset - 0x0

Figure 15-13. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in the following table.

Table 15-13. L1FINV0 field descriptions

Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8: 20	—	Reserved[1] for set extension
21 :26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 = The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.9.2 L1FINV1

The L1FINV1 register is shown in following figure.

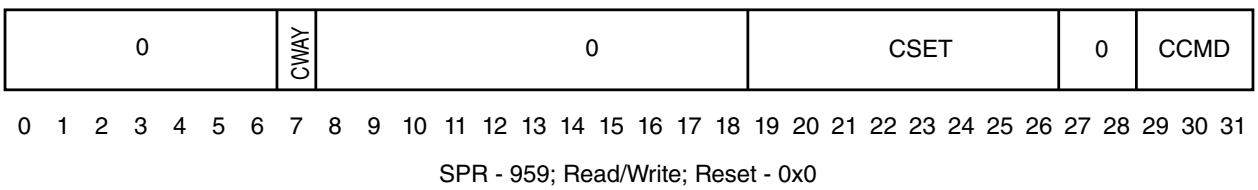


Figure 15-14. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 15-14. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:18	—	Reserved[1] for set extension
19 :26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.10 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR0[DCECE] and L1CSR1[ICECE] control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

15.7.10.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by L1CSR{0,1}$_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via L1CSR{0,1}$_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

15.7.11 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction or an L1FINV{0,1} invalidation operation.

15.8 Exceptions

Interrupts implemented in e200z710n3 and the exception conditions that cause them are listed in the following table.

Table 15-15. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt

Table continues on the next page...

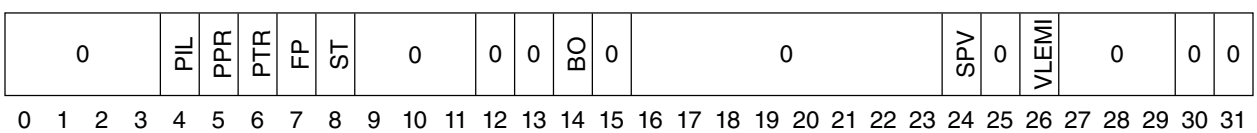
Table 15-15. Exceptions and Conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.



SPR - 62; Read/Write; Reset - 0x0

Figure 15-15. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 15-16. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception	Program

Table continues on the next page...

Table 15-16. ESR field descriptions (continued)

Bit(s)	Name	Description	Associated interrupt type
		For e200z710n3, PIL is used for both illegal and unimplemented instructions.	
5	PPR	Privileged Instruction exception	Program

27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

15.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z710n3 MSR is shown in the following figure.

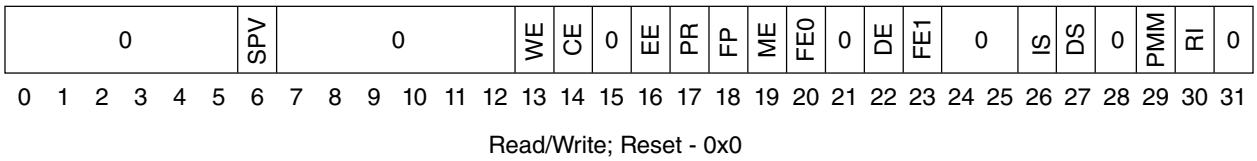

Figure 15-16. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 15-17. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/Embedded FP Double or Vector Unit instructions. **NOTE:** The e200z710n3 processor does not support these units in hardware. An Illegal Instruction exception is generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** this bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	Floating-Point Available 0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** The e200z710n3 processor does not support the PowerISA 2.06 floating point unit in hardware, and an Illegal Instruction exception is generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.

Table continues on the next page...

Table 15-17. MSR field descriptions (continued)

Bit(s)	Name	Description
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used) **NOTE:** The e200z710n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE0 is ignored, but cleared on exceptions.
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used) **NOTE:** The e200z710n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** The e200z710n3 processor does not support Address Spaces, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1. **NOTE:** The e200z710n3 processor does not support Address Spaces, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

15.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

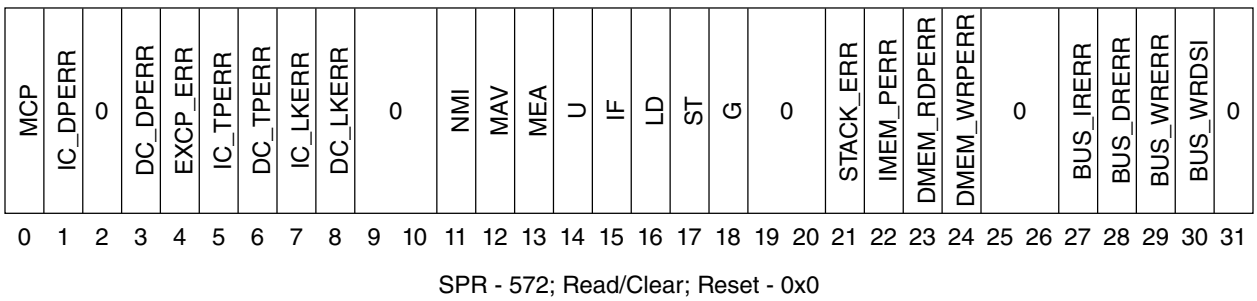

Figure 15-17. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 15-18. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error	Async Mchk	—

Table continues on the next page...

Table 15-18. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.		
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[2]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise

Table continues on the next page...

Table 15-18. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
2. Note that since no address translation mechanism is present on e200z710n3, the MEA value is always set to '0'.

15.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

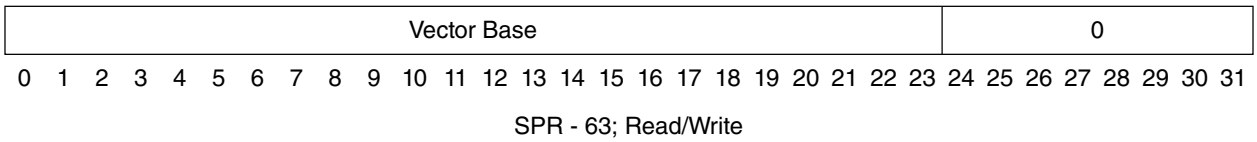

Figure 15-18. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 15-19. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.8.5 Interrupt Definitions

15.8.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 15-20. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored)					
	$IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.8.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 15-21. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0

Table continues on the next page...

Table 15-21. Machine Check Interrupt—register settings (continued)

Register	Setting description					
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

15.8.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 15-22. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

15.8.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 15-23. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

15.8.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 15-24. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					

Table continues on the next page...

Vector	$IVPR_{0:23}$ || 0x40 (autovectored) IVPR0:15 || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)

15.8.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

The following table lists register settings when an alignment interrupt is taken.

Table 15-25. Alignment Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	[ST], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	$IVPR_{0:23}$ || 0x50					

15.8.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception

- Privileged Instruction exception
- Trap exception

The e200z710n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z710n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z710n3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *Power ISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 15-26. Program Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt

MCSR	Unchanged	
DEAR	Unchanged	
Vector	$IVPR_{0:23}$ || 0x60	

15.8.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- $PMLCa x_{CE}$ = 11; that is, for the given counter the overflow condition is enabled.
- $PMC x_{OV}$ = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 15-27. Performance Monitor Interrupt—Register Settings

Register	Setting description					
SRR0/ DSRR0[1]	Set to the effective address of the next instruction to be executed.					
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.

15.8.5.11 Embedded Floating-point Data Interrupt (offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

The following table lists register settings when an EFPU Floating-point Data interrupt is taken.

Table 15-30. Embedded Floating-point Data Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting EFPU instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt

DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0xB0					

15.8.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 15-32. System Reset Interrupt—register settings

15.9 Memory Protection Unit (MPU)

15.9.1 MPU Overview

The e200z710n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

15.9.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

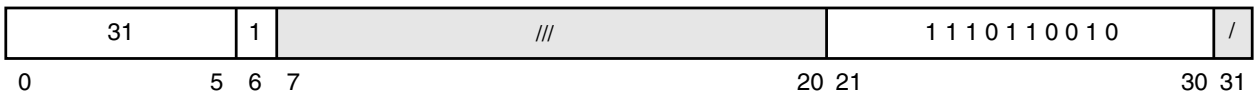
15.9.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

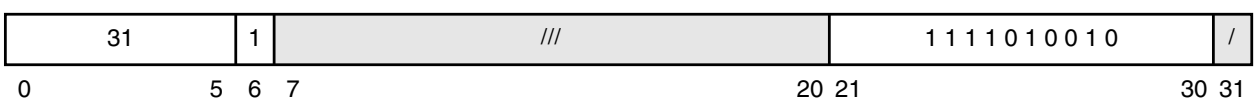
15.9.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

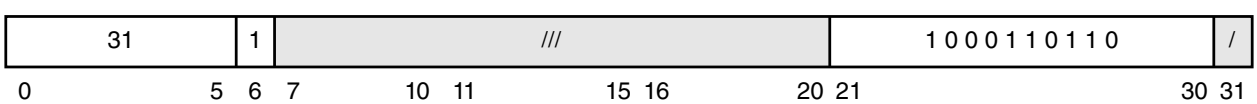
15.9.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the core.

mpusync

MPU Synchronize
mpusync

mpusync



15.9.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z710n3 MPU design. The MMUCFG register is shown in the following figure.

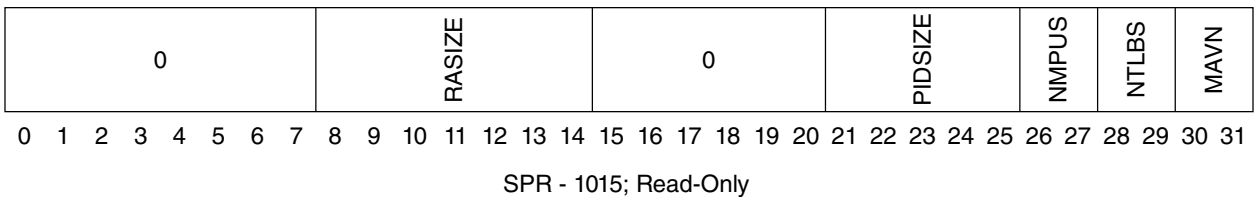


Figure 15-19. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 15-33. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

15.9.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z710n3 MPU. The MPU0CFG register is shown in following figure.

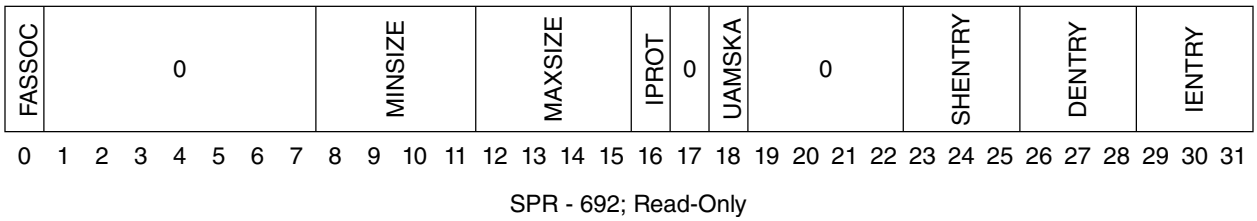

Figure 15-20. MPU0 Configuration Register (MPU0CFG)

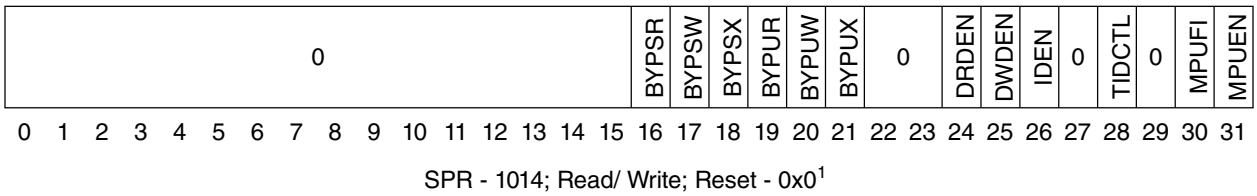
The MPU0CFG bits are described in the following table.

Table 15-34. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

15.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.



SPR - 1014; Read/ Write; Reset - 0x0[1]

Figure 15-21. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM} = 0$, as well as unconditionally by an internal power-on reset signal. If $EDBCR0_{EDM} = 1$, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 15-35. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses

Table continues on the next page...

Table 15-35. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses

Table continues on the next page...

Table 15-35. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

15.9.9 MPU Assist Registers (MAS)

The core uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 15-22. Fields are defined in Table 15-36.

VALID	IPROT	SEL	0	RO	DEBUG	INST	SHD	0	ESEL	0	UAMSK	UW	SW	UX/UR	SX/SR	IOVR	GOVR[1]	1	1	I	0	G[1]	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 624; Read/ Write; Reset - Unaffected

Figure 15-22. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 15-36. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 = This MPU entry is invalid 1 = This MPU entry is valid
1	IPROT	Invalidation Protect 0 = Entry is not protected from invalidation 1 = Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 = Reserved, no access 01 = Reserved, no access 10 = Select MPU 11 = Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 = This MPU entry is writable 1 = This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 = This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 = This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 = This MPU entry is used for matching data accesses only 1 = This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table.

Table continues on the next page...

Table 15-36. MAS0—MPU Read/Write and Replacement Control (continued)

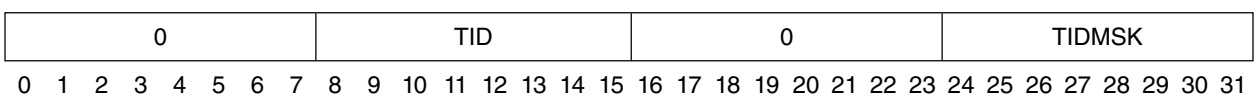
Bit	Name	Comments, or Function when Set
		0 = The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 = The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12 :15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 = No upper address bits are masked, address matching uses all 32 address bits for accesses 001 = The most significant access address bit is forced to zero before matching 010 = The two most significant access address bits are forced to zero before matching 011 = The three most significant access address bits are forced to 0 before matching 100 = The four most significant access address bits are forced to 0 before matching 101 = The upper five access address bits are forced to zero before matching 11x = Reserved, do not use
20	UW	User Mode Write PermissionDetermines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No User mode Write permission 1 = User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No Supervisor mode Write permission 1 = Supervisor mode has Write permission
22	UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 = No User mode Execute/ Read permission 1 = User mode has Execute/ Read permission
23	SX/SR	Supervisor Mode Execute / Read Permission

Table continues on the next page...

Table 15-36. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		Determines Supervisor mode Execute (X) permission when INST = 1, or Supervisor mode Read (R) permission when INST = 0. 0 = No Supervisor mode Execute/ Read permission 1 = Supervisor mode has Execute/ Read permission
24	IOVR	Cache-Inhibit attribute OverrideDetermines whether this matching entry overrides the I bit settings of other matching entries and the cache-inhibited region configuration signals 0 = No override of I attribute by entry 1 = Entry I bit overrides I attribute
25	GOVR/—	G attribute Override Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = No override of G attribute by entry 1 = Entry G bit overrides G attribute
26	—	Reserved
27	—	Reserved
28	I	Cache Inhibited This attribute may be overridden by the cache-inhibited region configuration input settings. When the core memory protection unit (CMPU) is disabled, the CMPU configuration is ignored and this bit is ignored also. 0 = This region is considered cacheable 1 = This region is considered cache-inhibited
29	—	Reserved
30	G/—	Guarded This attribute may be overridden by the guarded region configuration input settings.This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 = All loads and stores to this region are performed without speculation (i.e. they are known to be required)
31	—	Reserved

The MAS1 register is shown in Figure 15-23. Fields are defined in Table 15-37.



SPR - 625; Read/Write; Reset - Unaffected

Figure 15-23. MPU Assist Register 1 (MAS1)

Table 15-37. MAS1—Descriptor Context and Configuration Control

Bit	Name	Comments, or Function when Set
0:7	—	Reserved
8:15	TID	Region ID bits This field is compared with the current process ID of the access address. A TID value of 0 defines an entry as global and matches with all process IDs.
16:23	—	Reserved
24:31	TIDMSK	Region ID mask 0xxxxxxx = TID[0] comparison to PID0[0] not masked 1xxxxxxx = TID[0] comparison to PID0[0] is masked x0xxxxxx = TID[1] comparison to PID0[1] not masked x1xxxxxx = TID[1] comparison to PID0[1] is masked xx0xxxxx = TID[2] comparison to PID0[2] not masked xx1xxxxx = TID[2] comparison to PID0[2] is masked xxx0xxxx = TID[3] comparison to PID0[3] not masked xxx1xxxx = TID[3] comparison to PID0[3] is masked xxxx0xxx = TID[4] comparison to PID0[4] not masked xxxx1xxx = TID[4] comparison to PID0[4] is masked xxxxx0xx = TID[5] comparison to PID0[5] not masked xxxxx1xx = TID[5] comparison to PID0[5] is masked xxxxxx0x = TID[6] comparison to PID0[6] not masked xxxxxx1x = TID[6] comparison to PID0[6] is masked xxxxxxx0 = TID[7] comparison to PID0[7] not masked xxxxxxx1 = TID[7] comparison to PID0[7] is masked This field controls whether bits within the TID to PID0 comparison are masked for determining a range match. When a bit is masked, the value of that TID and PID0 bit is ignored for matching purposes.

The MAS2 register is shown in Figure 15-24. Fields are defined in Table 15-38.

Bit	Name	Comments, or Function when Set
0:31	UPPER BOUND	Upper bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

The MAS3 register is shown in Figure 15-25. Fields are defined in Table 15-39.

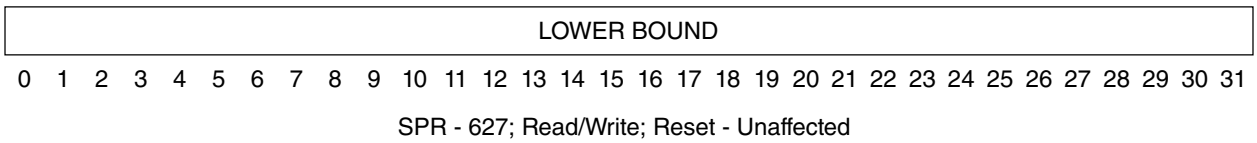

Figure 15-25. MPU Assist Register 3 (MAS3)

Table 15-39. MAS3—Lower Bound Control

Bit	Name	Comments, or Function when Set
0:31	LOWER BOUND	Lower bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

15.9.10 MAS Registers Summary

The MAS registers are summarized in the following figure.

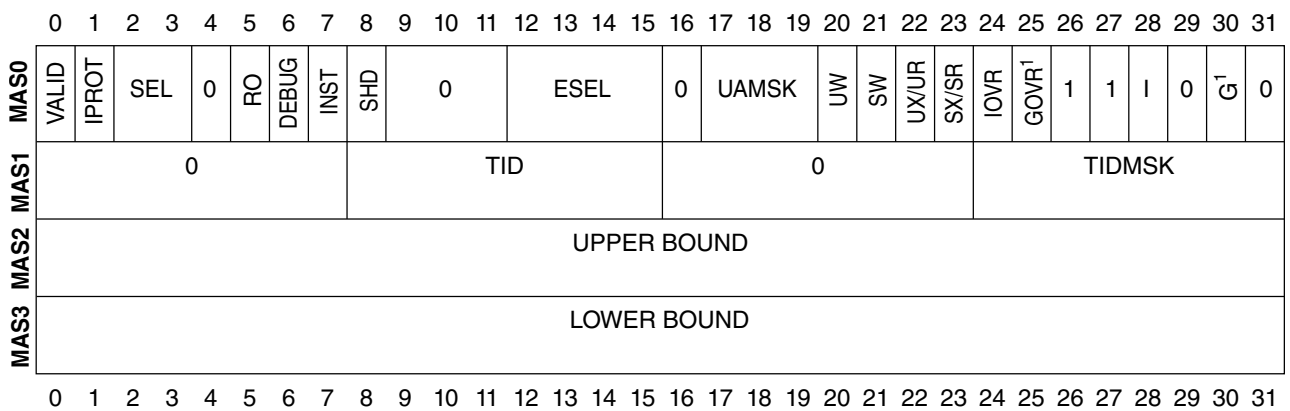

Figure 15-26. MPU Assist Registers Summary

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

15.10 Local memories

15.10.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity tightly coupled storage capability.

15.10.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.10.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z710n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

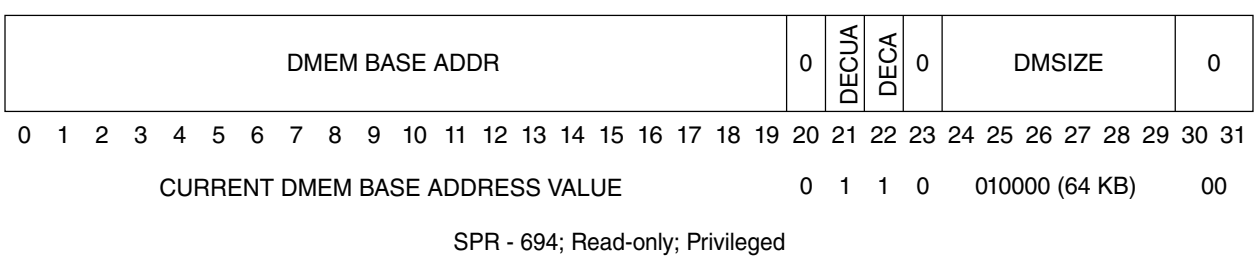

Figure 15-27. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 15-40. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port)

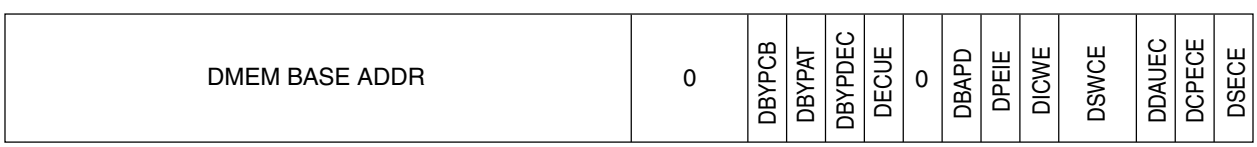
Table continues on the next page...

Table 15-40. DMEMCFG0 field descriptions (continued)

Bits	Name	Description
		This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

15.10.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.



DCR - 496; Read/Write; Reset[1] - 19'b0 || p_dmem_rstcfg[8,6:7,0] || 4'b0 || p_dmem_rstcfg[1:5]; Privileged

Figure 15-28. DMEM Control Register 0 (DMEMCTL0)

Note

[1] Reset by an internal power-on reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 15-41. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16 :18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[8]** input, which is internally hard coded.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[6]** input, which is internally hard coded.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface.

Table continues on the next page...

Table 15-41. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		Note: This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[7]** input, which is internally hard coded.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[0]** input which is internally hard coded.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits.
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected.

Table continues on the next page...

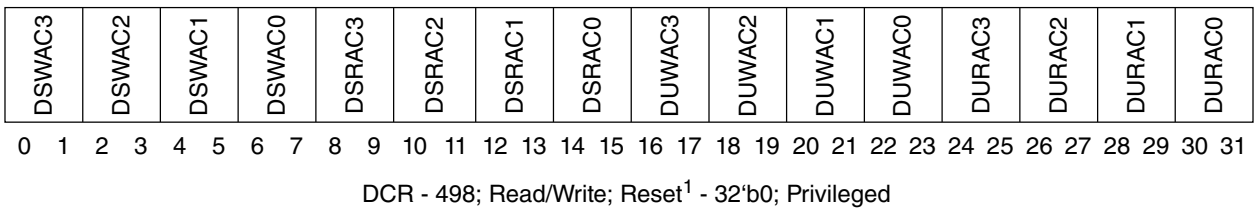
Table 15-41. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the values of the **p_dmem_rstcfg[1:2]** inputs, which are internally hard coded.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[3]** input, which is an internally hardcoded signal.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[4]** input, which is internally hard coded.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal based on the value of the **p_dmem_rstcfg[5]** input, which is an internally hard coded signal.

15.10.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally

sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed. All other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.



DCR - 498; Read/Write; Reset[1] - 32‘b0; Privileged

15.10.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the e200z710n3 local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in the following figure.

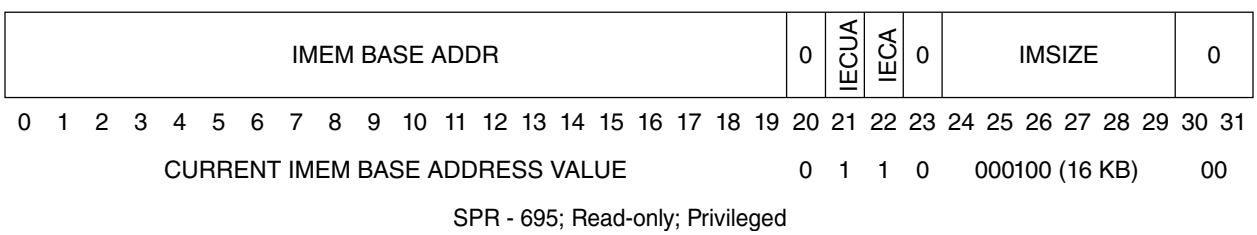

Figure 15-30. IMEM Configuration Register 0 (IMEMCFG0)

The IMEMCFG0 fields are described in the following table.

Table 15-43. IMEMCFG0 field descriptions

Bits	Name	Description
0:19	IMEM BASE ADDR	IMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the IMEM. This field reflects the value of the external IMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of IMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0's when the IMEM size is > 4 KB
20	—	Reserved
21	IECUA	IMEM Error Correction Update Available IECUA indicates an error scrubbing function for the IMEM is available. 0 Error Correction Update is not available

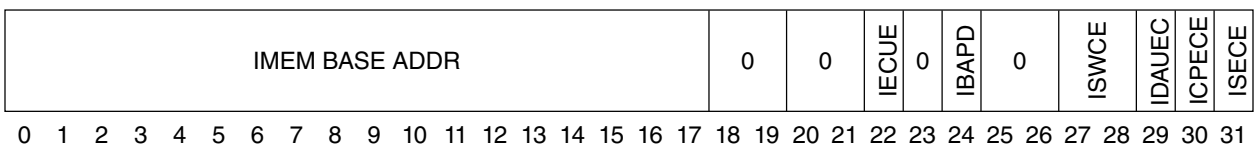
Table continues on the next page...

Table 15-43. IMEMCFG0 field descriptions (continued)

Bits	Name	Description
		1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access
22	IECA	IMEM Error Correction Available IECA indicates an error correction function for the IMEM is available. 0 Error Correction is not available 1 Error Correction is available
23	—	Reserved
24:29	IMEM Size	IMSIZE - IMEM Size 000100 The size of the IMEM is 16 KB
30:31	—	Reserved

15.10.2.5 IMEM Control Register 0 (IMEMCTL0)

The IMEM Control Register 0 (IMEMCTL0) controls operation of certain functions of the IMEM logic.



DCR - 497; Read/Write; Reset[1] - 22'b0 ||| p_imem_rstcfg[0] || 4'b0 || p_imem_rstcfg[1:5]; Privileged

Figure 15-31. IMEM Control Register 0 (IMEMCTL0)

Note

[1] Reset by an internal Power-On-Reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 15-44. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.
18:19	—	Reserved for Base Address extension
20:21	—	Reserved

Table continues on the next page...

Table 15-44. IMEMCTL0 field descriptions (continued)

Bits	Name	Description
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[0]** input, an internally hard coded signal. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1-, 2-, or 3-byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the values of the **p_imem_rstcfg[1:2]** inputs, which are internally hard coded signals.
29	IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[3]** input, which is an internally hard coded signal.
30	ICPECE	IMEM CPU Port ECC Enable (CPU port)

Table continues on the next page...

Table 15-44. IMEMCTL0 field descriptions (continued)

Bits	Name	Description
		0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[4]** input, which is an internally hard coded signal.
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** This field is updated by an internal Power_On_Reset signal or an internal Destructive Reset signal based on the value of the **p_imem_rstcfg[5]** input, which is an internally hard coded signal.

15.10.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

15.11 End-to-End ECC Support

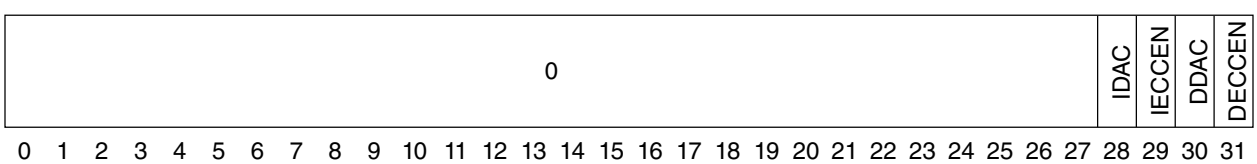
This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

15.11.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

15.11.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.



DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 15-33. e2eECC Control Register 0 (E2ECTL0)

Table 15-46. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses.

Table continues on the next page...

Table 15-46. E2ECTL0 field descriptions (continued)

Bits	Name	Description
		0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The E2ECTL0$_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.11.1.2 End-to-End ECC fault injection by software

Fault injection provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits). For the case of an external read access that receives an ERROR response (HRESP=ERR), the RCHKBIT field is written with all zeros.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 15-34. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 15-47. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked). If the CPU receives an ERROR response (HRESP=ERR) on an external read access, the RCHKBIT field is written with all zeros.
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further fault injection. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 16
System Integration Unit Lite2 (SIUL2)

16.1 Introduction

16.1.1 Overview

The System Integration Unit Lite2 (SIUL2) provides control over all the I/O ports on this device and supports 22 ports with 16 bits of bidirectional, general-purpose input and output signals. It supports ten external interrupts with trigger event configuration. The figure below is the block diagram of SIUL2 and its interfaces to other system components for this device.

The SIUL2 provides the GPIO ports on the device.

- When configured as output, you can write to the internal GPDO register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from the internal GPDI register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking the driven value on the associated I/O pad.

In order to assist in software development, there are different access mechanisms to the GPIO data registers. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16-bit ports in one access
- Read/Write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access

There are nine external interrupt/DMA inputs to the SIUL2 that map to EIRQ pins on the device. The interrupt/DMA sources can be configured to have a digital filter to reject short glitches on the inputs.

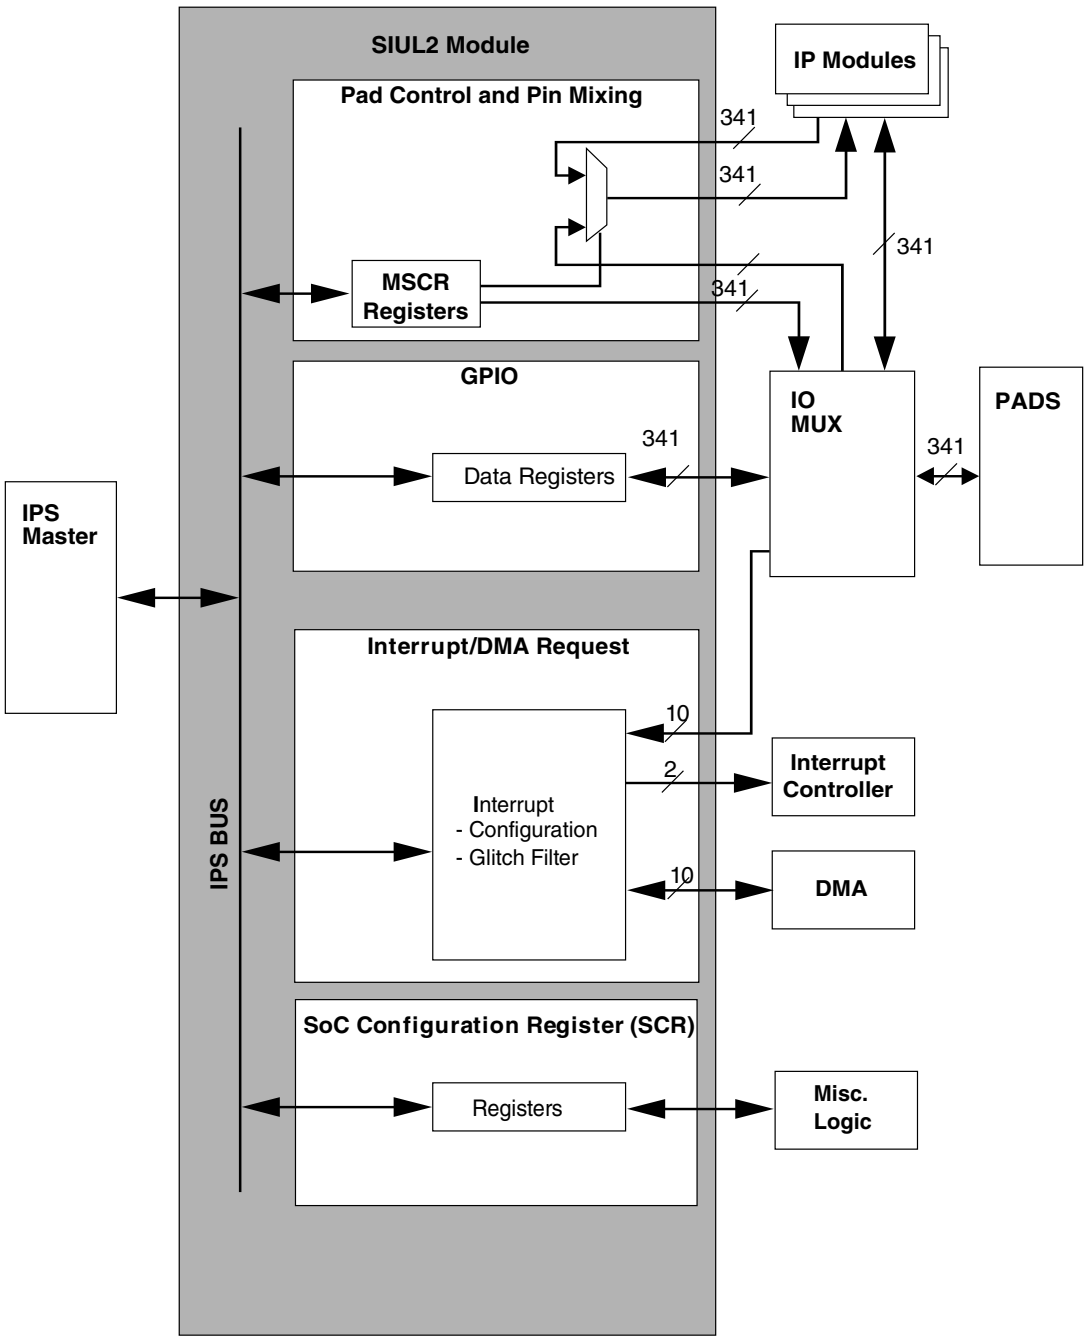


Figure 16-1. SIUL2 block diagram

16.1.2 Features

The SIUL2 supports these distinctive features:

- GPIO ports with data control
  - Drive data to up to 16 independent IO channels
  - Sample data from up to 16 independent IO channels

Read values on two (16-bit) ports at once (PGPDI register), or write values on two ports at once (PGPDO register) with a 32-bit r/w.

External interrupt/DMA request support with:

- Two system interrupt vectors for 10 interrupt sources (10 connected to EIRQ pins for this device) with independent interrupt mask
- 10 programmable digital glitch filters (one for each EIRQ)
- Independent DMA channel for each EIRQ pin
- Edge detection

Additionally the SIUL2 contains the multiplexed signal configuration registers that configure the electrical parameters and settings of all functional pads. These are used to configure the following pad features:

- Drive strength, output impedance, and slew rate control via OERC bits
- INV capability, HYS switch, and IBE switch for source input enable
- Open drain/source output enable
- Internal weak pull control
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration
- TTL, CMOS, and Automotive input levels

16.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0(SIUL2_DIRER0)

- SIUL2 DMA/Interrupt Request Select Register 0(SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0(SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0(SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0(SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 SoC Configuration Register0 (SIUL2_SCR0)
- SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

Details about the protected registers at specific addresses can be found in the Register Protection (REG_PROT) chapter and the Device Configuration chapter.

16.2 Memory map and register description

This section provides a detailed description of all registers accessible in this module.

The following table gives an overview of the module registers implemented.

NOTE

Reserved registers will be read as 0, write will have no effect. If supported and enabled in this MCU, a transfer error will be issued when trying to access completely reserved register space. A 8-bit or 16-bit access to an "only 32-bit supported access register" gives a transfer error. Unimplemented registers accesses give transfer error, i.e. due to register not being present.

NOTE

For SIUL2_MSCR_MUX_512-SIUL2_MSCR_MUX_1023, only 32/16-bit accesses are supported (8-bit writes don't occur and read zeros).

SIUL2 memory map

W																
Reset	0	0*	0*	0*	0*	0*	0	0	0*	0*	0*	1*	0*	0*	0*	0*

* Notes:
- MINOR_MASK field: Value is set at factory and will vary each revision of device.
- MAJOR_MASK field: Value is set at factory and will vary each revision of device.
- PKG field: Only possible to change value by modifying the side band signals (in the Test Flash). Software can not modify. Default is 0b1000. Values are set at factory and cannot be modified.

SIUL2_MIDR1 field descriptions

Field	Description
0–15 PARTNUM	MCU Part Number-These digits identify the part number of the chip. Default is 5777.
16 ED	Read back as '1' if an ED device. Read back as '0' in PD.
17–21 PKG	Package Settings-Can be read by software to determine the package type that is used for the particular device: 0b11000: 416-pin BGA 0b11101: 512-pin BGA All other bit combinations are reserved for future use.
22–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 MAJOR_MASK	Major Mask Revision.

Table continues on the next page...

SIUL2_MIDR2 field descriptions (continued)

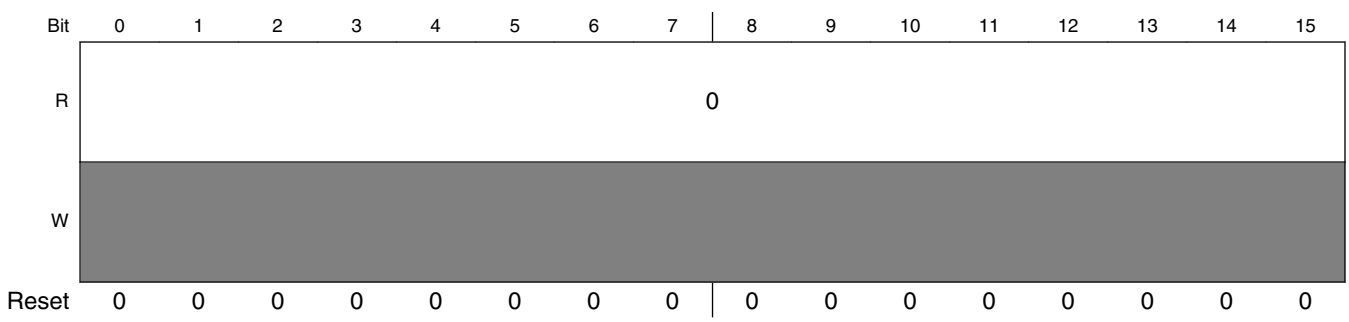
Field	Description
	0b1110: 256M 0b1111: 512M
5–8 FLASH_SIZE_2	Fine granularity for Flash memory size. Needs to be combined with FLASH_SIZE_1 to calculate the actual memory size: 0b0000: 0 x (FLASH_SIZE_1 / 8) 0b0001: 1 x (FLASH_SIZE_1 / 8) 0b0010: 2 x (FLASH_SIZE_1 / 8) ... 0b1110: 14 x (FLASH_SIZE_1 / 8) 0b1111: 15 x (FLASH_SIZE_1 / 8)
9–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 FAMILYNUM	ASCII character in MCU Part Number: 0x4D M All other values reserved for future use.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

16.2.3 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set irrespective of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) is enabled. The EIF bit remains set until cleared by software or through the servicing of a DMA request. The EIF bits are cleared by writing a '1' to the bits. A write of '0' has no effect.

This register contains the interrupt flags.

Address: 0h base + 10h offset = 10h



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_DISR0 field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 EIF11	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interruptor DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
21 EIF10	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
22 EIF9	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
23 EIF8	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIF5	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
27 EIF4	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
28 EIF3	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interruptor DMA request.

Table continues on the next page...

SIUL2_DISR0 field descriptions (continued)

Field	Description
	0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
29 EIF2	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
30 EIF1	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred
31 EIF0	External Interrupt Status Flag x-This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

16.2.4 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

Address: 0h base + 18h offset = 18h

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 EIRE11	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
21 EIRE10	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
22 EIRE9	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
23 EIRE8	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIRE5	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
27 EIRE4	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
28 EIRE3	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
29 EIRE2	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
30 EIRE1	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
31 EIRE0	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR

16.2.5 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/ Interrupt Request Enable Register0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

Address: 0h base + 20h offset = 20h

Field	Description
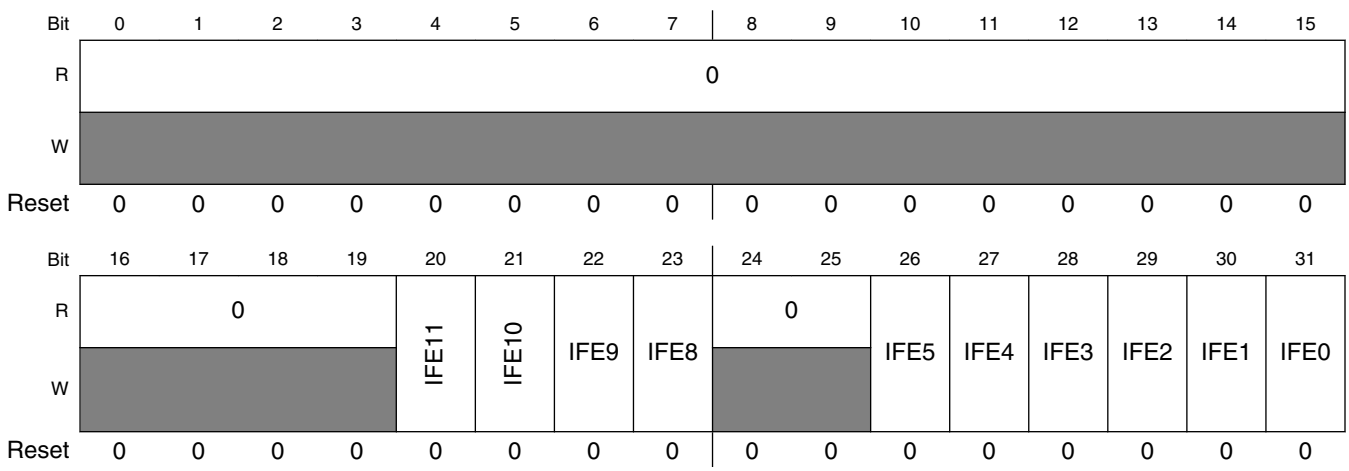
31 IFEE0	Enable falling-edge events to cause the EIF[x] bit to be set. 0 Falling-edge event is disabled 1 Falling-edge event is enabled

16.2.8 Interrupt Filter Enable Register0 (SIUL2_IFER0)

This register is used to enable a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs.

Address: 0h base + 38h offset = 38h



SIUL2_IFER0 field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 IFE11	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
21 IFE10	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
22 IFE9	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled

Table continues on the next page...

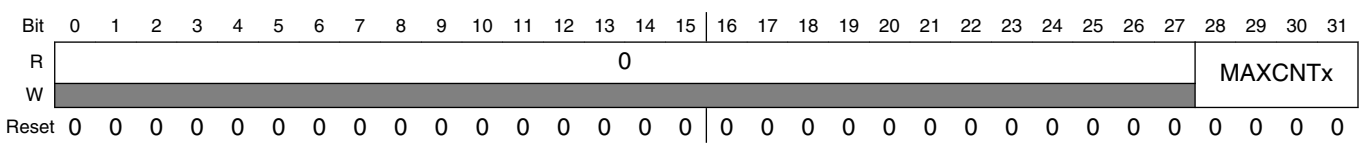
SIUL2_IFER0 field descriptions (continued)

Field	Description
23 IFE8	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 IFE5	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
27 IFE4	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
28 IFE3	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
29 IFE2	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
30 IFE1	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled
31 IFE0	Enable digital glitch filter on the interrupt pad input. 0 Filter is disabled 1 Filter is enabled

16.2.9 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR*n*)

These registers are used to configure the filter counter associated with each digital glitch filter.

Address: 0h base + 40h offset + (4d × i), where i=0d to 31d



SIUL2_IFMCR*n* field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MAXCNTx	Maximum Interrupt Filter Counter setting Filter Period = TCK*MAXCNTx + n*TCK where (n = -1 to 3) MAXCNTx can be 0 to 15 (for MAXCNT<3 filter will behave as all PASS filter) TCK is the Prescaled Filter Clock Period, which is the IRC clock prescaled to the IFCP value specified in SIUL2_IFCPR T(IRC) Basic Filter Clock Period: 62.5 ns (F=16 MHz) Also note that Filter delay is 2 system clock cycles more than Filter period. In general, Filter Period and Filter delay are not integer multiple of TCK because input to Filter is asynchronous whereas output is synchronous with respect to the TCK. T(DELAY)=(1 to 5)*TCK + MAXCOUNT*TCK. The SW is to expect the worst filter delay value.

16.2.10 Interrupt Filter Clock Prescaler (SIUL2_IFCPR)

This register configures a clock prescaler that selects the clock for all digital filters. The prescaler is applied to the input clock to the SIUL2, which is the system PBRIDGE clock counter in the SIUL2. See the clocking chapter for information on clocking.

Address: 0h base + C0h offset = C0h

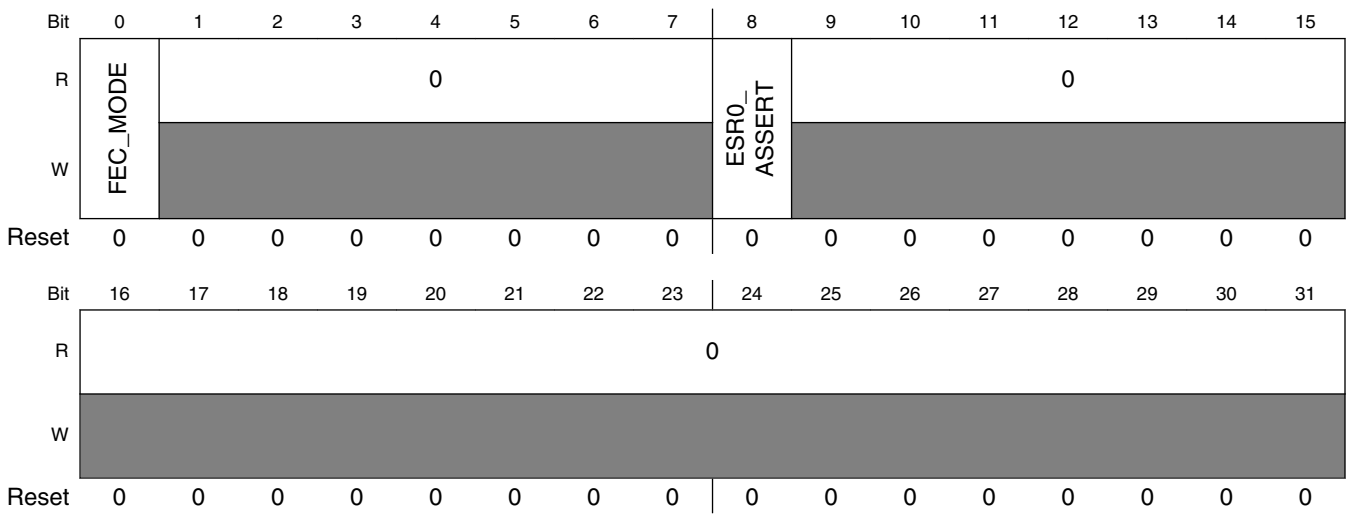
SIUL2_IFCPR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15

16.2.11 SoC Configuration Register0 (SIUL2_SCR0)

The FEC_MODE bit is used to select between the Media Independent Interface (MII) and the Reduced Media Independent Interface (RMII) mode for the Fast Ethernet controller (FEC)

Address: 0h base + 100h offset = 100h



SIUL2_SCR0 field descriptions

Field	Description
0 FEC_MODE	Fast Ethernet Controller mode setting. **NOTE:** MII/RMII pad configuration is done independently in the SIUL2 MSCRs. 0 RMII is the default state 1 MII is selected.
1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 ESR0_ASSERT	Active high signal enabling to force ESR0 as an strong pull-down 0 ESR0 status is controlled by RG 0 ESR0 status is forced low if ESR0 is configured as output only (associated DCF record DCF.UTEST_MISCELLANEOUS[ESR0_Gate] is low)
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

16.2.12 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO_*n*)

See Multiplexed Signal Configuration Registers for an introduction to the MSCRs.

This section defines the I/O pin MSCRs. These registers select the output function on the associated I/O pin.The I/O MSCRs control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, safe-mode operation, and analog input enable of the associated I/O pin.

NOTE

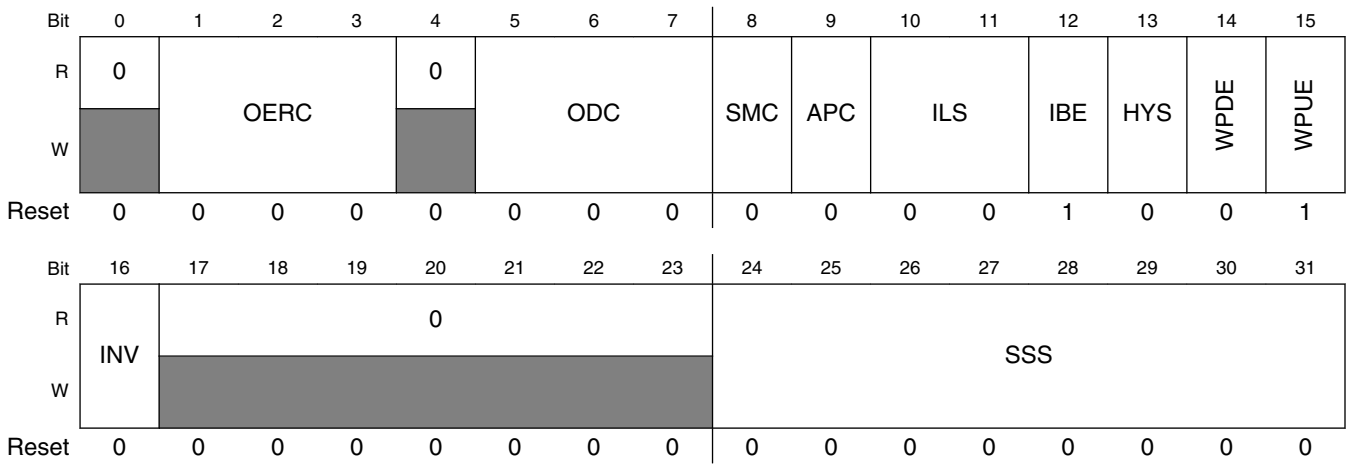
Not all pads have all bits i.e., only some pads have hysteresis. See the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

When an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs, and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

All bits and fields in the I/O MSCRs are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV, and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The MSCR reset state given in this section applies to all GPIO pins on the devices, which defaults to input/pull-up enabled. The exceptions to this are documented in the attached System_IO_Definition spreadsheet. Only the SMC, HYS, WPDE, and WPUE bits have exceptions to the default MSRC reset value.

Address: 0h base + 240h offset + (4d × i), where i=0d to 511d



SIUL2_MSCR_IO_*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 OERC	Output Edge Rate Control-Specifies the output impedance, drive strength, and slew rate of the associated pin. Refer to output Impedance columns in the I/O Signal Description Table for the applicable edge rates for each I/O pin on the device. The I/O Signal Description and Input Multiplexing Tables (Excel file) are attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. See the device data sheet for the electrical characteristics of the weak, medium, strong, and very strong pad types. **NOTE:** OERC[2] programming is required for forward compatibility. 000 Weak drive (800 ohm) 001 Medium drive (200 ohm) 010 Strong drive (50 ohm/10 ns) 011 Very strong drive (50 ohm/5 ns) 100 6 pF 101 12 pF 110 18 pF 111 30 pF
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 ODC	Output Drive Control-Specifies the type of output drive control for the associated pin. 000 Output buffer disabled 001 Open-drain 010 Push-pull 011 Open-source 100 Microsecond Channel LVDS 101 LFAST LVDS 110 Reserved 111 Reserved

Table continues on the next page...

SIUL2_MSCR_IO_*n* field descriptions (continued)

Field	Description
8 SMC	Safe Mode Control-Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. Resets to 0 except for PB[11] ERROR0 pin which resets to 1. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control-Enables the pin's analog-input-path switch if the associated pin has an analog input function. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10–11 ILS	Input Level Selection-Specifies the logic family for the associated pin, which determines its logic switching levels. See the device data sheet for the electrical characteristics of the I/O pad input buffer types. 00 Automotive 01 TTL 10 LVDS 11 CMOS
12 IBE	Input Buffer Enable-Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis-Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable-Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable-Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown. 0 Disabled 1 Enabled
16 INV	Invert-The output selected by the corresponding MSCR SSS field can be inverted before it is driven on the I/O pin with the INV bit. **NOTE:** Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection. 0 The output selected by the SSS field is not inverted before being driven to the pin 1 The output selected by the SSS field is inverted before being driven to the pin

Table continues on the next page...

SIUL2_MSCR_IO_*n* field descriptions (continued)

Field	Description
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 SSS	Source Signal Select-Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. See Chip-pin MSCR assignments and related information and Module-port MSCR assignments and SSS values.

16.2.13 Multiplexed Signal Configuration Register for Multiplexed Input Selection (SIUL2_MSCR_MUX_*n*)

See Multiplexed Signal Configuration Registers for an introduction to the MSCRs.

This section defines the multiplexed input selection MSCRs. These registers select the input source for IP blocks on the device that have inputs from multiple sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

Address: 0h base + A40h offset + (4d × i), where i=0d to 511d

SIUL2_MSCR_MUX_*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 INV	Invert- The input source signal selected by the corresponding SSS field for this MSCR can be inverted before it connects to the destination input with the INV bit. 0 SSS selected input signal is connected directly to the destination input 1 SSS selected input signal is inverted before it is connected to the destination input
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 SSS	Source Signal Select-Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value

Table continues on the next page...

SIUL2_MSCR_MUX_*n* field descriptions (continued)

Field	Description
	depends on the destination. See Chip-pin MSCR assignments and related information and Module-port MSCR assignments and SSS values.

16.2.14 GPIO Pad Data Out Register (SIUL2_GPDO*n*)

These registers can be used to set or clear a single GPIO pad with a byte access. For mapping of ports to GPDO registers, see the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Note that the GPDO registers do not apply for ports PA[5], PA[6], and PA[7]. The PA ports are JTAG pins with no GPIO. Writes to the GPDO register corresponding to these ports have no effect.

Address: 0h base + 1300h offset + (1d × i), where i=0d to 511d

Bit	0	1	2	3	4	5	6	7
Read	0							PDO
Write								
Reset	0	0	0	0	0	0	0	0

SIUL2_GPDO*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDO	Pad Data Out-This bit stores the data to be driven out on the external GPIO pad controlled by this register. 0 Logic low value is driven on the corresponding GPIO pad when the pad is configured as an output 1 Logic high value is driven on the corresponding GPIO padwhen the pad is configured as an output

16.2.15 GPIO Pad Data In Register (SIUL2_GPDI*n*)

These registers can be used to read the GPIO pad data with a byte access. For mapping of ports to GPDI registers, See the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.Note that the GPDI registers do not apply for ports PA[5], PA[6], and PA[7]. These three PA ports are JTAG pins with no GPIO. The GPDI values corresponding to these ports always read a value of zero.

Address: 0h base + 1500h offset + (1d × i), where i=0d to 511d

Bit	0	1	2	3	4	5	6	7
Read	0							PDI
Write								
Reset	0	0	0	0	0	0	0	0

SIUL2_GPDI*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDI	Pad Data In-This bit stores the value of the external GPIO pad associated with this register. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

16.2.16 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write. Note that the PGPDO registers do not apply for ports PA[5], PA[6], and PA[7]. These ports are JTAG pins with no GPIO. Writes to the PGPDO register corresponding to these ports have no effect.

NOTE

The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

Address: 0h base + 1700h offset + (2d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	PPDO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_PGPDO*n* field descriptions

Field	Description
0–15 PPDO	Parallel Pad Data Out-Write or read the data register that stores the value to be driven on the pad in output mode. Accesses to this register location are coherent with accesses to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit indices define which PPDO register bit is equivalent to which PDO register bit, according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

16.2.17 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read. Note that the GPDI registers do not apply for ports PA[5], PA[6], and PA[7]. These ports are JTAG pins with no GPIO. The GPDI values corresponding to these ports always read a value of zero

Address: 0h base + 1740h offset + (2d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	PPDI															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIUL2_PGPDI*n* field descriptions

Field	Description
0–15 PPDI	Parallel Pad Data In -Reads the current pad value. Accesses to this register location are coherent with accesses to the bit-wise GPIO Pad Data Input Registers (SIUL2_GPDI). The x and y bit indices define which PPDI register bit is equivalent to which PDI register bit, according to the following equation: PPDI[x][y] = PDI[(x*16)+y]

16.2.18 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)

This register can be used to selectively modify the pad values associated to PPDO[x] [0:15]. The MPGPDO[x] register may only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error response by the module. Read access will return 0. Note that the MPGPDO registers do not apply for ports PA[5], PA[6], and PA[7]. These are JTAG pins with no GPIO. Writes to the MPGPDO register corresponding to these ports have no effect

Address: 0h base + 1780h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIUL2_MPGPDO*n* field descriptions

Field	Description
0–15 MASK	Mask Field-Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0 The associated bit value in the MPPDO[x] field is ignored 1 The associated bit value in the MPPDO[x] field is written
16–31 MPPDO	Masked Parallel Pad Data Out-Write the data register that stores the value to be driven on the pad in output mode. Accesses to this register location are coherent with accesses to the bit-wise GPIO Pad Data Output Registers (PDO). The x and bit indices define which MPPDO register bit is equivalent to which PDO register bit, according to the following equation: MPPDO[x][y] = PDO[(x*16)+y]

16.2.19 Multiplexed Signal Configuration Registers

The MSCRs control the I/O pin function and electrical properties for each pin on the device, and are used to select the input signal for IP blocks on the device that have multiple input sources. There is a dedicated MSCR register for each I/O pin on the

device. Each MSCR is independent of the others, except in the case of an LVDS configuration, where two MSCRs must be configured together in this mode. When LVDS is configured, cmos pad is disabled (ibe and obe=0) and when LVDS is not configured, (either of two MSCRs not configured for lvds) then the lvds pad is disabled (lvds_ibe and lvds_obe=0).

The MSCRs are divided into two sets:

- I/O pin control registers, see I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO_*n*).
- Multiplexed input selection registers Multiplexed Signal Configuration Register for Multiplexed Input Selection (SIUL2_MSCR_MUX_*n*).

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in the following figure.

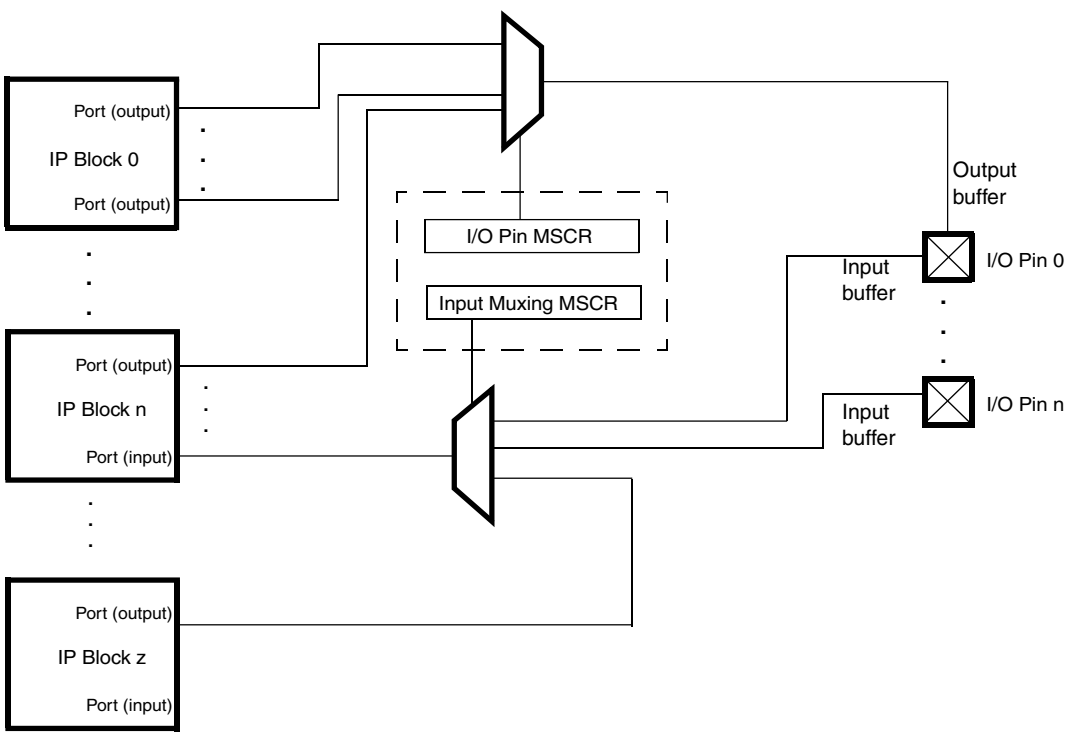

Figure 16-2. MSCR I/O Pin and IP Block Port Connectivity

16.2.20 Chip-pin MSCR assignments and related information

For device pin MSCR definitions, see the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

16.2.21 Module-port MSCR assignments and SSS values

For each internal module port that is or can be configured as an input and has more than one possible source. See the I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input Multiplexing Table tab. The Input Multiplexing Table shows the assigned MSCR, and the SSS values and their corresponding source signals.

16.3 Functional description

16.3.1 General

This section provides a complete functional description of the SIUL2.

16.3.2 Pad control

The SIUL2 is capable of controlling the electrical characteristic of 341 pads on this device. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features will be supported on all devices or on all pads as this is dependent on the specific application needs and the pads implemented on the device.

The required controls are:

- Slew rate control
  - This is needed to offer improved EMC performance.
  - Support for a fast and a slow slew rate.
- Output Impedance Control

    - 4 output impedances supported
- Drive strength control for EBI pins
    - This is needed to offer improved EMC performance.
    - Up to 4 different drive strength levels can be supported.
- Internal weak pull capability
    - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
    - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Control of analog path switches
- Safe Mode behavior configuration
- Open drain/source enable
    - Needed to support different pads muxed (e.g. mux IIC, with non open drain pads)
- Pin Function Assignment
    - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

16.3.3 General purpose input or output pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 341 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in the following figure, all port accesses are identical with each read or write being performed only at a different location to access a different port width.

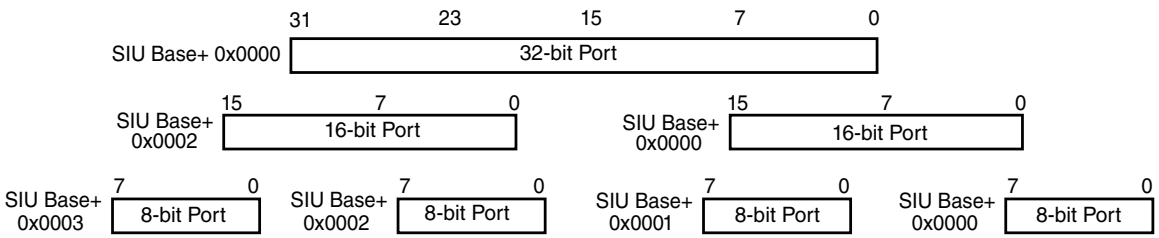

Figure 16-3. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non GPIO), this write will not be reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note

In case the bi-directional operation impacts some performances (e.g. ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only".

16.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports nine external interrupts that are allocated to EIRQ pins on the device.

The SIUL2 supports two interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support eight external interrupt sources from the device pads.

Refer to the following figure for an overview of the external interrupt implementation.

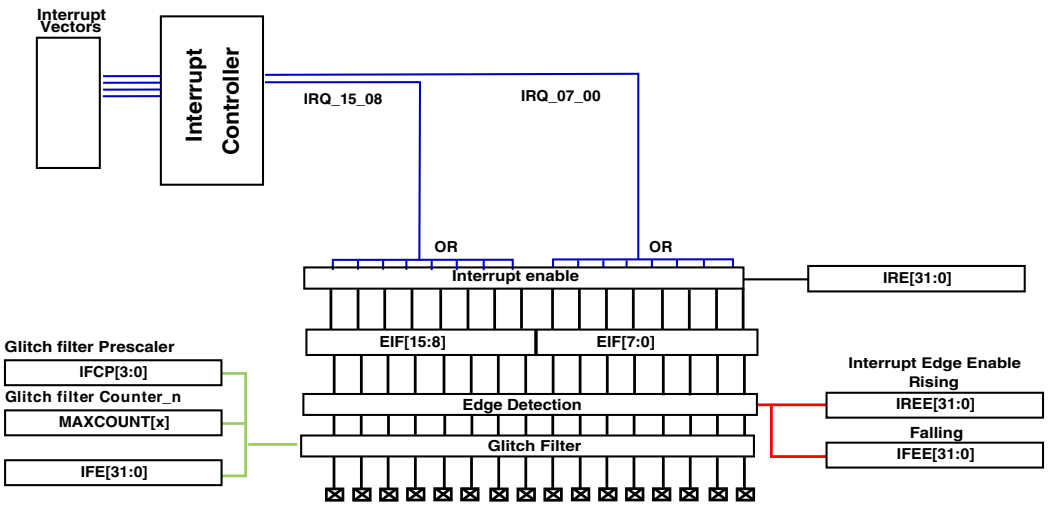

Figure 16-4. External interrupt pad diagram

All the external interrupt pads within a single group (max 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

16.3.5 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

1. Mask interrupts by clearing the EIREn bits in DIRER0.
2. Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
3. Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
   a. Clear the ODC bits to do disable output.
   b. Set the IBE bit to enable the pin's input buffer.
   c. If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note

MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

1. Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
2. Select the desired glitch filter setup for the pins by writing the following:
   a. Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
   b. Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR.
   c. Then enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

Note

The glitch filter clock runs on the internal RC oscillator clock whereas the SIUL logic runs off of the PBRIDGEx clock. The IRC clock is at a fixed frequency of 16 MHz. The PBRIDGEx clock can run as high as 50 MHZ when core clock is at 300 MHz.

The glitch filter is enabled on IRC clock, so make sure at least one IRC clock occurs after enabling it before trying to detect glitchless events.

3. Write to EIFn bits in DISR0 to as desired to clear any flags (For DMA, its self clearing).
4. Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

16.3.6 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (SIUL2_DIRER0—Figure 5). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag that is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

This device supports two SIUL2 interrupt vectors aggregating a total of nine external interrupt sources as shown in the following figure.

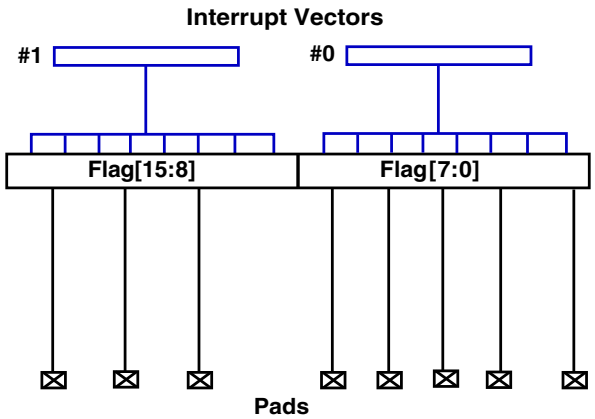

Figure 16-5. Interrupt to vector mapping at MCU level

16.3.7 External interrupt request

The EIRQ input pins on the device are sources for interrupt or DMA requests. The EIRQ pins for the device map to two interrupt requests. The mapping of interrupt requests and EIRQ pins is given in the following table.

Table 16-1. Interrupt source mapping to SIUL2 interrupt request output

Interrupt requests	EIRQ pins
0	EIRQ0 | EIRQ1 | EIRQ2 | EIRQ3 | EIRQ4 | EIRQ5
1	EIRQ8 | EIRQ9 | EIRQ10 | EIRQ11

16.3.8 Interrupt Vector

The EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note

See the Chapter 7, Device Configuration, Table 42 for Interrupt Vector table, DMA requests.

The EIRQ pins on the device map to an independent DMA request channel in the DMA controller.

Note

See the Chapter 7, Device Configuration, Table 45 for DMA request mapping table.

Chapter 17
Crossbar Switch (XBAR)

17.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

17.1.1 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
- • Concurrent accesses from different masters to different slaves
  • Configurable slave arbitration attributes on a slave-by-slave basis
- 64-bit datapath width
- Support for 8-, 16-, 32-, and 64-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers including a 4-beat, 64-bit burst for cache line accesses
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

17.2 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require two bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the Chip Configuration details for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

17.2.1 XBAR Priority Registers Slave (XBAR_PRS*n*)

NOTE

See Chip Configuration section for this device's reset values.

The priority registers (XBAR*x*_PRS*n*) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. The XBAR*x*_PRS*n* register is read-only; attempts to write to it have no effect on it and result in a bus-error response to the master initiating the write.

See the "Crossbar switch configuration" section in the chip-specific details for XBAR*x*_PRS*n*priority values.

XBAR_CRS*n* field descriptions

Field	Description
0 RO	Read only Forces both of the slave port's registers to be read-only. After set, only a hardware reset clears it. 0 The slave port's registers are writable. 1 The slave port's registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
1 HRP	Halt Request Priority Determines if a request to halt the crossbar is treated as the highest priority request, or the lowest priority request. 0 The halt request has the highest priority for arbitration on this slave port. 1 The halt request has the lowest initial priority for arbitration on this slave port.
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 HPE7	High Priority Enable Determines if Master 7 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 7 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 7 can temporarily elevate the priority level of the master's request to the slave.
9 HPE6	High Priority Enable Determines if Master 6 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 6 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 6 can temporarily elevate the priority level of the master's request to the slave.
10 HPE5	High Priority Enable Determines if Master 5 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 5 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 5 can temporarily elevate the priority level of the master's request to the slave.
11 HPE4	High Priority Enable Determines if Master 4 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 4 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 4 can temporarily elevate the priority level of the master's request to the slave.
12 HPE3	High Priority Enable

Table continues on the next page...

XBAR_CRS*n* field descriptions (continued)

Field	Description
	Determines if Master 3 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 3 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 3 can temporarily elevate the priority level of the master's request to the slave.
13 HPE2	High Priority Enable Determines if Master 2 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 2 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 2 can temporarily elevate the priority level of the master's request to the slave.
14 HPE1	High Priority Enable Determines if Master 1 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 1 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 1 can temporarily elevate the priority level of the master's request to the slave.
15 HPE0	High Priority Enable Determines if Master 0 is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master 0 are ignored and are treated the same as regular requests. 1 High Priority requests from Master 0 can temporarily elevate the priority level of the master's request to the slave.
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 ARB	Arbitration mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PCTL	Parking control Determines the slave port's parking control. The low-power park feature results in overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field.

Table continues on the next page...

XBAR_CRS*n* field descriptions (continued)

Field	Description
	01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11 Reserved
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **NOTE:** Only select master ports that are actually present on the device. If not, undefined behavior may occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

17.3 Functional description

This section provides the functional details of the crossbar switch.

17.3.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
- An outstanding request to one slave port that has a long response time and
- A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes. When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being IDLEd by the crossbar, it can park the slave port on the master port indicated by the XBAR*x*_CRS*n*[PARK]. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using XBAR*x*_CRS*n*[PCTL].

17.3.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

17.3.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

17.3.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the XBAR*x*_PRS*n* (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer or a locked transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master's priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

17.3.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

17.3.3.3 Priority assignment

Each master port needs to be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (XBAR*x*_PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

17.4 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

Chapter 18
Crossbar Integrity Checker (XBIC)

18.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core's decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

18.2 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
  - hready, hresp0, and hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

18.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in Figure 18-1 and Figure 18-2.

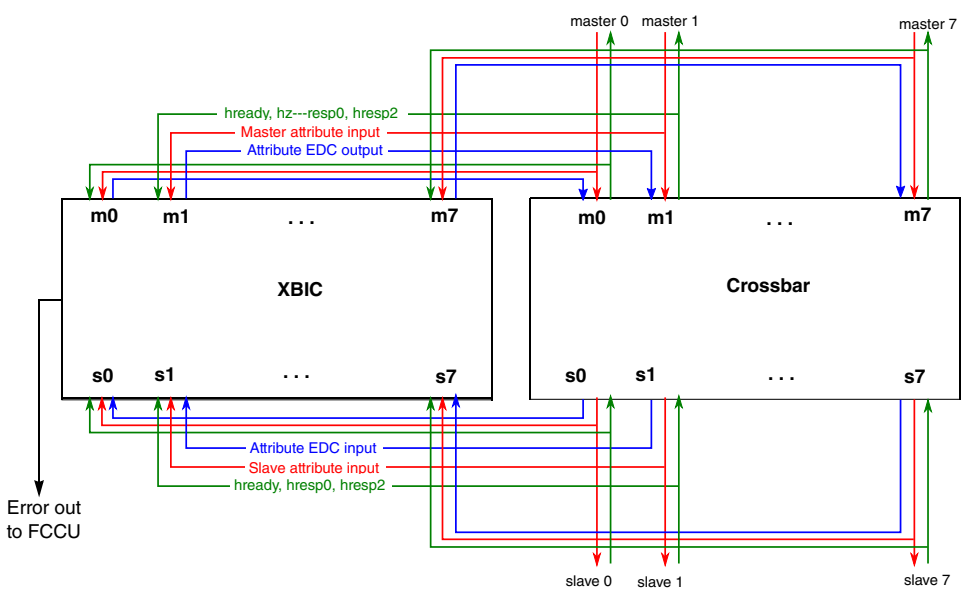

Figure 18-1. XBIC system block diagram

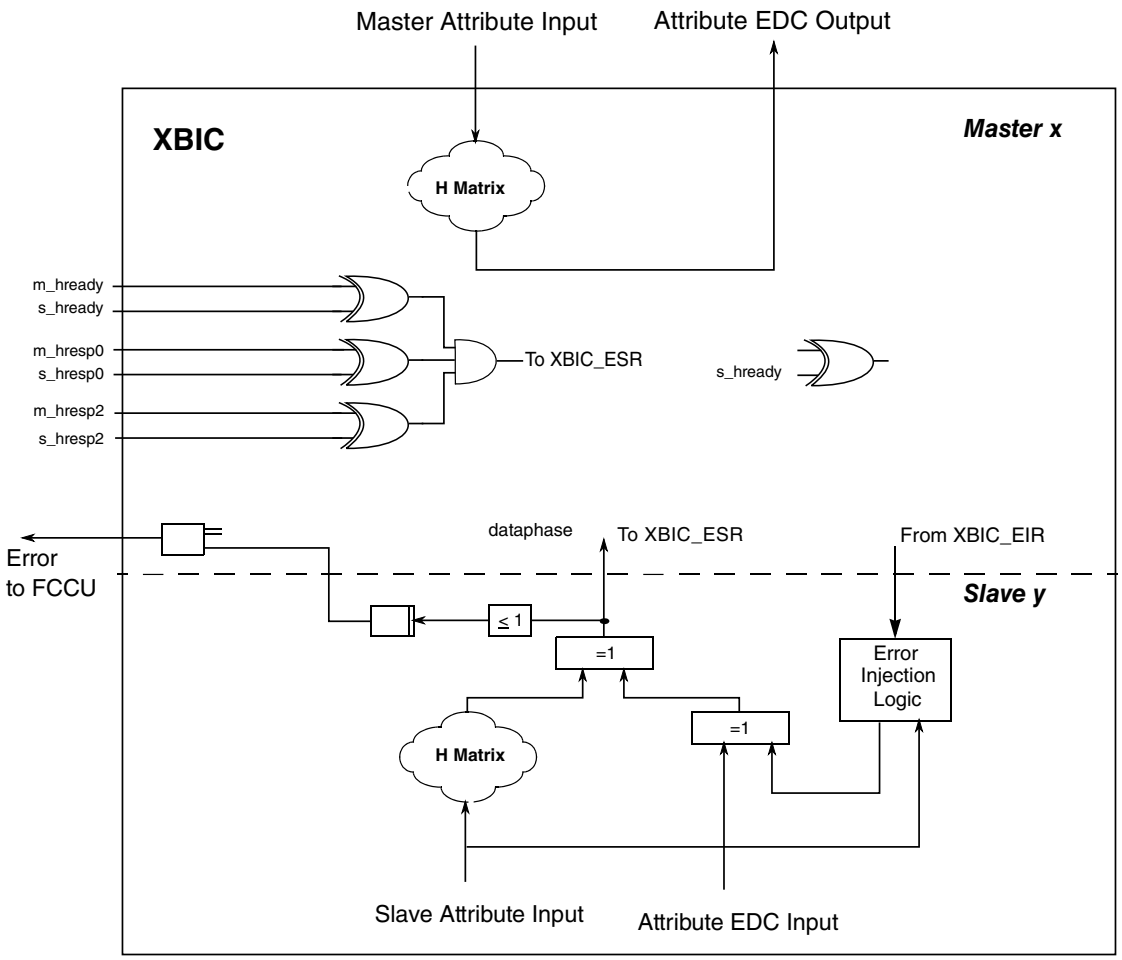

Figure 18-2. XBIC block diagram

18.4 External signal description

The XBIC has no external interface signals.

18.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

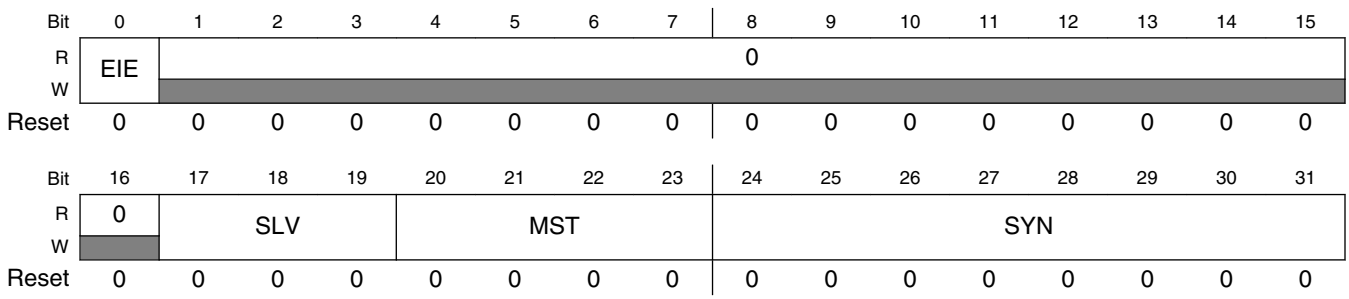
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

18.5.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Address: 0h base + 4h offset = 4h



XBIC_EIR field descriptions

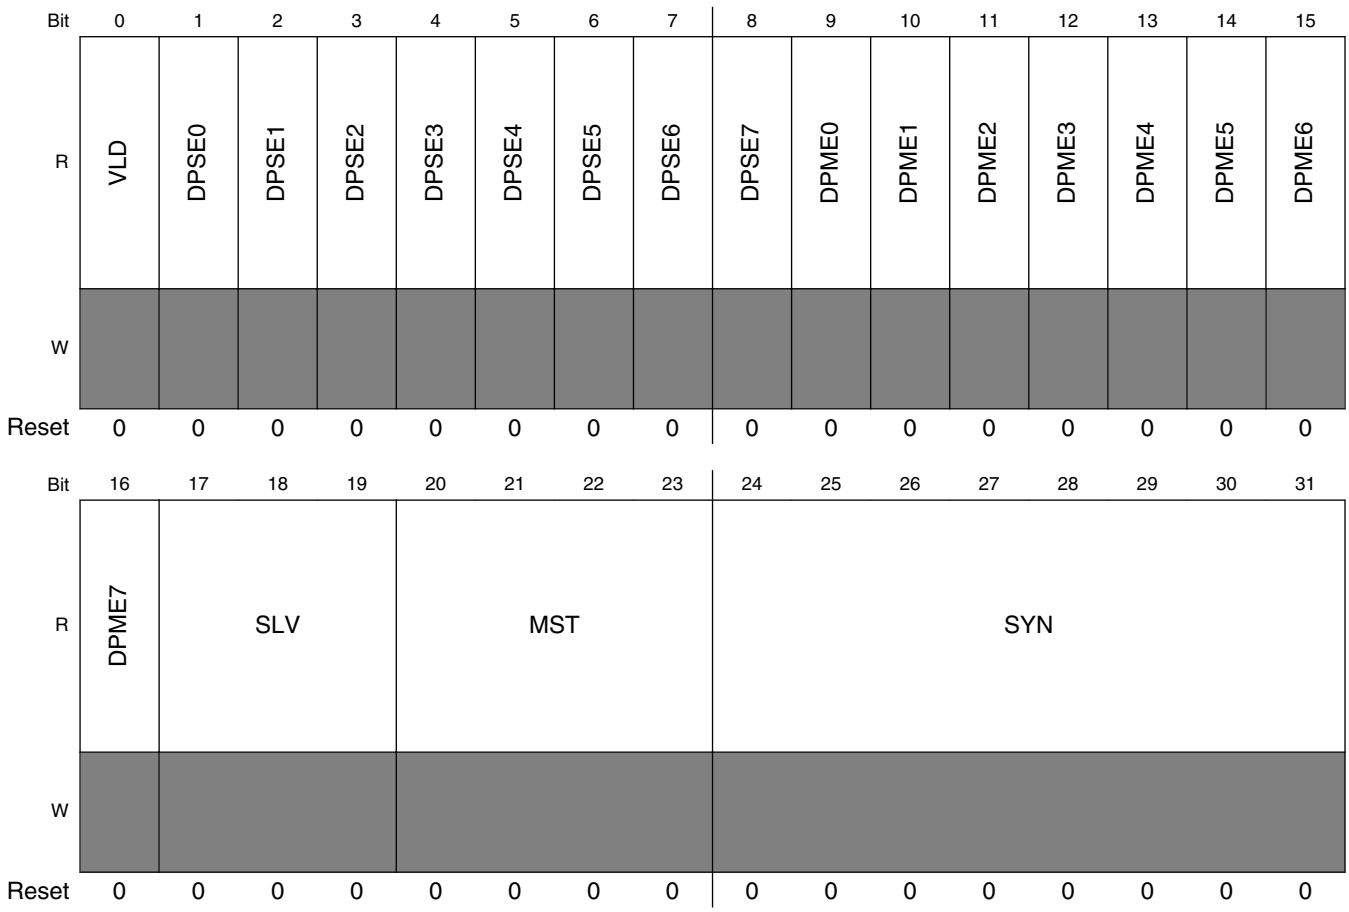
Field	Description
0 EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
1–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20–23 MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24–31 SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

18.5.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected the slave port, the master port, and the syndrome are captured in the SLV, MST, and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

Address: 0h base + 8h offset = 8h



XBIC_ESR field descriptions

Field	Description
0 VLD	Error Status Valid. 0 No error detected, other fields of the ESR and EAR are not valid. 1 Error detected, all fields of the ESR and EAR are valid.
1 DPSE0	Data phase slave port error. 0 No error on slave port 0 1 Data phase error on slave port 0

Field	Description
0–31 ADDR	The address of the last transfer with an error.

18.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal, and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified *without* compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

Forwarding errors (master to slave) are detected during the AHB address phase. When a forwarding error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in Table 18-1. Any other syndrome indicates a multi-bit error.

XBIC also detects backward signal (slave to master) errors during AHB data phase. For the three slave driven signals (hready, hresp0, and hresp2), XBIC performs the comparison between the input of the slave port and output of the master port during the AHB data phase. When a mismatch occurs, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE0-7, and the current master port will be registered in XBIC_ESR bit field DSME0-7.

Chapter 19
Peripheral Bridge (PBRIDGE)

19.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space. (Not all peripheral slots may be used. See the Device Configuration chapter or the Memory Map chapter for details on slot assignment.) The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

19.1.1 Fetures

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality

19.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

NOTE

FlexRay access to peripherals via the peripheral bridge is not supported.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map.

Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots.
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots.

All other 64-bit accesses result in an error response.

19.2 Memory map/register definition

19.2.1 Master Privilege Register A (PBRIDGE_MPRA)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. See Crossbar switch configuration for details about the master assignments to these registers.

The MPROT*n* field is defined as shown in Figure 19-1 and Table 19-1.

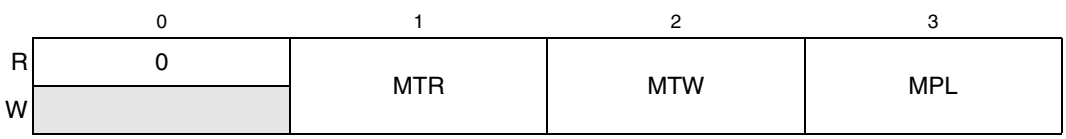

Figure 19-1. MPROT*n* fields

Table 19-1. MPROT*n* field descriptions

Field	Description
0	Reserved, should be cleared
1 MTR	Master trusted for read Determines whether the master is trusted for read accesses. 0: This master is not trusted for read accesses. 1: This master is trusted for read accesses.
2 MTW	Master trusted for writes Determines whether the master is trusted for write accesses. 0: This master is not trusted for write accesses. 1: This master is trusted for write accesses.
3 MPL	Master privilege level Determines how the privilege level of the master is determined.

Table 19-1. MPROT*n* field descriptions

Field	Description
	0: Accesses from this master are forced to user mode. 1: Accesses from this master are not forced to user mode.

19.2.3 Peripheral Access Control Register (PBRIDGE_PACR*n*)

Each of the on-platform peripherals has a four-bit PACR*n* field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. See Table 5-2 for the assignments for your particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes, and writes are ignored.

Each PACR*n* field is defined as shown in Figure 19-2.

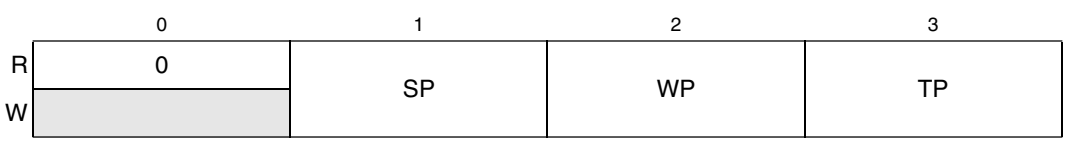

Figure 19-2. PACR*n* fields

The following table shows the top-level structure of the PACRs.

Table 19-2. PACR memory map

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

19.2.4 Off-platform Peripheral Access Control Register (PBRIDGE_OPACR*n*)

Each of the off-platform peripherals has a four-bit OPACR*n* field which defines the access levels supported by the given module. Eight OPACRs are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignments to each OPACR field are defined by the memory map slot to which the peripherals are assigned. See Table 5-2 for the assignments for your particular device. If a peripheral is absent, the corresponding OPACR is not implemented. Reads to the location return zeroes and writes are ignored.

The following table shows the top-level structure of the OPACR registers.

Table 19-4. OPACR*n* field descriptions

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0: This peripheral does not require supervisor privilege level for accesses. 1: This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT*n*[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0: This peripheral allows write accesses.

19.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

19.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

Chapter 20
System Memory Protection Unit (SMPU)

20.1 Overview

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

20.2 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, see Access evaluation macro.

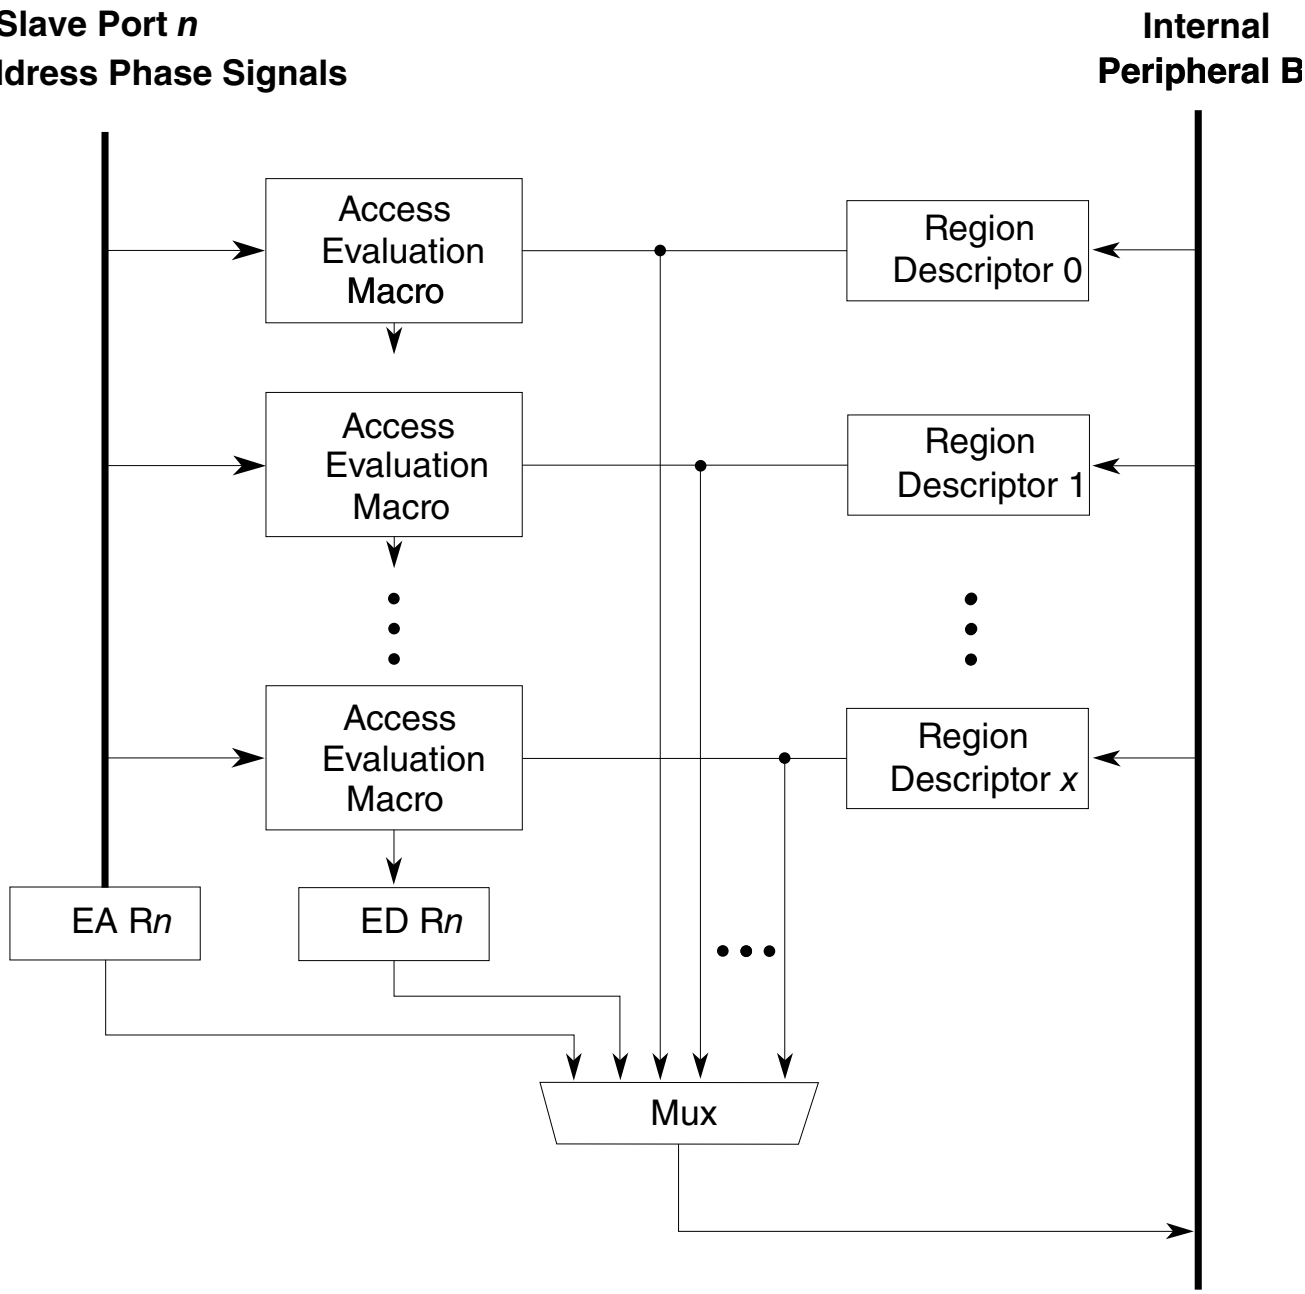

Figure 20-1. SMPU block diagram

20.3 Features

The SMPU feature set includes:

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24.)

    - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
        - Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
    - Read/write access control permissions defined in region descriptor
    - Cache-inhibit attribute indicator per region descriptor
    - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
    - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports
- Detects access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (see the documentation related to the core for details.)
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information

20.4 Memory map and register definition

The programming model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

The programming model can be accessed only in supervisor mode.

NOTE

See the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to eight region descriptors.

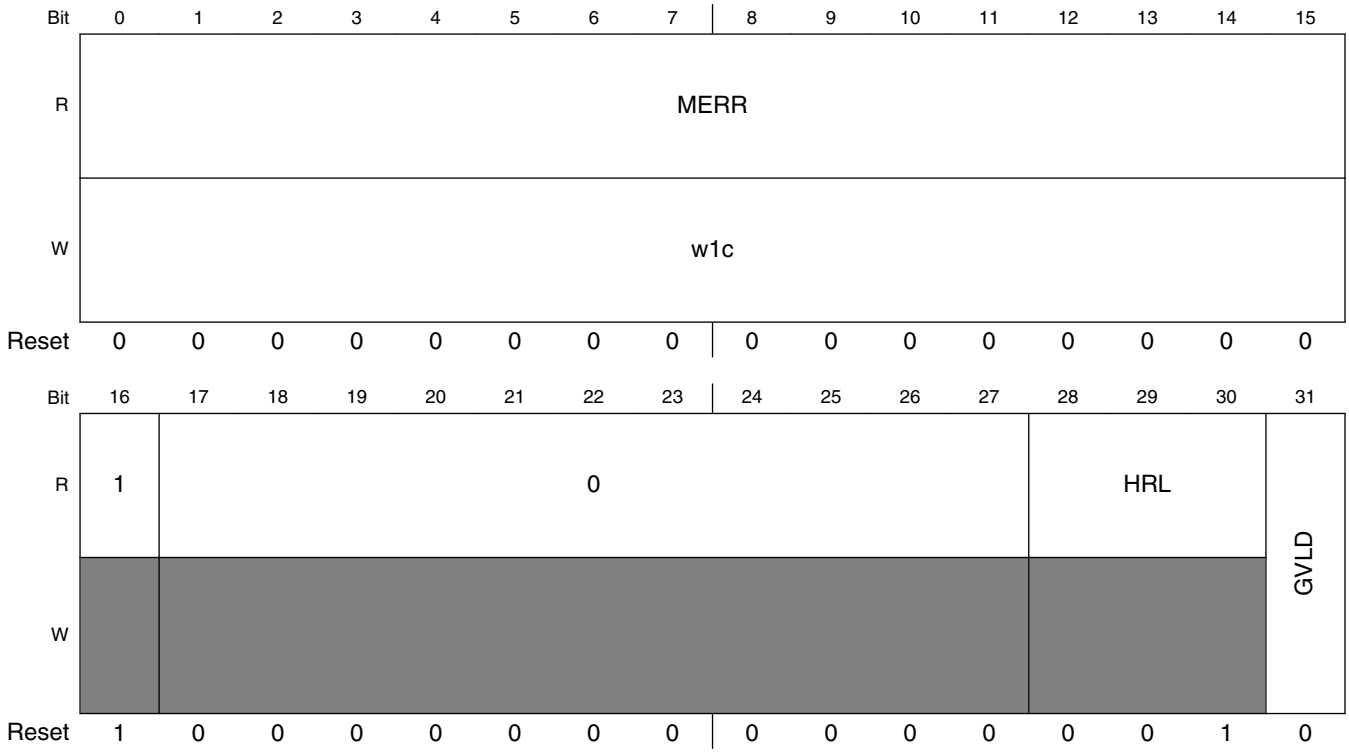
20.4.1 Control/Error Status Register 0 (SMPU_CESR0)

Address: FC01_0000h base + 0h offset = FC01_0000h



SMPU_CESR0 field descriptions

Field	Description
0–15 MERR	Master n error, where the bus master number matches the bit number Indicates a captured error in EARn and EDRn. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing '1' to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master n. 1 An error has occurred for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled

20.4.2 Control/Error Status Register 1 (SMPU_CESR1)

Address: FC01_0000h base + 4h offset = FC01_0004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MEOVR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	1	0											NRGD			
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	*	*	*	*

* Notes:
- NRGD field: NRGD[3] and NRGD[2] reset to 0. The reset value of the other bits is undefined.

SMPU_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master n error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master n has occurred before the previous error was processed. The details of the first error are recorded in the EARn and EDRn registers, and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master n. 1 An error overrun condition has been detected for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

20.4.3 Error Address Register, Bus Master n (SMPU_EAR*n*)

When the SMPU detects an access error on bus master n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Additional information about the faulting access is captured in the corresponding EDRn at the same time.

NOTE

The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the original error is processed.

Address: FC01_0000h base + 100h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_EAR*n* field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error

20.4.4 Error Detail Register, Bus Master n (SMPU_EDR*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time.

NOTE

The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the original error is processed.

Address: FC01_0000h base + 104h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

SMPU_EDR*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

20.4.5 Region Descriptor n, Word 0 (SMPU_RGD*n*_WORD0)

Address: FC01_0000h base + 400h offset + (16d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SRTADDR

SMPU_RGD*n*_WORD0 field descriptions

Field	Description
0–31 SRTADDR	Start address Defines the byte start address of the memory region.

20.4.6 Region Descriptor n, Word 1 (SMPU_RGD*n*_WORD1)

Address: FC01_0000h base + 404h offset + (16d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ENDADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. **NOTE:** The SMPU does not verify that ENDADDR >= SRTADDR.

20.4.7 Region Descriptor n, Word 2 Format 0 (SMPU_RGD*n*_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3[FMT] field.

NOTE

RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: FC01_0000h base + 408h offset + (16d × i), where i=0d to 11d

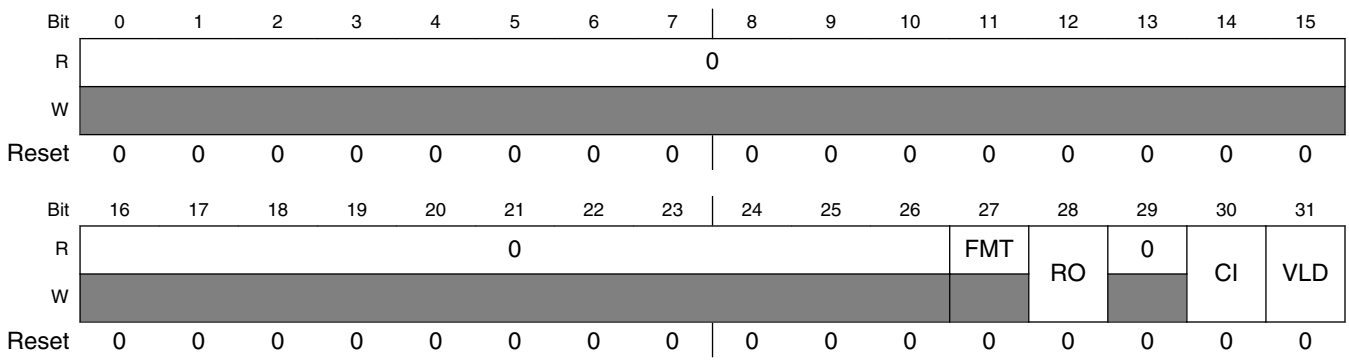
20.4.8 Region Descriptor n, Word 3 (SMPU_RGD*n*_WORD3)

The final word of the SMPU region descriptor contains the valid bit, the format select (FMT), plus other configuration bits.

Address: FC01_0000h base + 40Ch offset + (16d × i), where i=0d to 11d



SMPU_RGD*n*_WORD3 field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. **NOTE:** A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies. 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **NOTE:** Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect.

Table continues on the next page...

SMPU_RGD*n*_WORD3 field descriptions (continued)

Field	Description
	0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **NOTE:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0-2 clears this bit. 0 Region descriptor is invalid 1 Region descriptor is valid

20.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

20.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in Figure 20-2, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD*n*), then performs two major functions: region hit determination and detection of an access protection violation. Figure 20-2 shows a functional block diagram.

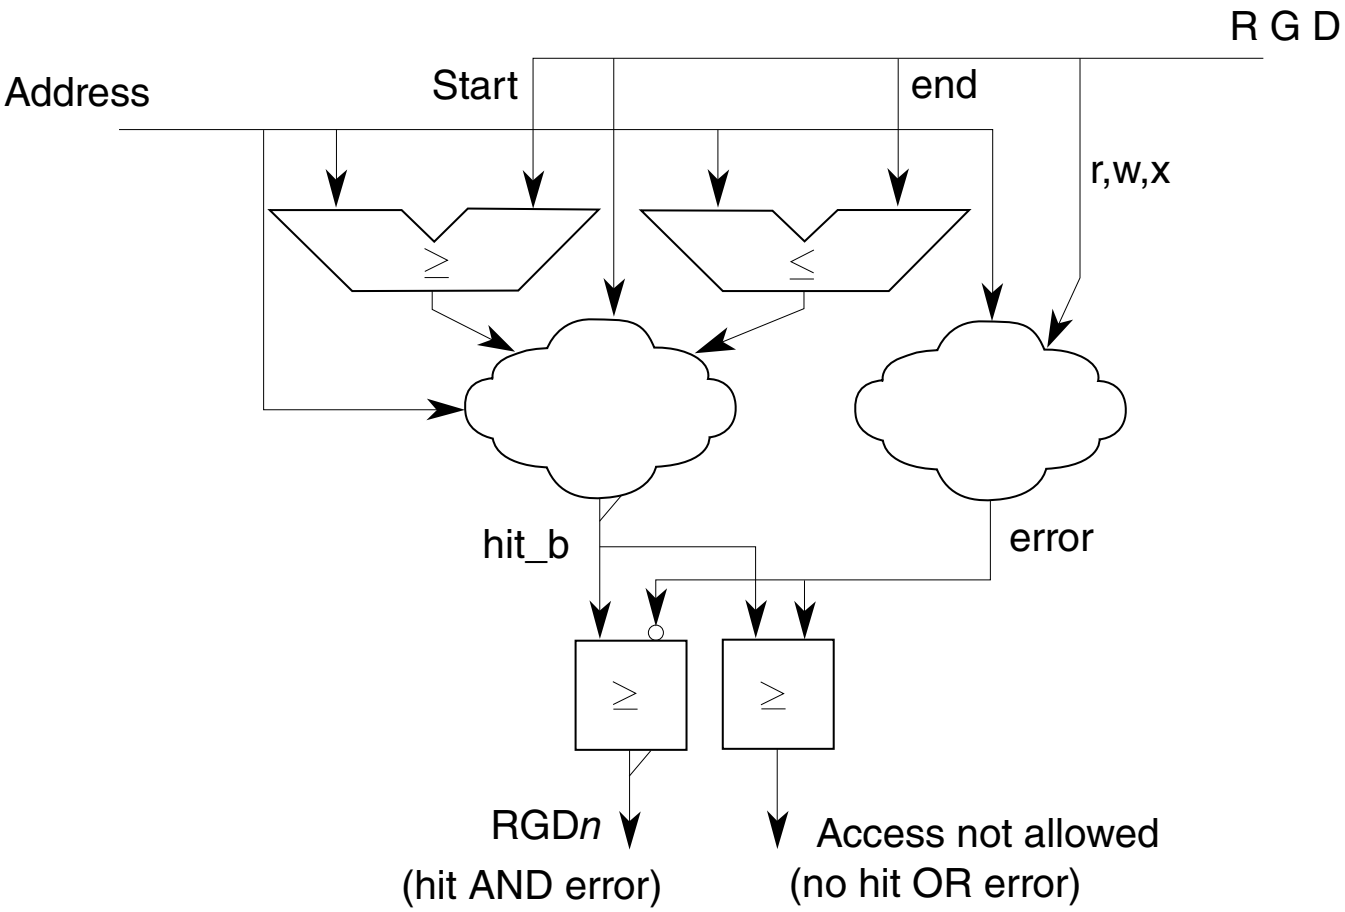


Figure 20-2. SMPU access evaluation macro

20.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit =          ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
                     (addr[0:31] <= RGDn_Word1[ENDADDR])) &
                     RGDn_Word3[VLD]
```

where addr is the current reference address, RGDn_Word0[SRTADDR] and RGDn_Word1[ENDADDR] are the start and end addresses, and RGDn_Word3[VLD] is the valid bit.

Note

The SMPU does not verify that ENDADDR ≥ SRTADDR.

Note

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

20.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in Table 20-1.

Table 20-1. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

20.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see Application information.

20.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGDn_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD] = 0). Next, load the appropriate region descriptors (RGD*n*), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

20.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Modifying a region descriptor—Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor—Clearing RGD*n*_Word3[VLD] deletes an existing region descriptor.
- Accessing the SMPU—Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus

master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals. The error registers contain the captured fault data.

- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters: the two processors (CP0, CP1) and two DMA engines (DMA1, a traditional data movement engine transferring data between RAM and peripherals, and DMA2, a second engine transferring data to/from the RAM only). Consider the following region descriptor assignments:

Table 20-2. Overlapping region descriptor example

Region description	RGDn	CP0	CP1	DMA1	DMA2	System memorymap space
CP0 code	0	rwx	r--	—	—	Flash
CP1 code	1	r--	rwx	—	—	
CP0 data & stack	2	rw-	—	—	—	RAM
CP0 → CP1 shared data	2 3	r--	r--	—	—	
CP1 → CP0 shared data	4					
CP1 data & stack	4	—	rw-	—	—	
Shared DMA data	5	rw-	rw-	rw	rw	
SMPU	6	rw-	rw-	—	—	Peripheral space
Peripherals	7	rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map (flash, RAM, and peripheral space). Each region indicates the specific permissions for each of the four bus masters, and this definition provides an assigned set of shared, private, and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1, and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1

to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the peripheral bus is partitioned into two regions: one containing the SMPU's programming model accessible only to the two processor cores and the remaining peripheral region accessible to both processors and the traditional DMA1 master.

This simple example is intended to show one possible application of the capabilities of the SMPU in a typical system.

Chapter 21
Intelligent AHB Gasket (IAHBG)

21.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 21-1 lists the available operation modes.

Table 21-1. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

21.2 Timing modes

21.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. The pending read can either be a single or burst transaction.

21.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is not shown because it is very similar to the 2:1 mode. The pending read can either be a single or burst transaction.

21.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master. The 1:4 mode is not shown because it is very similar to the 1:2 mode. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write..

Chapter 22
Semaphores2 (SEMA42)

22.1 Introduction

The peripheral platform shell includes a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

The capabilities provided by the hardware semaphore module are currently utilized in Freescale's dual-core AUTOSAR® implementations, and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

NOTE

What is AUTOSAR? From Wikipedia: AUTOSAR (AUTomotive Open System ARchitecture) is an open and standardized automotive software architecture, jointly developed by automobile manufacturers, suppliers and tool developers.

22.1.1 Multi-core programming 101: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism that is then used by system software to control access to shared data structures, shared hardware resources, and so on. These gating mechanisms are used by the software to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered to be locking (or closing) a software gate. Once the gate has been locked, a properly architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate; in other words, other processes/processors are locked out. Many software implementations include a *spin-wait loop* within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a gate variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but this does not matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*]

Next, consider the features, programming model, and functional operation of the hardware semaphore module.

22.1.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 16 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent core processor *X*
  - Gates appear as an *n*-entry byte-size array with read and write accesses (*n* = 16, 32, 64).
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked

if gate = 0x1, then state = locked by processor (master) 0
if gate = 0x2, then state = locked by processor (master) 1
…
if gate = 0xF, then state = locked by processor (master) 14

- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.

- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses

A simplified block diagram of the Semaphores module is shown in the following figure. In the diagram, the register blocks named gate0, gate1,…, gate (n-2), gate (n-1) include the finite state machines implementing the semaphore gates.

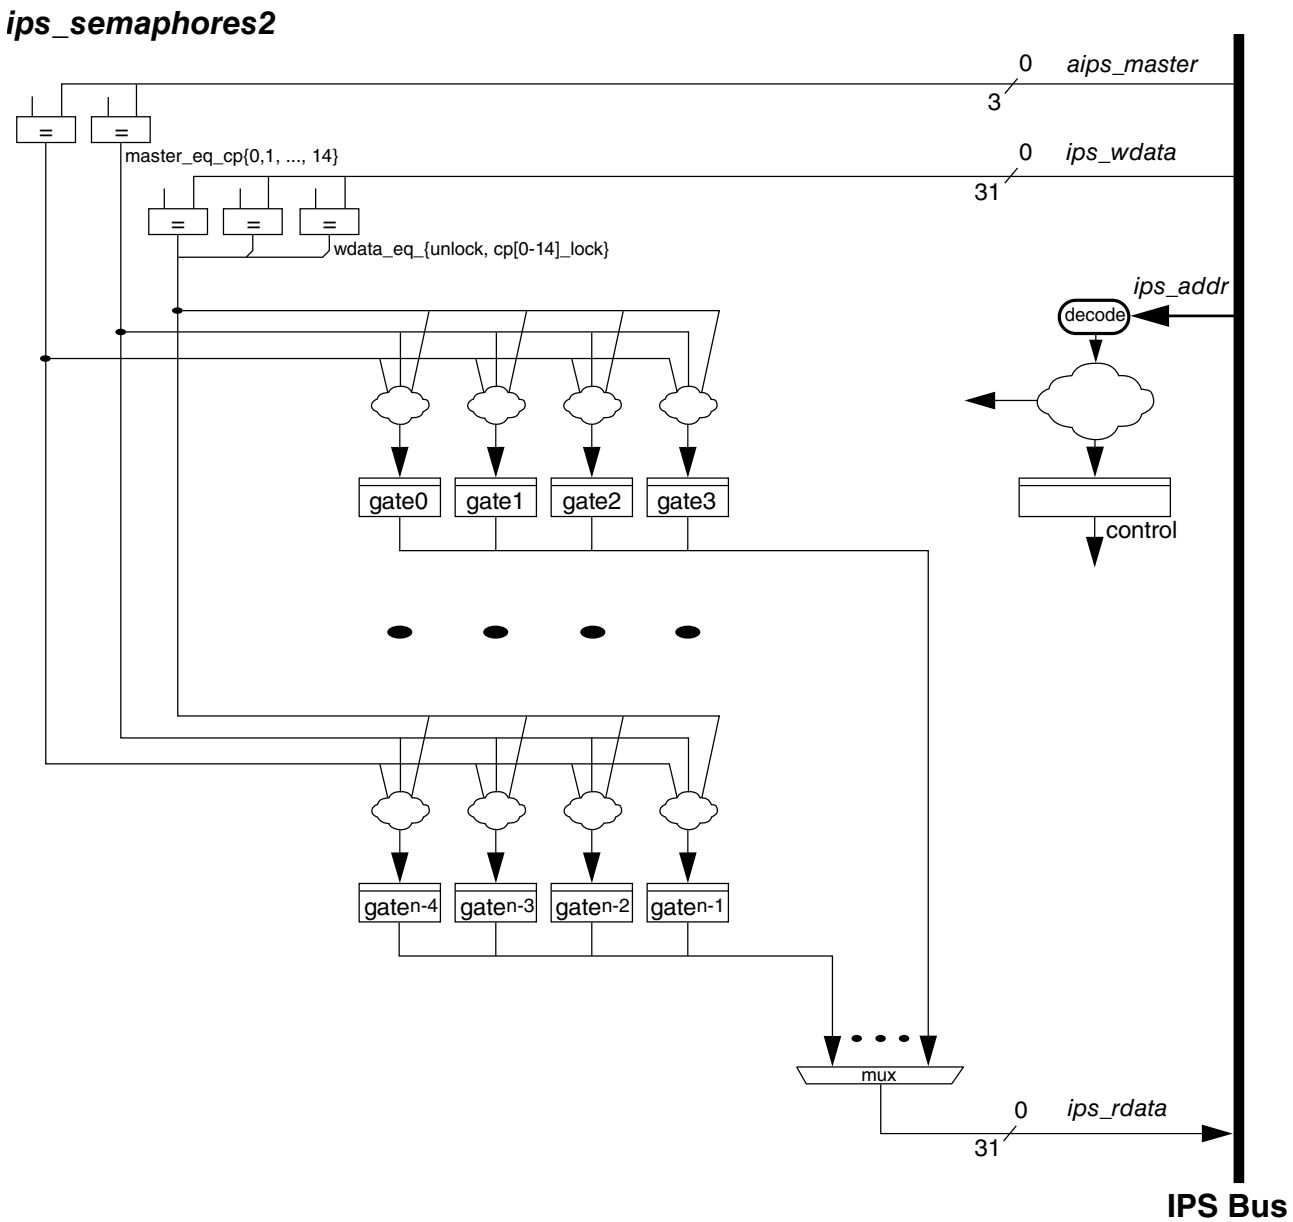

Figure 22-1. Semaphores2 block diagram

22.2 Memory map/register definition

Only Supervisor Mode accesses are allowed on these registers. User accesses generate an error termination.

SEMA42 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Gate Register (SEMA42_GATE0)	8	R/W	00h	22.2.1/830

22.2.1 Gate Register (SEMA42_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read	0				GTFSM			
Write								
Reset	0	0	0	0	0	0	0	0

SEMA42_GATE*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14.

22.2.2 Reset Gate Write (SEMA42_RSTGT_W)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA42_RSTGT memory location. The most significant byte (SEMA42_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA42_RSTGT location. For this write, the upper byte (SEMA42_RSTGT[RSTGDP]) is the logical

complement of the first data pattern (0x1D) and the lower byte (SEMA42_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or in the case where SEMA42_RSTGT[RSTGTN] = 64 or greater, all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.

3. Reads of the SEMA42_RSTGT location return information on the 2-bit state machine (SEMA42_RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (SEMA42_RSTGT[RSTGMS], and the gate number(s) last cleared (SEMA42_RSTGT[RSTGTN]). Reads of the SEMA42_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								RSTGTN							
Write	RSTGDP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA42_RSTGT_W field descriptions

Field	Description
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes by the same processor to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

22.2.3 Reset Gate Read (SEMA42_RSTGT_R)

See description for Reset Gate Write (SEMA42_RSTGT_W).

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		RSTGSM		RSTGMS				RSTGTN							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA42_RSTGT_R field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA42_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software cannot observe this state. 11 This state encoding is never used and therefore reserved.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

22.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA42_GATEn registers are provided as follows.

As described previously, each of the SEMA42_GATEn registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in Figure 22-2.

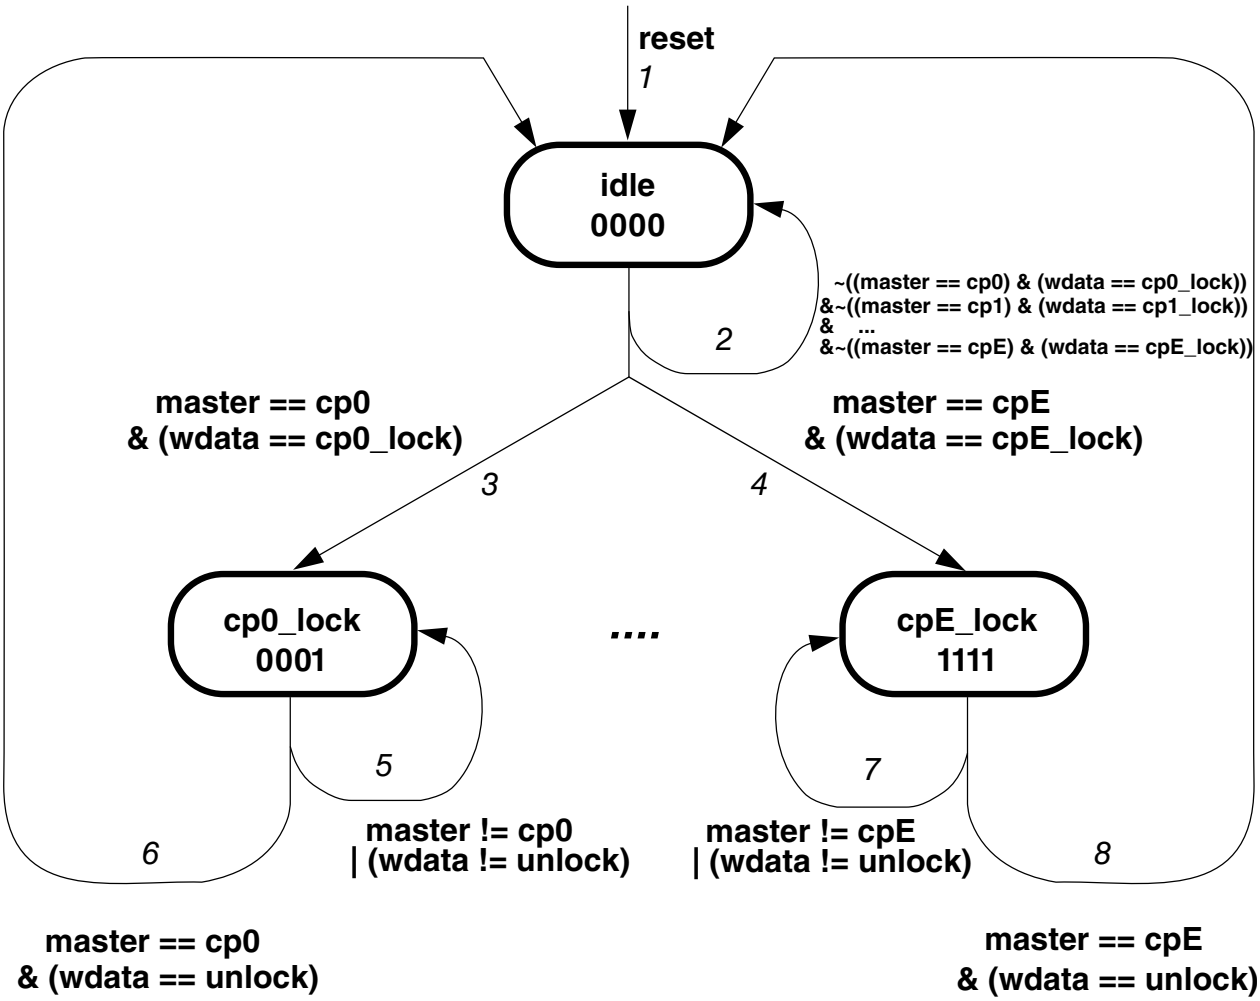

Figure 22-2. SEMA42_GATEn state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number (`hmaster[3:0]`) through the AIPS controller and drives the `aips_master[3:0]` signal to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA42_GATEn are defined in Table 22-1.

Table 22-1. SEMA42_GATEn state transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.

Table continues on the next page...

Table 22-1. SEMA42_GATEn state transitions (continued)

Current State	Next State	Transition	Description
idle	cpE_lock	4	When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

The following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

Chapter 23
Interrupt Controller (INTC)

23.1 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

23.2 Block diagram

The following figure shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

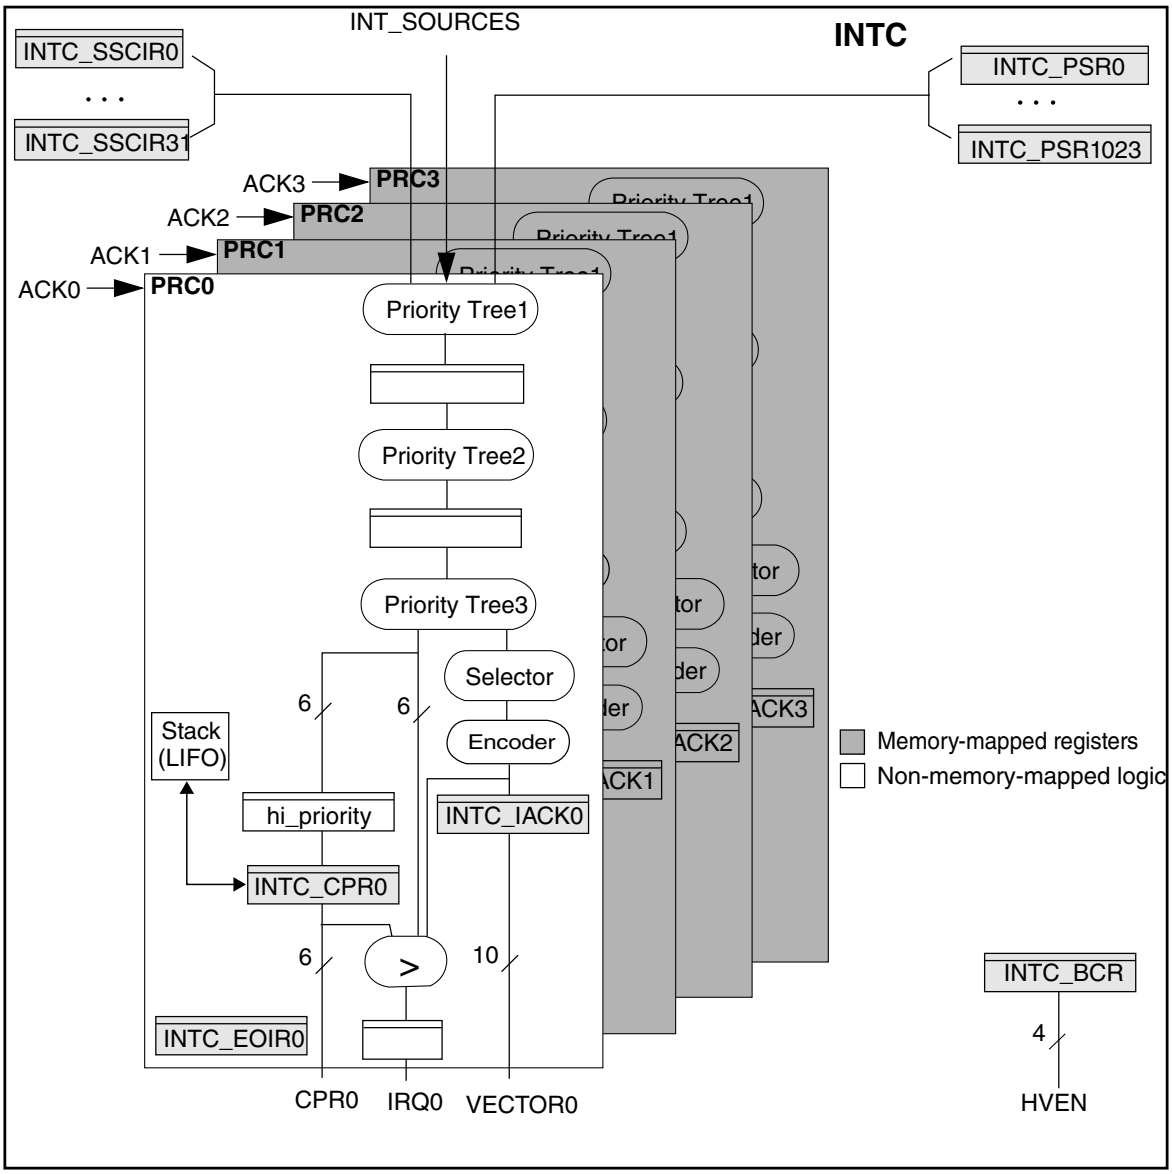

Figure 23-1. Block diagram for an INTC with four processors

23.3 Features

- Each peripheral interrupt source is software-steerable to any combination of interrupt request outputs to the following:
  - Processor 0
  - Processor 1
  - Processor 2
  - Processor 3

- 32 software-settable interrupt request sources
- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request

23.4 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

23.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRCn bit in the INTC_BCR is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers. Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn onto the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

23.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVENn bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKRn, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

23.5 Memory map and register definition

A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

With the exception of the INTC_SSCIR *n* and INTC_PSR *n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

When writing to INTC_PSRs or INTC_SSCIRs, the following restrictions (illustrated in Figure 23-2) apply:

- For PSRs, write accesses must not span 16-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).
- For SSCIRs, write accesses must not span 8-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).

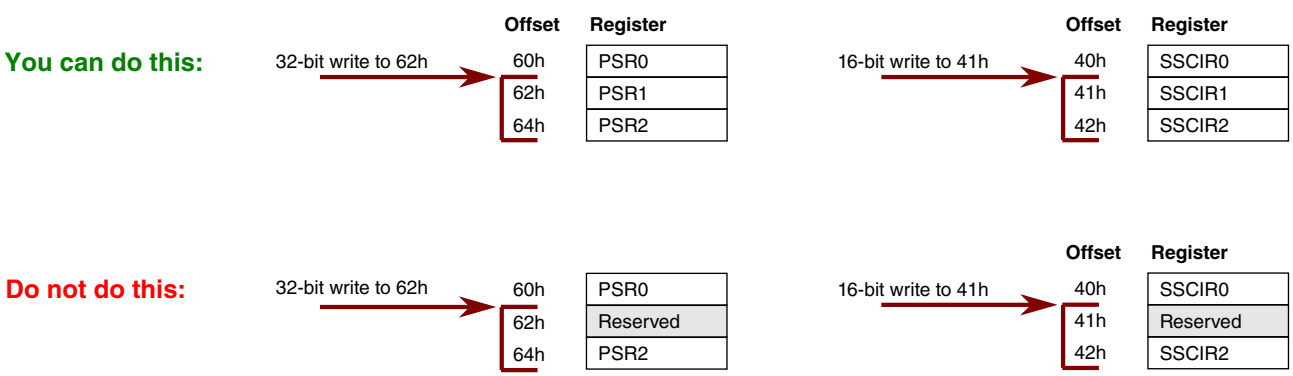

Figure 23-2. INTC_PSR*n* and INTC_SSCIR*n* write restrictions

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR *n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR *n*) does not affect the operation of the write.

23.5.1 INTC Block Configuration Register (INTC_BCR)

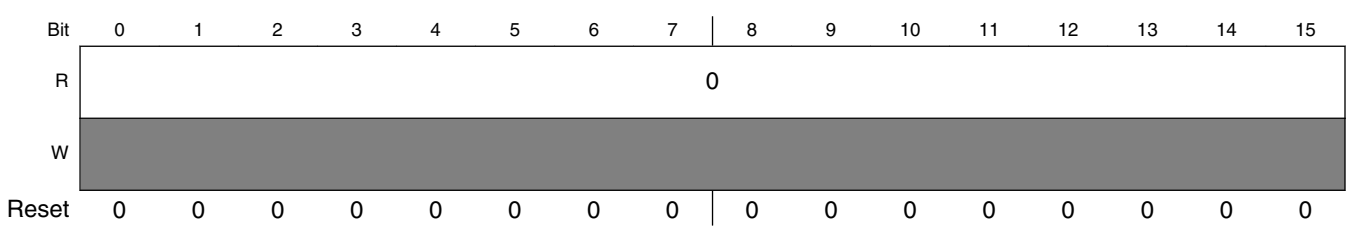
The Block Configuration Register is used to configure options of the INTC.

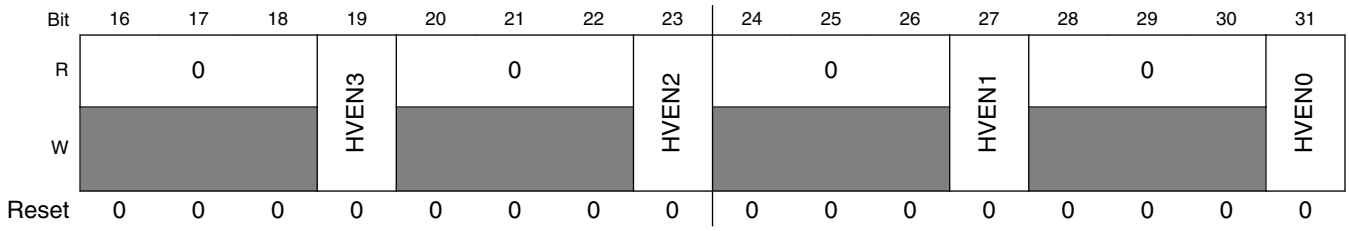
The master ID is used to determine if this register can be written by a given processor. Only the processor with master ID zero will be allowed write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Address: 0h base + 0h offset = 0h





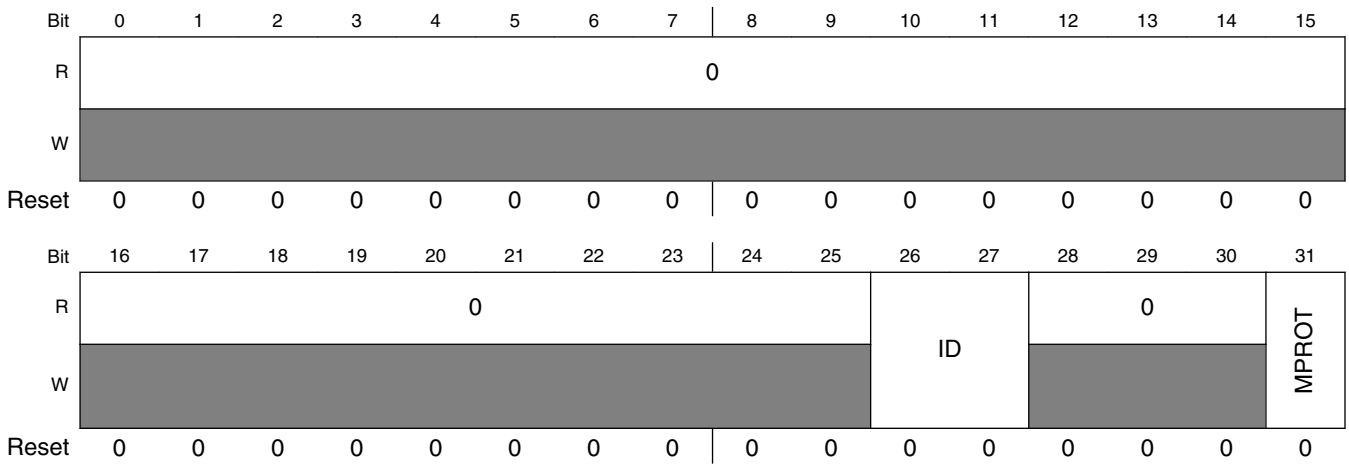
INTC_BCR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 HVEN3	Hardware vector enable for processor 3. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HVEN2	Hardware vector enable for processor 2. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 HVEN1	Hardware vector enable for processor 1. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HVEN0	Hardware vector enable for processor 0. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

23.5.2 INTC Master Protection Register (INTC_MPROT)

The Master Protection Register is used to protect cores from writing to other cores INTC registers.

Address: 0h base + 4h offset = 4h



INTC_MPROT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error. 00 master0 (reset default) 01 master1 10 master2 11 master3
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

23.5.3 INTC Current Priority Register for Processor 0 (INTC_CPR0)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

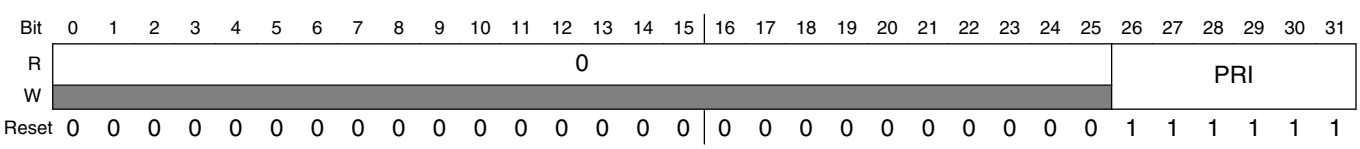
If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 10h offset = 10h



INTC_CPR0 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

23.5.4 INTC Current Priority Register for Processor 1 (INTC_CPR1)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 14h offset = 14h

INTC_CPR1 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

23.5.5 INTC Current Priority Register for Processor 2 (INTC_CPR2)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

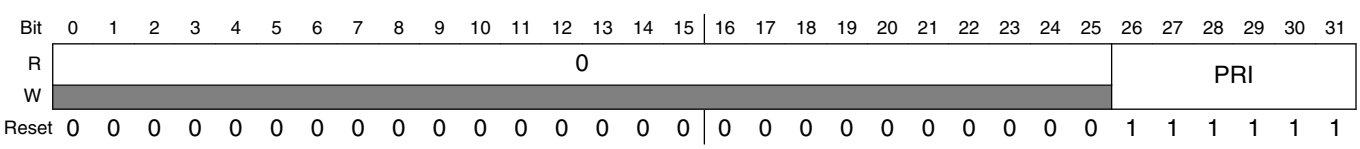
If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 18h offset = 18h



INTC_CPR2 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

23.5.6 INTC Current Priority Register for Processor 3 (INTC_CPR3)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

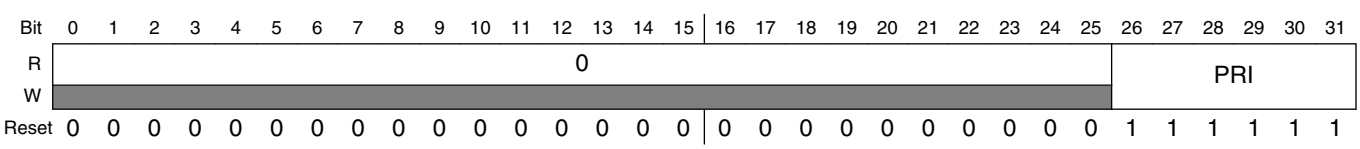
If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 1Ch offset = 1Ch



INTC_CPR3 field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

23.5.7 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

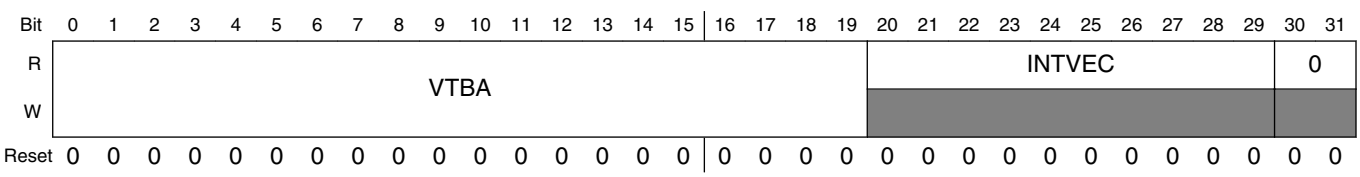
If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 20h offset = 20h



INTC_IACKR0 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

23.5.8 INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

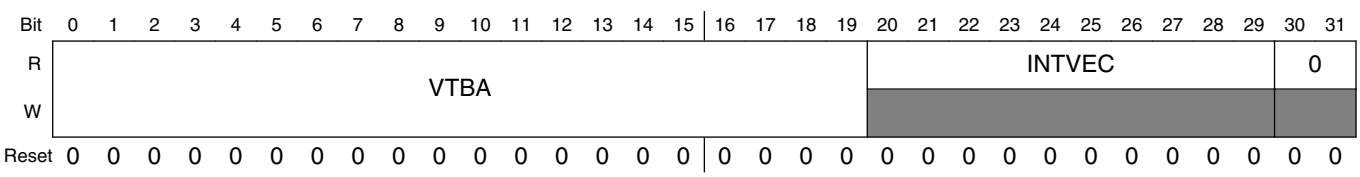
If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 24h offset = 24h



INTC_IACKR1 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

23.5.9 INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

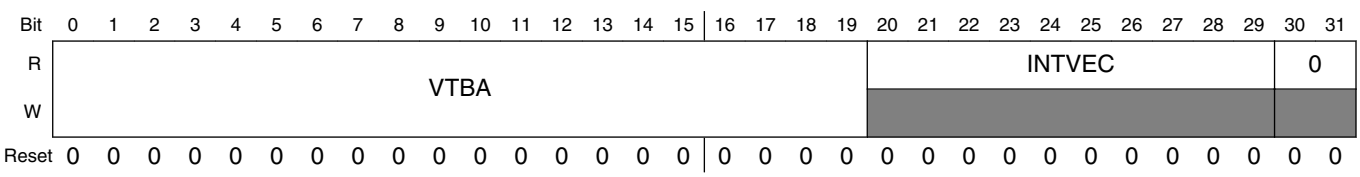
If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 28h offset = 28h



INTC_IACKR2 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

23.5.10 INTC Interrupt Acknowledge Register for Processor 3 (INTC_IACKR3)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

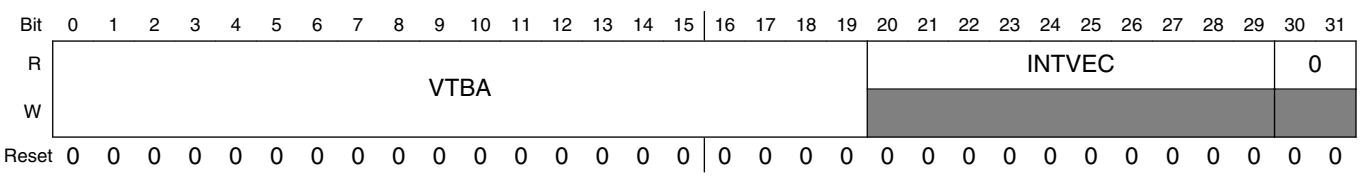
If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 2Ch offset = 2Ch



INTC_IACKR3 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

23.5.11 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)

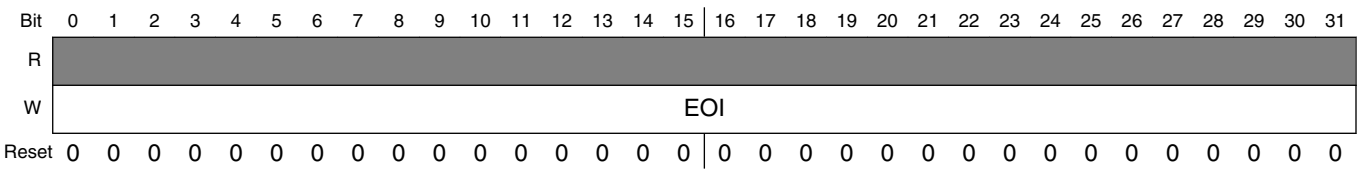
Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 30h offset = 30h



INTC_EOIR0 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.5.12 INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)

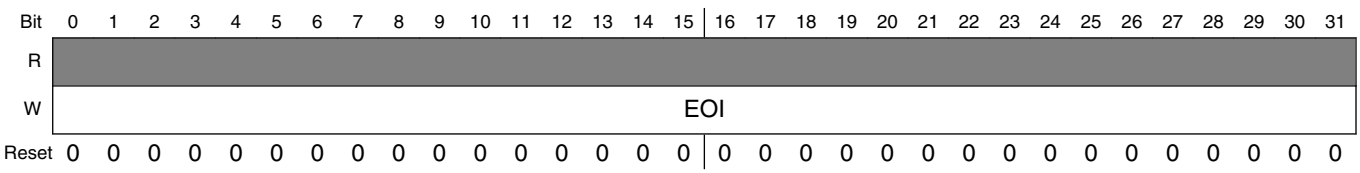
Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 34h offset = 34h



INTC_EOIR1 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.5.13 INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)

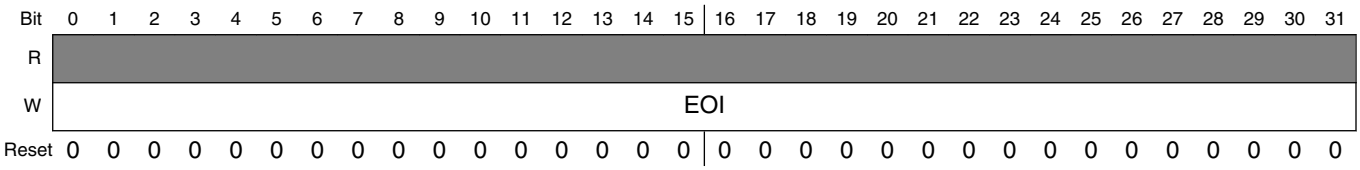
Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 38h offset = 38h



INTC_EOIR2 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.5.14 INTC End Of Interrupt Register for Processor 3 (INTC_EOIR3)

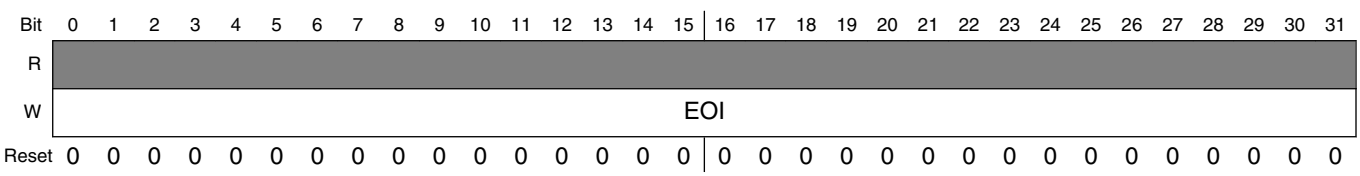
Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

The master ID is used to determine if this register can be written by a given processor. The processor with master ID zero will be allowed write access. Only the corresponding processor will have write access, otherwise, a termination error is asserted.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Address: 0h base + 3Ch offset = 3Ch



INTC_EOIR3 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.5.15 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIRn registers. The CLR bit will only be writable by the processor which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SEL]. An attempt by any other processor to write the CLR bit and not the SET bit will result in a termination error.

See Figure 23-2 for limitations on writing to this register.

NOTE

Since the four software setable interrupts in a word can be assigned to different processors, the cores with non-zero master IDs must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIRn registers.

If INTC_MPROT[MPROT]=0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit, otherwise, a termination error is asserted.

NOTE

If INTC_MPROT[MPROT] is enabled, processors with master ID != INTC_MPROT[ID] must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Address: 0h base + 40h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	0						0	CLR
Write							SET	w1c
Reset	0	0	0	0	0	0	0	0

INTC_SSCIR*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

23.5.16 INTC Priority Select Register (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC_PSR32-1023, respectively.

Only the processor with master ID zero will be allowed to write the INTC_PSRn[PRC_SEL,SWT]. When writing the INTC_PSR[PRI], only the processor with master ID 0 and the processor who's master ID matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the PSRn[PRIn] will result in a termination error.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SEL,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID (0-3) = INTC_MPROT[ID] and

the processor whose master ID (0-3) matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.

See Figure 23-2 for limitations on writing to this register.

NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

NOTE

Interrupts are not detected while the PSRs are being written.

NOTE

If INTC_MPROT[MPROT] is enabled, the core with master ID (0-3) = INTC_MPROT[ID] will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (i.e the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

NOTE

The core with master ID 0 will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the PSRn[PRIn] bits (i.e the odd addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

INTC_PSR*n* field descriptions

Field	Description
0 PRC_SELN0	Processor select 0. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 0. 0 Interrupt request not sent to processor 0 1 Interrupt request sent to processor 0
1 PRC_SELN1	Processor select 1. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 1. 0 Interrupt request not sent to processor 1 1 Interrupt request sent to processor 1
2 PRC_SELN2	Processor select 2. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 2. 0 Interrupt request not sent to processor 2 1 Interrupt request sent to processor 2
3 PRC_SELN3	Processor select 3. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 3. 0 Interrupt request not sent to processor 3 1 Interrupt request sent to processor 3
4–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWTN	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 PRIN	Priority select. Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

23.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

23.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

23.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

23.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SELn] bits.

23.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

23.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

23.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in Figure 23-1 are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

23.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

23.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

23.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

23.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

23.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

Although the INTC supports up to 64 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

23.6.3 Handshaking with processor

This section describes handshaking with the processor.

23.6.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

23.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to Figure 23-3.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 23-3. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in Software vector mode.

23.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

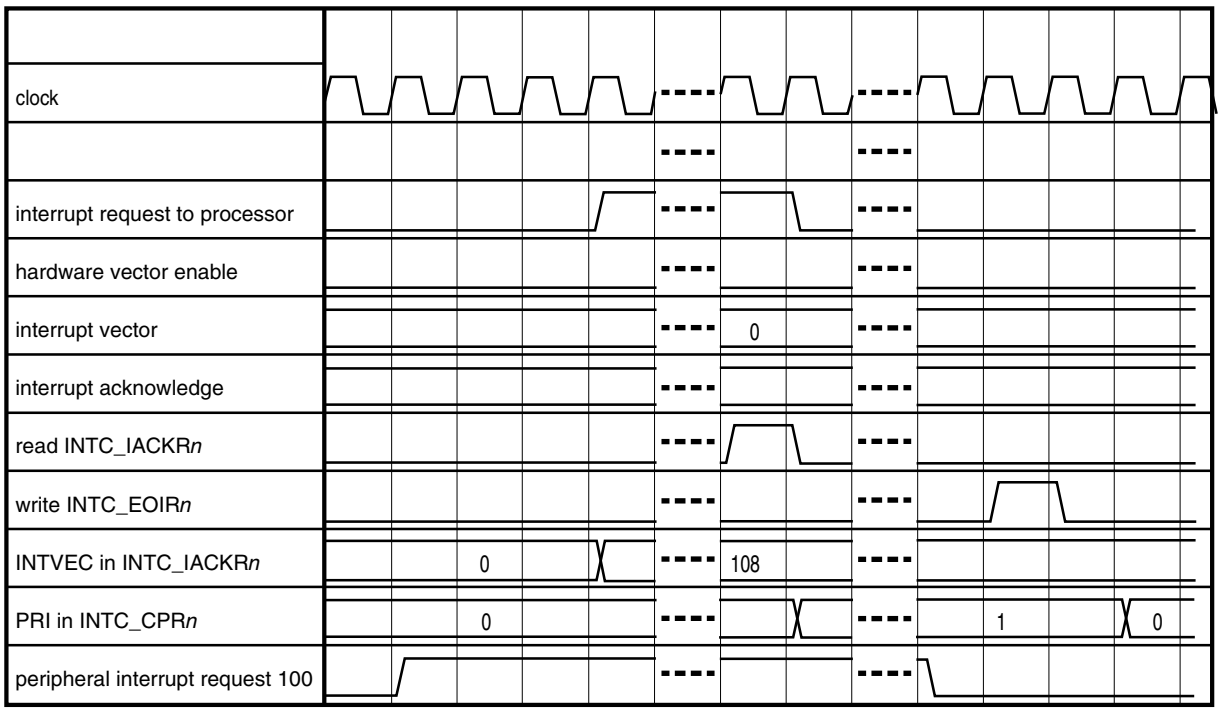

Figure 23-3. Timing diagram of software vector mode handshaking

23.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 23-4. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in Hardware vector mode.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See End of interrupt exception handler.

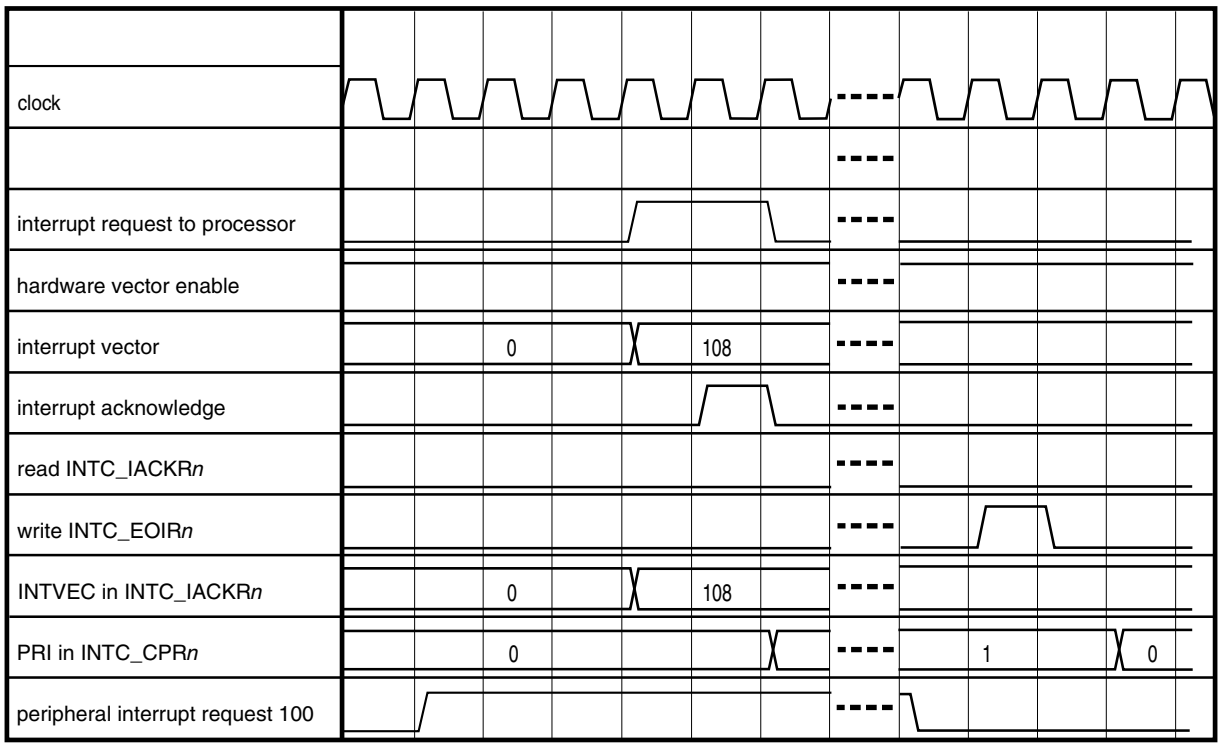

Figure 23-4. Timing diagram for hardware vector mode handshaking

23.7 Initialization/application information

This section contains initialization/application information.

23.7.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 63. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:
  - Configure HVENn in INTC_BCR.
  - Configure VTBAn in INTC_IACKRn.
  - Raise the PRIn fields and set the PRC_SELn fields to the desired processor in INTC_PSRn.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.

- Lower PRI in INTC_CPRn to zero.
- Enable processor(s) recognition of interrupts.

23.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

23.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

23.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

23.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 23-1. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1

Table continues on the next page...

Table 23-1. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

23.7.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

23.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

23.7.5.2 Ensuring coherency

This section discusses how to ensure coherency.

23.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
        wrteei 0                # disable external interrupts to the Processor
        raise PRI                # Write to CPR, cache inhibit, guarded
        mbar                    # flush out writes from store buffer
        wrteei 1                # enable external interrupts to the Processor
        isync                    # re-fetch Processor pipeline

ReleaseResource:
        mbar                    # flush out writes from store buffer
        wrteei 0                # disable external interrupts to the Processor
        lower PRI                # Write to CPR, cache inhibit, guarded
        wrteei 1                # enable external interrupts to the Processor
```

23.7.5.2.1.1 Interrupt request to processor

Referencing Figure 23-1, the interrupt request logic to the processor is shown in the following figure.

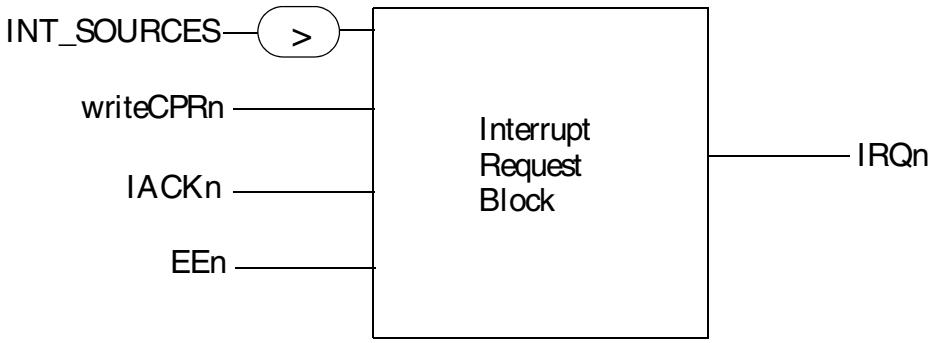

Figure 23-5. Interrupt Request Block Diagram

Assuming that there are no IRQn deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPRn, then interrupt request to the processor (IRQn) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EEn bit has been cleared by the wrteei instruction (see the code sequence in Interrupt with blocked priority), IRQn will be re-evaluated when processor n writes to the INTC_CPRn while processor n ignores IRQn

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPRn.

23.7.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

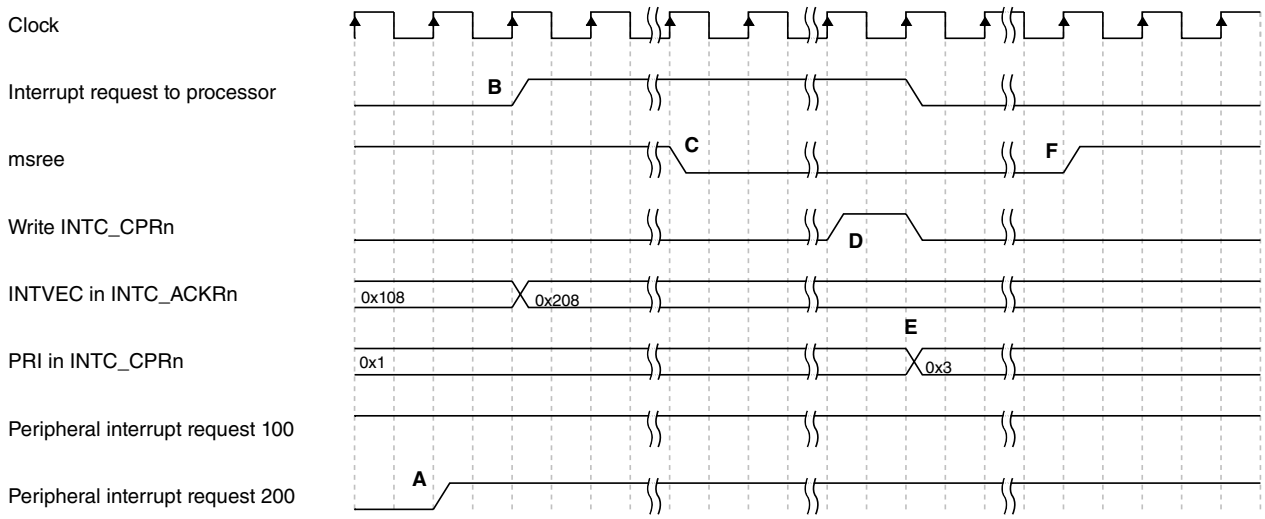

Figure 23-6. Timing diagram of raised priority preserved

Table 23-2. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

23.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

23.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

23.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit

in INTC_SSCIR*n*. Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

23.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

23.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in Scheduling a lower priority portion of an ISR) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

Lowering the PRI value in INTC_CPR*n* within an ISR to below the ISR's corresponding PRI value in INTC_PSR*n* allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

23.7.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

23.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

23.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

23.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to End of interrupt exception handler for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

23.7.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
      wrteei 0                # disable processor recognition of external interrupts
      oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)

pop_lifo:
      store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
      examine INTC_CPRn[PRI], and store onto stack
      if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
      branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
      load stacked PRI value and store to INTC_CPRn
      load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
      if stacked PRI values are not depleted, branch to push_lifo

      INTC_CPRn    = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
      wrteei 1                # enable processor recognition of interrupts
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

23.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

Chapter 24
Enhanced Direct Memory Access (eDMA)

24.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 64 channels.

The following figure illustrates the eDMA module.

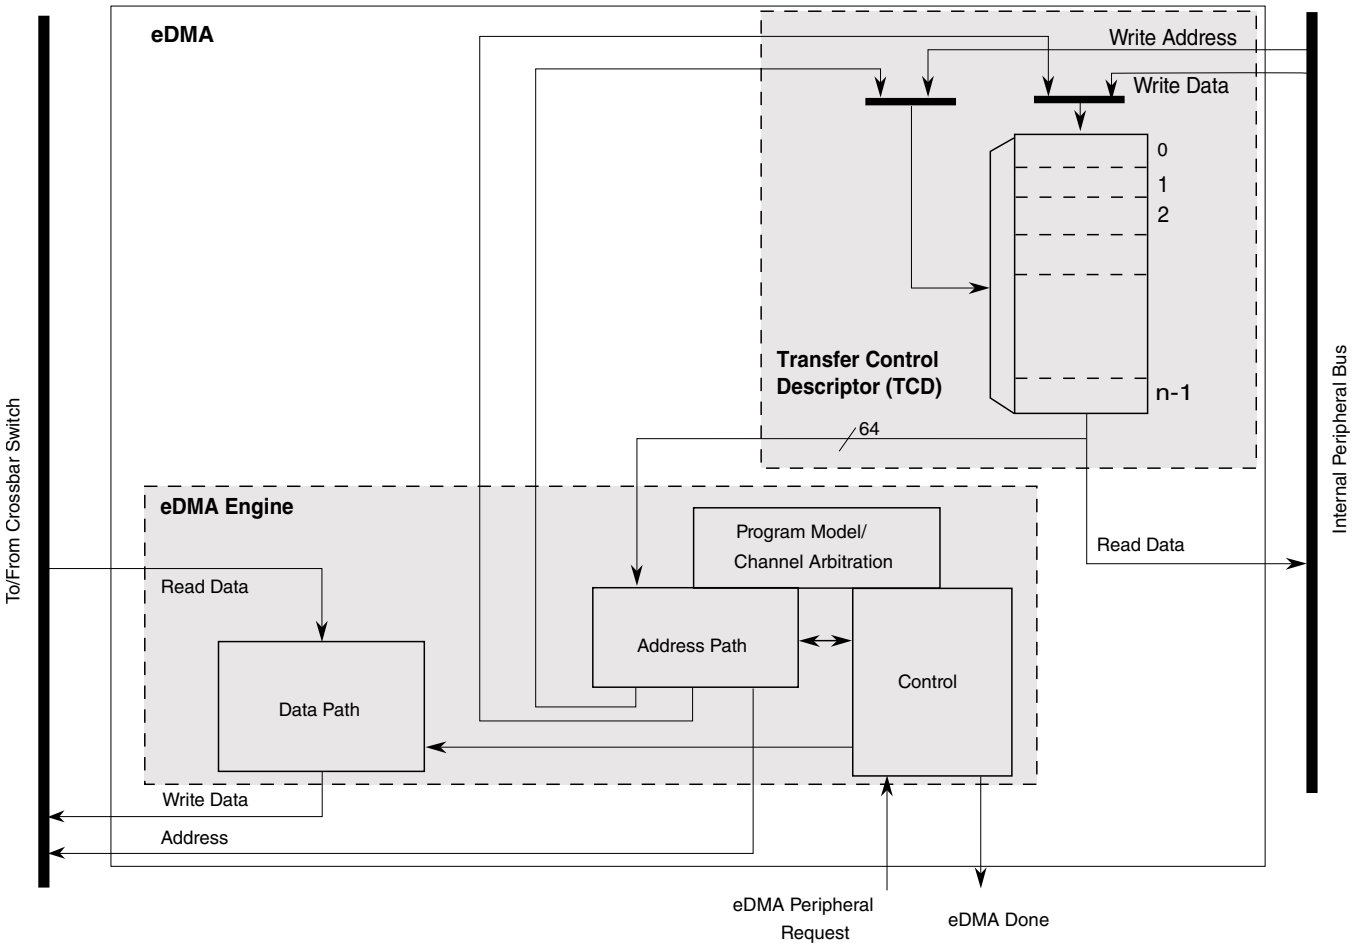

Figure 24-1. eDMA block diagram

24.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers—read from source, write to destination:

  Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes

- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor

    - Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers
    - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
    - 32-byte TCD stored in local memory for each channel
    - An inner data transfer loop defined by a minor byte transfer count
    - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
    - Explicit software initiation
    - Initiation via a channel-to-channel linking mechanism for continuous transfers
    - Peripheral-paced hardware requests (one per channel)
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
    - One interrupt per channel, optionally asserted at completion of major iteration count
    - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing
- Support for complex data structures
- Support to cancel transfers via software

Throughout this chapter, *n* is used to reference the channel number.

24.2 Modes of operation

The eDMA supports the following modes of operation.

24.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

24.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

24.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

24.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 63. Each TCDn definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

24.3.1 Control Register (eDMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in four groups (0, 1, 2, 3) of 16 channels each. Group 3 contains channels 63-48; group 2 contains channels 47-32; group 1 contains channels 31-16; and group 0 contains channels 15-0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (see the DCHPRI*n* registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

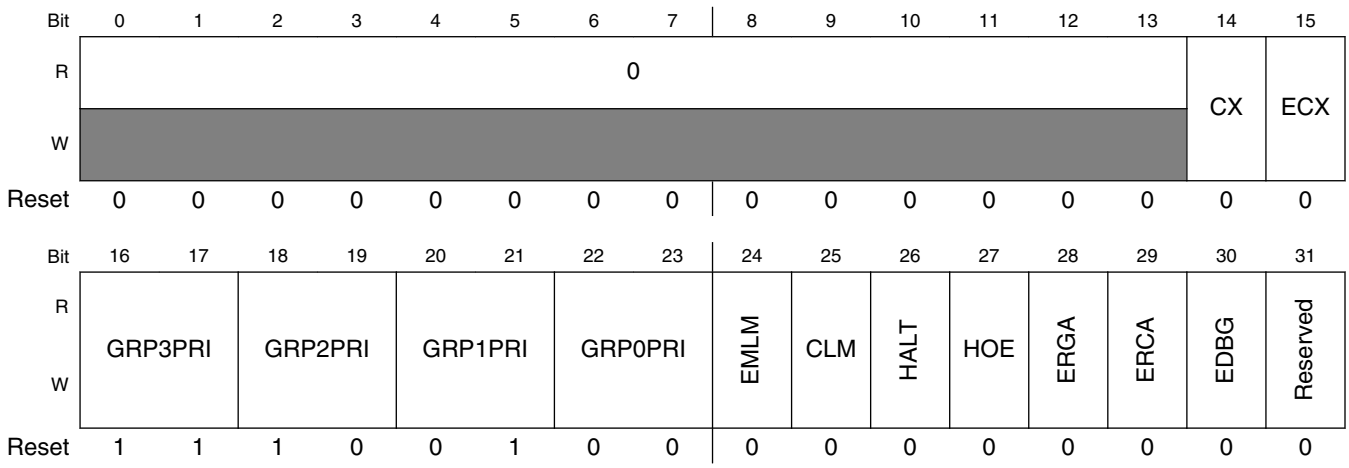
NOTE

Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

Memory map/register definition

Address: FC0A_0000h base + 0h offset = FC0A_0000h



eDMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt.
16–17 GRP3PRI	Channel group 3 priority Group 3 priority level when fixed-priority group arbitration is enabled.
18–19 GRP2PRI	Channel group 2 priority Group 2 priority level when fixed-priority group arbitration is enabled.
20–21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22–23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCD*n*.word2 is defined as a 32-bit NBYTES field 1 Enabled. TCD*n*.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.

Table continues on the next page...

eDMA_CR field descriptions (continued)

Field	Description
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection. 1 Round-robin arbitration is used for channel selection.
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.
31 Reserved	This field is reserved.

24.3.2 Error Status (eDMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

See Error reporting and handling for more details.

Field	Description
0 VLD	ERRH and ERRL status bits 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer cancelled 0 No cancelled transfers 1 The last recorded entry was a cancelled transfer by the error cancel transfer input
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18–23 ERRCHN	Error channel number or cancelled channel number GPE and/or last recorded error cancelled transfer
24 SAE	Source address error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCD*n*_SADDR field. TCD*n*_SADDR is inconsistent with TCD*n*_ATTR[SSIZE]
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SOFF field. TCD*n*_SOFF is inconsistent with TCD*n*_ATTR[SSIZE].

Field	Description
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DADDR field. TCD*n*_DADDR is inconsistent with TCD*n*_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DOFF field. TCD*n*_DOFF is inconsistent with TCD*n*_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_NBYTES or TCD*n*_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD*n*_CSR[ESG] is enabled. TCD*n*_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

24.3.3 Enable Request Register High (eDMA_ERQH)

The ERQ{H,L} registers provide a bitmap for the 64 implemented channels to enable the request signal for each channel. ERQH supports channels 63-32, while EQRL covers channels 31-00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ{H,L}.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

Address: FC0A_0000h base + 8h offset = FC0A_0008h

24.3.7 Set Enable Request Register (eDMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQ{H,L} to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ{H,L} to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 18h offset = FC0A_0018h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAER	SERQ					
Reset	0	0	0	0	0	0	0	0

eDMA_SERQ field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register

Table continues on the next page...

eDMA_SERQ field descriptions (continued)

Field	Description
1 SAER	Set all enable requests 0 Set only those ERQ bits specified in the SERQ field 1 Set all bits in ERQL{H,L}
2–7 SERQ	Set enable request Sets the corresponding bit in ERQL{H,L}

24.3.8 Clear Enable Request Register (eDMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQ{H,L} to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ{H,L} to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 19h offset = FC0A_0019h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAER	CERQ					
Reset	0	0	0	0	0	0	0	0

eDMA_CERQ field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 CAER	Clear all enable requests 0 Clear only those ERQ bits specified in the CERQ field 1 Clear all bits in ERQ
2–7 CERQ	Clear enable request Clears the corresponding bit in ERQL{H,L}

24.3.9 Set Enable Error Interrupt Register (eDMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEI{H,L} to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI{H,L} contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Ah offset = FC0A_001Ah

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAEE	SEEI					
Reset	0	0	0	0	0	0	0	0

eDMA_SEEI field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 SAEE	Sets all enable error interrupts 0 Set only those EEI bits specified in the SEEI field. 1 Sets all bits in EEI
2–7 SEEI	Set enable error interrupt Sets the corresponding bit in EEIL{H,L}

24.3.10 Clear Enable Error Interrupt Register (eDMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEI{H,L} to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI{H,L} contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Bh offset = FC0A_001Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAEE	CEEI					
Reset	0	0	0	0	0	0	0	0

eDMA_CEEI field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 CAEE	Clear all enable error interrupts 0 Clear only those EEI bits specified in the CEEI field 1 Clear all bits in EEI
2–7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEIL{H,L}

24.3.11 Clear Interrupt Request Register (eDMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INT{H,L} to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT{H,L} to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT{H,L} to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Ch offset = FC0A_001Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAIR	CINT					
Reset	0	0	0	0	0	0	0	0

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register

Table continues on the next page...

eDMA_CINT field descriptions (continued)

Field	Description
1 CAIR	Clear all interrupt requests 0 Clear only those INT bits specified in the CINT field 1 Clear all bits in INTL{H,L}
2–7 CINT	Clear interrupt request Clears the corresponding bit in INTL{H,L}

24.3.12 Clear Error Register (eDMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR{H,L} to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR{H,L} to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR{H,L} contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Dh offset = FC0A_001Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CAEI	CERR					
Reset	0	0	0	0	0	0	0	0

eDMA_CERR field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 CAEI	Clear all error indicators 0 Clear only those ERR bits specified in the CERR field 1 Clear all bits in ERR
2–7 CERR	Clear error indicator Clears the corresponding bit in ERRL{H,L}

24.3.13 Set START Bit Register (eDMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Eh offset = FC0A_001Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	SAST	SSRT					
Reset	0	0	0	0	0	0	0	0

eDMA_SSRT field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 SAST	Set all START bits (activates all channels) 0 Set only those TCD*n*_CSR[START] bits specified in the SSRT field 1 Set all bits in TCD*n*_CSR[START]
2–7 SSRT	Set START bit Sets the corresponding bit in TCD*n*_CSR[START]

24.3.14 Clear DONE Status Bit Register (eDMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000h base + 1Fh offset = FC0A_001Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0	0					
Write	NOP	CADN	CDNE					
Reset	0	0	0	0	0	0	0	0

eDMA_CDNE field descriptions

Field	Description
0 NOP	No operation 0 Normal operation 1 No operation, ignore bits 1-7 of this register
1 CADN	Clears all DONE bits 0 Clears only those TCD*n*_CSR[DONE] bits specified in the CDNE field 1 Clears all bits in TCD*n*_CSR[DONE]
2–7 CDNE	Clear DONE bit Clears the corresponding bit in TCD*n*_CSR[DONE]

24.3.15 Interrupt Request Register High (eDMA_INTH)

The Interrupt Request Register High (DMA_INTH) provides a bit map for the upper half of 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptions, the eDMA engine generates an interrupt on a data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

Address: FC0A_0000h base + 20h offset = FC0A_0020h

24.3.16 Interrupt Request Register Low (eDMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the lower half of the 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

24.3.17 Error Register High (eDMA_ERRH)

The ERR{H,L} provides a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63-32, while ERRL covers channels 31-00. The eDMA engine signals the occurrence of a error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16, 32, and 64 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a nonzero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

24.3.18 Error Register Low (eDMA_ERRL)

The ERR{H,L} provides a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63-32, while ERRL covers channels 31-00. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16, 32, and 64 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

24.3.19 Hardware Request Status Register High (eDMA_HRSH)

The HRS{H,L} provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. HRSH supports channels 63-32, while HRSL covers channels 31-00. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQ{H,L} fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ{H,L} bits.

24.3.21 Channel Priority Register (eDMA_DCHPRI*n*)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRI*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRI*n* registers. The group priority is assigned in the DMA control register.

Address: FC0A_0000h base + 100h offset + (1d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7
Read Write	ECP	DPA	GRPPRI		CHPRI			
Reset	0	0	*	*	0	0	0	0

* Notes:
- GRPPRI field: Undefined at reset

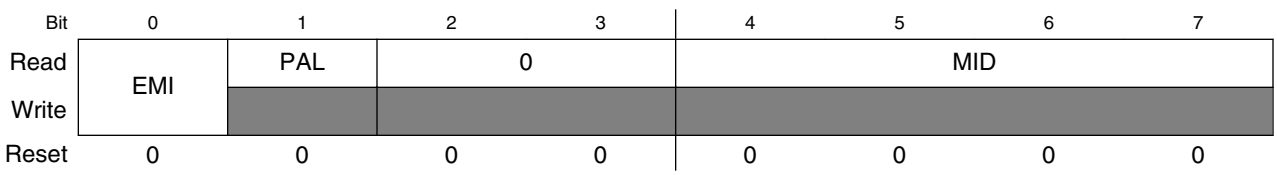
eDMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel *n* cannot be suspended by a higher priority channel's service request 1 Channel *n* can be temporarily suspended by the service request of a higher priority channel
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel *n* can suspend a lower priority channel 1 Channel *n* cannot suspend any channel, regardless of channel priority
2–3 GRPPRI	Channel *n* current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4–7 CHPRI	Channel *n* arbitration priority Channel priority when fixed-priority arbitration is enabled **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.

24.3.22 Channel Master ID Register (eDMA_DCHMID*n*)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (a core, for example) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID*n* registers.

Address: FC0A_0000h base + 140h offset + (1d × i), where i=0d to 63d



eDMA_DCHMID*n* field descriptions

Field	Description
0 EMI	Enable Master ID replication 0 Master ID replication is disabled 1 Master ID replication is enabled
1 PAL	Privileged Access Level The protection level captured in this register reflects the level used when writing the channel's control attributes; lower byte of TCD Word 7. 0 User protection level for DMA transfers 1 Privileged protection level for DMA transfers
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MID	Master ID DMA's master ID when channel *n* is active and master ID replication is enabled. **NOTE:** The master ID captured in this register reflects the ID used when writing the channel's control attributes; lower byte of TCD Word 7.

24.3.23 TCD Source Address (eDMA_TCD*n*_SADDR)

See TCD Source Address register figure and DMA_TCDn_SADDR field descriptions table as follows.

eDMA_TCD*n*_ATTR field descriptions

Field	Description
0–4 SMOD	Source address modulo. 0: Source address modulo feature is disabled

Table continues on the next page...

eDMA_TCD*n*_ATTR field descriptions (continued)

Field	Description
	Not 0: This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 Reserved 100 16-byte 101 Reserved 110 Reserved 111 Reserved
8–12 DMOD	Destination address modulo See the SMOD definition
13–15 DSIZE	Destination data transfer size See the SSIZE definition

24.3.25 TCD Signed Source Address Offset (eDMA_TCD*n*_SOFF)

See TCD Signed Source Address Offset register figure and DMA_TCDn_SOFF field descriptions table as follows.

Address: FC0A_0000h base + 1006h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SOFF															
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:
- SOFF field: Undefined at reset

eDMA_TCD*n*_SOFF field descriptions

Field	Description
0–15 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

24.3.26 TCD Minor Byte Count Minor Loop Disabled (eDMA_TCD*n*_NBYTES_MLNO)

See TCD Minor Byte Count (Minor Loop Disabled) register figure and DMA_TCDn_NBYTES_MLNO field descriptions table below.

If minor loop mapping is disabled (CR[EMLM] = 0), TCD word 2 is defined as follows.

Address: FC0A_0000h base + 1008h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NBYTES																															
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:
- NBYTES field: Undefined at reset

eDMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

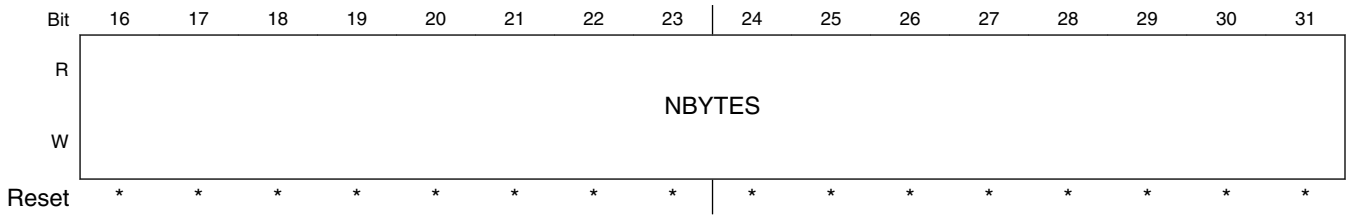
24.3.27 TCD Signed Minor Loop Offset Minor Loop Enabled and Offset Disabled (eDMA_TCD*n*_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

Address: FC0A_0000h base + 1008h offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	SMLOE	DMLOE	NBYTES													
Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*



* Notes:
- NBYTES field: Undefined at reset
- DMLOE field: Undefined at reset
- SMLOE field: Undefined at reset

eDMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

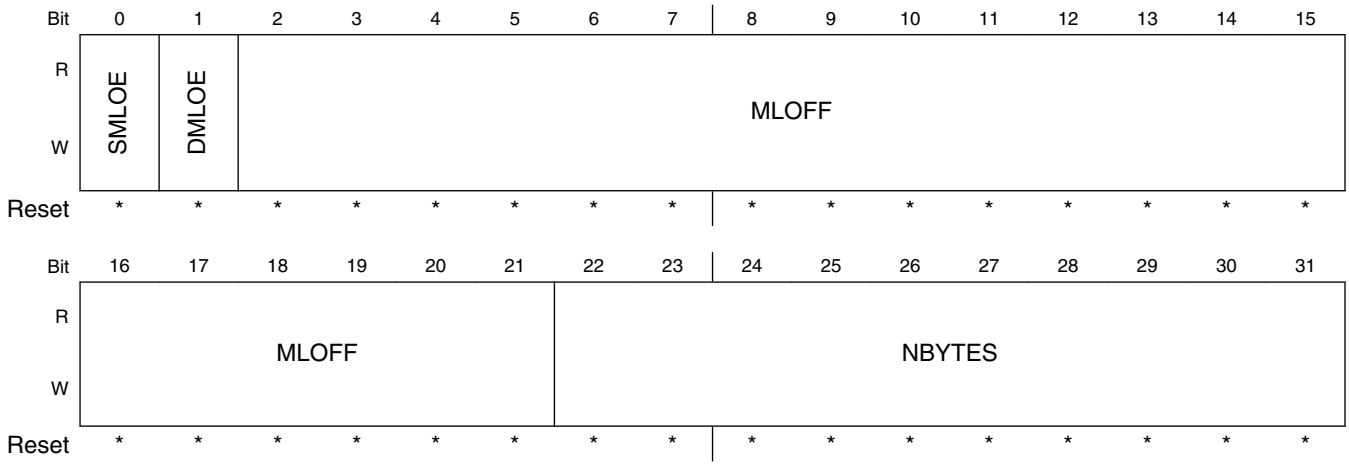
24.3.28 TCD Signed Minor Loop Offset Minor Loop and Offset Enabled (eDMA_TCD*n*_NBYTES_MLOFFYES)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset enabled (SMLOE or DMLOE = 1)

Memory map/register definition

Address: FC0A_0000h base + 1008h offset + (32d × i), where i=0d to 63d



* Notes:
- NBYTES field: Undefined at reset
- MLOFF field: Undefined at reset
- DMLOE field: Undefined at reset
- SMLOE field: Undefined at reset

eDMA_TCD*n*_NBYTES_MLOFFYES field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

24.3.29 TCD Last Source Address Adjustment (eDMA_TCD*n*_SLAST)

Address: FC0A_0000h base + 100Ch offset + (32d × i), where i=0d to 63d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

eDMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–6 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.
7–15 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (e.g., final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field.

Table continues on the next page...

eDMA_TCD*n*_CITER_ELINKYES field descriptions (continued)

Field	Description
	NOTE: When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

24.3.32 TCD Current Minor Loop Link, Major Loop Count Channel Linking Disabled (eDMA_TCD*n*_CITER_ELINKNO)

See TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) register figure and DMA_TCDn_CITER_ELINKNO field descriptions table as follows.

Address: FC0A_0000h base + 1014h offset + (32d × i), where i=0d to 63d

eDMA_TCD*n*_CSR field descriptions

Field	Description
0–1 BWC	Bandwidth control

Table continues on the next page...

eDMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBAR). **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w

2–7
MAJORLINKCH
	Link channel number
	If (MAJORELINK = 0) then
	• No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted.
	else
	• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.

8 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
9 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
11 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.

Table continues on the next page...

eDMA_TCD*n*_CSR field descriptions (continued)

Field	Description
12 DREQ	Disable request {H,L} 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER is set, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled 1 The half-point interrupt is enabled
14 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
15 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started 1 The channel is explicitly started via a software initiated service request

24.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

24.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
  - Address path:

This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n* _{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the TCD*n* _CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.

- Data path:

  This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

  The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).

- Program model/channel arbitration:

  This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).

- Control:

This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

- Transfer control descriptor memory
  - Memory controller:

    This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

    As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
  - Memory array:

    TCD storage is implemented using a single-port, synchronous RAM array.

24.4.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments. As shown in Figure 24-2, the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

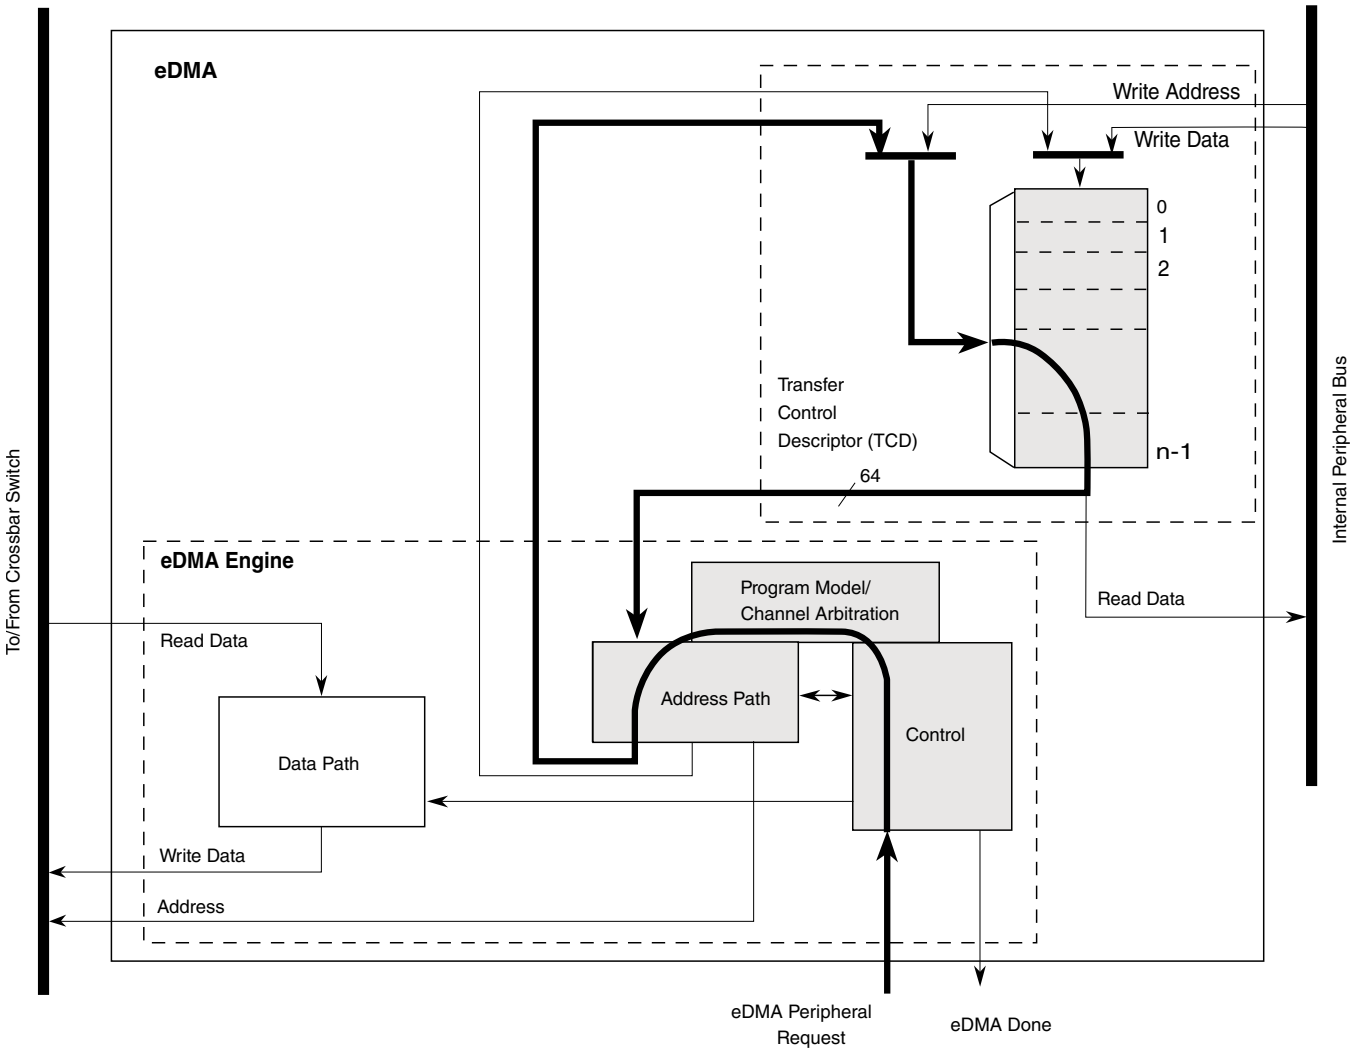

Figure 24-2. DMA operation, part 1

In the second part of the basic data flow as shown in Figure 24-3 the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

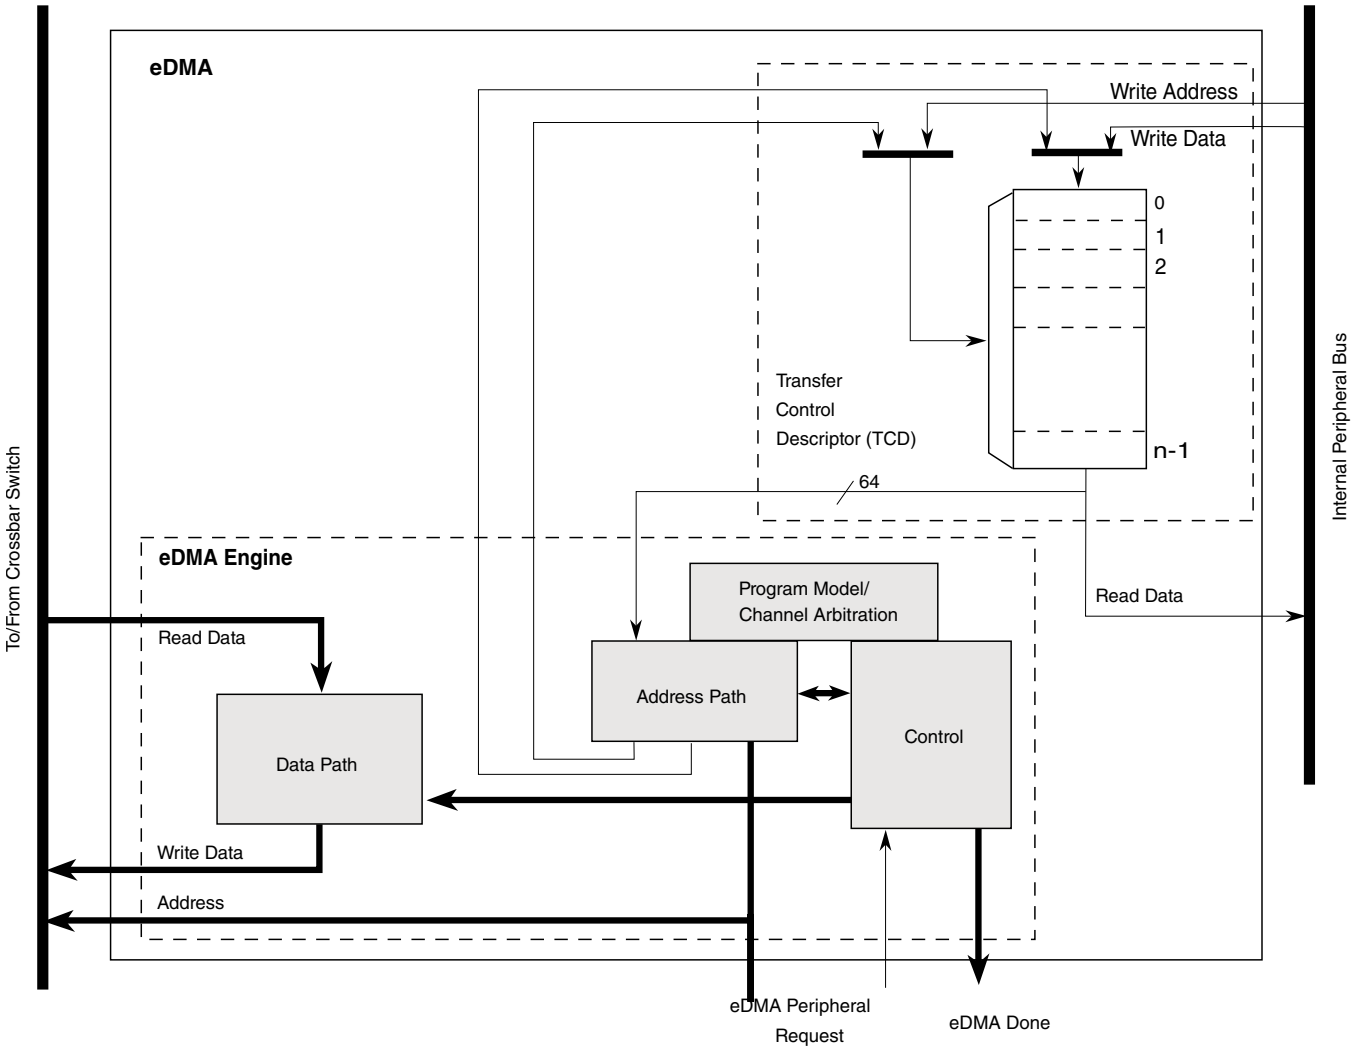

Figure 24-3. DMA operation, part 2

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in Figure 24-4.

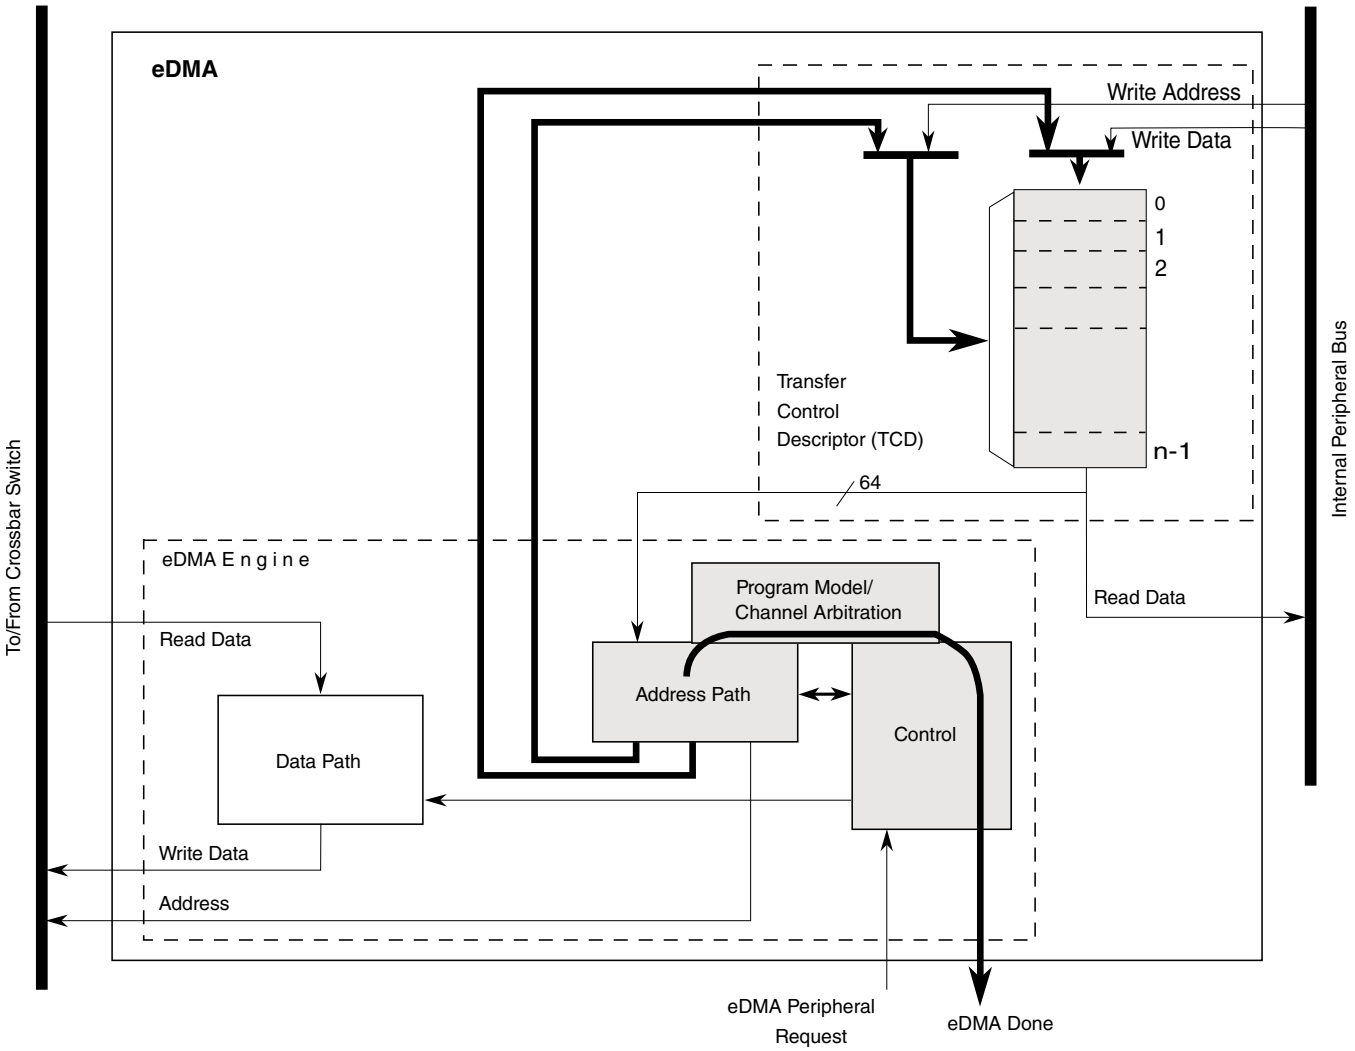

Figure 24-4. DMA operation, part 3

24.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in fixed-arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle.

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups. All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when fixed arbitration mode is enabled.
- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD*n*_CITER[E_LINK] bit does not equal the TCD*n*_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

24.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRI*n*[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRI*n*[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be

defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

24.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in Table 24-1 and Table 24-2. The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- All internal peripheral bus accesses are 32 bits in size.
- All internal SRAM accesses are 64 bits in size.

Table 24-1 presents a peak transfer rate comparison, measured in megabytes per second.

Table 24-1. eDMA peak transfer rates (MB/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from

internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD*n* _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* Word 7).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
- Cycles 8 to *x* : The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

  The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles. For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles.
- Cycle *x*[1] + 1: This cycle represents the data phase of the last destination write.
- Cycle *x*[1] + 2: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* Word 7 is read and checked for channel linking or scatter/gather requests.
- Cycle *x*[1] + 3: The appropriate fields in the first part of the TCD*n* are written back into the local memory.

40. "x" represents an undefined cycle value dependant on transfer sizes and response times for the channel's read and write accesses.

- Cycle x[1] + 4: The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle *x*[1] + 5: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles (4 + (3 + 3)/2 + 3). This is the time from Cycle 4 to Cycle x + 5. The resulting peak request rate, as a function of the system frequency, is shown in Table 24-2. This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

Table 24-2. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

$$PEAKreq = freq/[entry + (1 + read\_ws) + (1 + write\_ws) + exit]$$

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.

- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150\,\text{MHz}/[4+(1+0)+(1+1)+3]\text{cycles} = 15.0\,\text{Mreq/s}$$

For an internal peripheral bus-to-SRAM transfer,

$$\text{PEAKreq} = 150\,\text{MHz}/[4+(1+1)+(1+0)+3]\text{cycles} = 15.0\,\text{Mreq/s}$$

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCD*n*_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

24.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

24.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.

4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by software (setting the TCD*n*_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in Table 24-3) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD*n*_SADDR) to the destination (as defined by the destination address, TCD*n*_DADDR) continue until the specified number of bytes (TCD*n*_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

Table 24-3. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

Figure 24-5 shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

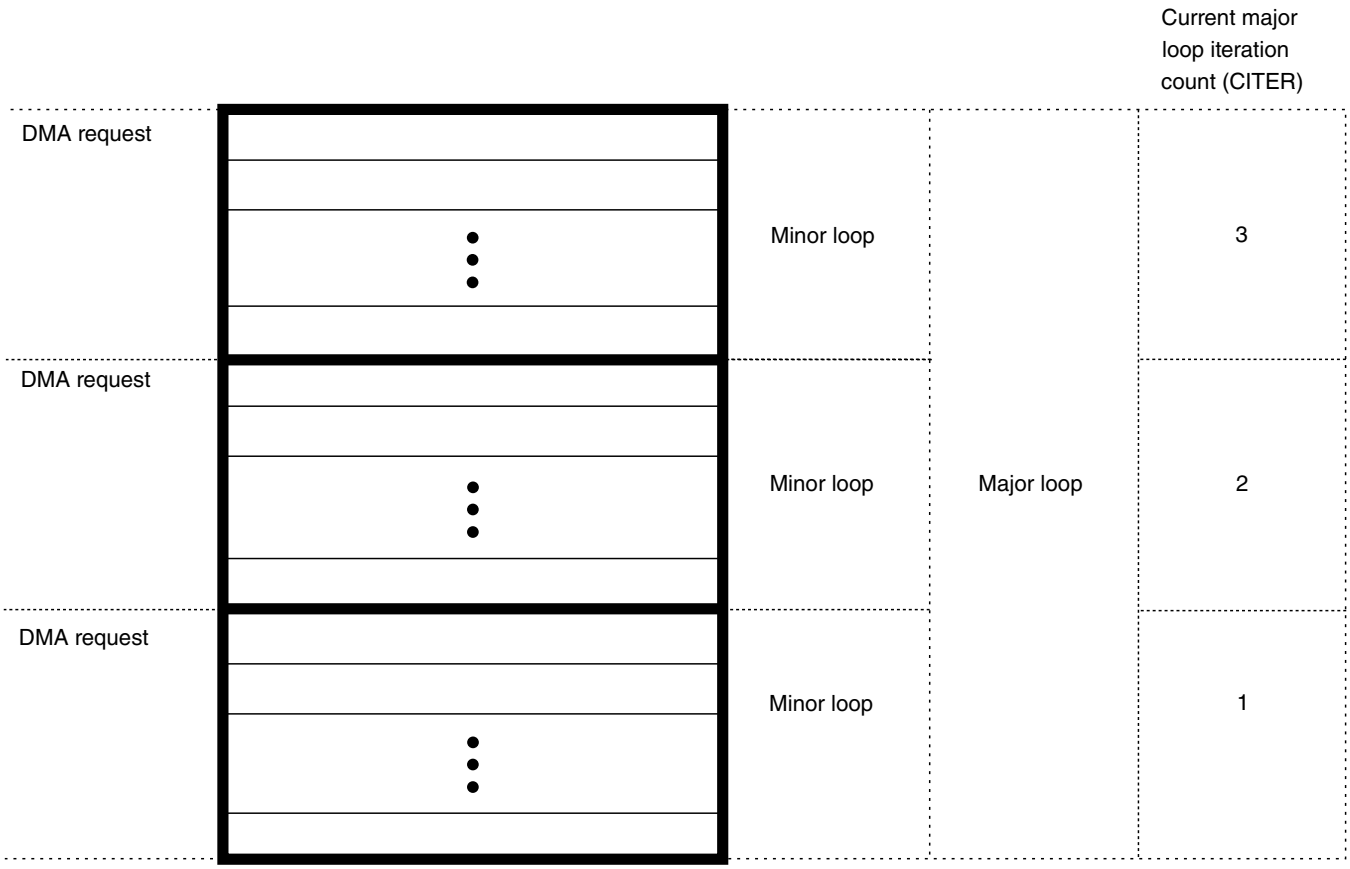

Figure 24-5. Example of multiple loop iterations

Figure 24-6 lists the memory array terms and how the TCD settings interrelate.

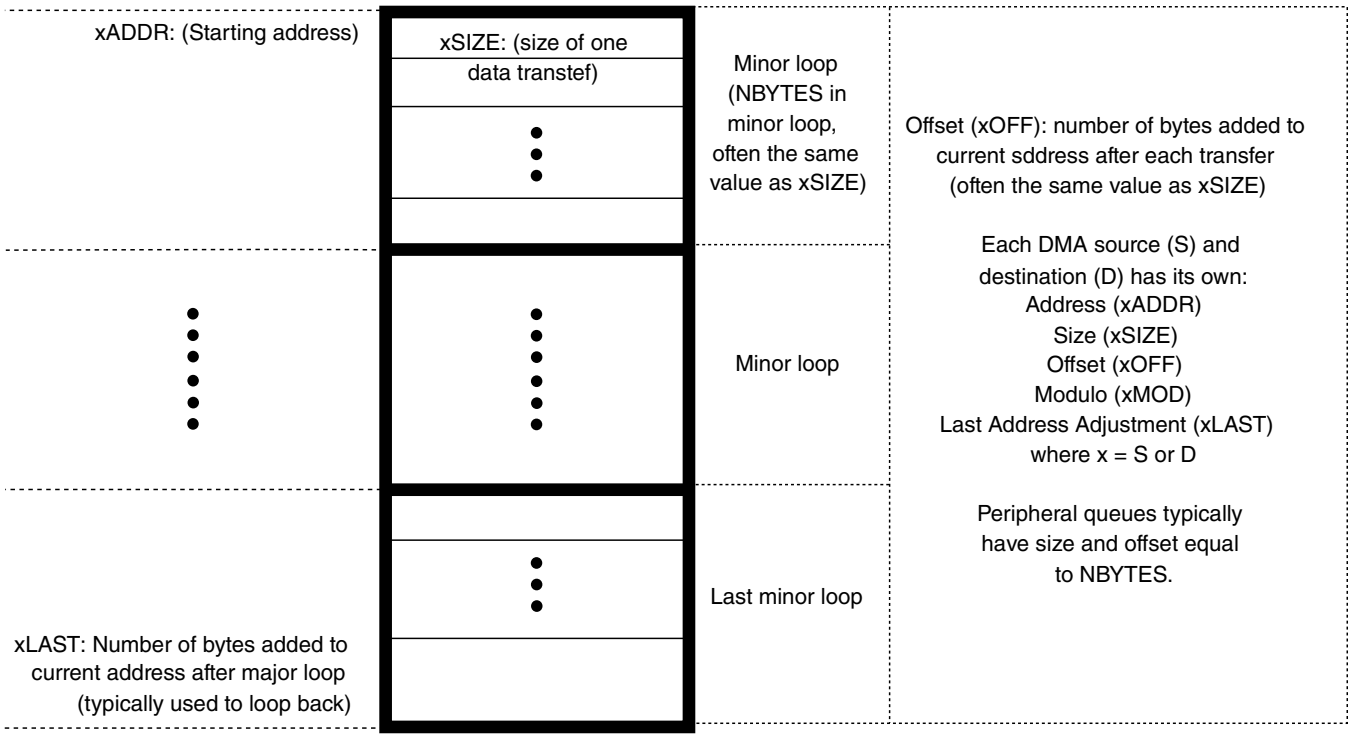

Figure 24-6. Memory array terms

24.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: group priority error (ES[GPE]) and channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes.
2. Group 3 is the highest priority and all channels are unique in that group.
3. Group 2 is the next highest priority and has two channels with the same priority level.
4. If Group 3 has any service requests, those requests will be executed.

5. Once all of Group 3 requests have completed, Group 02 will be the next active group.
6. If Group 2 has a service request, then an undefined channel in Group 02 will be selected and a channel priority error will occur.
7. This repeats until all of the Group 02 requests have been removed or a higher priority Group 13 request comes in.

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

24.5.3 DMA arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

24.5.3.1 Fixed group arbitration, fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller —that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

24.5.3.2 Round-robin group arbitration, fixed channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with an service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

24.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in Round-robin group arbitration, fixed channel arbitration, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

24.5.3.4 Fixed group arbitration, r ound-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, c hannels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get very much longer and longer as the group priority decreases.

24.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

24.5.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
```

```
TCDn_CSR[START] = 1 (Should be written last after all other fields have been
                initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

24.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as previous. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.

8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop ® major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2(TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

24.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 24-4. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

24.5.5 eDMA TCD*n* status monitoring

This section discusses how to monitor eDMA status.

24.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Table 24-5. TCD status sequence – software activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Table 24-6. TCD status sequence – hardware activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit. The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

24.5.5.2 Active channel TCD*n* reads

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

24.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal (constantly rotating) when round-robin arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

24.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 24-7. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

24.5.7 Dynamic programming

The following sections describe dynamic programming.

24.5.7.1 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

- Switch to round-robin channel arbitration mode, change the channel priorities, then switch back to fixed arbitration mode.
- Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to round-robin group arbitration mode, change the group priorities, then switch back to fixed arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

24.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in the following table is recommended when executing a dynamic channel link request.

Table 24-8. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: • If TCD.major.e_link = 1b, the dynamic link attempt was successful. • If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

24.5.7.3 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

24.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in the following table may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 24-9. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.
3	Write theTCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: • If e_sg = 1b, the dynamic link attempt was successful. • If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). • If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

24.5.7.3.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in the following table may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 24-10. Coherency model for method 2

Step	Action
1	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.
2	Write theTCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: • If e_sg = 1b, the dynamic link attempt was successful. • If e_sg = 0b, read the 32 bit TCD dlast_sga field. • If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). • If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

Chapter 25
Direct Memory Access Multiplexer (DMAMUX)

25.1 Introduction

25.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

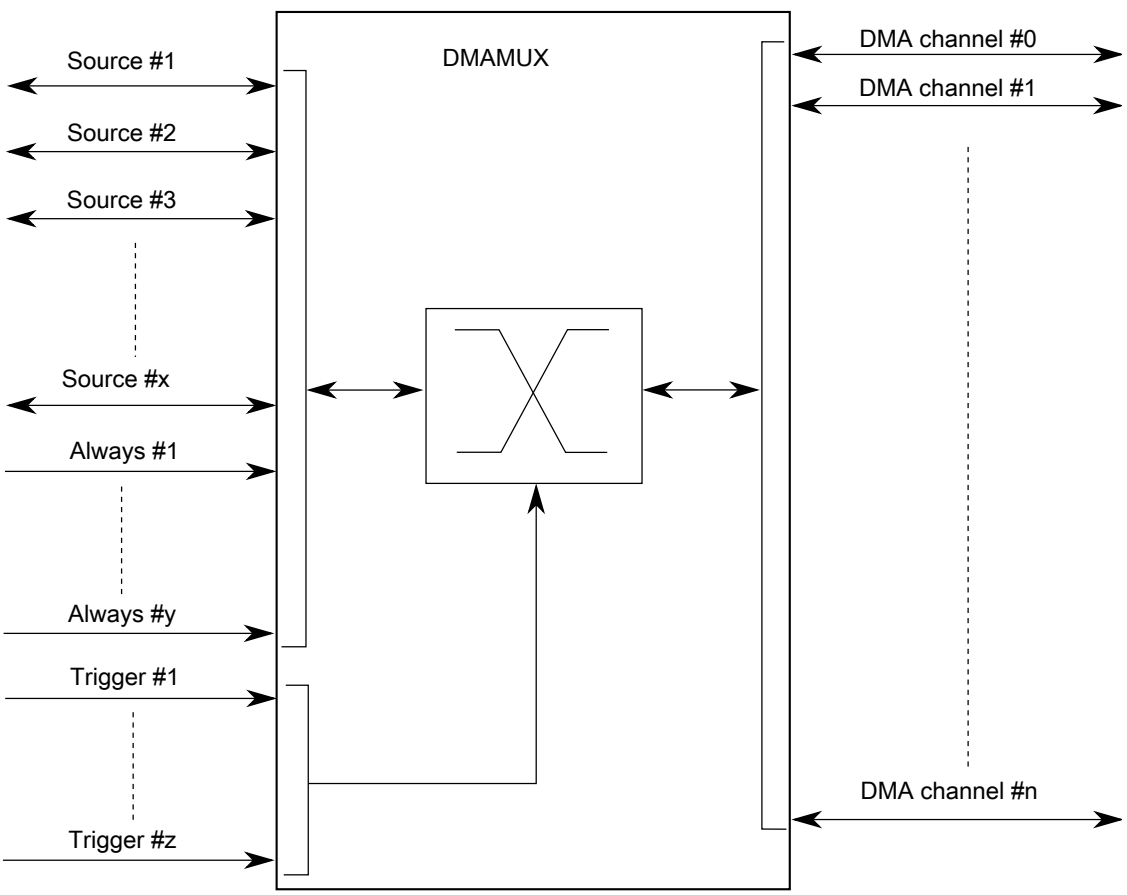

Figure 25-1. DMAMUX block diagram

25.1.2 Features

The DMAMUX module provides these features:

- Up to 64 peripheral slots and up to six always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first eight channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

25.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically. Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–.

25.2 External signal description

The DMAMUX has no external pins.

25.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	25.3.1/1073
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	25.3.1/1073
2	Channel Configuration register (DMAMUX_CHCFG2)	8	R/W	00h	25.3.1/1073
3	Channel Configuration register (DMAMUX_CHCFG3)	8	R/W	00h	25.3.1/1073
4	Channel Configuration register (DMAMUX_CHCFG4)	8	R/W	00h	25.3.1/1073
5	Channel Configuration register (DMAMUX_CHCFG5)	8	R/W	00h	25.3.1/1073
6	Channel Configuration register (DMAMUX_CHCFG6)	8	R/W	00h	25.3.1/1073
7	Channel Configuration register (DMAMUX_CHCFG7)	8	R/W	00h	25.3.1/1073
8	Channel Configuration register (DMAMUX_CHCFG8)	8	R/W	00h	25.3.1/1073
9	Channel Configuration register (DMAMUX_CHCFG9)	8	R/W	00h	25.3.1/1073
A	Channel Configuration register (DMAMUX_CHCFG10)	8	R/W	00h	25.3.1/1073
B	Channel Configuration register (DMAMUX_CHCFG11)	8	R/W	00h	25.3.1/1073
C	Channel Configuration register (DMAMUX_CHCFG12)	8	R/W	00h	25.3.1/1073
D	Channel Configuration register (DMAMUX_CHCFG13)	8	R/W	00h	25.3.1/1073
E	Channel Configuration register (DMAMUX_CHCFG14)	8	R/W	00h	25.3.1/1073
F	Channel Configuration register (DMAMUX_CHCFG15)	8	R/W	00h	25.3.1/1073

25.3.1 Channel Configuration register (DMAMUX_CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read Write	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
1 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

25.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

25.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention. The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

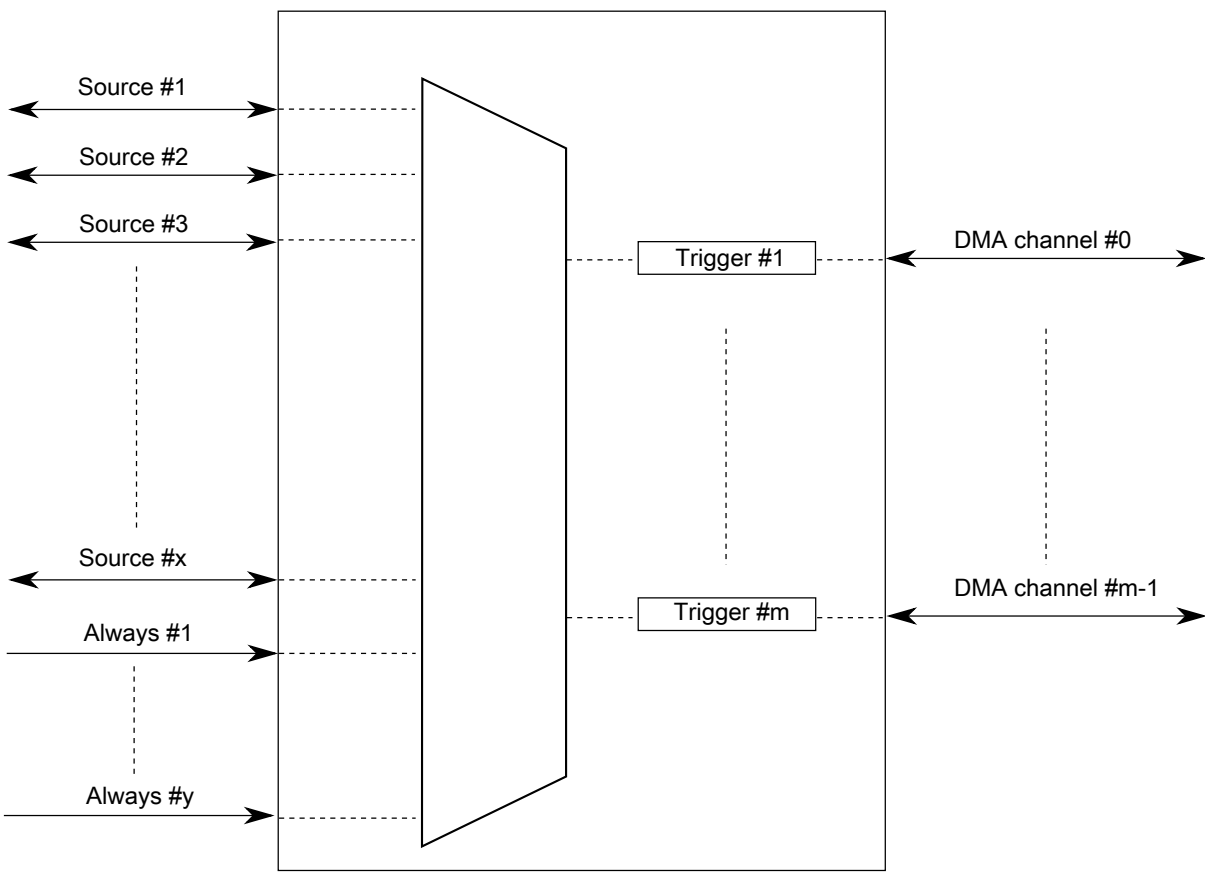

Figure 25-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

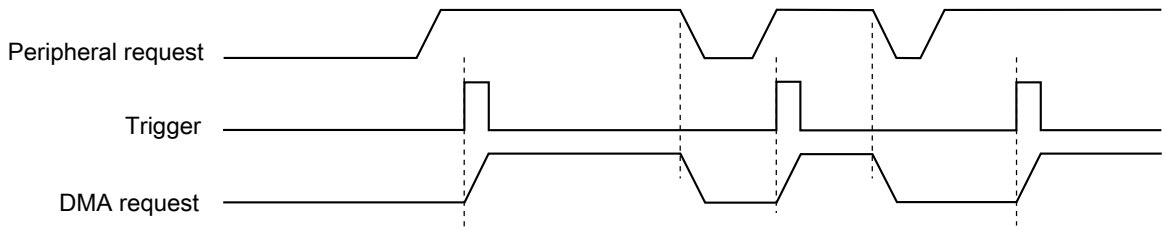

Figure 25-3. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

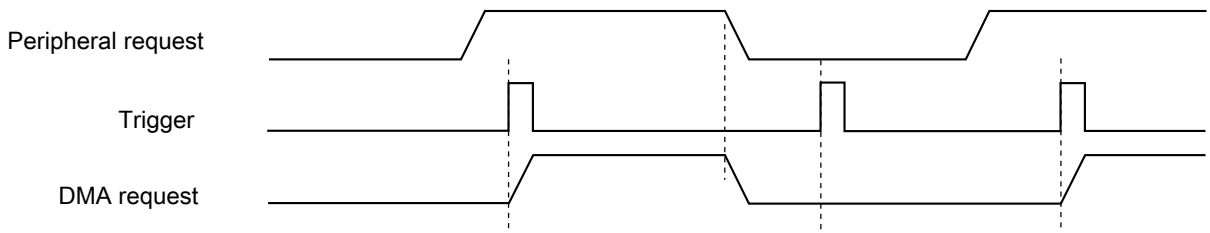

Figure 25-4. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 μs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

25.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

25.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are six additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

25.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

25.5.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

25.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8 (base address + 0x08).
3. Write 0x87 to CHCFG8 (base address + 0x08). (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 26
Clocking

26.1 Introduction

This chapter describes the architecture of the system level clocks and includes the following information:

- System clock specifics.
- Clock architecture.
- Clock sources.
- Clock monitoring.
- Programmable clock dividers.
- Clock control registers.
- Progressive Clock Switching (PCS).

Note

This chapter only covers clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The system clock (CLKOUT) services the computational shell (includes the main CPUs Main Core_0 and Checker Core_0s), modules that run in the high-speed domain, memories and debug logic. Its independence from the peripheral clocks allows CLKOUT to be a frequency modulated (FM) clock with reduced electromagnetic emissions while having a precise clock for the peripheral timer and communication functions. It can be reduced during low computational activity periods to lower power consumption while providing a fixed frequency to the communication interfaces and timers.

The internal 16 MHz RC oscillator (IRCOSC) services device boot up and may be enabled via the Mode Entry Module as a backup clock in the event of PLL or external oscillator failure. See the “Mode Entry Module (MC_ME)” chapter for details.

The alternative clock sources are:

- External oscillator/crystal (XOSC).
- Internal 16 MHz RC oscillator (IRCOSC).
- PLL0 (PLL0_PHI).
- PLL1 (PLL1_PHI).

Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM) allow developers to select an independent clock source for each system peripheral. There is an additional System Clock Selector used exclusively for the system clock.

The outputs of the module clock selectors have individual dividers that can divide the clock selector outputs by up to 512 for a given peripheral.

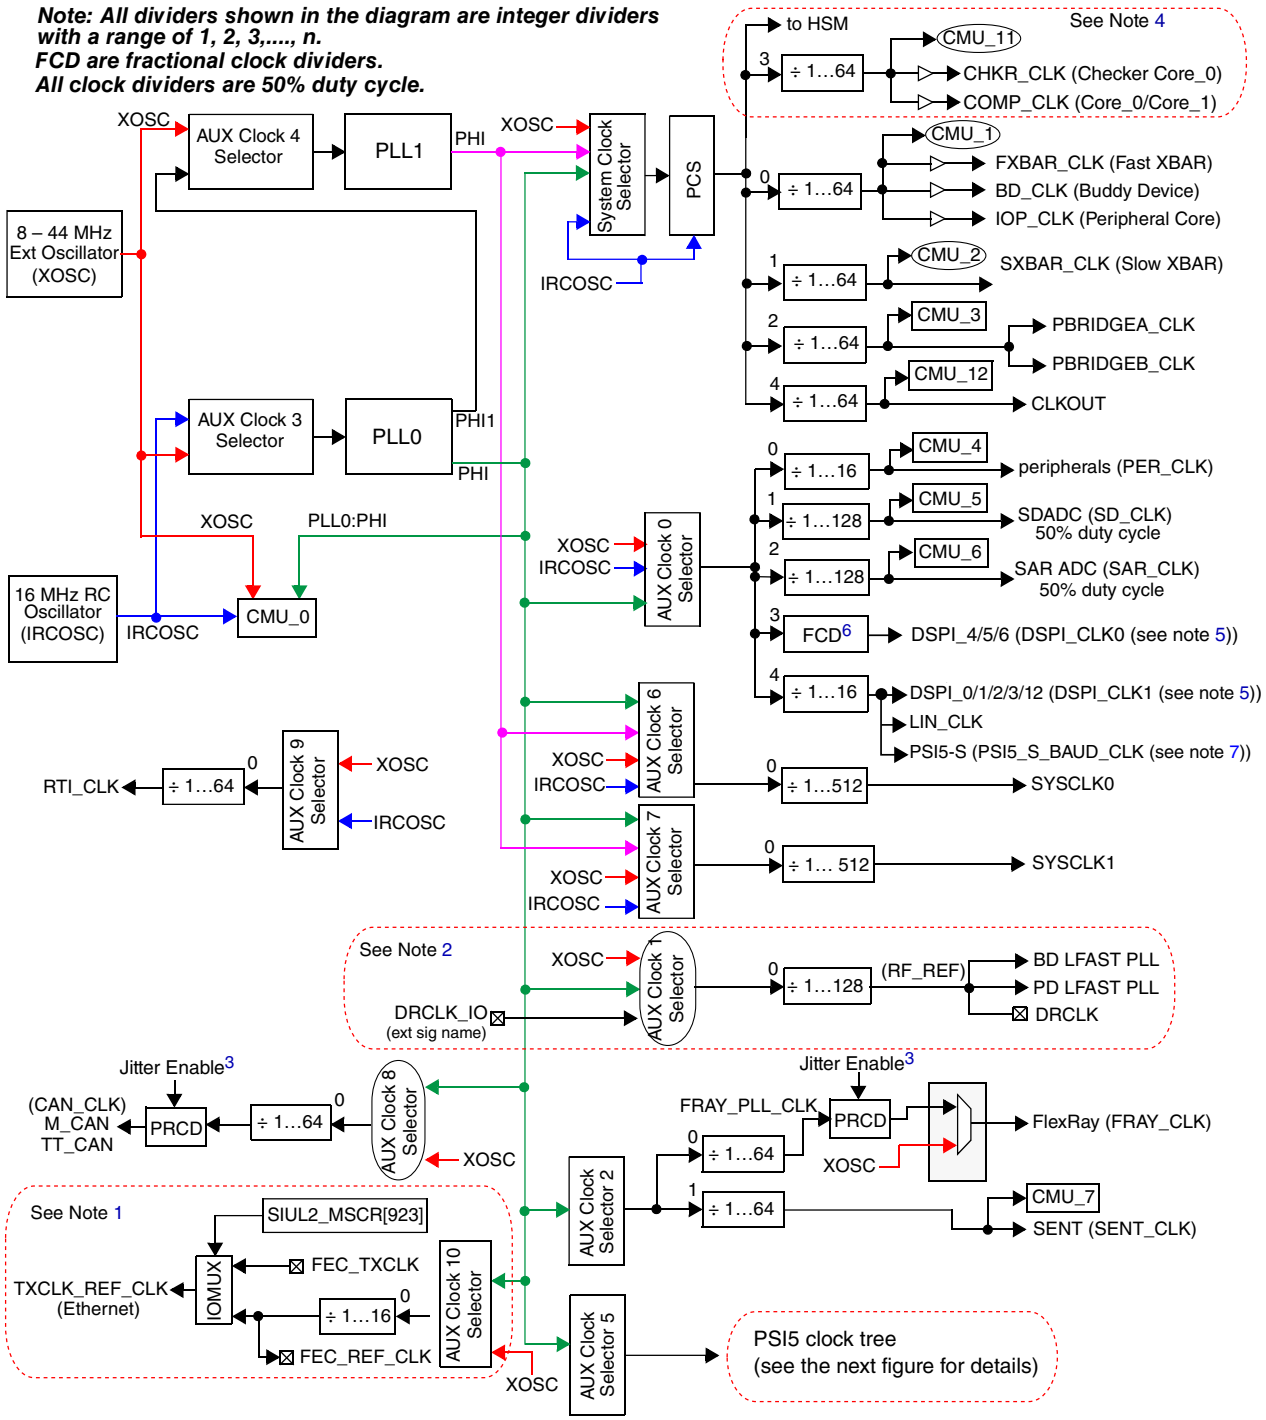
Clock Monitor Units (CMUs) are connected to outputs of clock dividers to verify that clock frequencies stay within operating limits and can be configured to signal an interrupt or initiate a system reset when an issue with a clock is found.

26.2 Clock generation

The top-level clock generation architecture can be seen in Figure 26-1. See the Clock Generation Module (MC_CGM) chapter for details on the Fractional Clock Dividers. All clock selectors and dividers are located and programmed in the MC_CGM, with the exception of the Hardware Security Module (HSM) clock divider. All dividers are integer dividers (1, 2, 3, …, *n*) with the ranges shown in the divider blocks in Figure 26-1. All dividers connected to the System Clock Selector must have 50% duty cycle outputs.

Note

Clock Monitoring Units CMU1 to CMU12 in Figure 26-1 use IRCOSC as their reference clock. The user can select either IRCOSC or XOSC as the reference clock for CMU_0.



1. See the "Device Ethernet clocking" figure for Ethernet clocking details
2. See the "Device LFAST clocking" figure for LFAST clocking details
3. See the “Password and Device Security Module (PASS)” chapter for Jitter Enable details.
4. The COMP_CLK and CHKR_CLK clock trees are isolated downstream of System Clock Divider 3. Isolation is maintained in the phyiscal design of the clock trees.
5. DSPI_CLK1 and DSPI_CLK0 are the protocol clocks as described in the “Deserial Serial Peripheral Interface (DSPI)” chapter.
6. See the MC_CGM chapter for details of the Fractional Clock Divider (FCD).
7. Referred to as ipg_baud_clk in the PSI5-S chapter.

Figure 26-1. Clock generation (part 1 of 2)

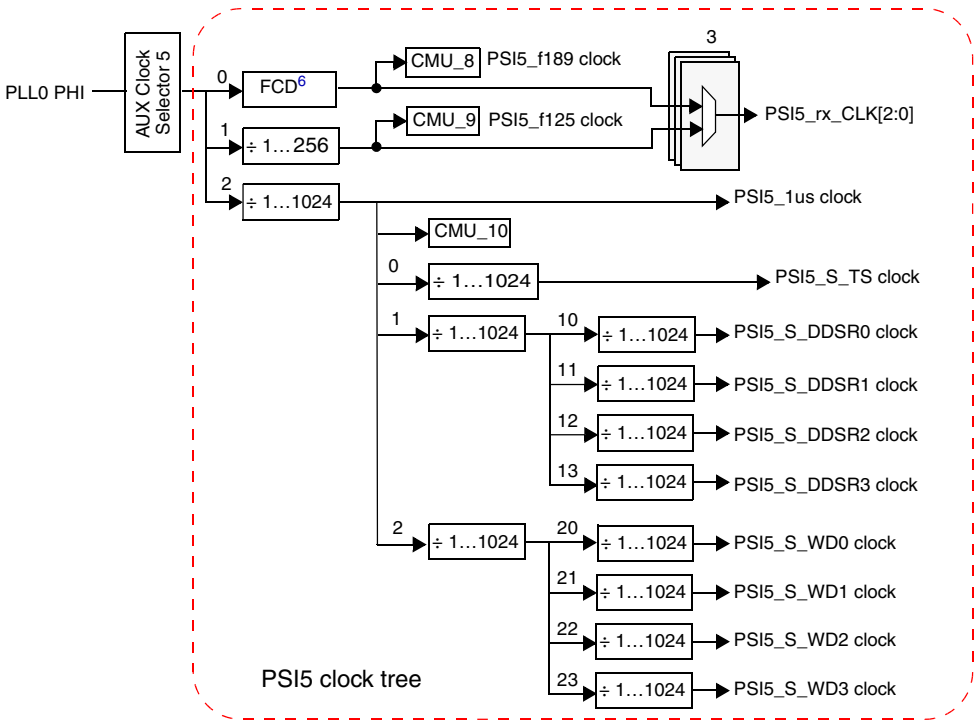


Figure 26-2. Clock generation (part 2 of 2)

26.2.1 MC_CGM registers

Table 26-1 shows the relationship between the clocks in Figure 26-1 and the MC_CGM registers.

See the Clock Generation Module (MC_CGM) for specifics on register implementation.

Table 26-1. MC_CGM relationship to clocks

1. CMU_0 is not shown in table since it does not monitor an output clock from the MC_CGM.

26.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks are shown in Table 26-2.

The user is responsible to verify that these values are not exceeded. See Figure 26-1 for clocking architecture overview.

Table 26-2. Maximum system level clock frequencies

Clock Selector	Nominal programmed Max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
System clock selector[1]	600	0	CMU_1 IOP core FXBAR Core_0 Core_0s Core_1	200

1. System clock selection is a component of the device run mode switching process. See the Mode Entry Module (ME_ME) chapter for details.
2. Each peripheral bridge (PBRIDGE_A, PBRIDGE_B) is capable of clocking the bus interface of each peripheral slot individually at the slow XBAR frequency, or at the slow XBAR frequency divided by two. The GTM is clocked at the slow XBAR frequency, and all other peripherals on both AIPS bridges are clocked at the slow XBAR frequency divided by two.

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

Note

HSM_CLK and PBRIDGEx_CLK are not required to be at the same frequency, but the frequency of COMP_CLK must equal CHKR_CLK, and FXBAR_CLK must equal IOP_CLK.

26.3.1 JTAG frequencies

Table 26-3 shows the maximum frequencies of the JTAG interface.

Table 26-3. JTAG frequencies

Device	Configuration	e200z7 max. internal JTAG frequency	Buddy device max. RWA internal frequency	Max. external JTAG frequency	Notes
PD[1]	Unconfigured clock	—	N/A	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock on PD (IRC) with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 300 MHz	150 MHz			JTAG usable at 1/2 CPU frequency
ED[2]	BD only powered	N/A	22.4 MHz		BD clocked by internal 64 MHz RC clock (RCOSC64) with +/- 30% tolerance and BD RWA usable at /2 frequency
	PD and BD powered, unconfigured clock	—	—		ED clocked by internal 8 MHz RC clock (IRC) with +/- 1.5% tolerance, and BD RWA usable at /2 frequency
	PD and BD powered, PD clock configured clock to 200 MHz	100 MHz	100 MHz		100 MHz JTAG achievable using LFAST mode debug, or s/w mode JTAGM. JTAG messages are generated internally by JTAGM and stay within BD and PD domain. The external tool interface is LFAST only

1. PD = Production Die
2. ED = Emulation and Debug Device = Production Die + Buddy Die

26.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to '1' at power on reset.

26.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- External oscillator (XOSC)/External clock (EXTAL bypass)
- 16 MHz internal RC oscillator (IRCOSC)

26.5.1 PLL

The Dual PLL provides separate system and peripheral clocks as shown in Figure 26-1. The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in Figure 26-3.

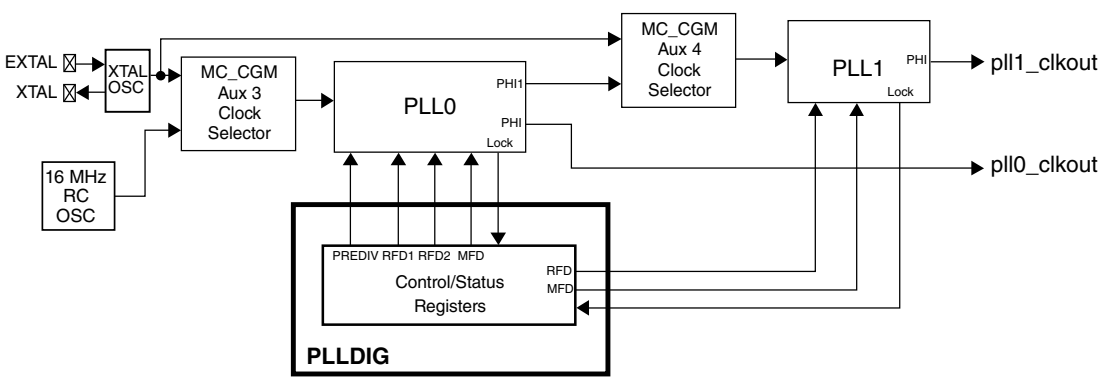

Figure 26-3. MPC5777M Dual PLL digital interface block diagram

26.5.1.1 PLL0 — base PLL (non-FM)

This primary PLL provides a clock that is not Frequency Modulated to the peripheral IPs and the reference clock to PLL1.

The input clock sources for PLL0 are:

- XOSC
- IRCOSC
- The external reference clock (input on the EXTAL pin)

The output clocks from PLL0 are:

- PHI—drives the peripheral clock and the system clock when PLL1 is not locked or active.
- PHI1—provides the input reference clock for PLL1.

26.5.1.2 PLL1 — FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

The input clocks to PLL1 are:

- PHI1 output clock from PLL0
- The external reference clock.

The output clock from PLL1 is:

- PHI—drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

26.5.1.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the "Dual PLL Digital Interface" chapter.

26.5.1.4 PLL register write protection

The PLL registers defined in Table 26-4 have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the PLL register write protection.

Table 26-4. PLL register write protection

Offset	Register[1]	Protection
00h	PLL0 Control Register (PLL0CR)	Yes

Table continues on the next page...

Table 26-4. PLL register write protection (continued)

Offset	Register[1]	Protection
04h	PLL0 Status Register (PLL0SR)	No
08h	PLL0 Divider Register (PLL0DIVR)	Yes
20h	PLL1 Control Register (PLL1CR)	Yes
24h	PLL1 Status Register (PLL1SR)	No
28h	PLL1 Divider Register (PLL1DIVR)	Yes
2Ch	PLL1 Frequency Modulation Register (PLL1FMR)	Yes
30h	PLL1 Fractional Divider Register (PLL1FDR)	Yes

1. See Register Protection Configuration chapter for bit field details.

26.5.1.5 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in the following table. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 26-5. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset value (hex)
0008	PLL0DV — PLL0 Divider Register	0000_0000
0028	PLL1DV — PLL1 Divider Register	0000_0000
0034	CLKMUX — Clock Multiplexer Control Register	0000_0000
0038	Reserved	—

26.5.1.6 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition. Software may enable or disable an optional backup clock in the PLL.

26.5.1.7 PLLDIG initialization information

Configure PLL0 and related modules.

1. With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.

2. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].

3. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).

4. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

Turn on XOSC and PLL0.

5. Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<mode>_MC[XOSCON] = 1 and MC_ME_<mode>_MC[PLL0ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0(PLL0 PHI output) as the sysclk.

6. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

7. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- XOSC counter expires (if the new mode configuration changes MC_ME_<mode>_MC[XOSCON] = 1), and
- PLL is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL0ON] = 1)

8. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Configure PLL1 and related modules.

9. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.

10. Program PLL1DV[MFD] and PLL1DV[RFDPHI].

11. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

Turn on PLL1.

12. Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL1 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<mode>_MC[XOSCON] = 1, MC_ME_<mode>_MC[PLL1ON] = 1 and MC_ME_<mode>_MC[PLL1ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.

13. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

14. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:

- XOSC counter expires (if the new mode configuration changes XOSCON to 1), and
- PLL1 is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL1ON] = 1).

15. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Note: See the "Mode Entry Module (MC_ME)" chapter in this Reference Manual more details.

26.5.2 External oscillator (XOSC)

The external oscillator (XOSC):

- Is a reference for the on-chip PLLs.
- Can be used as a clock source for the ADCs, timer, serial interfaces, RTI, LFAST and as a system clock source.
- Is available for observation on either of the CLKOUT pins.
- Is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators.
- Automatic Loop Control (ALC) to remove need for external series resistor.
- Gain selection for <= 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues.
- Reference clock to PLL0.
- Reference clock to CMU0 (IRCOSC trimming).
- Option to drive the CAN and FlexRay protocol clocks directly from the XOSC.

The XOSC provides support for 8 – 44 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor.

26.5.2.1 XOSC Start-up

Enabling of the oscillator at startup is determined by a bit in the UTEST row of flash memory. The default value has the XOSC disabled:

- UTEST Miscellaneous[7] = 0 (XOSC EN).

If enabled, the oscillator is started in PHASE 3 of the reset sequence: after negation of the internal POR circuits but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors:

- UTEST Miscellaneous[6] = 1 (XOSC EXT LOAD).

Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. See the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During PHASE 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module.

Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values:

- UTEST Miscellaneous[5:1] = 00000b (XOSC LOAD CAP SEL).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value causing an undetectable error in the system.

The XOSC has the ability to be started with either 8 MHz–20 MHz, or 40 MHz–44 MHz crystal. The default value of this field is for an 8 MHz–20 MHz crystal:

- UTEST Miscellaneous[10] = 0 (XOSC EN_40MHz).

See the flash memory chapter for more information on the UTEST row programming.

26.5.2.2 XOSC register write protection

The XOSC registers defined in Table 26-6 have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the XOSC register write protection.

Table 26-6. XOSC register write protection

Offset	Register[1]	Protections?
00h	XOSC_CTL—XOSC Control Register	Yes

1. See Register Protection Configuration chapter for bit field details

26.5.2.3 XOSC reset value

The following table shows the default reset value for the XOSC registers.

Table 26-7. XOSC register reset values

Offset	Register	Reset value
00h	XOSC_CTL—XOSC Control Register	0030_8000h

26.5.3 16 MHz internal RC oscillator (IRCOSC)

The 16 MHz internal RC oscillator default clock is always enabled on reset and can be the clock source for the PLLs. The register interface is for user trimming of the oscillator and dividing output from 1 to 32.

26.5.3.1 IRCOSC register interface

A dedicated digital interface for the IRCOSC has a user register for fine tuning the IRCOSC frequency. Other read-only registers contain settings and values for the IRCOSC temperature sensor, voltage regulator and capacitor trimming.

26.5.3.2 IRCOSC reset value

Table 26-8 shows the default reset value for the IRCOSC registers.

Table 26-8. IRCOSC register reset values

Offset	Register	Reset value
00h	CTL—IRCOSC Control Register	0000_0000h
04h	NT—IRCOSC Native Trimming Register	0000_0000h
08h	TT—IRCOSC Temperature Trimming Register	0000_0000h

26.5.3.3 IRCOSC register write protection

The IRCOSC registers do not utilize write protection.

26.6 Peripheral clocks

The following figure shows the clock distribution to the cores and peripheral modules.

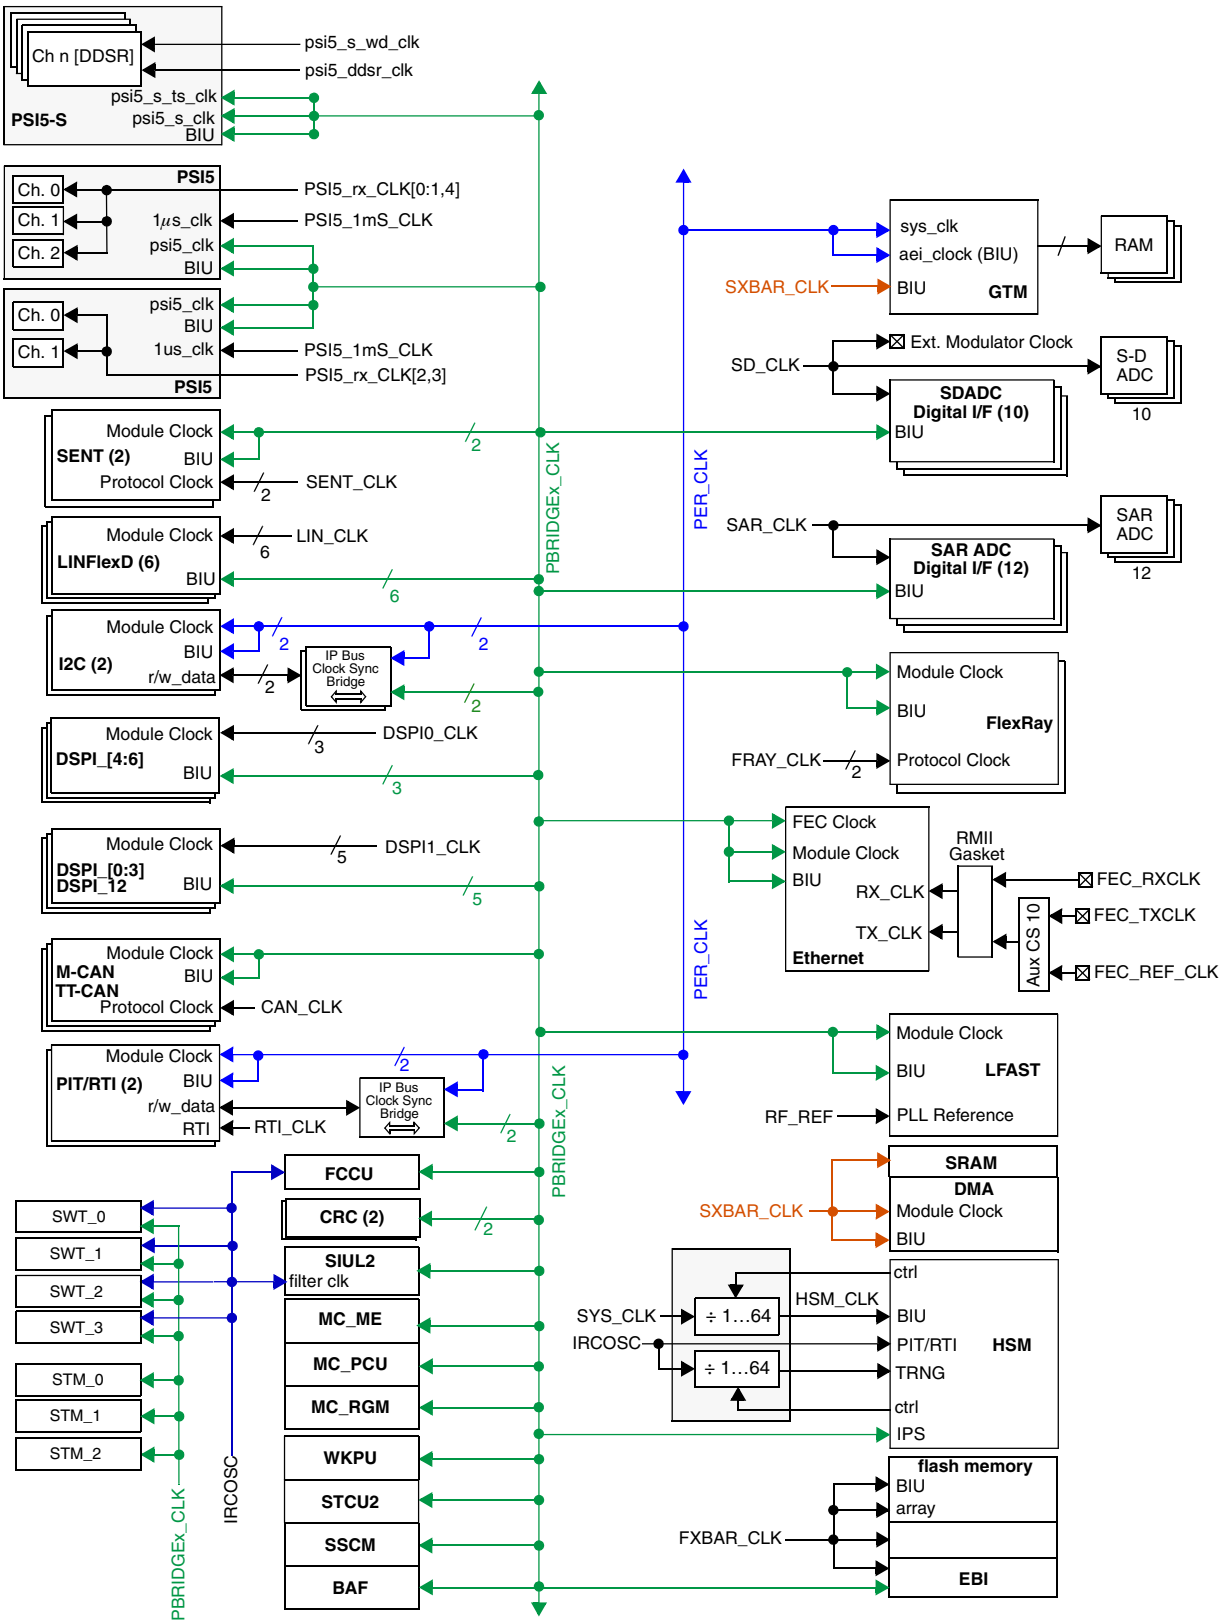

Figure 26-4. Clock distribution

26.6.1 HSM clock divider

The clock dividers for the HSM core and random number generator (TRNG) are located outside the HSM, but not in the MC_CGM. These dividers are controlled by the HSM.

The HSM contains an internal PIT/RTI block, which is clocked by the IRCOSC.

The HSM has an internal clock monitor on its input clock, so there is no need for a Clock Monitoring Unit (CMU) for the HSM_CLK in Figure 26-1.

26.6.2 PSI5 clock dividers

The MPC5777M microcontroller includes three PSI5 modules, all of which use the three common clocks shown in Figure 26-1. The required frequencies for these clocks are generated from PLL0 as follows:

- $F_{PSI5\_f189\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC0[DIV] + 1) / 10CGM_AC5_DC0[FMT]) = 6.048 MHz ±0.1%
- $F_{PSI5\_f125\_CLK} = F_{PLL0\_PHI}$ / (CGM_AC5_DC1[DIV] + 1) = 4 MHz
- $F_{PSI5\_1us\_CLK} = F_{PLL0\_PHI}$ / (CGM_AC5_DC2[DIV] + 1) = 1 MHz

The PSI5-S transceiver clock (ipp_psi5_uart_tclk in the PSI5-S chapter) is sourced from PSI5_f189_CLK. The transceiver clock operates in the range of 2 to 8 times the UART baud rate (up to 6.25 Mbit/sec).

- $F_{PSI5\_S\_UART\_TCLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC0[DIV] + 1) / 10CGM_AC5_DC0[FMT])
- 12.4 MHz < $F_{PSI5\_S\_UART\_TCLK}$ < 50 MHz

CAUTION

Since the PSI5 modules and the PSI5-S module use the PSI5_f189_CLK clock at significantly different frequencies, the PSI5 modules and PSI5-S module should not be used simultaneously.

The remaining PSI5-S clocks are generated by dividing the PSI5_1µs_CLK further via a second and a third level of 'cascaded' clock dividers. The individual frequencies are, therefore, derived from the PLL0 PHI frequency as follows:

- $F_{PSI5\_S\_TS\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC0[DIV]+1))

- $F_{PSI5\_S\_DDSR0\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC10[DIV]+1))
- $F_{PSI5\_S\_DDSR1\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC11[DIV]+1))
- $F_{PSI5\_S\_DDSR2\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC12[DIV]+1))
- $F_{PSI5\_S\_DDSR3\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC1[DIV]+1) * (CGM_AC5_CDC13[DIV]+1))
- $F_{PSI5\_S\_WD0\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC20[DIV]+1))
- $F_{PSI5\_S\_WD1\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC21[DIV]+1))
- $F_{PSI5\_S\_WD2\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC22[DIV]+1))
- $F_{PSI5\_S\_WD3\_CLK} = F_{PLL0\_PHI}$ / ((CGM_AC5_DC2[DIV] +1) * (CGM_AC5_CDC2[DIV]+1) * (CGM_AC5_CDC23[DIV]+1))

26.6.3 LFAST clocking

The MPC5777M includes two LFAST modules:

- In conjunction with the SIPI module for interprocessor communications.
- In conjunction with the JTAGM module for high speed debug.

High-speed operation of both LFAST modules is supported by a single LFAST PLL requiring a 10–20 MHz reference. Low-speed LFAST operation uses the reference clock directly.

The LFAST PLL reference clock source may be:

- PLL0:PHI output.
- External oscillator (XOSC).
- Input from the external LFAST device via the DRCLK_IO package pin.

When the reference clock is generated internally, it can be output on the DRCLK_IO pin.

The debug LFAST module only supports the operation mode where it outputs the reference clock to a connected LFAST capable tool as the DRCLK pin only supports output of the DRCLK reference.

On Emulation and Debug Devices (ED), the Buddy Device (BD) LFAST module connects to the package debug pins in place of the Production Device (PD) debug LFAST module. This module has a separate, dedicated LFAST PLL and the DRCLK pin only supports output of the reference clock to a connected LFAST capable tool (as with the Production Device).

Figure 26-5 shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

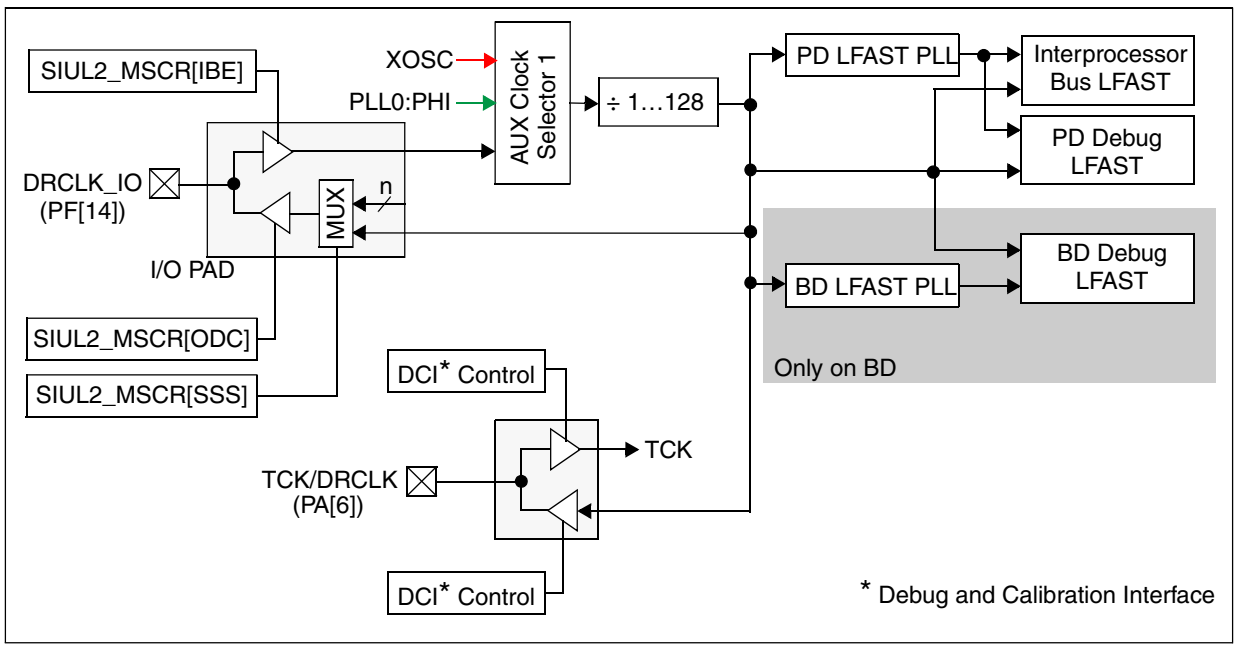

Figure 26-5. Device LFAST clocking

26.6.4 Ethernet clocking

Both internal and external clocks sources for MII and RMII Ethernet interface modes are supported. The MII clocks (FEC_TXCLK/FEC_RXCLK) are 25 MHz, and the RMII clock (FEC_REF_CLK) is 50 MHz. The following figure gives the connections for the Ethernet clocks.

The RXCLK pin is an input used in MII mode only and ignored by the RMII gasket in RMII mode.

The FEC_TXCLK pin is an input used in MII mode only but is shared with the FEC_REF_CLK input of the RMII gasket. The Aux clock selector is therefore required to select between FEC_TXCLK and FEC_REF_CLK for MII and RMII modes.

The FEC_REF_CLK can be generated internally or input to the device. For MII mode, the FEC_REF_CLK can be used for the 25 MHz reference for the external Ethernet PHY, which provides the TXCLK/RXCLK clocks back to the device. For RMII m ode, FEC_REF_CLK can be generated internally and fed to both the PHY device and to the RMII gasket by enabling the FEC_REF_CLK pad input and output buffers. FEC_REF_CLK can also be provided externally as an input to the device.

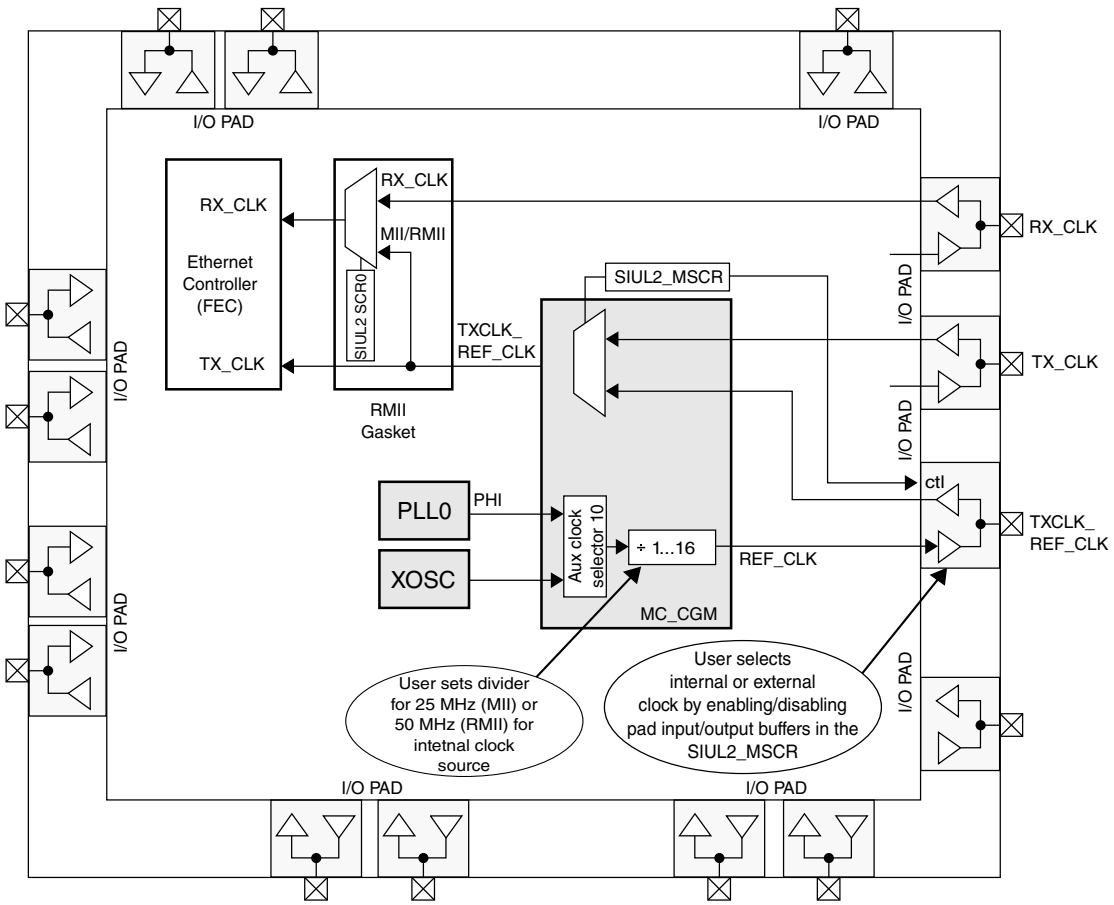

Figure 26-6. Device Ethernet clocking

26.6.5 FlexRay clocking

The FlexRay protocol clock is sourced from the PLL0_PHI clock or the external oscillator (XOSC), but its source selection is different from other modules:

1. PLL0_PHI enters the MC_CGM where it is divided by a value configured in the CGM_AC2_DC0 register and output as FRAY_PLL_CLK.
2. FRAY_PLL_CLK passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides FRAY_PLL_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

3. An internal multiplexer selects the PRCD output or XOSC as the resultant FRAY_CLK.

PLL0_PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

When XOSC is the input clock to the FlexRay controller, a 40 MHz crystal is required for proper operation. Both edges of the clock are used by the module to achieve the required 80 MHz frequency.

Selection of PLL or XOSC as the FlexRay clock is shown in Figure 29-7 in the Clock Generation Module (MC_CGM) chapter.

26.6.6 M_TTCAN/M_CAN clocking

The CAN_CLK is configured in the CGM via the following registers:

- CGM_AC8_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC8_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

CAN_CLK passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

26.6.7 Sigma-Delta ADC clocking

The analog portion of the Sigma-Delta ADC (SDADC) works with either an internal or external modulator.

When the internal modulator in the SDADC in enabled the internal clock (SD_CLK) is always used, see Figure 26-4).

When the external modulator is enabled (by disabling the internal modulator), an SDADC internal mux selects either:

- An external input clock (BS_CK).
- An internally generated output clock (SD_CLK) connected to the external modulator clock package pin (BS_CK).

In order to provide an internal clock option when the internal modulator is enabled, the SD_CLK output from the MC_CGM must be connected to the BS_CK pin as shown in Figure 26-7.

The MSCR in the SIUL2 control of the input/output direction of the BS_CK pin.

Each SDADC is connected as shown in Figure 26-7, with the SD_CLK being common to all modules, but each SDADC having a dedicated BS_CK pin.

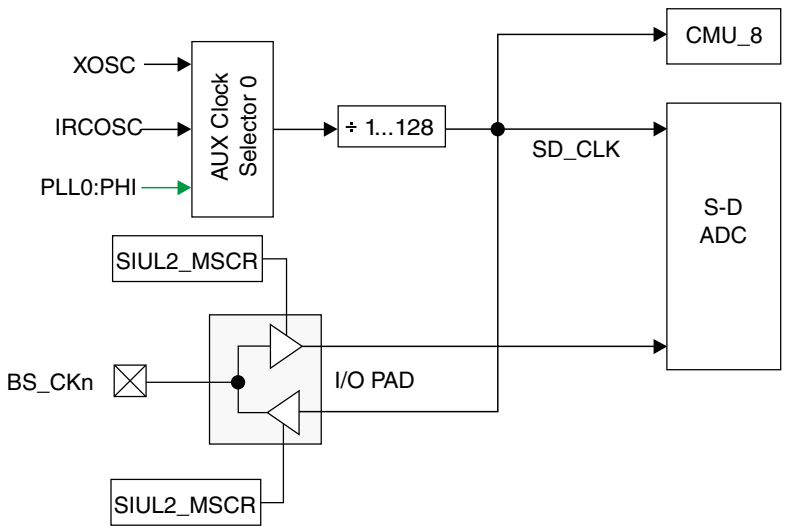

Figure 26-7. Sigma-Delta ADC clocking

26.6.8 System Clock/GTM output clock/Ethernet clock pin muxing

The two system clocks (SYSCLK[1:0]) have an independant source clock selected from:

- PLL0_PHI and PLL1_PHI.
- Internal oscillator (IRCOSC)
- External oscillator (XOSC)

The registers CGM_AC6_SC and CGM_AC7_SC configure the clocks for SYSCLK0 and SYSCLK1 respectively. See Figure 26-1.

There are three GTM output clocks available on package pins, EXTCLK[2:0]:

- EXTCLK[1:0] are muxed on the same pins as SYSCLK[1:0].
- EXTCLK[2] is muxed on the same pin as the Ethernet RMII clock (FEC_REF_CLK).

The selection of EXTCLK[n], SYSCLK[n] or FEC_REF_CLK is handled in the SIUL2_MSCR registers. See Figure 26-8.

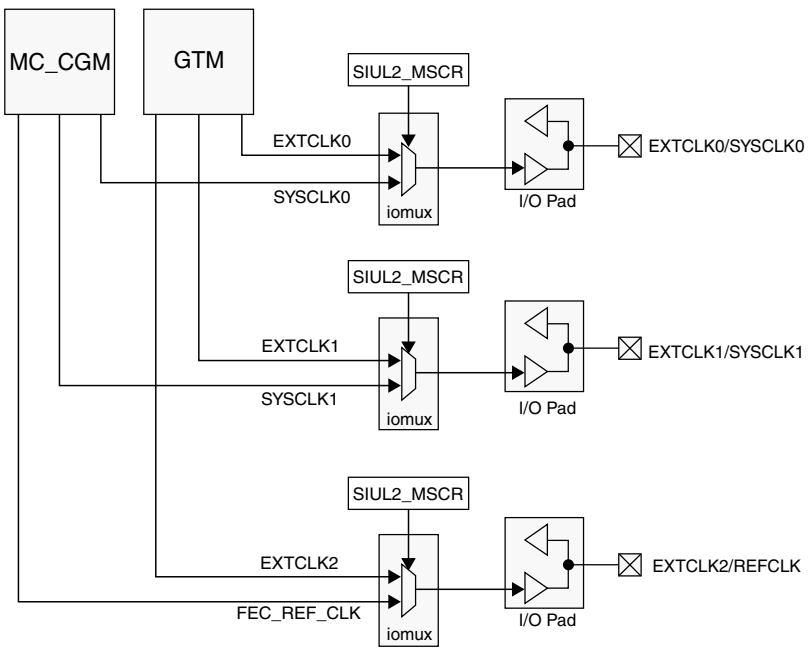

Figure 26-8. SYSCLK/EXTCLK/REF_CLK pin muxing

26.7 Clock monitoring

For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency.

Each CMU is programmed independently (see Figure 26-1 for CMU distribution) and uses the IRCOSC or XOSC as the clock monitor reference.

Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

26.7.1 CMU configuration

This section explains the CMU configuration.

Figure 26-9 shows the block diagram for CMU0 on the MPC5777M.

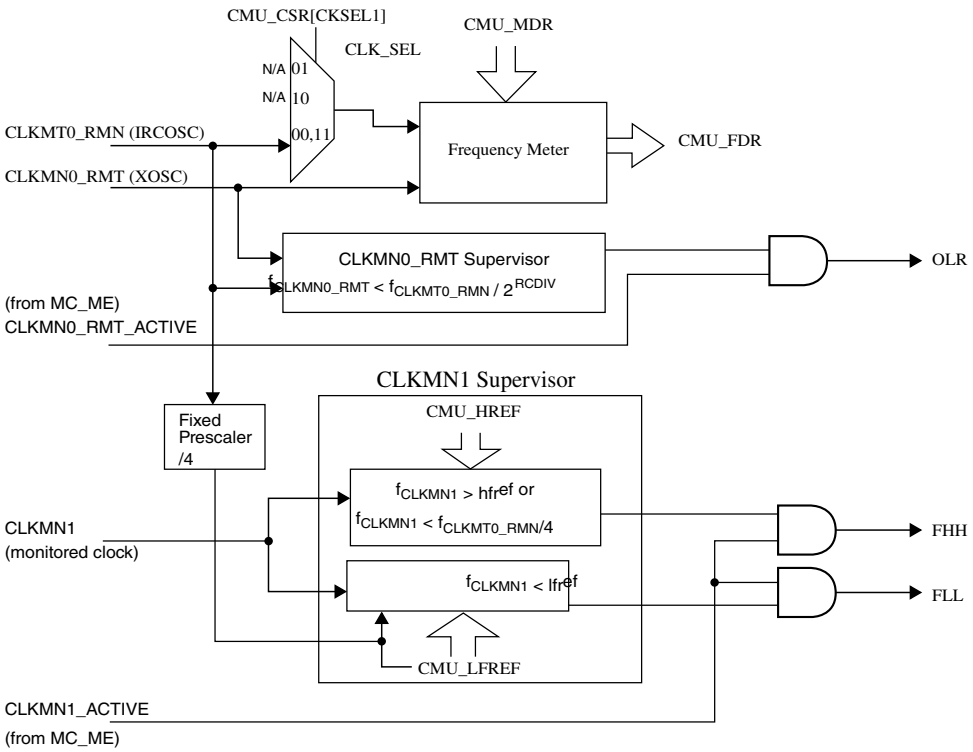

Figure 26-9. CMU0 block diagram

Figure 26-10 shows the block diagram for CMU[1:12] on the MPC5777M.

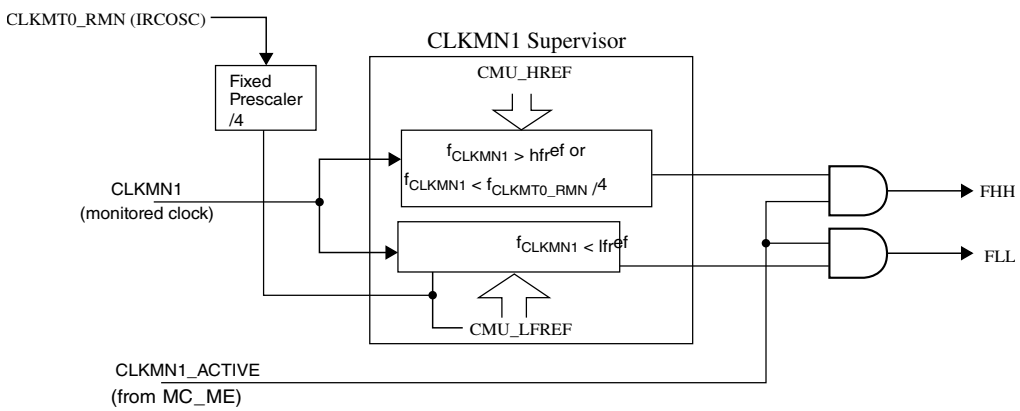

Figure 26-10. CMU[1:12] block diagram

26.7.1.1 Clock input sources

The following table shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 26-9. Clock input sources

Clock module	Monitored clock
CMU0	PLL0:PHI, XOSC, IRCOSC
CMU1	Peripheral Core_2, FXBAR_CLK, BD_CLK
CMU11	Main Core_1, Safety Core (Main Core_0, Checker Core_0s)
CMU12	CLKOUT

26.7.1.2 CMU registers and field availability

Table 26-10 specifies which registers and fields are available for a given CMU.

Table 26-10. CMU register availability

Address offset	Register	CMU	Note
0000h	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CKSEL1] in CMU0 only.
0004h	CMU_FDR	CMU0	—
0008h	CMU_HFREFR	All	—
000Ch	CMU_LFREFR	All	—
0010h	CMU_ISR	All	CMU_ISR[OLRI] in CMU0 only.
0014h	Reserved	—	—
0018h	CMU_MDR	CMU0	—

26.7.1.3 CMU register write protection

The CMU registers defined in Table 26-11 have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the CMU register write protection.

Table 26-11. CMU register write protection

Offset	Register[1]	Protection
0000h	CMU Control Status Register (CMU_CSR)	Yes
0004h	CMU Frequency Display Register (CMU_FDR)	No
0008h	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	No
000Ch	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	No
0010h	CMU Interrupt Status Register (CMU_ISR)	No
0014h	Reserved	No
0018h	CMU Measurement Duration Register (CMU_MDR)	No

1. See Register Protection chapter for bit field details.

26.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

26.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

26.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

26.7.5 System clock monitors

A CMU is assigned to monitor the frequency of the computational core, IOP core, fast and slow XBAR, both peripheral bridges, peripheral, PSI5, SENT and ADC clocks (refer to Figure 26-1).

26.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. Figure 26-11 gives a high-level view of the loss of clock logic.

26.8.1 Loss of PLL/XOSC clock

As shown in Figure 26-11, each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU.

When a clock failure occurs, the FCCU can be programmed to generate:

- An interrupt: only the backup clock in the PLL can provide clocks to the system in order to perform a system clock switch. There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).
- A short reset sequence: the clock configuration is maintained but also in this situation the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.
- A long reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC

26.8.2 Loss of IRCOSC clock

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure is a catastrophic failure.

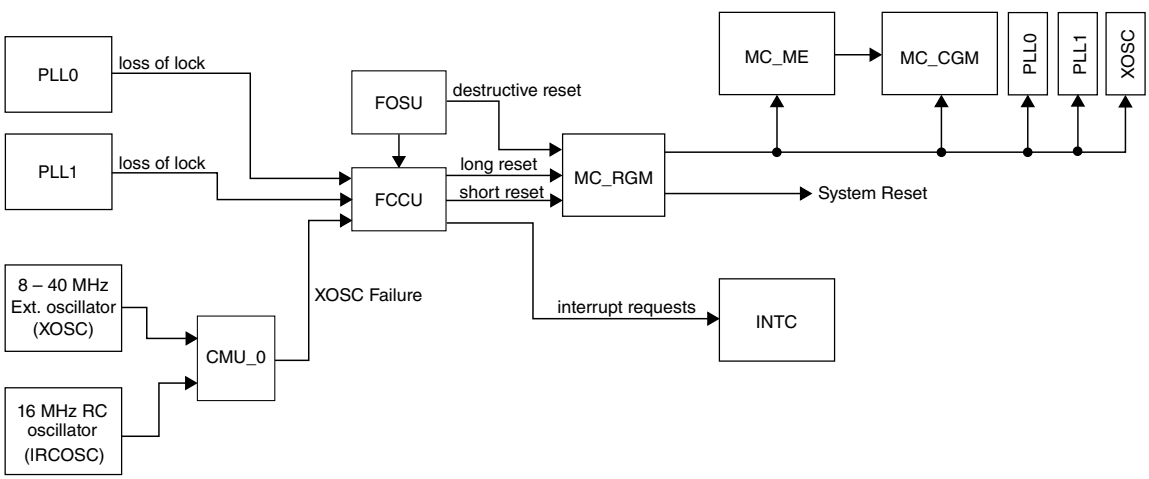

Figure 26-11. Loss of clock logic

26.9 Progressive clock switching

The Progressive Clock Switching (PCS) blocks are shown in the system-level clock diagram in Figure 26-1. They are used for ramping the system and peripheral clocks and for obtaining the precise clock frequency input for the PSI5 module. See the clock Generation Module (MC_CGM) chapter for more information on the PCS.

Chapter 27
Dual PLL Digital Interface (PLLDIG)

27.1 Introduction

The Dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

27.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

27.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.

- The loss of lock indication is sent to the FCCU via the system glue logic.

27.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG].

NOTE

Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<*mode*>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

27.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference which can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

NOTE

While powering down the PLLs and if PLL0:PHI1 is used as the source for PLL1, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Configuring the appropriate MC_ME_<*mode*>_MC register to start PLL1 should only be done after PLL0 has achieved lock.

27.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

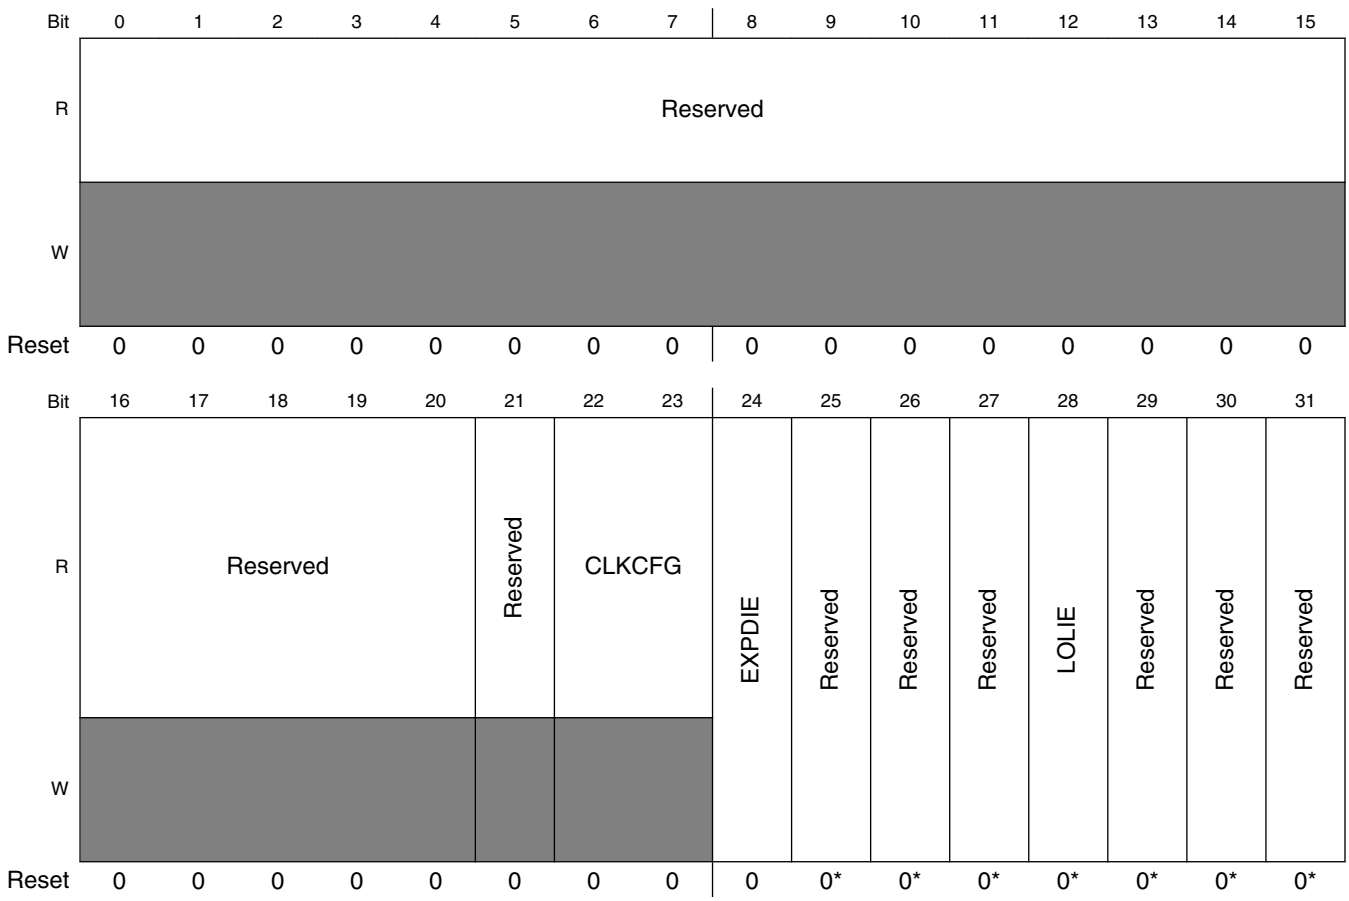
PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)	32	R/W	See section	27.5.1/1114
4	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	32	R/W	See section	27.5.2/1116
8	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)	32	R/W	See section	27.5.3/1118
20	PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)	32	R/W	See section	27.5.4/1120
24	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)	32	R/W	See section	27.5.5/1122
28	PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)	32	R/W	See section	27.5.6/1123
2C	PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)	32	R/W	See section	27.5.7/1125
30	PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)	32	R/W	0000_0000h	27.5.8/1127

27.5.1 PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)

The PLL0CR is shown in the following table.

Address: 0h base + 0h offset = 0h



* Notes:
- This field can be written at any time, but writes are ignored. Read returns previously written value.
- LOLIE field: See the "Clocking" chapter for details on configuring this field.

PLLDIG_PLL0CR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 CLKCFG	Clock Configuration This field indicates the operational state of PLL.

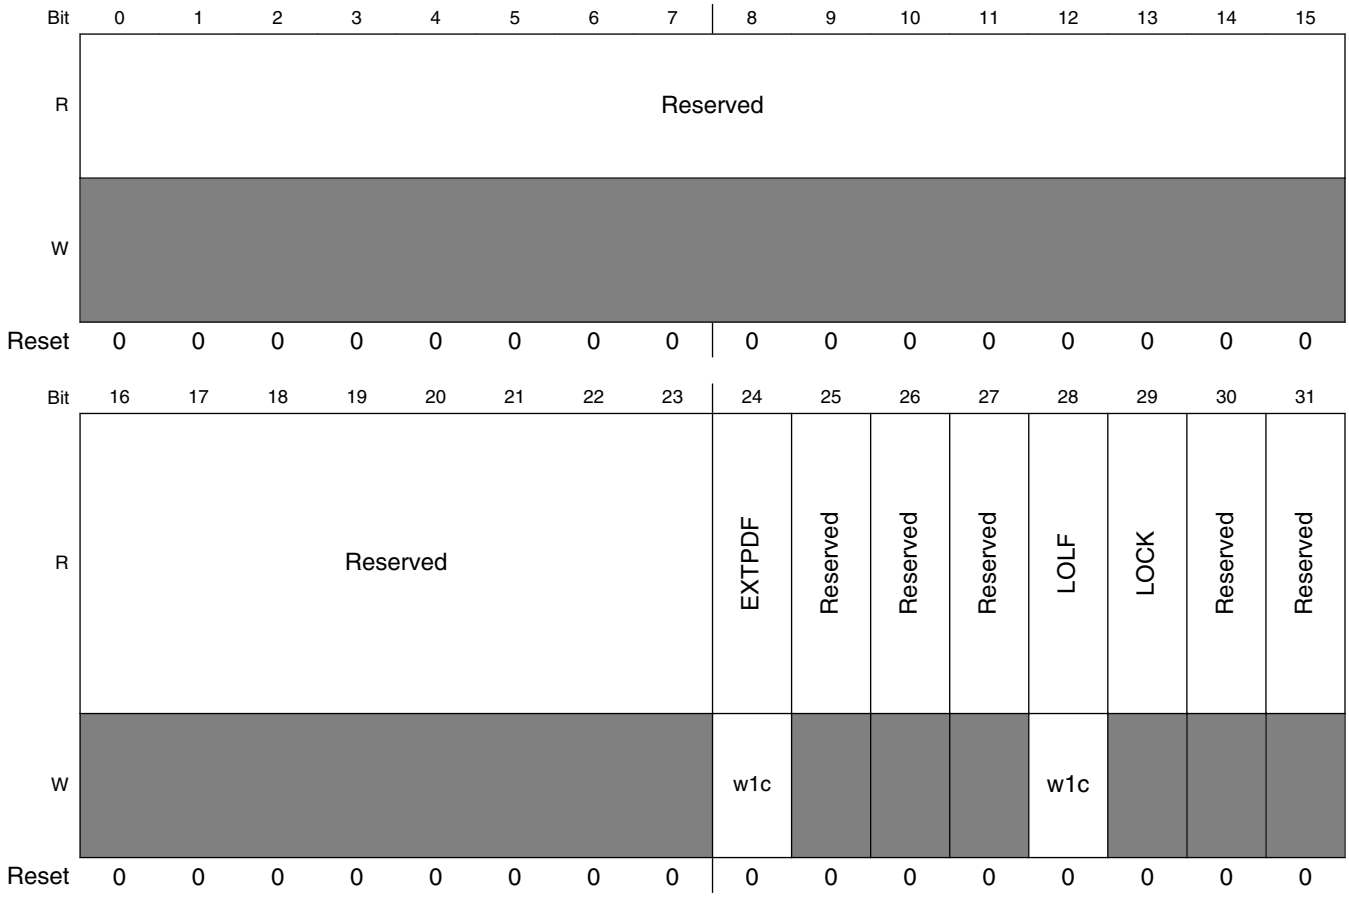
Table continues on the next page...

PLLDIG_PLL0CR field descriptions (continued)

Field	Description
	When PLLs are externally powered down the CLKCFG field changes to 00b. **NOTE:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1. **NOTE:** CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_< *mode* >_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details). 00 PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running.
24 EXPDIE	External Power Down Cycle Complete indication interrupt enable. This bit enables generation of an interrupt when the external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 Reserved	This field is reserved.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

27.5.2 PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)

Address: 0h base + 4h offset = 4h



PLLDIG_PLL0SR field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.

Table continues on the next page...

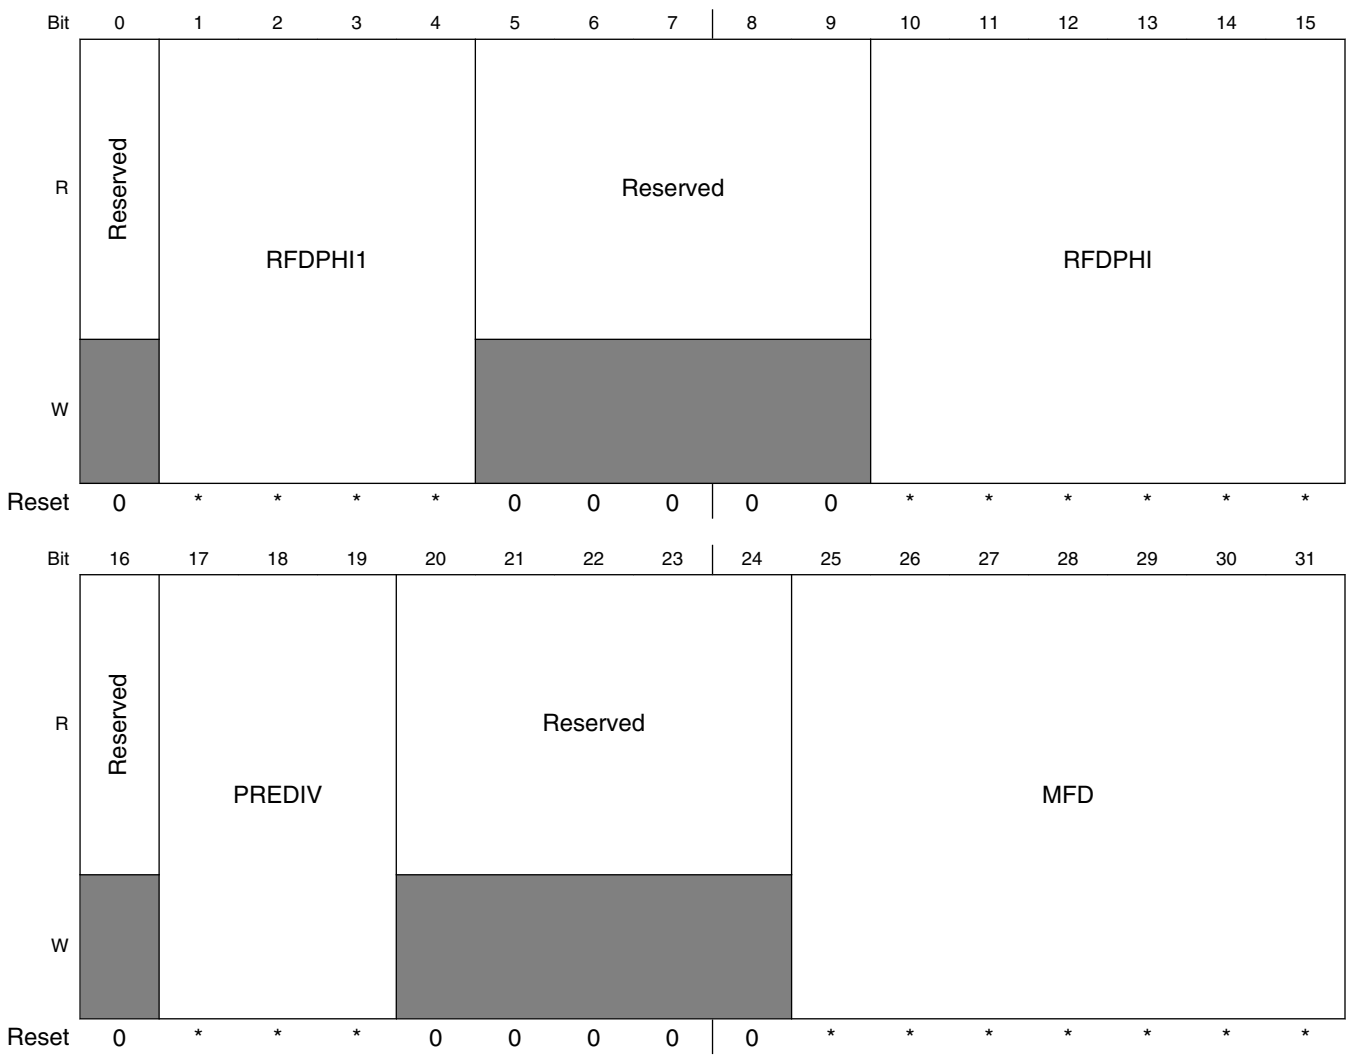
PLLDIG_PLL0SR field descriptions (continued)

Field	Description
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

27.5.3 PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. PLL0DV can be modified at anytime, but the changes become effective only after the PLL is disabled, then reenabled. If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled. The reduced frequency divider bitfields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective when PLL0 is disabled, then reenabled.

Address: 0h base + 8h offset = 8h



* Notes:
- MFD field: See Clocking chapter for reset value
- PREDIV field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value

- RFDPHI1 field: See Clocking chapter for reset value

PLLDIG_PLL0DV field descriptions

Field	Description
0 Reserved	This field is reserved.
1–4 RFDPHI1	PHI1 reduced frequency divider. This 4-bit field determines the VCO clock post divider for driving the PHI1 output clock. RFDPHI1 has a range of 4..15 (4h..Fh). All other values are reserved.
5–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16 Reserved	This field is reserved.
17–19 PREDIV	Input clock predivider. This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. The PREDIV value 000b causes the input clock to be inhibited. 000 Clock inhibit 001 Divide by 1 010 Divide by 2 011 Divide by 3 100 Divide by 4 101 Divide by 5 110 Divide by 6 111 Divide by 7
20–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 8...127 (8h...7Fh). All other values are reserved (see Clock configuration for details).

27.5.4 PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)

The PLL1CR is shown in the following table. It contains the operational state of PLL1, and is used to enable/disable PLL specific interrupts.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

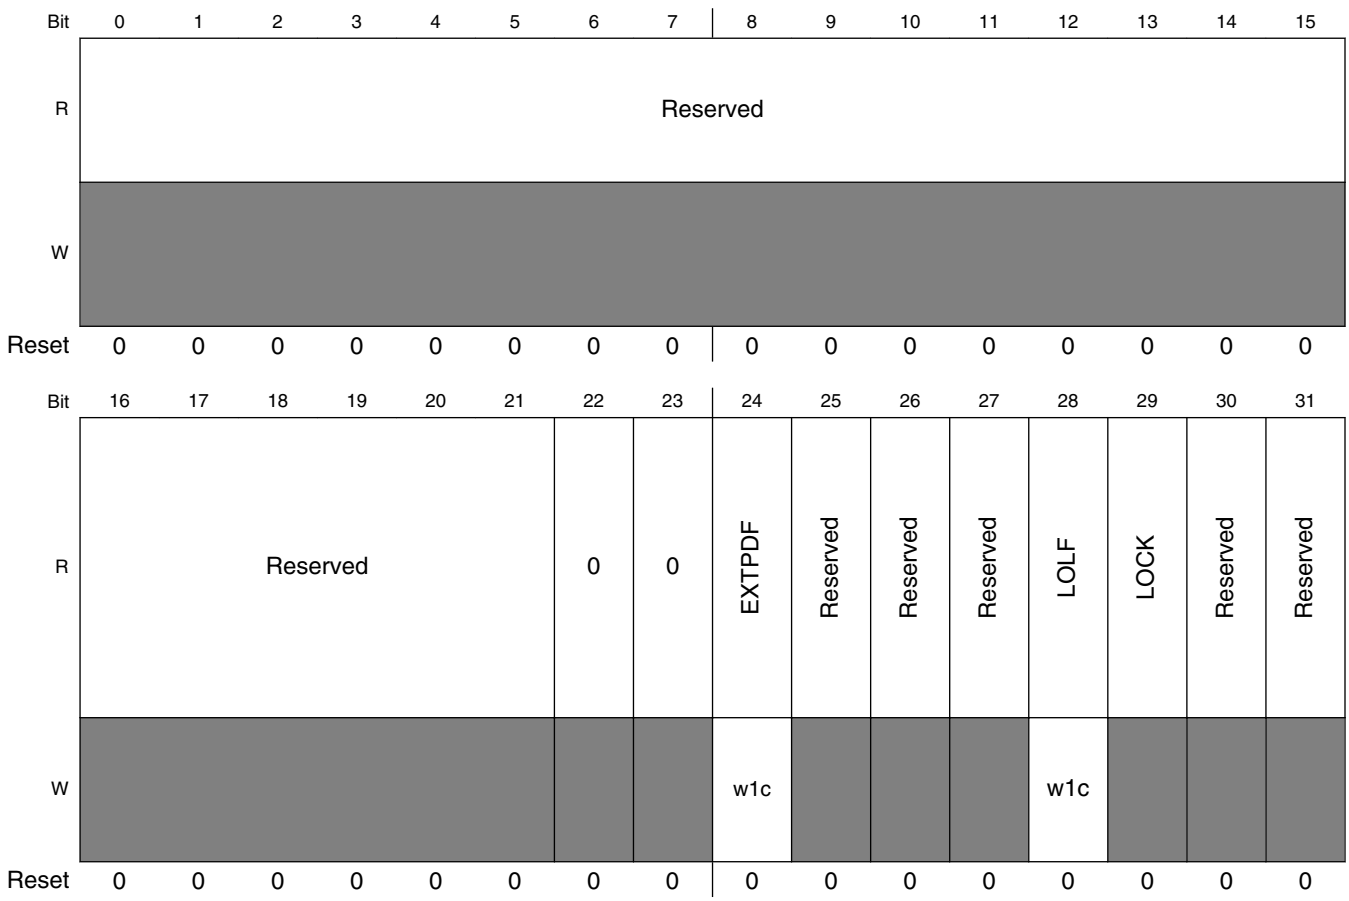
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

27.5.5 PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)

PLL1SR contains status flags showing the current state of the PLL.

Address: 0h base + 24h offset = 24h



PLLDIG_PLL1SR field descriptions

Field	Description
0–21 Reserved	This field is reserved.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested

Table continues on the next page...

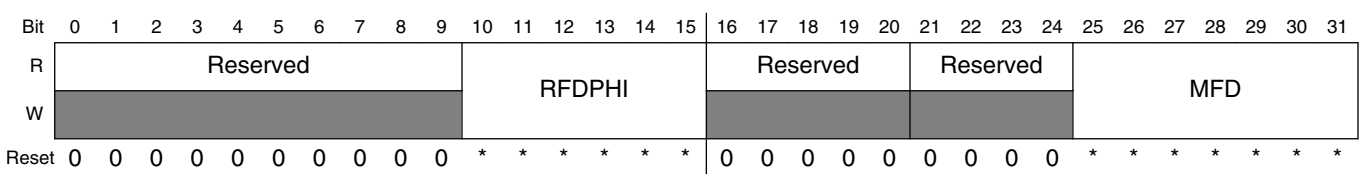
PLLDIG_PLL1SR field descriptions (continued)

Field	Description
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

27.5.6 PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)

The values of the reduced frequency divider (RFDPHI) and loop multiplication factor divider (MFD) can be modified at anytime, but the new values only become effective after the PLL is disabled, then reenabled.

Address: 0h base + 28h offset = 28h



* Notes:
- MFD field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value

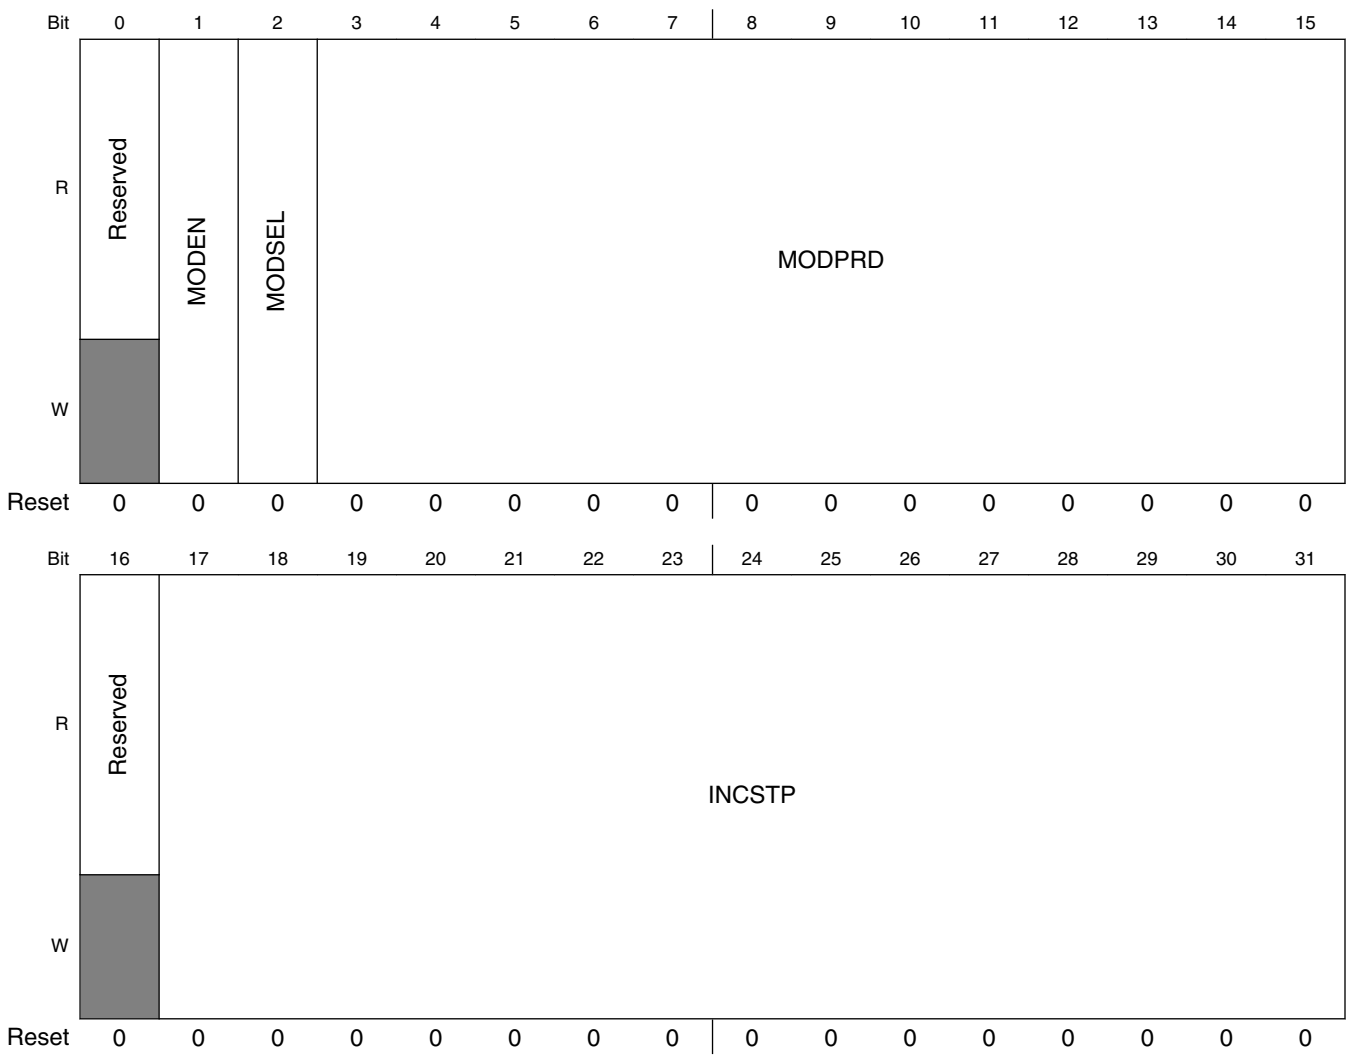
PLLDIG_PLL1DV field descriptions

Field	Description
0–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16–20 Reserved	This field is reserved.
21–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 16...34 (10h...22h). All other values are reserved.

27.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)

The PLL1FM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). The PLL would then be required to be power cycled to regain normal functionality. Modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock.

Address: 0h base + 2Ch offset = 2Ch



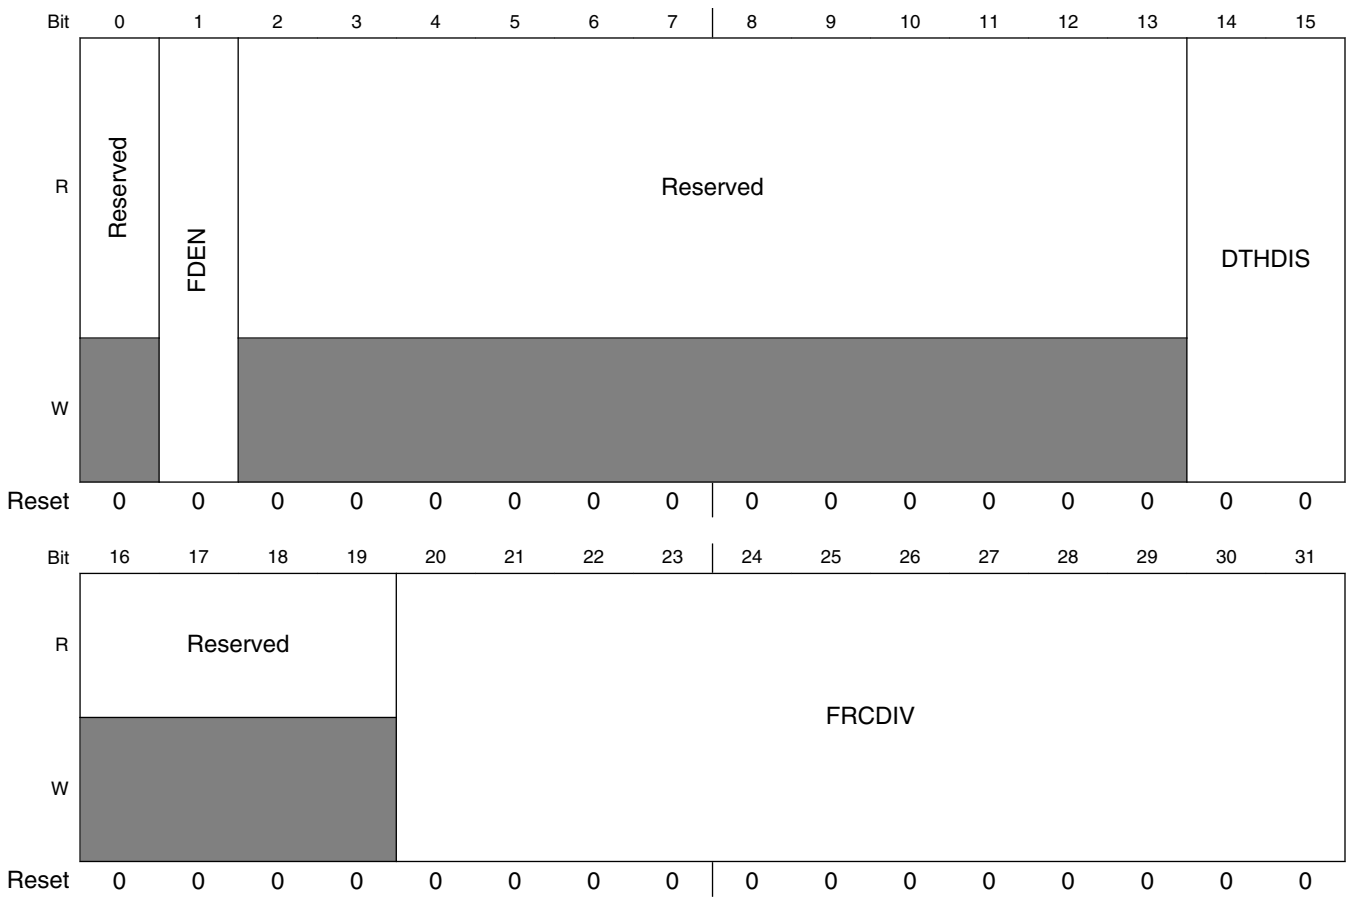
PLLDIG_PLL1FM field descriptions

Field	Description
0 Reserved	This field is reserved.
1 MODEN	Modulation enable. This bit enables the frequency modulation. 0 Frequency modulation disabled. 1 Frequency modulation enabled.
2 MODSEL	Modulation selection. This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Centre Spread Modulation - Modulation centred around nominal frequency. 1 Down Spread Modulation - Modulation spread below nominal frequency.
3–15 MODPRD	Modulation period. MODPRD is the modulation period variable derived from the formulas shown in Frequency modulation.
16 Reserved	This field is reserved.
17–31 INCSTP	Increment step. This field is the INCSTP variable derived from the formulas shown in Frequency modulation.

27.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (PLL*n*CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The dither disable (PLLDIG_PLL1FD[DTHDIS]) and fractional divider (PLLDIG_PLL1FD[FRCDIV]) fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates.

Address: 0h base + 30h offset = 30h



PLLDIG_PLL1FD field descriptions

Field	Description
0 Reserved	This field is reserved.

Table continues on the next page...

PLLDIG_PLL1FD field descriptions (continued)

Field	Description
1 FDEN	Fractional Divide Enable This bit enables the fractional divider in the loop divider for PLL1. 0 Fractional divide disabled. 1 Fractional divide enabled.
2–13 Reserved	This field is reserved.
14–15 DTHDIS	Dither Disable. **Important:** This field must be written 00b. 00 Dither enabled 01 Dither disabled 10 Dither enabled 11 Dither disabled
16–19 Reserved	This field is reserved.
20–31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in the section Clock configuration.

27.6 Register classification for safety requirements

This module is classified as ViMo (Vital Modules) for functional safety. Hence, the registers of this module have been classified as shown in the Functional Safety chapter.

27.7 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

27.7.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLLs are discussed in detail in the *Data Sheet*.

27.7.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0\_phi} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

Equation 1. PLL0 PHI Output Frequency

$$f_{pll0\_phi1} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Equation 2. PLL0 PHI1 Output Frequency

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 3. PLL1 PHI Output Frequency

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0\_VCO} = \frac{f_{pll0\_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

Equation 4. PLL0 VCO Frequency

$$f_{pll1\_VCO} = f_{pll1\_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} \right)$$

Equation 5. PLL1 VCO Frequency

NOTE

f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of the PLL*n*DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Initialization information.

27.7.3 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 27-1. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

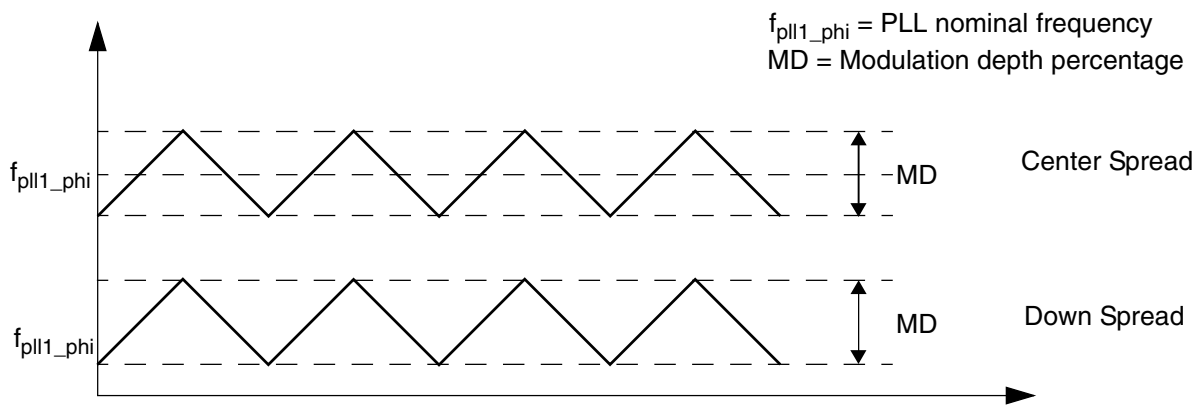


Figure 27-1. Triangular frequency modulation

NOTE

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{max} = f_{sys} \times (1 + (MD\% / 100))$.

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the output frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$PLL1FM[MODPRD] = round\left(\frac{f_{pll1\_ref}}{4 \times f_{mod}}\right)$$

Equation 6. PLL1FM[MODPRD] Calculation

The equation to determine PLL1FM[INCSTP] is shown in Equation 7 on page 1131.

$$PLL1FM[INCSTP] = round\left(\frac{(2^{15}-1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

Equation 7. PLL1FM[INCSTP] Calculation

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Equation 8. PLL1FM[MODPRD] and PLL1FM[INCSTP] Restriction

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is shown in Equation 9 on page 1131.

$$ModulationDepth = round\left(\frac{PLL1FM[MODPRD] \times PLL1FM[INCSTP] \times 100 \times 5}{(2^{15} - 1) \times PLL1DV[MFD]}\right)$$

Equation 9. Modulation Depth

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 0, followed by a mode change.

2. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].
3. Program the PLL1FM while PLL1 is powered down.
4. Power up the PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

27.7.4 Maximum lock time

This describes the maximum lock time of the PLL across process, supply voltages, and junction temperature. Maximum lock time is for the condition when the operating mode of the PLL has changed from power-down to Normal mode, input control bits are stable, and supplies (analog and digital) have attained levels shown in the *Data Sheet*. It is also the time in which the PLLs regain lock after a loss of lock event, assuming all inputs are stable and supplies are within specifications.

27.8 Initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The Dual PLLDIG initialization procedure is described in the "Clocking" chapter.

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

Chapter 28
Clock Monitor Unit (CMU)

28.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

28.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ n clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

28.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

28.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 28-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

28.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	28.4.1/1136
4	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	28.4.2/1137
8	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	28.4.3/1138
C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	28.4.4/1138
10	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	28.4.5/1139
18	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	28.4.6/1140

28.4.1 CMU Control Status Register (CMU_CSR)

Address: 0h base + 0h offset = 0h

- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 RCDIV	CLKMT0_RMN division factor.

Table continues on the next page...

CMU_CSR field descriptions (continued)

Field	Description
	These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0\_RMN} \div 2^{RCDIV}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

28.4.2 CMU Frequency Display Register (CMU_FDR)

The FDR is used to determine the measured frequency being monitored by the CMU.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												FD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

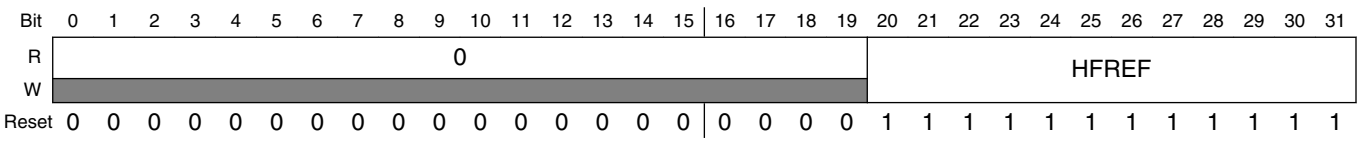
CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: $f_{sel} = (f_{CLKMN0\_RMT} \times CMU\_MDR[MD]) \div CMU\_FDR[FD]$

28.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the HFREFR register.

Address: 0h base + 8h offset = 8h



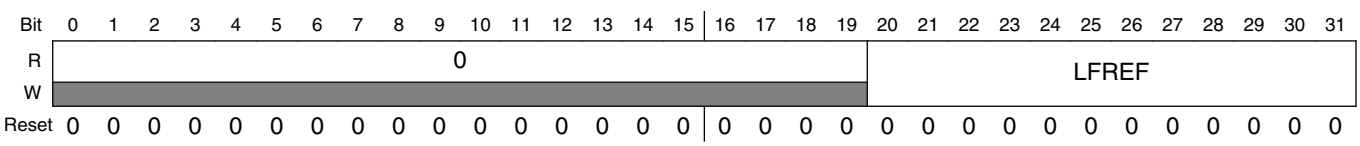
CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: (HFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

28.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the LFREFR register.

Address: 0h base + Ch offset = Ch



CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CMU_LFREFR field descriptions (continued)

Field	Description
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

28.4.5 CMU Interrupt Status Register (CMU_ISR)

NOTE

All the flags in CMU_ISR set asynchronously. This register must be read only after an interrupt(safe mode entry) is triggered by the CMUas confirmed by MC_RGM. Otherwise, the read access on this register may fetch an incorrect value.

NOTE

Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved.
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value, and CLKMN1 is 'ON' as signaled by the MC_ME. Software clears this field by writing a '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{CLKMT0_RMN} \div 2^{RCDIV}$event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0_RMN} \div 2^{RCDIV}$frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. **NOTE:** While entering STOP mode, OLRI may be triggered. To avoid this when the system is running on the PLL, disable XOSC before entering STOP mode. 0 No OLR event 1 OLR event occurred

28.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																MD															
W

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits

Table continues on the next page...

CMU_MDR field descriptions (continued)

Field	Description
	This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

28.5 Functional description

28.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

$$f_{sel} = f_{CLKMN0\_RMT} \times \frac{CMU\_MDR[MD]}{CMU\_FDR[FD]}$$

28.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN $\div 2^{CMU\_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

f_{CLKMN0_RMT} must be greater than $f_{CLKMT0\_RMN} \div 2^{CMU\_CSR[RCDIV]}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

28.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

An example of determining the $HFREF_{Actual}$ is as follows. Assume a f_{CLKMT0_RMN} = 16 MHz with a accuracy of +/-5%. In order to monitor a f_{CLKMN1} = 200 MHz, the ideal $HFREF_{Ideal}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($HFREF_{Actual} = (HFREF_{Ideal} \div 0.95)$.

The actual LFREF value will be 762 when accuracy is taken into consideration ($LFREF_{Actual} = LFREF_{Ideal} \div 1.05$).

Chapter 29
Clock Generation Module (MC_CGM)

29.1 Introduction

29.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the chip blocks. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). A set of MC_CGM registers controls the clock dividers which are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

Figure 29-1 shows the MC_CGM block diagram.

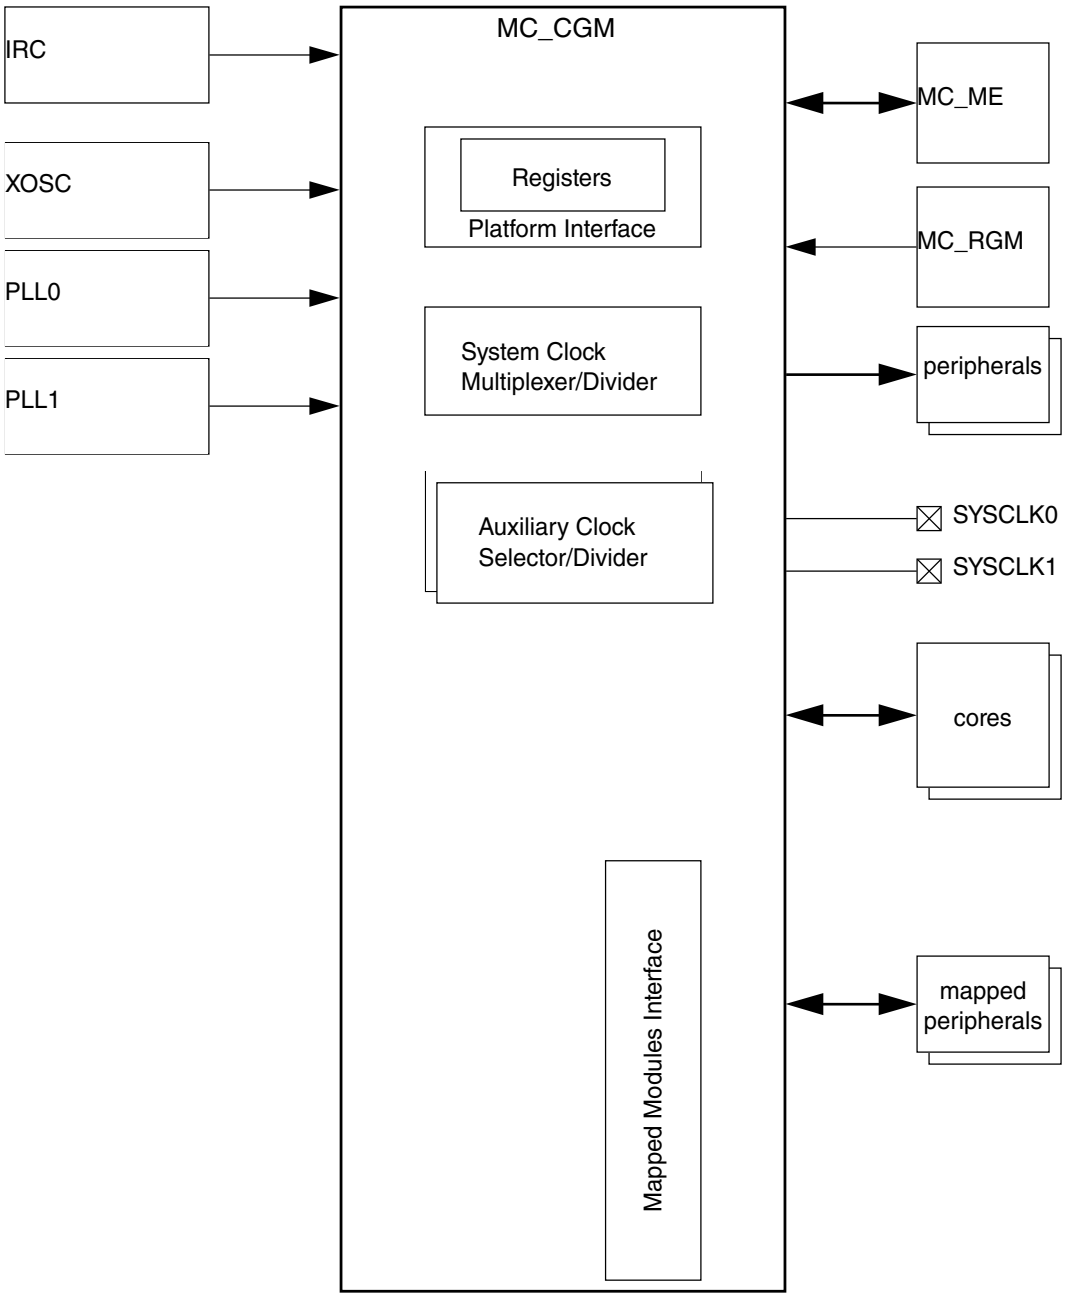

Figure 29-1. MC_CGMBlock Diagram

29.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control

- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

29.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use and/or observation.

29.3 Memory map and register definition

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

NOTE

All registers will be accessible in "User mode" provided the access to this mode is enabled through REGPROT settings. Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error(only if SSCM_ERROR[RAE] is set)

1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 DIV	Divider Division Value - The resultant peripheral clock will have a period '(DIV + 1) x (CGM_AC5_CDC2[DIV] + 1) x (CGM_AC5_DC2[DIV] + 1)' times that of auxiliary clock 5. If DE is set to 0 (divider is disabled), any write access to the DIV field is ignored and the peripheral clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

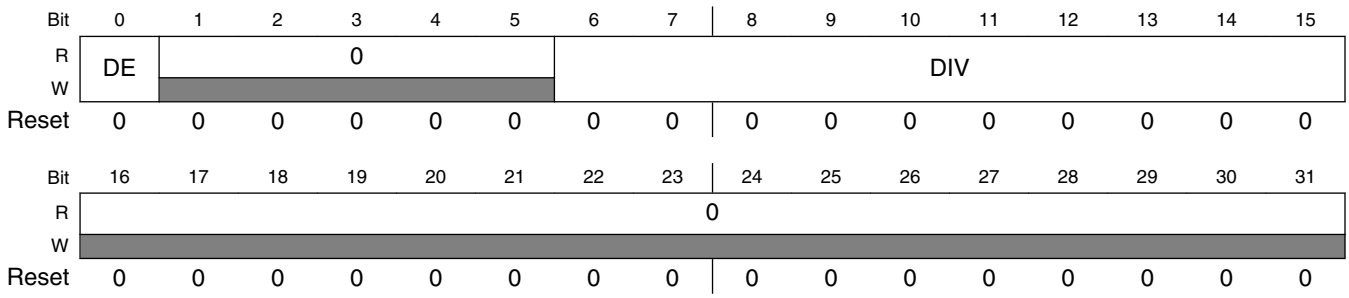
29.3.10 Auxiliary Clock 5 Cascaded Divider 22 Configuration Register (MC_CGM_AC5_CDC22)

This register controls auxiliary clock 5 cascaded divider 22.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Address: 0h base + 6A8h offset = 6A8h



MC_CGM_AC5_CDC22 field descriptions

Field	Description
0 DE	Divider Enable 0 Disable auxiliary clock 5 cascaded divider 22 1 Enable auxiliary clock 5 cascaded divider 22
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 DIV	Divider Division Value - The resultant peripheral clock will have a period '(DIV + 1) x (CGM_AC5_CDC2[DIV] + 1) x (CGM_AC5_DC2[DIV] + 1)' times that of auxiliary clock 5. If DE is set to 0 (divider is disabled), any write access to the DIV field is ignored and the peripheral clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

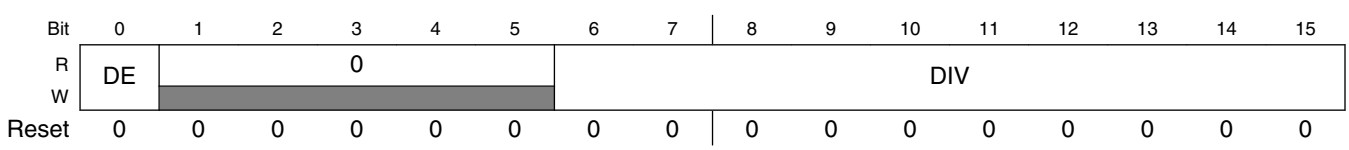
29.3.11 Auxiliary Clock 5 Cascaded Divider 23 Configuration Register (MC_CGM_AC5_CDC23)

This register controls auxiliary clock 5 cascaded divider 23.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Address: 0h base + 6ACh offset = 6ACh



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 DIV	Divider Division Value - The resultant peripheral clock will have a period '(DIV + 1) x (CGM_AC5_CDC2[DIV] + 1) x (CGM_AC5_DC2[DIV] + 1)' times that of auxiliary clock 5. If DE is set to 0 (divider is disabled), any write access to the DIV field is ignored and the peripheral clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.3.12 PCS Switch Duration Register (MC_CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See Progressive system clock switching for details on how to set this value.

Address: 0h base + 700h offset = 700h

Bit	0	1	2	3	4	5	6	7
Read Write	SDUR							
Reset	0	0	0	0	0	0	0	0

MC_CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration - This value defines the duration of one PCS clock switch step in terms of 16 MHz int. RC osc. cycles.

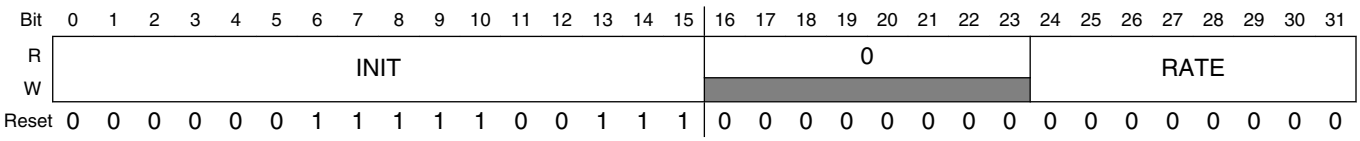
29.3.13 PCS Divider Change Register 1 (MC_CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the external crystal osc. on ramp-up and ramp-down, respectively. See Progressive system clock switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 704h offset = 704h



MC_CGM_PCS_DIVC1 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to the external crystal osc..
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the external crystal osc..

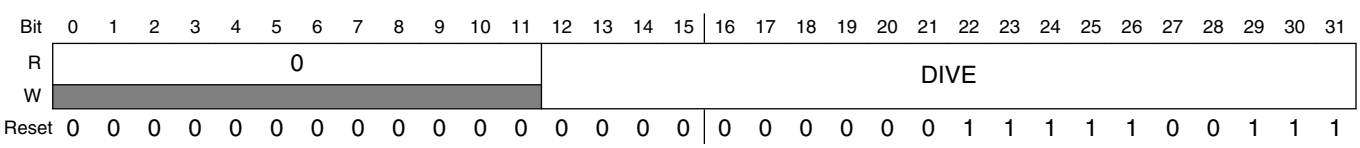
29.3.14 PCS Divider End Register 1 (MC_CGM_PCS_DIVE1)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the external crystal osc. on ramp-down. See Progressive system clock switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 708h offset = 708h



MC_CGM_PCS_DIVE1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the external crystal osc..

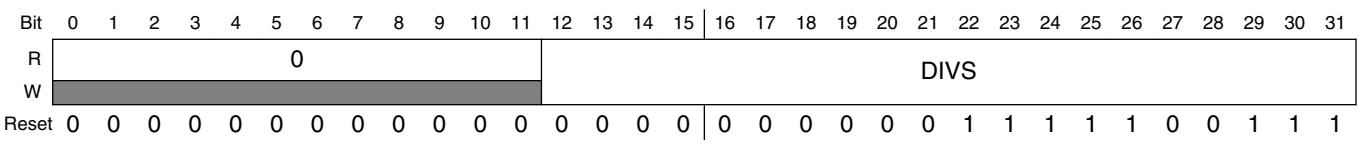
29.3.15 PCS Divider Start Register 1 (MC_CGM_PCS_DIVS1)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the external crystal osc. on ramp-up. Register *n* corresponds to system clock source *n* . See Progressive system clock switching for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 70Ch offset = 70Ch



MC_CGM_PCS_DIVS1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the external crystal osc..

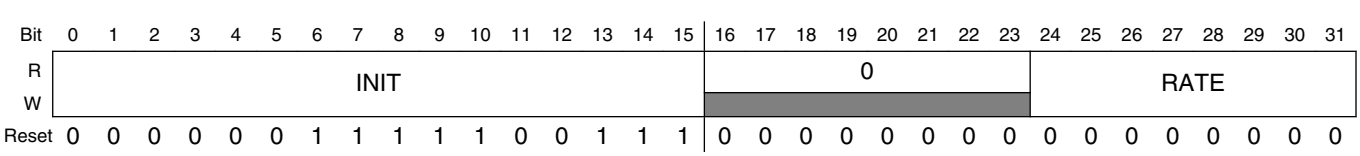
29.3.16 PCS Divider Change Register 2 (MC_CGM_PCS_DIVC2)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL0 PHI on ramp-up and ramp-down, respectively. See Progressive system clock switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 710h offset = 710h



MC_CGM_PCS_DIVC2 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL0 PHI.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL0 PHI.

29.3.17 PCS Divider End Register 2 (MC_CGM_PCS_DIVE2)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the PLL0 PHI on ramp-down. See Progressive system clock switching for details on how to set This value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 714h offset = 714h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_CGM_PCS_DIVS2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL0 PHI.

29.3.19 PCS Divider Change Register 4 (MC_CGM_PCS_DIVC4)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL1 PHI on ramp-up and ramp-down, respectively. See Progressive system clock switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 728h offset = 728h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MC_CGM_PCS_DIVC4 field descriptions

Field	Description
0–15 INIT	Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL1 PHI.

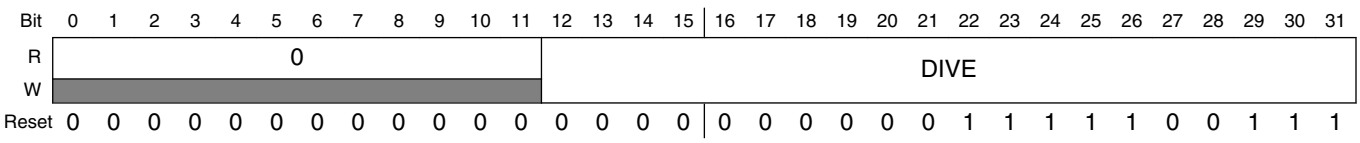
29.3.20 PCS Divider End Register 4 (MC_CGM_PCS_DIVE4)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the PLL1 PHI on ramp-down. See Progressive system clock switching for details on how to set This value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 72Ch offset = 72Ch



MC_CGM_PCS_DIVE4 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the PLL1 PHI.

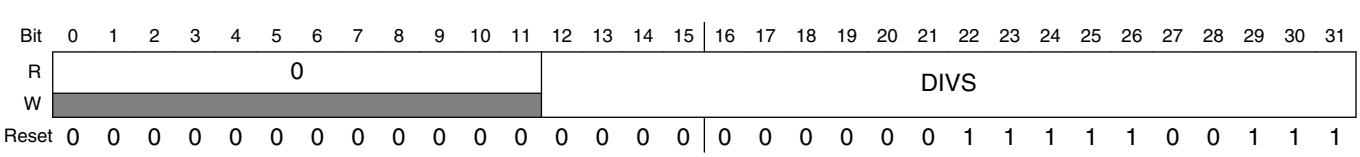
29.3.21 PCS Divider Start Register 4 (MC_CGM_PCS_DIVS4)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the PLL1 PHI on ramp-up. See Progressive system clock switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 730h offset = 730h



MC_CGM_PCS_DIVS4 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.

29.3.22 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

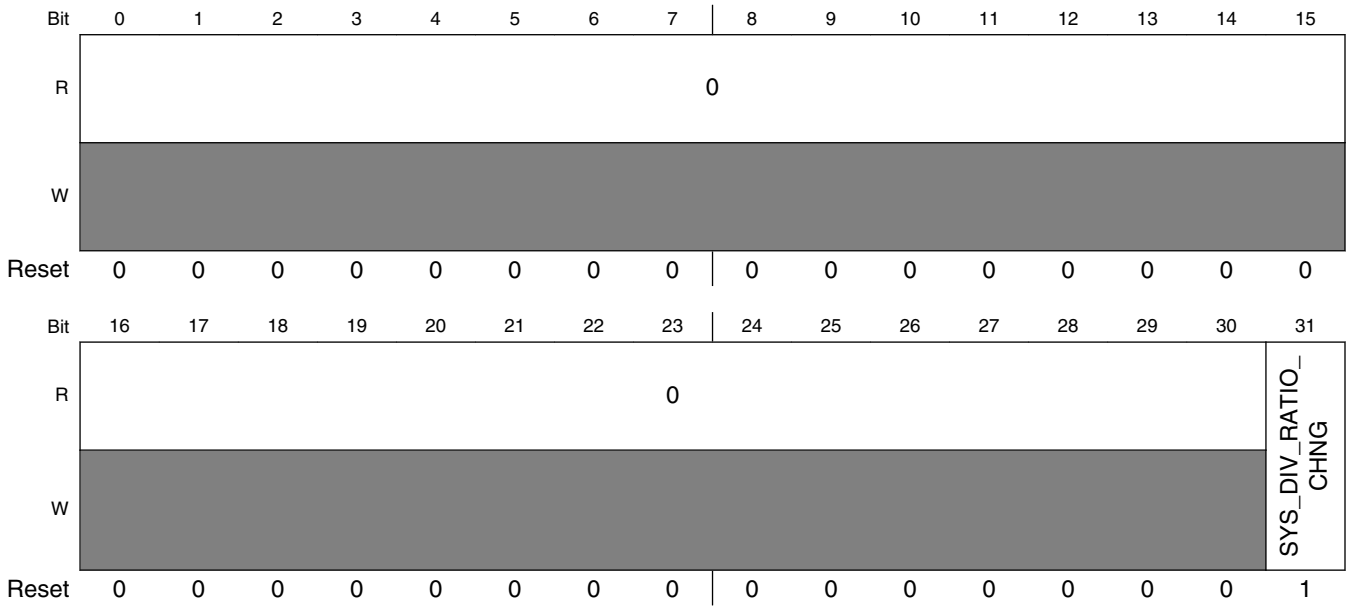
An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations. An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3. The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

See Divider update triggering for details.

CAUTION

Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

Address: 0h base + 7D0h offset = 7D0h



MC_CGM_SC_DIV_RC field descriptions

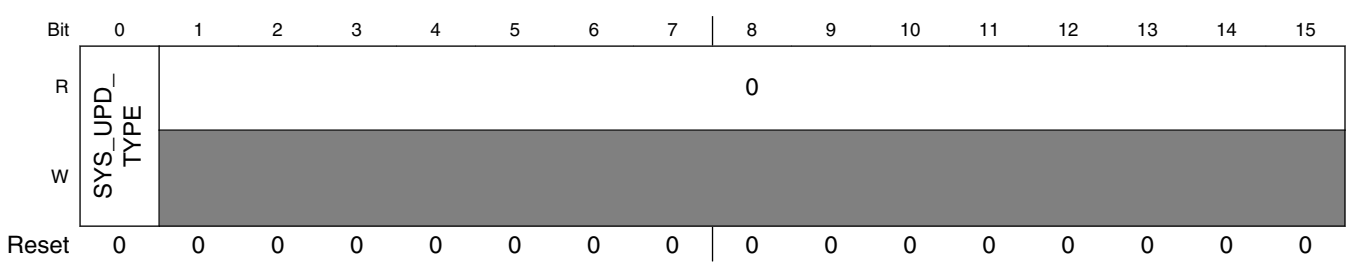
Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SYS_DIV_ RATIO_CHNG	System Clock Divider Ratio Change 0 The system clock divider ratios will not change with the next system clock divider configuration update 1 The system clock divider ratios will change with the next system clock divider configuration update

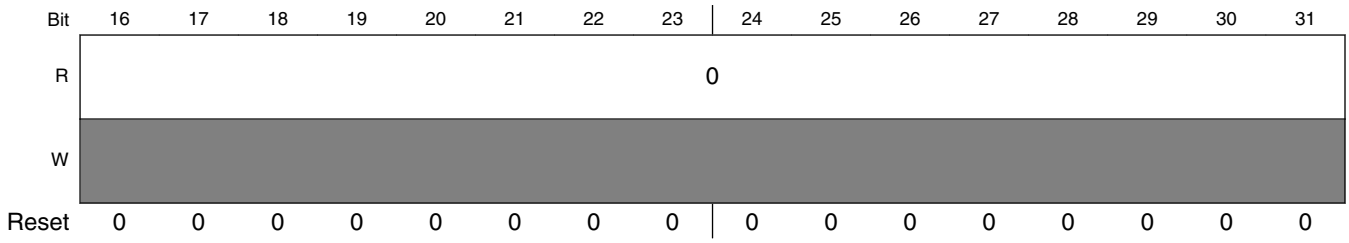
29.3.23 Divider Update Type Register (MC_CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.

See Divider update triggering for details.

Address: 0h base + 7D4h offset = 7D4h





MC_CGM_DIV_UPD_TYPE field descriptions

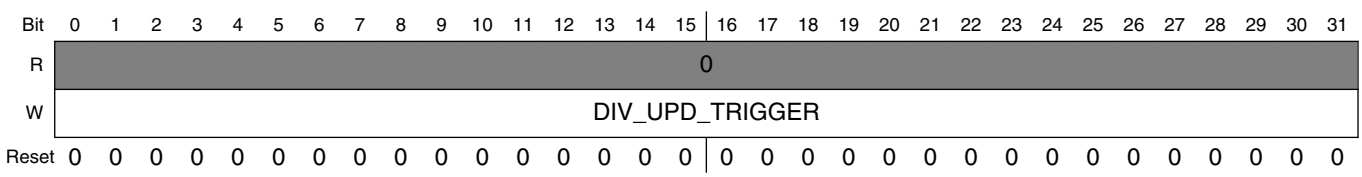
Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type 0 The configuration for each system clock divider is updated immediately on writing to the corresponding CGM_SC_DCi register 1 The configuration for each system clock divider is pre-loaded on writing to the corresponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.3.24 Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to ‘1’ in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

See Divider update triggering for details.

Address: 0h base + 7D8h offset = 7D8h



MC_CGM_DIV_UPD_TRIG field descriptions

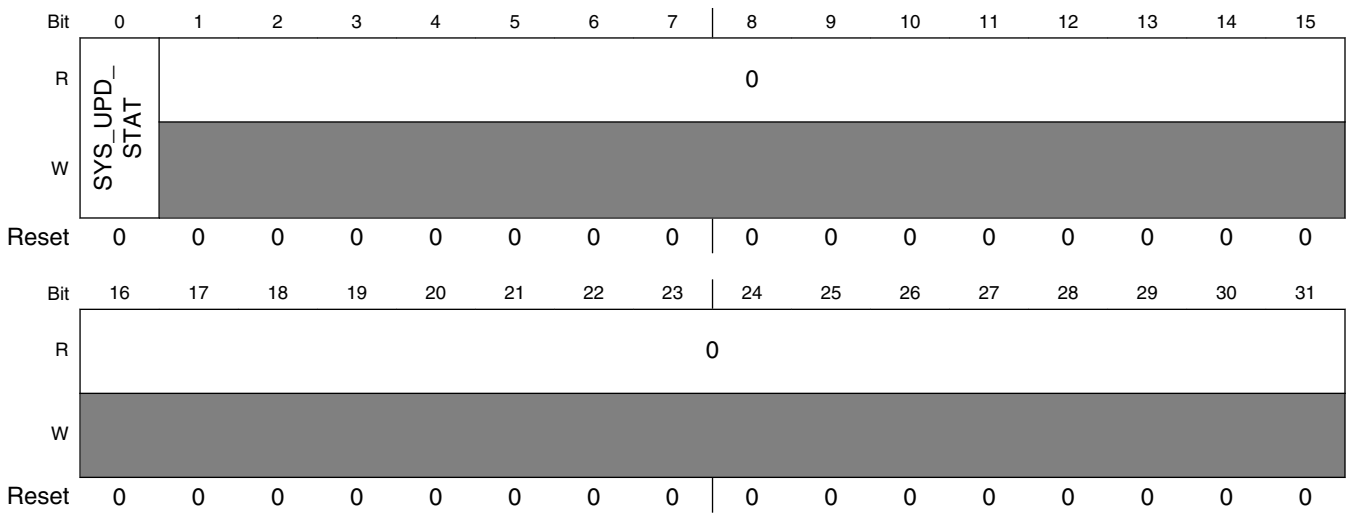
Field	Description
0–31 DIV_UPD_ TRIGGER	Writing any value to this register will cause all dividers that have corresponding bits set to ‘1’ in the CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

29.3.25 Divider Update Status Register (MC_CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the CGM_DIV_UPD_TYPE[i] is ‘0’, CGM_DIV_UPD_STAT[i] is set to ‘1’ immediately on writing to one of the corresponding divider configuration registers. Otherwise, CGM_DIV_UPD_STAT[i] is set to ‘1’ immediately on writing to the CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. CGM_DIV_UPD_STAT[i] is cleared to ‘0’ as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

See Divider update triggering for details.

Address: 0h base + 7DCh offset = 7DCh



MC_CGM_DIV_UPD_STAT field descriptions

Field	Description
0 SYS_UPD_STAT	System Clock Divider Update Status 0 The configuration for at least one system clock divider is not being updated 1 The configuration for at least one system clock divider is being updated
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.3.26 System Clock Select Status Register (MC_CGM_SC_SS)

This register provides the current system clock source selection.

Address: 0h base + 7E4h offset = 7E4h

1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 DIV	Divider Division Value - The resultant PSI5_f125 clock will have a period 'DIV + 1' times that of auxiliary clock 5. If DE is set to 0 (divider 1 is disabled), any write access to the DIV field is ignored and the PSI5_f125 clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

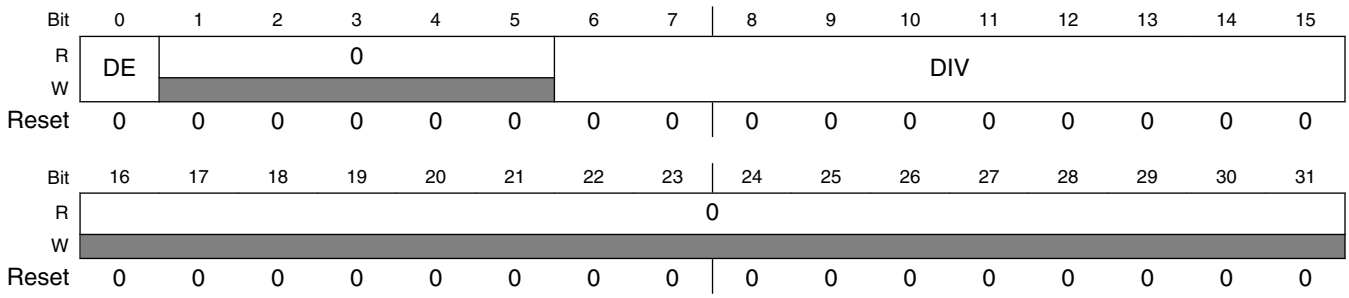
29.3.50 Auxiliary Clock 5 Divider 2 Configuration Register (MC_CGM_AC5_DC2)

This register controls auxiliary clock 5 divider 2.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 8B0h offset = 8B0h



MC_CGM_AC5_DC2 field descriptions

Field	Description
0 DE	Divider Enable 0 Disable auxiliary clock 5 divider 2 1 Enable auxiliary clock 5 divider 2
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 DIV	Divider Division Value - The resultant PSI5_1us clock will have a period 'DIV + 1' times that of auxiliary clock 5. If DE is set to 0 (divider 2 is disabled), any write access to the DIV field is ignored and the PSI5_1us clock remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

29.3.51 Auxiliary Clock 6 Select Control Register (MC_CGM_AC6_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 6 divider 0: SYSCLK0 pin clock

See Figure 29-11 for details.

Address: 0h base + 8C0h offset = 8C0h

29.4 Functional description

29.4.1 System clock generation

Figure 29-2 shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz int. RC osc. as the system clock and to ignore the system clock select.

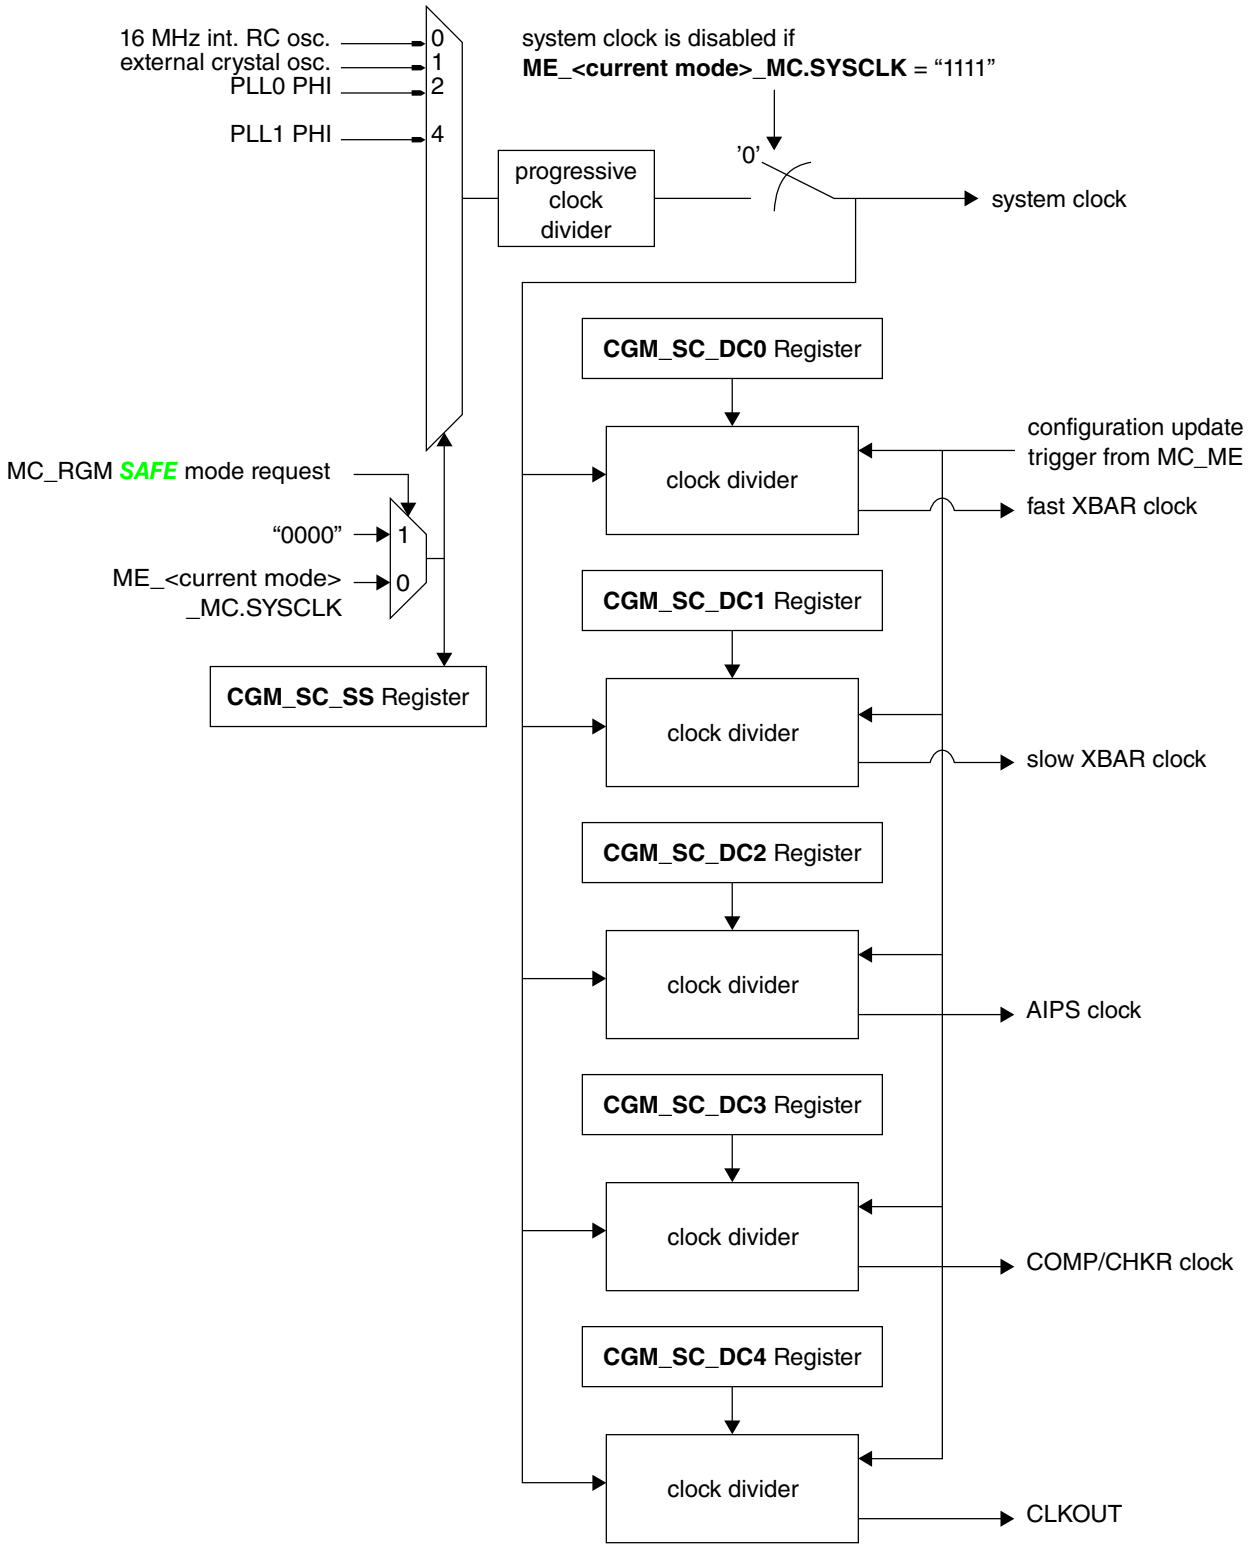

Figure 29-2. MC_CGM system clock generation overview

29.4.1.1 System clock source selection

During normal operation, the system clock selection is controlled

- on a ***SAFE*** mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

29.4.1.2 Progressive system clock switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up based on the power level values of the current and target modes. During ramp-down, the rate of the frequency change is based on the **CGM_PCS_SDUR**, **CGM_PCS_DIVC*n***, and **CGM_PCS_DIVE*n*** registers, where *n* corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the **CGM_PCS_SDUR**, **CGM_PCS_DIVC*n***, and **CGM_PCS_DIVS*n*** registers, where *n* corresponds to the target system clock source selection.

29.4.1.2.1 Generic clock change requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in the following equation.

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

Equation 10. Equation for a_{max}

29.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field **CGM_PCS_SDUR[SDUR]** defines the duration of one system clock switch step in terms of 16 MHz int. RC osc.. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

29.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the **PCS_DIVC*n*[RATE]** register is given in Table 29-1.

Table 29-1. MC_CGM CGM_PCS_DIVC*n*[RATE] values

a_{max}	d = CGM_PCS_DIVC*n*[RATE]
0.05	12
0.10	48
0.15	112
0.20	184

29.4.1.2.4 Generic clock change properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

Equation 11. Equation for k

29.4.1.2.5 Clock ramp-down

The clock ramp-down starts with the divider value 1 and with the given divider increment value **PCD_DIVC*n*[RATE]** and ends with the given divider value **PCS_DIVE*n*[DIVE]**.

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS\_DIVEn}[\text{DIVE}] = \frac{f_{src}}{16MHz} \times 1000 - 1$$

Equation 12

Where f_{curr} is the frequency of the currently selected system clock source.

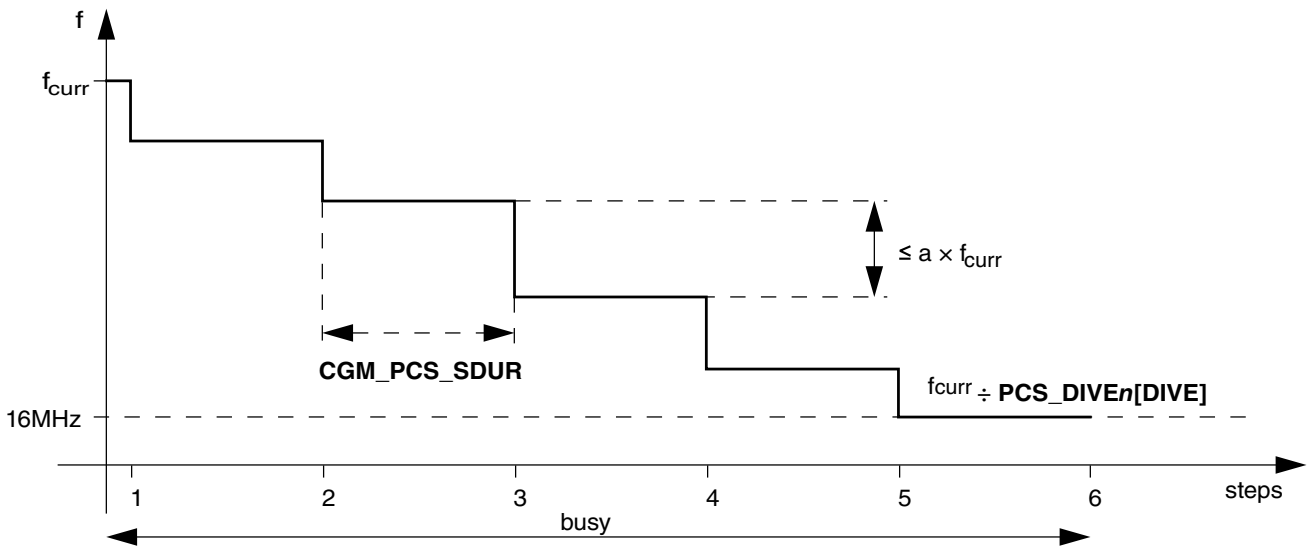

Figure 29-3. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

29.4.1.2.6 Clock ramp-up

The clock ramp-up starts with the given divider value **PCS_DIVS*n*[DIVS]** and with the given divider decrement value **PCD_DIVC*n*[INIT]** and ends with the divider value 1.

The initial divider change start value **PCS_DIVC*n*[INIT]** for system clock ramp-up is given in the following equation.

$$\text{PCS\_DIVCn[INIT]} = d \times k \times 1000$$

Equation 13

Where k is calculated from Equation 11 on page 1204 using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in the following equation.

$$\text{PCS\_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Equation 14

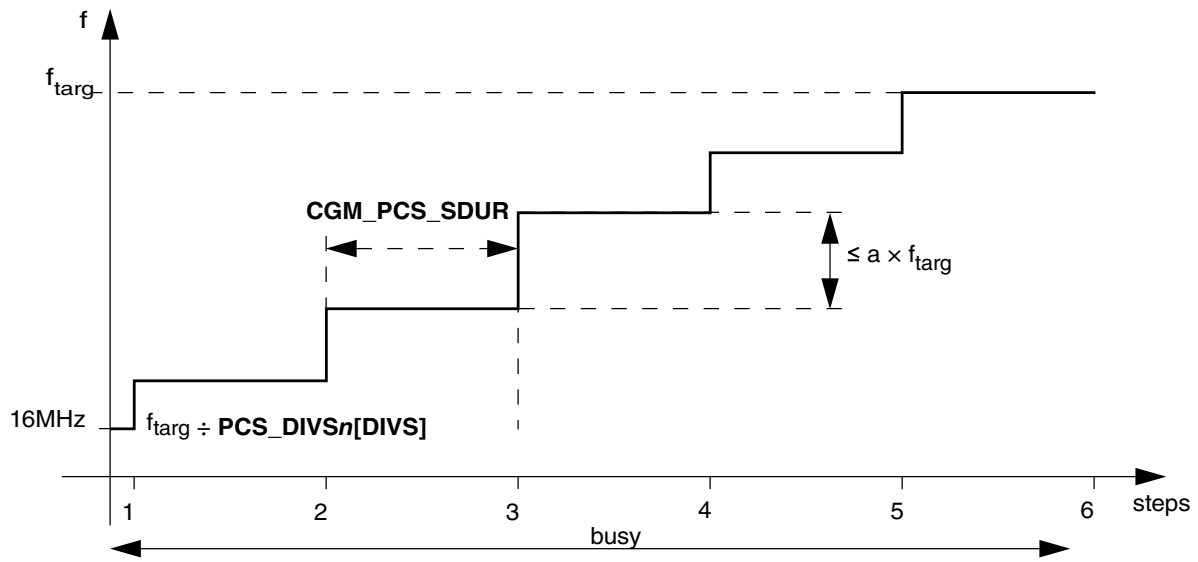

Figure 29-4. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

29.4.1.3 System clock disable

During the TEST mode, the system clock can be disabled by the MC_ME.

29.4.1.4 System clock dividers

The MC_CGM generates the following derived clocks from the system clock:

- fast XBAR clock - controlled by the CGM_SC_DC0 register
- slow XBAR clock - controlled by the CGM_SC_DC1 register
- AIPS clock - controlled by the CGM_SC_DC2 register
- COMP/CHKR clock - controlled by the CGM_SC_DC3 register
- CLKOUT - controlled by the CGM_SC_DC4 register

29.4.1.4.1 System clock divider synchronization

The system clock dividers are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

example

Correct system clock divider configuration

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 2 is an integer multiple of 1, its configuration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

Table 29-2. MC_CGM example system clock division values compatible with divider synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** = 0
1	2	**CGM_SC_DC1[DIV]** = 1
2	6	**CGM_SC_DC2[DIV]** = 5

example

Incorrect system clock divider configuration

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 4 is an integer multiple of 1, its configuration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is not an integer multiple of 4, its configuration is incorrect.

Table 29-3. MC_CGM example system clock division values incompatible with divider synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** = 0
1	4	**CGM_SC_DC1[DIV]** = 3
2	6	**CGM_SC_DC2[DIV]** = 5

warning

Configuring the system clock dividers incorrectly will cause the divided clocks to become un-synchronized. This may lead to lost communication between the clock domains and/or the inability to further change the system clock divider division factors without first disabling them or performing a reset.

NOTE

For 300MHz Core 0 / Core 1 and 200MHz Core 2 / FXBAR operation, the following configuration is allowed:

Table 29-4. Configuration allowed for 300MHz Core 0 / Core 1 and 200MHz Core 2 / FXBAR operation

Divider	Division Factor	Register Value
2	1 2	CGM_ SC_DC 2[DIV] = 11
1	6	CGM_ SC_DC 1[DIV] = 5
0	3	CGM_ SC_DC 0[DIV] = 2
3	2	CGM_ SC_DC 3[DIV] = 1

29.4.1.4.2 Supported External Bus Interfaces clock frequencies

The supported maximum clock frequencies of the External Bus Interface (EBI) and the fast XBAR are as follows:

- EBI clock supported max frequency = 66.67MHz
- fast XBAR clock supported max frequency = 200MHz

The EBI clock is required to be an integer divide relative to the fast XBAR clock, and the CGM dividers need to be programmed correctly to maintain this relationship.

Therefore, the supported combination of fast XBAR and EBI clocks frequencies are as follows:

Table 29-5. Possible combination of fast XBAR and EBI clock frequencies

Ratio	Fast XBAR and EBI clock frequencies
1:1	66.67MHz:66.67MHz, 50MHz:50MHz, and 16MHz:16MHz
2:1	100MHz:50MHz
3:1	200MHz:66.67MHz (normal use case)
4:1	200MHz:50MHz

29.4.1.4.3 System clock divider update triggering

As opposed to the auxiliary clock dividers, which update immediately on a configuration change, the system clock dividers are updated only with the next software triggered mode change. This is to ensure that the system clock dividers are updated simultaneously and that no intermediate inconsistent configurations can occur. It also ensures that the divider configurations are aligned with the target mode's system clock selection.

The system clock divider configuration update sequence is as follows:

1. Set the CGM_DIV_UPD_TYPE, SYS_UPD_TYPE field as "1" to enable the update via a software trigger.
2. Configure the **CGM_SC_DC0…2** registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in System clock divider synchronization.
3. **Optional Step:** If the divider ratios are not changing with respect to the previous configuration, the CGM_SC_DIV_RC, SYS_DIV_RATIO_CHNG field may be reset to 0 to disable the crossbar halt handshake mechanism.
4. Write any non-zero value to the CGM_DIV_UPD_TRIG register to trigger the divider update.

See Mode Entry Module (MC_ME) chapter for details on how to configure modes and make mode change requests.

29.4.2 Auxiliary clock generation

Figure 29-5 through Figure 29-15 show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- System Clock Divider 3 Configuration Register (MC_CGM_SC_DC3)
- Auxiliary Clock 1 Select Control Register (MC_CGM_AC1_SC)
- Auxiliary Clock 3 Select Control Register (MC_CGM_AC3_SC)
- Auxiliary Clock 4 Select Control Register (MC_CGM_AC4_SC)
- Auxiliary Clock 6 Select Control Register (MC_CGM_AC6_SC)
- Auxiliary Clock 7 Select Control Register (MC_CGM_AC7_SC)
- Auxiliary Clock 8 Select Control Register (MC_CGM_AC8_SC)
- Auxiliary Clock 9 Select Control Register (MC_CGM_AC9_SC)
- Auxiliary Clock 10 Select Control Register (MC_CGM_AC10_SC)

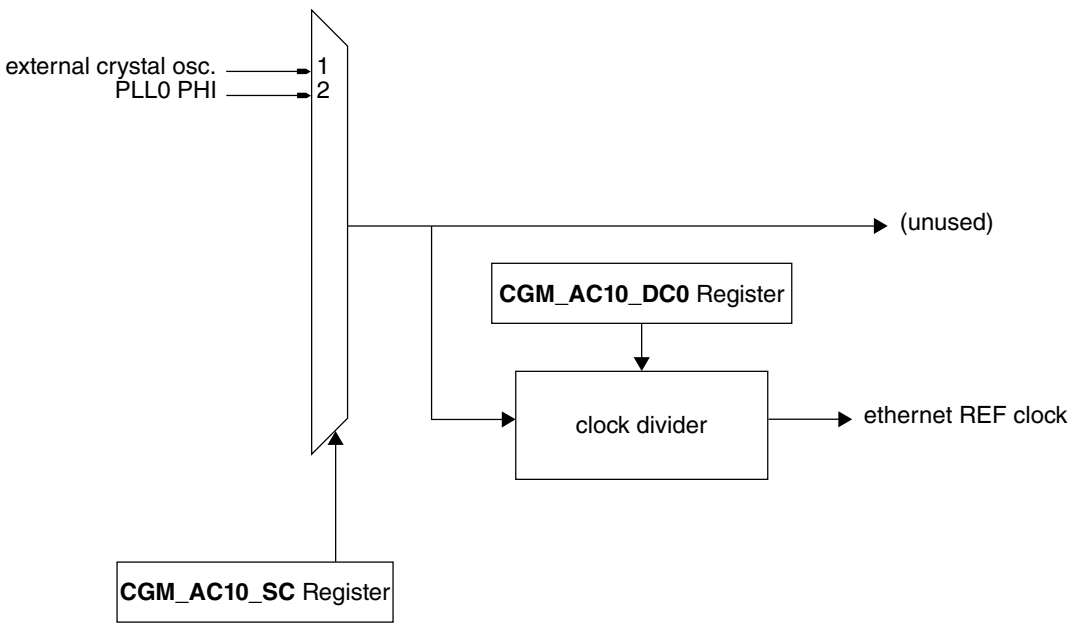

Figure 29-15. MC_CGM Auxiliary Clock 10 Generation Overview

29.4.2.1 Auxiliary clock dividers

The MC_CGM generates the following derived clocks:

- peripheral clock - controlled by the CGM_AC0_DC0 register
- sigma delta ADC clock - controlled by the CGM_AC0_DC1 register

- SAR ADC clock - controlled by the CGM_AC0_DC2 register
- DSPI clock 0 - controlled by the CGM_AC0_DC3 register
- LFAST clock - controlled by the CGM_AC1_DC0 register
- FlexRay clock - controlled by the CGM_AC2_DC0 register
- SENT clock - controlled by the CGM_AC2_DC1 register
- PSI5_f189 clock - controlled by the CGM_AC5_DC0 register
- PSI5_f125 clock - controlled by the CGM_AC5_DC1 register
- PSI5_1us clock - controlled by the CGM_AC5_DC2 register
- SYSCLK0 pin clock - controlled by the CGM_AC6_DC0 register
- SYSCLK1 pin clock - controlled by the CGM_AC7_DC0 register
- CAN clock - controlled by the CGM_AC8_DC0 register
- RTI clock - controlled by the CGM_AC9_DC0 register
- ethernet REF clock - controlled by the CGM_AC10_DC0 register

29.4.3 Dividers functional description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System Clock Divider 0 Configuration Register (MC_CGM_SC_DC0)
- System Clock Divider 1 Configuration Register (MC_CGM_SC_DC1)
- System Clock Divider 2 Configuration Register (MC_CGM_SC_DC2)
- System Clock Divider 3 Configuration Register (MC_CGM_SC_DC3)
- System Clock Divider 4 Configuration Register (MC_CGM_SC_DC4)
- Auxiliary Clock 0 Divider 0 Configuration Register (MC_CGM_AC0_DC0)
- Auxiliary Clock 0 Divider 1 Configuration Register (MC_CGM_AC0_DC1)
- Auxiliary Clock 0 Divider 2 Configuration Register (MC_CGM_AC0_DC2)
- Auxiliary Clock 0 Divider 3 Configuration Register (MC_CGM_AC0_DC3)
- Auxiliary Clock 0 Divider 4 Configuration Register (MC_CGM_AC0_DC4)

- Auxiliary Clock 1 Divider 0 Configuration Register (MC_CGM_AC1_DC0)
- Auxiliary Clock 2 Divider 0 Configuration Register (MC_CGM_AC2_DC0)
- Auxiliary Clock 2 Divider 1 Configuration Register (MC_CGM_AC2_DC1)
- Auxiliary Clock 5 Divider 0 Configuration Register (MC_CGM_AC5_DC0)
- Auxiliary Clock 5 Divider 1 Configuration Register (MC_CGM_AC5_DC1)
- Auxiliary Clock 5 Divider 2 Configuration Register (MC_CGM_AC5_DC2)
- Auxiliary Clock 6 Divider 0 Configuration Register (MC_CGM_AC6_DC0)
- Auxiliary Clock 7 Divider 0 Configuration Register (MC_CGM_AC7_DC0)
- Auxiliary Clock 8 Divider 0 Configuration Register (MC_CGM_AC8_DC0)
- Auxiliary Clock 9 Divider 0 Configuration Register (MC_CGM_AC9_DC0)
- Auxiliary Clock 10 Divider 0 Configuration Register (MC_CGM_AC10_DC0)

The reset value of all counters is '1'. If a divider has its **DE** bit in the respective configuration register set to '0' (the divider is disabled), any value in its **DIV** field is ignored.

29.4.3.1 Divider jitter injection

The clock dividers for the FlexRay clock and the CAN clock inject a jitter so that off-chip communication via the associated peripherals is not possible. For details on enabling this feature, see the "Production Disable" and "CAN Jitter Enable" sections of the PASS chapter.

In addition, PLL0 PHI is always selected to source the FlexRay clock when jitter injection is enabled (see Figure 29-7).

29.4.3.2 Fractional divider details

The clock dividers used to generate the PSI5_f189 clock and the DSPI clock 0 divide the selected clock source frequency by a fractional value given by the **DIV** and **DIV_FMT** fields of the **CGM_AC5_DC0** register.

$$F_{\text{divided clock}} = F_{\text{source clock}} \div \left((\text{DIV} + 1) \div 10^{\text{DIV\_FMT}} \right)$$

Equation 15. Equation for $F_{\text{divided clock}}$

The divided clock frequency is actually an average frequency, since the divider uses only the available rising and falling edges of the source clock. Therefore, the actual frequency switches between two frequencies which are the two frequencies closest to the desired frequency (above and below) which can be extracted by a division factor $n/2$, where n is an integer greater than 1. The switching between the two frequencies is such that the resultant clock's rising edge never deviates from the ideal clock's rising edge by more than 25% of the source clock period and that the resultant average frequency over **DIV** + 1 source clock periods (= $10^{\mathbf{DIV\_FMT}}$ divided clock periods) is the desired frequency.

example

Fractional clock division

Desired division factor = 2.3

DIV = 22

DIV_FMT = 1

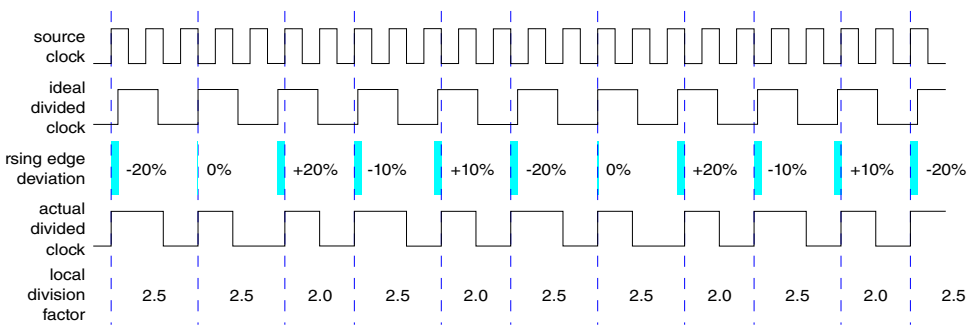

Figure 29-16. MC_CGM fractional division example waveform (divide by 2.3)

$$F_{\text{divided clock}}\big|_{\text{max}} = F_{\text{source clock}} \div 2.0$$

Equation 16. Equation for $F_{\text{divided clock, max}}$

$$F_{\text{divided clock}}\big|_{\text{min}} = F_{\text{source clock}} \div 2.5$$

Equation 17. Equation for $F_{\text{divided clock, min}}$

$$F_{\text{divided clock}}\big|_{\text{ave}} = F_{\text{source clock}} \div \frac{((2.5\times 6)+(2.0\times 4))}{10}$$

Equation 18. Equation for $F_{\text{divided clock, ave}}$

Therefore,

$$F_{\text{divided clock}}\big|_{\text{ave}} = F_{\text{source clock}} \div 2.3$$

Equation 19. Equation for $F_{\text{divided clock, ave}}$

As can be seen in Figure 29-16, the rising edge of the actual divided clock is 'snapped' to the rising or falling edge of the source clock closest to the rising edge of the ideal divided clock. This results in a theoretical maximum deviation, or jitter, of ±25% of the source clock period. In this particular case, the maximum deviation is ±20% of the source clock period.

29.4.3.3 Divider update triggering

There are two methods for updating the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the CGM_DIV_UPD_TYPE register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the CGM_UPD_STAT register is set. This bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

29.4.3.3.1 Immediate divider update

If a divider group has been configured to be updated immediately (i.e., the corresponding CGM_DIV_UPD_TYPE register bit = '0'), the configuration of a divider in that group will be applied immediately on the write to that divider’s configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

29.4.3.3.2 Software-triggered divider update

If a divider group has been configured to be updated via a software trigger (i.e., the corresponding CGM_DIV_UPD_TYPE register bit = '1'), the configuration of a divider in that group will not be applied immediately on the write to that divider’s configuration register. Instead, the configuration in the corresponding configuration register will be applied only when software writes any value to the CGM_DIV_UPD_TRIG register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

In the case of the system clock dividers, if the SYS_DIV_RATIO_CHNG bit in the CGM_SC_DIV_RC register = '1', the crossbar switch is requested to halt its ongoing transactions, and only after the crossbar switch has acknowledged the request does the update of the system clock dividers take place. Once these updates have completed, the halt request to the crossbar is deasserted.

NOTE

If halting the crossbar can cause a bus master to starve and thus lead to lost data or other problems, it is recommended to vary the system clock divider configurations without changing the ratios and to set CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] to '0'.

NOTE

In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (i.e., all relevant bits in the CGM_DIV_UPD_STAT register are ‘0’) before triggering a new update via the CGM_DIV_UPD_TRIG register.

The software-triggered divider update sequence for system clocks is as follows:

1. Set the CGM_DIV_UPD_TYPE, SYS_UPD_TYPE field as "1" to enable the update via a software trigger.
2. Configure the **CGM_SC_DC0…2** registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in System clock divider synchronization.
3. **Optional Step:** If the divider ratios are not changing with respect to the previous configuration, the CGM_SC_DIV_RC, SYS_DIV_RATIO_CHNG field may be reset to 0 to disable the crossbar halt handshake mechanism.
4. Write any non-zero value to the CGM_DIV_UPD_TRIG register to trigger the divider update.

Poll the status register CGM_DIV_UPD_STAT, SYS_UPD_STAT field to check when the divider update completes.

Chapter 30
OSC Digital Interface (XOSC)

30.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provide the register interface for the programmable features. Selection of the XOSC as a source clock is controlled by the Clock Generation Module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry Module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

30.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to the PLLs and can be selected as the reference clock for many of the peripherals on the device.

The table below shows the possible configurations of the XOSC.

Table 30-1. XOSC configurations

OSC EN (from MC_ME)	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	Crystal, or left opened	Crystal, or left opened	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

30.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see "Mode Entry Module (MC_ME)" chapter). The ME_<*mode*>_MC[XOSCON] controls the power down of oscillator based on the current device mode (see "MC_ME Memory Map" table for available *modes*). The status of the XOSC is shown in the MC_ME_GS[S_XOSC].

30.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the analog portion of the oscillator is enabled at powerup. If enabled, the analog portion of the oscillator is powered-up during Phase3 of the device reset sequence (pre-self-test sequence). In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL0).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note

It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

30.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

30.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

NOTE

The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

NOTE

Power down from the MC_ME will have no effect on the oscillator. The bypass clock will continue running in the device. It is ensured that mode transitions from the MC_ME complete successfully by providing bypass information to the MC_ME.

30.3 Memory map and register definition

XOSC memory map

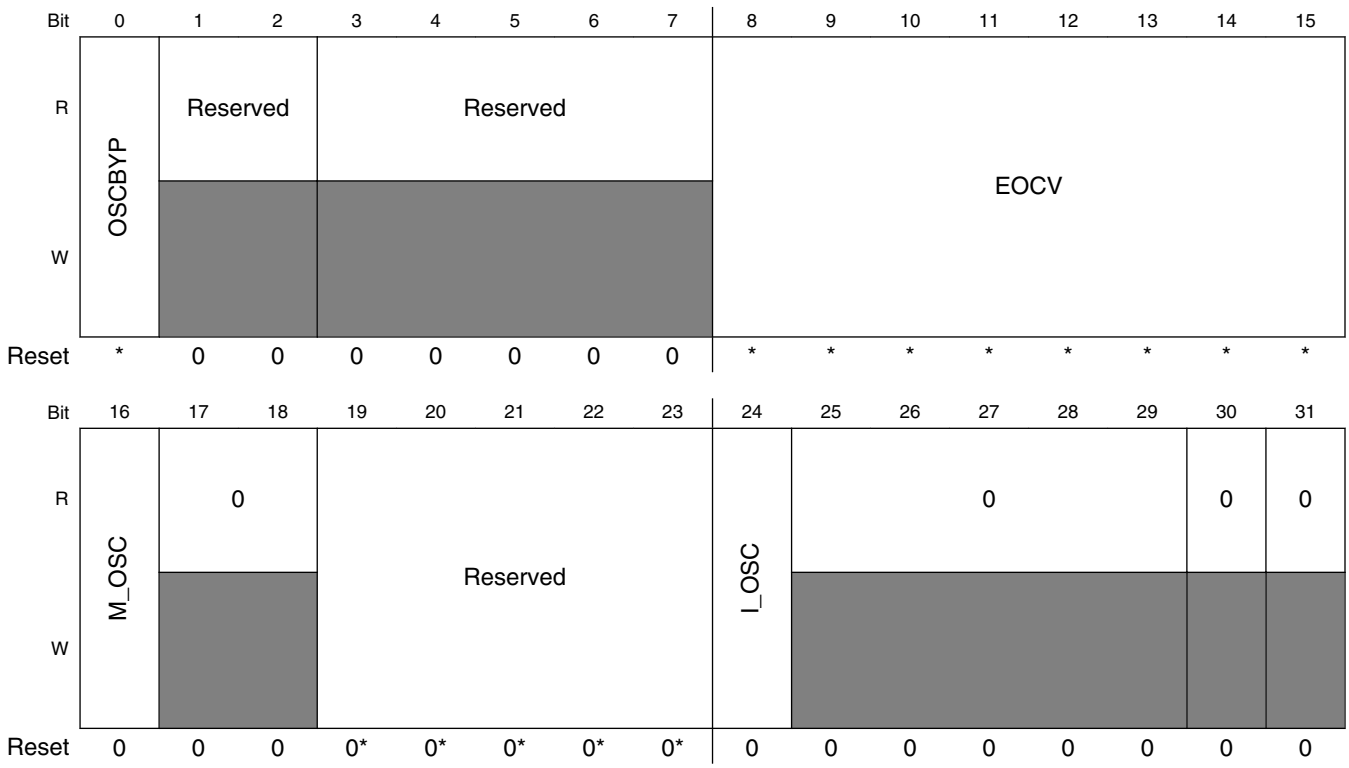
Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	XOSC Control Register (XOSC_CTL)	32	R/W	See section	30.3.1/1226

30.3.1 XOSC Control Register (XOSC_CTL)

NOTE

The XOSC_CTL is only writable in supervisor mode.

Address: 0h base + 0h offset = 0h



* Notes:

- Reserved field: This field can be written at any time, but writes have no effect. Reads return the previously written value.
- M_OSC field: See Clocking chapter for reset value.
- EOCV field: See Clocking chapter for reset value.
- OSCBYP field: See Clocking chapter for reset value.

XOSC_CTL field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
1–2 Reserved	This field is reserved.

Table continues on the next page...

XOSC_CTL field descriptions (continued)

Field	Description
3–7 Reserved	This field is reserved.
8–15 EOCV	End of Count Value These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV × 512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24 I_OSC	Crystal oscillator clock interrupt This bit is set by hardware when OSCCNT counter reaches the count value EOCV x 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.
25–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Chapter 31
IRCOSC Digital Interface

31.1 Introduction

The Internal RC Oscillator Digital Interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

31.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see the Data Sheet for timing details) which is required for stabilization. The IRCOSC status is updated in the MC_ME_GS[S_IRC] field (see the "Mode Entry Module MC_ME" chapter).

The IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

31.3 Memory map and register definition

IRCOSC memory map

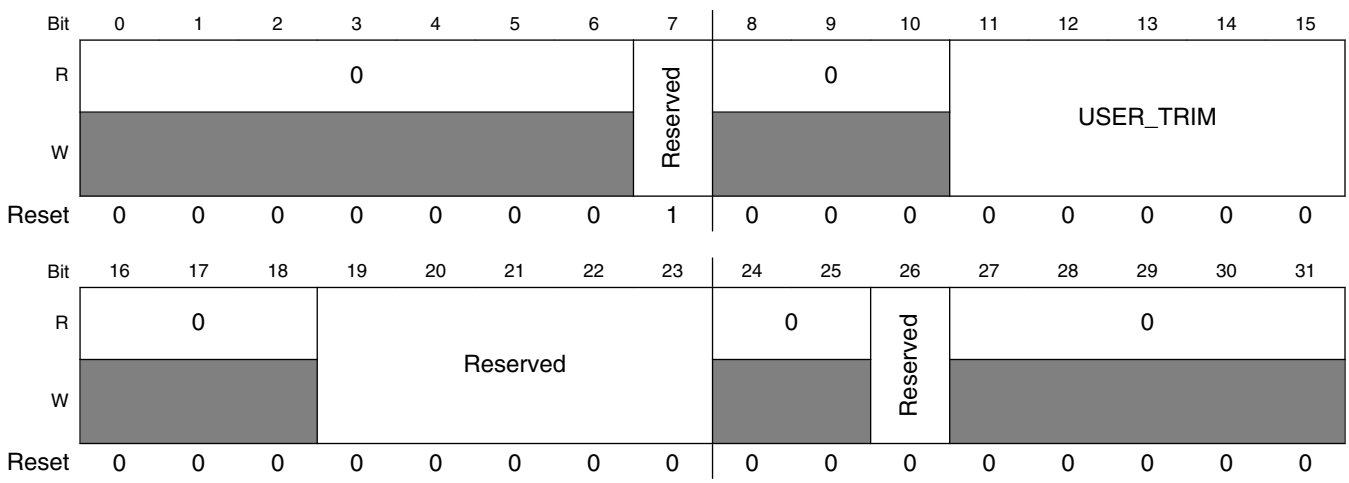
Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	IRCOSC Control Register (IRCOSC_CTL)	32	R/W	See section	31.3.1/1230

31.3.1 IRCOSC Control Register (IRCOSC_CTL)

The IRCOSC_CTL contains user programmable parameters.

IRCOSC_CTL is writable only in supervisor mode.

Address: 0h base + 0h offset = 0h



IRCOSC_CTL field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This bit can be written with any value, but writes are ignored. A read returns last written value.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 USER_TRIM	User trimming bits with respect to nominal factory frequency The MSB of the USER_TRIM bits is used to determine whether the frequency will be increased or decreased. If MSB = 0 then a change in USER_TRIM[3:0] will decrease the frequency, and likewise, if MSB = 1 then a change in USER_TRIM[3:0] will increase the frequency. Frequency trimming calculation shows how RCOSC_CTL[USER_TRIM] field is used to trim the IRCOSC frequency.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IRCOSC_CTL field descriptions (continued)

Field	Description
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.2 Frequency trimming calculation

Table 31-1. IRCOSC_CTL[USER_TRIM] frequency trimming calculation

USER_TRIM[4:0] value	Frequency
....	....
10011	$F + (3 \times \delta F_{var\_SW})$
10010	$F + (2 \times \delta F_{var\_SW})$
10001	$F + \delta F_{var\_SW}$
10000	F
00000	F
00001	$F - \delta F_{var\_SW}$
00010	$F - (2 \times \delta F_{var\_SW})$
00011	$F - (3 \times \delta F_{var\_SW})$
....	....

NOTE

See the data sheet for δF_{var_SW} value and min/max frequency variations.

Chapter 32
RAM Controller (PRAMC)

32.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. Shown below in Figure 32-1 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

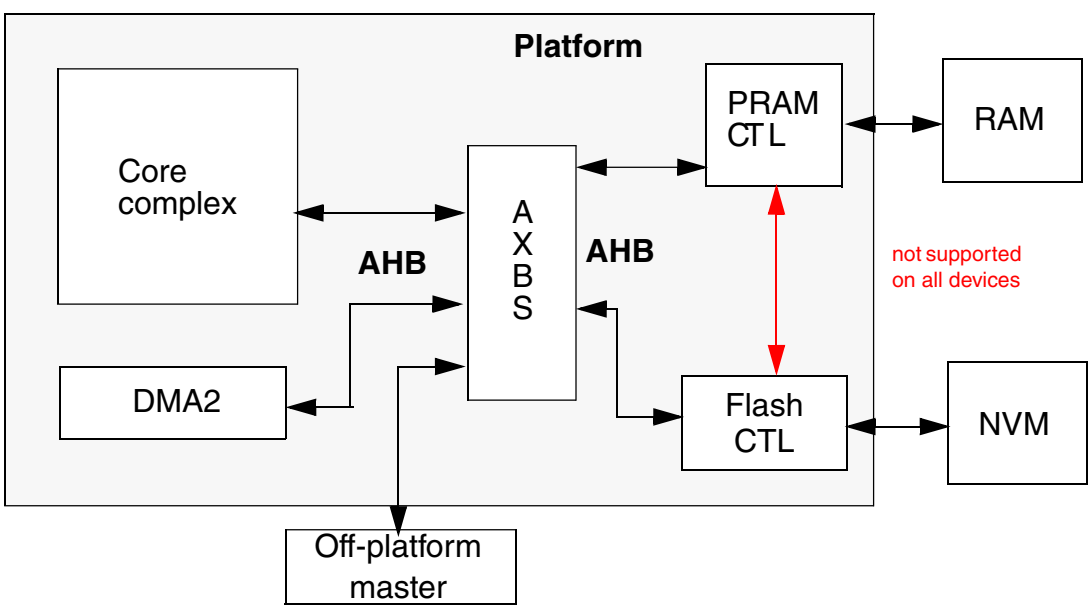


Figure 32-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

32.2 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE
